Debug Reset and Powerdown Support

This chapter describes the reset and powerdown support in the Debug architecture. It contains the following sections:

- *About Debug over powerdown* on page H6-6520.
- *Power domains and debug* on page H6-6521.
- *Core power domain power states* on page H6-6522.
- *Emulating low-power states* on page H6-6525.
- *Debug OS Save and Restore sequences* on page H6-6527.
- *Reset and debug* on page H6-6531.

**Note**

Where necessary, Table K13-1 on page K13-7390 disambiguates the general register references used in this chapter.
H6.1 About Debug over powerdown

Debug over powerdown is a facility for an operating system to save and restore the PE state on behalf of a self-hosted or external debugger or both.

For external debug over powerdown, the architecture defines the OS Lock, OS Double Lock, and the logical split of the hardware on which a PE executes into the Core power domain and the Debug power domain. See:

• Power domains and debug on page H6-6521.
• Core power domain power states on page H6-6522.
H6.2 Power domains and debug

The external debug component of ARMv8-A has two logical power domains, each with its own reset:

- The debug power domain contains the interface between the PE and the external debugger, and is powered up whenever an external debugger is connected to the SoC. It remains powered up while the external debugger is connected. Registers in this domain are reset by an external debug reset.

- The core power domain contains the rest of the PE, and is allowed to power up and power down independently of the Debug power domain.

The core power domain contains several types of registers:

- Non-debug logic refers to all registers and logic that are not associated with debug.

- Self-hosted debug logic refers to registers and logic associated solely with the self-hosted debug aspects of the architecture.

- Shared debug logic refers to registers and logic associated with both the self-hosted and external debug aspects of the architecture.

- External debug logic refers to registers and logic associated solely with the external debug aspects of the architecture.

--- Note ---

- The model of two logical power domains has an impact on the reset and access permission requirements of the debug programmers’ model.

- The power domains are described as logical because the architecture defines the requirements but does not require two physical power domains. Any power domain split that meets the requirements of the programmers’ model is a valid implementation.

Figure H6-1 shows the recommended power domain split. The signals DBGPWRUPREQ, DBGNOPWRDWN, and DBGWPWRDUP shown in Figure H6-1 provide an interface between the power controller and the PE debug logic that is in the debug power domain. They are part of the recommended interface. See Appendix K2 Recommended External Debug Interface.

---

Figure H6-1 Recommended power domain split between core and debug power domains
H6.3 Core power domain power states

The ARM architecture does not define the power states of the PE as these are not normally visible to software. However, they are visible to the external debugger. The Debug architecture uses a four logical power states model for the core power domain. The four logical power states are as follows:

Normal
The core power domain is fully powered up and the debug registers are accessible.

Standby
The core power domain is on, but there are measures to reduce energy consumption. In a typical implementation, the PE enters standby by executing a `WFI` or `WFE` instruction, and exits on a wake-up event. There can be other IMPLEMENTATION DEFINED measures the OS can take to enter standby.

The PE preserves the PE state, including the debug logic state. Changing from standby to normal operation does not involve a reset of the PE.

Standby is the least invasive OS energy saving state. Standby implies only that the PE is unavailable and does not clear any debug settings. For standby, the Debug architecture requires only the following:

- An External Debug Request debug event is a wake-up event when halting is allowed. This means that the PE must exit standby to handle the debug event. If the PE executed a `WFE` or a `WFI` instruction to enter standby, then it retires that instruction,
- If the external debug interface is accessed, the PE must respond to that access. ARM recommends that, if the PE executed a `WFI` or `WFE` instruction to enter standby, then it does not retire that instruction.

Standby is transparent, meaning that to software and to an external debugger it is indistinguishable from normal operation.

Retention
The OS takes some measures, including IMPLEMENTATION DEFINED code sequences and registers, to reduce energy consumption. The PE state, including debug settings, is preserved in low-power structures, allowing the core power domain to be at least partially turned off.

Changing from low-power retention to normal operation does not involve a reset of the PE. The saved PE state is restored on changing from low-power retention state to normal operation. If software has to use an IMPLEMENTATION DEFINED code sequence before entering, or after leaving, a retention state, this is referred to as a software-visible retention state. It is IMPLEMENTATION DEFINED whether the value of `DBGPRCR.CORENPDRQ` is set to the value of `EDPRCR.COREPURQ` on leaving the software-visible retention state.

External Debug Request debug events stay pending and debug registers in the core power domain cannot be accessed.

Note
This model of retention does not include implementations where the PE exits the state in response to a debug register access. From the Debug architecture perspective, implementations like this are forms of standby.

Powerdown
The OS takes some measures to reduce energy consumption by turning the core power domain off. These measures must include the OS saving any PE state, including the debug settings, that must be preserved over powerdown.

If ARMv8.4-Debug is implemented, it is implementation defined whether OS Double Lock is implemented and used during powerdown.

Changing from powerdown to normal operation must include:

- A Cold reset of the PE after the power level has been restored.
- The OS restoring the saved PE state.

External Debug Request debug events stay pending and debug registers in the core power domain cannot be accessed.
An implementation might support enabling and disabling threads, either dynamically or once at reset time. Threads that are disabled in this way must appear to the external debugger as either:

- Powered off, meaning they are either:
  - In a powerdown state.
  - In a retention state.
- Held in reset state.

The Debug architecture uses a simpler two states model for the Debug power domain. The two states are:

**Off**
- The debug power domain is turned off.

**On**
- The debug power domain is turned on.

The available power states, including the cross-product of core power domain and debug power domain power states is IMPLEMENTATION DEFINED. Implementations are not required to implement all of these states and might include additional states. These additional states must appear to the debugger as one of the logical power states defined by this model. The control of power states is IMPLEMENTATION DEFINED.

---

**Note**
As a result, it is IMPLEMENTATION DEFINED whether it is possible for the debug power domain to be on when the core power domain is off.

---

### H6.3.1 EDPRSR.{DLK, SPD, PU} and the Core power domain

Software interprets EDPRSR.{DLK, SPD, PU} to determine whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read.

<table>
<thead>
<tr>
<th>EDPRSR</th>
<th>Core power domain</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DLK</td>
<td>SPD</td>
<td>PU</td>
</tr>
<tr>
<td>0 0 1</td>
<td>On</td>
<td>OK</td>
</tr>
<tr>
<td>0 1 1</td>
<td>On</td>
<td>OK</td>
</tr>
<tr>
<td>1 X 1</td>
<td>On</td>
<td>Error</td>
</tr>
<tr>
<td>X 1 0</td>
<td>Off</td>
<td>Error</td>
</tr>
<tr>
<td>X 0 0</td>
<td>Not known</td>
<td>Error</td>
</tr>
</tbody>
</table>

When ARMv8.4-Debug is implemented, EDPRSR.DLK is always 0, and it is implementation defined whether the OS Double Lock is implemented.

If ARMv8.4-Debug and OS Double Lock are implemented, and `DoubleLockStatus()` == TRUE, the behavior of all registers and fields except EDPRSR.DLK is the same as their behavior if ARMv8.4-Debug is not implemented.

If the Core power domain is powered up and `DoubleLockStatus()` == TRUE, then:

- When ARMv8.2-Debug is not implemented, EDPRSR.{DLK, SPD, PU} can read either \{1, UNKNOWN, 1\} or \{UNKNOWN, 0, 0\}.
- When ARMv8.2-Debug is implemented, EDPRSR.{DLK, SPD, PU} can only read \{UNKNOWN, 0, 0\}. 
H6.3.2  **EDPRSR.SPD when the Core domain is in either retention or powerdown state**

When the Core power domain is in either the retention or powerdown state, **EDPRSR.SPD** is not cleared following a read of **EDPRSR** and it is IMPLEMENTATION DEFINED whether:

- **EDPRSR.SPD** shows whether the state of the debug registers in the Core power domain has been lost since the last time that **EDPRSR** was read. This means that:
  - When the Core power domain is in the powerdown state, **EDPRSR.SPD** is RAO, this indicates that the state of the debug registers has been lost.
  - When the Core power domain is in the retention state, **EDPRSR.SPD** indicates whether the state of the debug registers was lost before the Core power domain entered retention state.

- **EDPRSR.SPD** is RAZ, and:
  - On leaving the powerdown state, **EDPRSR.SPD** is set to 1 which indicates that the state of the debug registers has been lost.
  - On leaving the retention state, **EDPRSR.SPD** reverts the value it had on entering the retention state.

--- Note ---

ARM recommends that an implementation makes **EDPRSR.SPD** fixed as RAO when in the power-down state, particularly if it does not support a low-power retention state.

---

H6.3.3  **EDPRSR.{DLK, R} and reset state**

From ARMv8.2, it is IMPLEMENTATION DEFINED whether OS Double Lock is implemented.

If OS Double Lock is not implemented, **EDPRSR.DLK** is RES0 and DoubleLockStatus() always returns FALSE.

If OS Double Lock is implemented and enabled, the behavior of all registers and fields except **EDPRSR.DLK** is the same as their behavior if ARMv8.4-Debug is not implemented.

If ARMv8.4-Debug is implemented **EDPRSR.DLK** is always 0 and does not give any information about the OS Double Lock.

**EDPRSR.R** is UNKNOWN when DoubleLockStatus() == TRUE. OSDLR_EL1.DLK is cleared to 0 by a reset. If the Core power domain is powered up and entered reset state with the OS Double Lock locked, it is CONSTRAINED UNPREDICTABLE whether a read of **EDPRSR** while the PE is in reset state returns:

- **EDPRSR.{DLK, R, PU}** == {1, UNKNOWN, 1} indicating that the OS Double Lock is locked. This is not permitted from ARMv8.2.
- **EDPRSR.{DLK, R, PU}** == {0, 1, 1} indicating that the PE is in reset state.
- **EDPRSR.{DLK, R, PU}** == {UNKNOWN, UNKNOWN, 0} indicating that the registers in the Core power domain cannot be accessed because the OS Double Lock is locked.

If the PE was powered up and the OS Double Lock was unlocked when the PE was reset, then **EDPRSR.{DLK, R, PU}** reads as {0, 1, 1} while the PE is in reset state.

On leaving reset state, **EDPRSR.{DLK, R}** reads as {0, 0}. 
**H6.4 Emulating low-power states**

The control registers `DBGPRCR.CORENPDRQ` and `EDPRCR.COREPURQ` provide an interface between the power controller and the PE. They typically map directly to signals in the recommended external debug interface. With this interface the external debugger can request the power controller to:

- Emulate states where the core power domain is completely off or in a low-power state where the core power domain registers cannot be accessed. This simplifies the requirements on software by sacrificing entirely realistic behavior.
- Restore full power to the core power domain.

`EDPRSR.{SPD, PU}` indicates the core power domain power state. For more information see:

- The `DBGPRCR_EL1` and `DBGPRCR` System register descriptions.
- The `EDPRCR` and `EDPRSR` external debug register descriptions.
- Appendix K2 Recommended External Debug Interface.

The measures to emulate powerdown are IMPLEMENTATION DEFINED. The ability of the debugger to access the state of the PE and the system might be limited as a result of the measures adopted.

In an emulated powerdown state, the debugger must be able to access all debug, PMU, CTI, and trace unit registers that are accessible on the external debug interface and are in one of:

- The debug power domain.
- The core power domain.
- When a trace unit with a separate trace unit core power domain is implemented, and the trace unit core power domain is powered on, the trace unit core power domain.

That is, the debugger must be able to read and write to such registers without receiving errors. This allows an external debugger to debug the powerup sequence.

ARM recommends that any IMPLEMENTATION DEFINED registers that are on the external debug interface and in either the core power domain or the debug power domain are also accessible in an emulated powerdown state.

If the OS Double Lock is implemented, to stop the OS Double Lock preventing access to debug registers when powerdown is being emulated, `DoubleLockStatus() == FALSE` when `DBGPRCR.CORENPDRQ == 1`.

Otherwise, the behavior of the PE in emulated powerdown must be similar to that in a real powerdown state. In particular, the PE must not respond to other system stimuli, such as interrupts.

Example H6-1 and Example H6-2 are examples of two approaches to emulating powerdown.

---

**Example H6-1 An example of emulating powerdown**

The PE is held in Standby state, isolated from any system stimuli. It is IMPLEMENTATION DEFINED whether the PE can respond to debug stimuli such as an External Debug Request debug event.

If the PE can enter Debug state, then the external debugger is able to use the ITR to execute instructions, such as loads and stores. This causes the external debugger to interact with the system. If the external debugger restarts the PE, the PE leaves Standby state and restarts fetching instructions from memory.

---

**Example H6-2 Another example of emulating powerdown**

The PE is held in Warm reset. This limits the ability of an external debugger to access the resources of the PE. For example, the PE cannot be put into Debug state.
On exit from emulated powerdown the PE is reset. However, the debug registers that are only reset by a Cold reset must not be reset. Typically this means that a Warm reset is substituted for the Cold reset. As such, the effect of accessing any register that is reset by a Warm reset while the PE is in the emulated powerdown state will have an IMPLEMENTATION DEFINED effect on that register.

--- Note ---

- Warm reset and Cold reset have different effects apart from resetting the debug registers. In particular, RMR_ELx is reset by a Cold reset and controls the reset state on a Warm reset. This means that if a Cold reset is substituted by a Warm reset, the behavior of the reset code might be different.

- The timing effects of powering down are typically not factored in the powerdown emulation. Examples of these timing effects are clock and voltage stabilization.

- Emulation does not model the state lost during powerdown, meaning that it might mask errors in the state storage and recovery routines.
H6.5 Debug OS Save and Restore sequences

In ARMv8-A, the following registers provide the OS Save and restore mechanism:

- The OS Lock Access Register, OSLAR, locks the OS Lock to restrict access to debug registers before starting an OS Save sequence, and unlocks the OS Lock after an OS Restore sequence.
- The OS Lock Status Register, OSLSR, shows the status of the OS Lock.
- The External Debug Execution Control Register, EDECR, can be configured to generate a debug event when the OS Lock is unlocked.
- The OS Double Lock Register, OSDLR, locks out an external debug interface entirely. This is only used immediately before a powerdown sequence.

See also:
- Reset and debug on page H6-6531
- Appendix K8 Example OS Save and Restore Sequences

H6.5.1 Debug registers to save over powerdown

Table H6-2 shows the different requirements for self-hosted debug over powerdown and external debug over powerdown:

- The column labeled Self-hosted lists registers that software must preserve over powerdown so that it can support self-hosted debug over powerdown. This does not require use of the OS Save and Restore mechanism.
- The column labeled External lists registers that software must preserve over powerdown so that it can support external debug over powerdown. This requires use of the OS Save and Restore mechanism:
  - Some external debug registers are not normally accessible to software executing on the PE. Additional debug registers are provided that give software the required access to save and restore these external debug registers when OSLSR.OSLK is locked. These registers include OSECCR, OSDTRRX, and OSDTRTX.
  - Some registers might only present in some implementations, or might not be accessible at all Exception levels or in Non-secure state. DBGVCR32_EL2 and SDER32_EL3 are only required to support AArch32.

Table H6-2 does not include registers for the OPTIONAL Trace and Performance Monitor extensions.

**H6.5 Debug OS Save and Restore sequences**

**H6.5.2 OS Save sequence**

To preserve the debug logic state over a powerdown, the state must be saved to nonvolatile storage. This means the OS Save sequence must:

1. Lock the OS Lock by:
   - Writing the key value 0xC5ACCE55 to the DBGOSLAR in AArch32 state.
   - Writing 1 to OSLR_EL1.OSLK in AArch64 state.
2. Execute an `ISB` instruction.
3. Walk through the debug registers listed in [Debug registers to save over powerdown](#) on page H6-6527 and save the values to the nonvolatile storage.

If the OS Double Lock is implemented, before removing power from the core power domain, software must:

1. Lock the OS Double Lock by writing 1 to OSDLR_EL1.DLK.
2. Execute a **Context synchronization event**.

**H6.5.3 OS Restore sequence**

After a powerdown, the OS Restore sequence must perform the following steps to restore the debug logic state from the non-volatile storage:

1. Lock the OS Lock, as described in **OS Save sequence**. The OS Lock is generally locked by the Cold reset, but this step ensures that it is locked.
2. Execute an `ISB` instruction.
3. To ensure that, if an external debugger clears the OS Lock before the end of this sequence, no debug exceptions are generated:
   - Write 0 to MDSCR_EL1 if executing in AArch64 state.
   - Write 0 to DBGDSCRext if executing in AArch32 state.
4. Walk through the debug registers listed in [Debug registers to save over powerdown](#) on page H6-6527, and restore the values from the nonvolatile storage. The last register to be restored must be:
   - MDSCR_EL1 if executing in AArch64 state.
   - DBGDSCRext if executing in AArch32 state.
5. Execute an ISB instruction.

6. Unlock the OS Lock by:
   • Writing any non-key value to DBGOSLAR if executing in AArch32 state.
   • Writing 0 to OSLAR_EL1.OSLK if executing in AArch64 state.

7. Execute a Context synchronization event.

--- Note ---
The OS Restore sequence overwrites the debug registers with the values that were saved. If there are valid values in these registers immediately before the restore sequence, then those values are lost.

H6.5.4 Debug behavior when the OS Lock is locked

The main purpose of the OS Lock is to prevent updates to debug registers during an OS Save or OS Restore operation. The OS Lock is locked on a Cold reset.

When the OS Lock is locked:

• Access to debug registers through the System register interface is mainly unchanged except that:
  — Certain registers are read and written without side-effects.
  — Fields in DSCR and OSECCR that are normally read-only become read/write.

This allows the state to be saved or restored. For more information, see the relevant register description in Chapter H9 External Debug Register Descriptions.

• Access to debug registers by the external debug interface is restricted to prevent an external debugger modifying the registers that are being saved or restored. For more information see External debug interface register access permissions summary on page H8-6549.

• Debug exceptions, other than Breakpoint Instruction exceptions are not generated.

• Breakpoint and Watchpoint debug events are not generated. The OS Lock has no effect on Breakpoint Instruction exceptions and other debug events.

H6.5.5 Debug behavior when the OS Lock is unlocked

When the OS Lock is unlocked, the PE sets EDESR.OSUC to 1 if EDESR.OUCE is set to 1 and the PE is in Non-debug state, meaning the OS Unlock Catch debug event becomes pending. See OS Unlock Catch debug event on page H3-6476.

H6.5.6 Debug behavior when the OS Double Lock is locked

If the OS Double Lock is implemented, software locks the OS Double Lock immediately before a powerdown sequence.

The OS Double Lock ensures that it is safe to remove core power by forcing the debug interfaces to be quiescent.

When DoubleLockStatus() == TRUE:

• The external debug interface only has restricted access to the debug registers, so that it is quiescent before removing power. See External debug interface register access permissions summary on page H8-6549.

• Debug exceptions, other than Breakpoint Instruction exceptions, are not generated.

• Halting is prohibited. See Halting allowed and halting prohibited on page H2-6419.

--- Note ---
Pending Halting debug events might be lost when core power is removed.
• No asynchronous debug events are WFI or WFE wake-up events.

If the OS Double Lock is not implemented, the PE ensures these conditions are met before allowing power to be removed.

Software must synchronize the update to OSDLR before it indicates to the system that core power can be removed. The interface between the PE and its power controller is IMPLEMENTATION DEFINED.

Typically software indicates that core power can be removed by entering the Wait For Interrupt state. This means that software must explicitly synchronize the OSDLR update before issuing the WFI instruction.

OSDLR.DLK is ignored and DoubleLockStatus() == FALSE if either:
• The PE is in Debug state.
• DBGPRCR.CORENPDRQ is set to 1.

--- Note ---
It is possible to enter Debug state with OSDLR.DLK set to 1. This is because a Context synchronization event is required to ensure the OS Double Lock is locked, meaning that Debug state might be entered before the OSDLR update is synchronized.

Because OSDLR.DLK is ignored when DBGPRCR.CORENPDRQ is set to 1, an external debugger can write to DBGPRCR.CORENPDRQ, and the OS Double Lock is not always implemented, software must not rely on using the OS Double Lock to disable debug exceptions or to prohibit halting, or both. ARM deprecates use of the OS Double Lock for these purposes, and instead recommends that software:
• Uses the OS Lock to disable debug exceptions during save or restore sequences.
• Uses the debug authentication interface to prohibit halting and external debug access to debug registers at times other than immediately prior to removing power.

As the purpose of the OS Double Lock is to ensure that it is safe to remove core power, if the OS Double Lock is implemented, it is important to avoid race conditions that defeat this purpose. ARM recommends that:
• Once the write to OSDLR.DLK has been synchronized by a Context synchronization event and DoubleLockStatus() == TRUE, a PE must:
  — Not allow a debug event generated before the Context synchronization event to cause an entry to Debug state or act as a wake-up event for a WFI or WFE instruction after the Context synchronization event has completed.
  — Complete any external debug access started before the Context synchronization event by the time the Context synchronization event completes.

--- Note ---
A debug register access might be in progress when software sets OSDLR.DLK to 1. An implementation must not permit the synchronization of locking the OS Double Lock to stall indefinitely while waiting for that access to complete. This means that any debug register access that is in progress when software sets OSDLR.DLK to 1 must complete or return an error in finite time.

• If a write to DBGPRCR or EDPRCR made when OSDLR.DLK == 1 changes DBGPRCR.CORENPDRQ or EDPRCR.CORENPDRQ from 1 to 0, meaning DoubleLockStatus() changes from FALSE to TRUE, then before signaling to the system that the CORENPDRQ field has been cleared and emulation of powerdown is no longer requested, meaning the system can remove core power, the PE must ensure that all the requirements for DoubleLockStatus() == TRUE listed in this section are met.

In a standard OS Save sequence, the OS Lock is locked before the OS Double Lock is locked. This means that writes to CORENPDRQ are ignored by the time the OS Double Lock is locked. However, if DoubleLockStatus() == FALSE, an external debugger can clear the OS Lock at any time, and then write to EDPRCR.
H6.6 Reset and debug

All registers in the Core power domain are either:
- Reset by both a Cold and a Warm reset.
- Reset only by a Cold reset and are not changed by a Warm reset.

For more information, see Reset on page D1-2154.

All registers in the Debug power domain are reset by an External Debug reset.

Figure H6-2 shows this reset scheme. The following three reset signals are an example implementation of the reset scheme:
- CORERESET, which must be asserted for a Warm reset.
- CPUPORESET, which must be asserted for a Cold reset.
- PRESETDBG, which must be asserted for an External Debug reset.

As shown in the figure, the external debug logic is split between the Debug power domain and the Core power domain.

---

**Note**

In this scheme, logic in the Warm reset domain is reset by asserting either CORERESET or CPUPORESET. This implies a particular implementation style that permits these approaches.

CPUPORESET is not normally asserted on moving from a low-power state, where power has not been removed, to a full-power state. This can occur, for example, on exiting a low-power retention state. See also Emulating low-power states on page H6-6525 and the EDPRSR register description.
H6.6.1 External debug interface accesses to registers in reset

If a reset signal is asserted and the external debug interface:

- Writes a register, or indirectly writes a register or register field as a side-effect of an access:
  - Then, if the register or register field is reset by that reset signal, it is CONSTRAINED UNPREDICTABLE whether the register or register field takes the reset value or the value written. The reset value might be UNKNOWN.
  - Otherwise the register or register field takes the value that is written.
- Reads a register, or indirectly reads a register or register field, as part of an access:
  - Then, if the register or register field is reset by that reset signal, the value returned is UNKNOWN.
  - Otherwise, the value of the register or register field is returned.

It is IMPLEMENTATION DEFINED whether any register can be accessed when External Debug reset is being asserted. The result of these accesses is IMPLEMENTATION DEFINED.
Chapter H7
The PC Sample-based Profiling Extension

This chapter describes the OPTIONAL PC Sample-based Profiling Extension that provides a non-invasive external debug component.

It contains the following section:
•  About the PC Sample-based Profiling Extension on page H7-6534.
H7.1 About the PC Sample-based Profiling Extension

The PC Sample-based Profiling Extension is an **optional** extension that provides coarse-grained, non-invasive profiling by an external debugger. See also *Non-invasive behavior on page D6-2528.*

PC Sample-based Profiling creates samples so that tools can populate a statistical model of the performance of software executing on the PE.

--- **Note** ---

Data returned by periodic sampling of PC Sample-based Profiling registers is sufficient to allow tools to estimate the distribution of time spent executing software on the PE.

The delay between an instruction being executed by the PE and its address appearing in the PC Sample Register is not defined, and ARMv8 does not require that the sampled instruction was recently executed. For example, if a piece of software executes a load instruction that reads the PC Sample Register of the PE it is running on, there is no guaranteed relationship between the address of the load instruction and the value read. The PC Sample Register is intended only for use by an external agent to provide statistical information for software profiling.

---

It must be possible to sample references to branch targets. It is **implementation defined** whether references to other instructions can be sampled. The branch target for a conditional branch instruction that fails its condition check is the instruction that follows the conditional branch instruction. The branch target for an exception is the exception vector address.

To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the sampled data is acceptable. ARM does not define a *reasonable degree of inaccuracy* but recommends the following guidelines:

- In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the sample to represent an instruction that was not committed for execution.
- Under unusual non-repeating pathological cases, the sample can represent an instruction that was not committed for execution. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in sampling is very unlikely.
- Under normal operating conditions, the sample must reference an instruction that was committed for execution, including its context, and must not reference instructions that are fetched but not committed for execution.

--- **Note** ---

In the Armv7 PC Sample-based Profiling Extension, an offset was applied to the sampled program counter value and this offset and the instruction set state indicated in bits [1:0] of the sampled value. In the Armv8 PC Sample-based Profiling Extension, the sampled value is the address of an instruction that has executed, with no offset and no indication of the instruction set state.

---

**H7.1.1 Controlling the PC Sample-based Profiling Extension**

PC Sample-based Profiling is controlled by the **implementation defined** authentication interface `ExternalNoninvasiveDebugEnabled()`.

PC Sample-based Profiling is prohibited unless both:

- It is allowed by the **implementation defined** authentication interface `ExternalNoninvasiveDebugEnabled()`.
- At least one of the following applies:
  - The PE is executing in Non-secure state.
  - EL3 is not implemented.
— EL3 is implemented, the PE is executing in Secure state, and non-invasive debug is allowed by the IMPLEMENTATION DEFINED authentication interface ExternalSecureNoninvasiveDebugEnabled() 
— EL3 is implemented, EL3 or EL1 is using AArch32, the PE is executing at EL0 in Secure state, and the value of SDER.SUNIDEN is 1.

The state of the IMPLEMENTATION DEFINED authentication interface is visible through DBGAUTHSTATUS_EL1. See Recommended authentication interface on page K2-7235.

H7.1.2 Registers implemented by the PC Sample-based Profiling Extension

The options for implementing the PC Sample-based Profiling extension are:

- The extension is implemented in the external debug register space. EDDEVID.PCSample and identifies the implemented level of profiling, and EDDEVID1.PCSROffset also indicates that this option is implemented. From Armv8.2 this option is not permitted.
- ARMv8.2-PCSample is implemented, meaning the PC Sample-based Profiling extension is implemented in the Performance Monitors memory-mapped register space. PMDEVID.PCSample identifies the implemented level of profiling.

If PC Sample-based Profiling is implemented in the external debug register space:

- The following external debug registers can be implemented:
  — EDCIDSR.
  — EDPCSR.
  — EDVIDSR.

See External debug interface register map on page H8-6551.

- If ARMv8.1-VHE is implemented, EDSCR.SC2 controls what PC Sample-based Profiling samples.

If ARMv8.2-PCSample is implemented, the following registers can be implemented in the Performance Monitors memory-mapped register space:

- PMCID1SR and PMCID2SR.
- PMPCSR.
- PMVIDSR.

See Performance Monitors external register views on page I5-6738.

If the PC Sample-based Profiling Extension is implemented with ARMv8.2-PCSample but the Performance Monitors Extension is not implemented, then the PC Sample-based Profiling Extension is implemented in its own memory-mapped register space, within the area that is reserved for the Performance Monitors, see Table H7-1. If CoreSight compliance is required:

- The management registers are defined as in Table K2-3 on page K2-7237.
- The support for PC Sample-based profiling is defined in the following registers:
  — PMDEVTYPE.MAJOR has the value 0x0.
  — PMDEVARCH.ARCHID has the value 0x0A10.

H7.1.3 Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN

The architecture permits IMPLEMENTATION DEFINED extensions to external debug to define mechanisms that make the values of the PC Sample-based profiling registers UNKNOWN. However, it requires that any such mechanism is disabled by default. This means that powerup or a hard reset of the PE must leave the PE in a state where the PC Sample-based Profiling Extension, if implemented, exhibits its architecturally-defined behavior.

Note

A mechanism that, when enabled, makes the PC Sample-based profiling registers UNKNOWN might use other sample-based profiling events that are appropriate for a use that is independent of PC Sample-based Profiling.

When EDPCSR or PMPCSR are read by the PE for the first time after exiting Debug state or Reset state, PMPCSR or EDPCSR will return the value 0xFFFFFFFF. Any subsequent read of PMPCSR or EDPCSR will return sampled instruction address values.

H7.1.4 Pseudocode description of PC Sample-based Profiling

When PC Sample-based Profiling is implemented but not with ARMv8.2-PCSample, the functionality is described by the pseudocode functions:

- `CreatePCSample()`, which populates a variable of type PCSample.
- `EDPCSRlo[]`, which writes a PC sample to the EDPCSR and associated registers.

When ARMv8.2-PCSample is implemented, the functionality is described by the pseudocode functions:

- `CreatePCSample()`, which populates a variable of type PCSample.
- `PMPCSR[]`, which writes a PC Sample to the PMPCSR and associated registers.
Chapter H8
About the External Debug Registers

This chapter provides some additional information about the external debug registers. It contains the following sections:

- Relationship between external debug and System registers on page H8-6538.
- Endianness and supported access sizes on page H8-6539.
- Synchronization of changes to the external debug registers on page H8-6540.
- Memory-mapped accesses to the external debug interface on page H8-6544.
- External debug interface register access permissions on page H8-6547.
- External debug interface registers on page H8-6551.
- Cross-trigger interface registers on page H8-6556.
- External debug register resets on page H8-6558.

Note: Where necessary Table K13-1 on page K13-7390 disambiguates the general register references used in this chapter.
H8.1 Relationship between external debug and System registers

Table H8-1 shows the relationship between external debug registers and System registers. Where no relationship exists, the registers are not listed.

In addition:
- EDSCR.{{TXfull, RXfull}} are read-only aliases for DCCSR.{{TXfull, RXfull}}.
- EDPDCR.CORENPDQR is a read/write alias for DBGPRC.CORENPDQR.
- EDPRSR.OSLK is a read-only alias for OSLR.OSLK.
- EDPRSR.DLK is a read-only function of OSLR.DLK.

---

*a. This is a word of a 64-bit register.*
The debug registers, Performance Monitors registers, and CTI registers are implemented as memory-mapped peripherals. The ARM architecture requires memory-mapped peripherals to be little-endian.

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the debug registers, Performance Monitors registers, and CTI registers, implementations must:

- Comply with the requirements of Supported access sizes on page I1-6710.
- Support word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations, even if no PE in the system implements AArch32.

Note

These requirements mean that a system implementing the debug registers using a 32-bit bus, such as a AMBA APB3, with a wider system interconnect must implement a bridge between the system and the debug bus that can split 64-bit accesses.

For accesses from the external debug interface, the size of an access is determined by the interface. For an access from an ADIv5-compliant Memory Access Port, MEM-AP, this is specified by the MEM-AP CSW register.
H8.3 Synchronization of changes to the external debug registers

This section describes the synchronization requirements for the external debug interface.

For more information on how these requirements affect debug, see:

- Synchronization and debug exceptions on page D2-2330 for exceptions taken from AArch64 state, or
- Synchronization and debug exceptions on page G2-5420 for exceptions taken from AArch32 state.
- Synchronization and Halting debug events on page H3-6479.
- Synchronization of DCC and ITR accesses on page H4-6494.

This section refers to accesses from the external debug interface as external reads and external writes. It refers to accesses to System registers as direct reads, direct writes, indirect reads, and indirect writes.

Note

Synchronization requirements for AArch64 System registers on page D12-2663 and Synchronization of changes to AArch32 System registers on page G8-5640 define direct read, direct write, indirect read, and indirect write, and classifies external reads as indirect reads, and external writes as indirect writes.

For general information about synchronization, access completion, ordering, and observability, see Synchronization of memory-mapped registers on page I1-6712.

Writes to the same register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes. With the exception of DBGBCR<n>_EL1, DBGVR<n>_EL1, DBGWCR<n>_EL1, and DBGWVR<n>_EL1, external writes to different registers are not necessarily observed in the same order by all observers as the order in which they complete.

Synchronization of DCC and ITR accesses on page H4-6494 describes the synchronization requirements for the DCC and ITR.

Changes to the IMPLEMENTATION DEFINED authentication interface are external writes to the authentication status registers by the master of the authentication interface. See Synchronization and the authentication interface on page H8-6541.

The external agent must be able to guarantee completion of a write. For example by:

- Marking the memory as Device-nGnRnE and executing a DSBB barrier, if the system supports this property.
- Reading back the value written.
- Some guaranteed property of the connection between the PE and the external agent.

Note

For an external Debug Access Port, access completion is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, accesses complete in order.

However, the external agent cannot force synchronization of completed writes without halting the PE. Executing an ISB instruction, either in Debug state or in Non-debug state, and exiting from Debug state forces synchronization. If the PE is in Debug state, executing an ISB instruction is guaranteed to explicitly synchronize any external reads, external writes, and changes to the authentication interface that are ordered before the external write to EDITR.

For any given observer, external writes to the following register groups are guaranteed to be observable in the same order in which they complete:

- The breakpoint registers, DBGBCR<n>_EL1 and DBGBVR<n>_EL1.
- The watchpoint registers, DBGWCR<n>_EL1 and DBGWVR<n>_EL1.

This guarantee only applies to external writes to registers within one of these groups. There is no guarantee regarding the ordering of the observability of external writes within these groups with respect to external writes to registers, for example EDSCR, or between breakpoints and watchpoints, including watchpoints linked to context matching breakpoints.
Note
This means that a debugger can rely on the external writes to be observed in the same order in which they complete. It does not mean that a debugger can rely on the external writes being observed in finite time.

In a simple sequential execution an indirect write that occurs as a side-effect of an access happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

If two or more interfaces simultaneously access a register, the behavior must be as if the accesses occurred atomically and in any order. This is described in Examples of the synchronization of changes to the external debug registers.

Some registers have the property that for certain bits a write of 0 is ignored and a write of 1 has an effect. This means that simultaneous writes must be merged. Registers that have this property and support both external debug and System register access include DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, PMCR_EL0.[C,P], PMOVSET_EL0, PMOVSLR_EL0, PMCNTENSET_EL0, PMCNTENCLR_EL0, PMINTENSET_EL1, PMINTENCLR_EL1, and PMSWINC_EL0. This last register is OPTIONAL and deprecated in the external debug interface.

H8.3.1 Synchronization and the authentication interface

Changes to the authentication interface are indirect writes to the state of the PE by the master of the authentication interface.

For an external debug interface read of any Authentication Status register, or an indirect read of the authentication interface made in determining the response to a subsequent external debug interface access, a change on the authentication interface must be observable following a subsequent explicit Context synchronization event, and:

- It is IMPLEMENTATION DEFINED whether a change is guaranteed to be observable in finite time.
- It is IMPLEMENTATION DEFINED whether a change is guaranteed to be observable following an entry to Debug state.

For a System register read of DBGAUTHSTATUS_EL1, a change on the authentication interface is guaranteed to be observable only after a Context synchronization event.

Note
- In some systems the authentication interface is fixed by configuration, or changed under the control of software. These systems can require explicit synchronization for any change to the authentication interface.
- In other systems, the authentication interface is controlled dynamically by an external agent. In these systems, it is desirable that changes to the authentication interface do not require explicit synchronization by software executing on the PE to be observable by subsequent external debug interface accesses, and are either observable in finite time or are synchronized by entry to Debug state. Otherwise there are scenarios where a debugger is not able to halt and debug the system.

H8.3.2 Examples of the synchronization of changes to the external debug registers

Example H8-1, Example H8-2 on page H8-6542, and Example H8-3 on page H8-6542 show the synchronization of changes to the external debug registers.

Example H8-1 Order of synchronization of Breakpoint and Watchpoint register writes

Initially DBGBVR<n>_EL1 is 0x8000 and DBGBCR<n>_EL1 is 0x0181. This means that a breakpoint is enabled on the halfword T32 instruction at address 0x8000.

A sequence of external writes occurs in the following order:
1. 0x0000 is written to DBGBCR<n>_EL1, disabling the breakpoint.
2. 0x9000 is written to DBGBVR<n>_EL1[31:0].
3. 0x0061 is written to DBGBCR<n>_EL1, enabling a breakpoint on the halfword at address 0x9002.

The external writes must be observable to indirect reads in the same order as the external writes complete. This means that at no point is there a breakpoint enabled on either of the halfwords at address 0x8002 and 0x9000.

Similarly a breakpoint or watchpoint must be disabled:

- If both halves of a 64-bit address have to be updated.
- If any of the DBGBCR<n>_EL1 or DBGWCR<n>_EL1 fields are modified at the same time as updating the address.

---

**Example H8-2 Simultaneous accesses to DTR registers**

Initially EDSCR.{TXfull, TXU, ERR} are 0. Then:

- 0x00C0DA7A is directly written to DBGDTRTX_EL0 by an MSR instruction.
- DBGDTRTX_EL0 is indirectly read by the external debug interface.

These accesses might happen at the same time and in any order.

If the direct write of 0x00C0DA7A to DBGDTRTX_EL0 is handled first, then:

- The external debug interface read of DBGDTRTX_EL0 clears EDSCR.TXfull to 0.
- EDSCR.{TXU, ERR} are unchanged.
- The external debug interface read returns 0x00C0DA7A.

If the indirect read of DBGDTRTX_EL0 by the external debug interface is handled first, then:

- The external debug interface read of DBGDTRTX_EL0 causes an underrun and as a result EDSCR.{TXU, ERR} are both set to 1.
- The external debug interface returns an UNKNOWN value.
- Writing 0x00C0DA7A to DBGDTRTX_EL0 sets DTRTX to 0x00C0DA7A and EDSCR.TXfull to 1.

---

**Example H8-3 Simultaneous writes to CLAIM registers**

Initially all CLAIM tag bits are 0. Then:

- 0x01 is written to DBGCLAIMSET_EL1 by a direct write, followed by an explicit **Context synchronization event**.
- 0x02 is written to DBGCLAIMSET_EL1 by an external write.

These events might happen at the same time and in either order.

After this:

- DBGCLAIMCLR_EL1 is read by a direct read.
- DBGCLAIMCLR_EL1 is read by an external read.

In this case, a direct read can return either 0x01 or 0x03, and the external read can return either 0x02 or 0x03.

The only permitted final result for the CLAIM tags is the value 0x03, because this would be the result regardless of whether 0x01 or 0x02 is written first. This is because the external write is guaranteed to be observable to a direct read in finite time. See **Synchronization requirements for AArch64 System registers on page D12-2663**.

It is not possible for a direct read to return 0x01 and the external read to return 0x02, because the writes to DBGCLAIMCLR_EL1 are serialized.

In the following scenario, there is only one permitted result. Both observers observe the value 0x03, and then, at the same time, two writes occur:

- 0x04 is written to DBGCLAIMSET_EL1 by a direct write, followed by an explicit **Context synchronization event**.
- 0x01 is written to DBGCLAIMCLR_EL1 by an external write.
In this case only permitted final result for the CLAIM tags is the value 0x06.
H8.4 Memory-mapped accesses to the external debug interface

Support for memory-mapped access to the external debug interface is OPTIONAL. When memory-mapped access to the external debug interface is supported, the external debug interface is accessed as a little-endian memory-mapped peripheral.

If the external debug interface is CoreSight compliant, then an OPTIONAL Software Lock can be implemented for memory-mapped accesses to each component.

The Software Lock is OPTIONAL and deprecated. If ARMv8.4-Debug is implemented, the Software Lock is not implemented. If it is not implemented, the behavior is as if it is unlocked. The Software Locks are controlled by EDLSR and EDLAR, PMLSR and PMLAR, and CTILSR and CTILAR. See Management registers and CoreSight compliance on page K2-7237.

With the exception of these registers and the effect of the Software Lock, the behavior of the memory-mapped accesses is the same as for other accesses to the external debug interface.

Note

The recommended memory-mapped accesses to the external debug interface are not compatible with the memory-mapped interface defined in ARMv7. In particular:

- The memory map is different.
- Memory-mapped accesses do not behave differently to Debug Access Port accesses when OSLR.OSLK == 1, meaning that the OS Lock is locked.

The following sections give more information about these memory-mapped accesses:

- Register access permissions for memory-mapped accesses.
- Synchronization of memory-mapped accesses to external debug registers on page H8-6545.

See also Supported access sizes on page I1-6710.

H8.4.1 Register access permissions for memory-mapped accesses

It is IMPLEMENTATION DEFINED whether unprivileged memory-mapped accesses are allowed. Privileged software is responsible for controlling memory-mapped accesses using the MMU.

If ARMv8.4-Debug is implemented, the Secure view of a debug component is mapped into Secure physical memory and the Non-secure view is mapped into Non-secure physical memory.

If ARMv8.4-Debug is implemented, the access permissions are different in each Security state, but Secure and Non-secure views of the debug components are identical. ARM recommends the views are located at the same address in the Secure and Non-secure physical address maps.

If memory-mapped accesses are made through an ADIv5 interface, the Debug Access Port can block the access using DBGSWENABLE. This is outside the scope of the ARMv8-A architecture. See ARM® Debug Interface Architecture Specification ADIv5.0 to ADIv5.2.

Effect of the OPTIONAL Software Lock on memory-mapped access

For memory-mapped accesses, if other controls permit access to a register, the OPTIONAL Software Lock is implemented, and EDLSR.SLK, PMLSR.SLK, or CTILSR.SLK is set to 1, meaning the Software Lock is locked, then with the exception of the LAR itself:

- If other controls permit access to a register, then writes are ignored. That is:
  - Read/write (RW) registers become read-only, writes ignored (RO/WI).
  - Write-only (WO) registers become writes ignored (WI).

- Reads and writes have no side-effects. A side-effect is where a direct read or a direct write of a register creates an indirect write of the same or another register. When the Software Lock is locked, the indirect write does not occur.
• Writes to EDLR, PMLAR, and CTILAR are unaffected.

This behavior must also apply to all IMPLEMENTATION DEFINED registers.

For example, if EDLSR.SLK is set to 1:

• EDSCR.\{TXfull, TXU, ERR\} are unchanged by a memory-mapped read from DBGDTRTX_EL0.
• EDSCR.\{RXfull, RXO, ERR\} are unchanged by a memory-mapped write to DBGDTRRX_EL0 that is ignored.
• EDSCR.\{ITE, ITO, ERR\} are unchanged by a memory-mapped write to EDITR that is ignored.
• OSLSR.OSLK is unchanged by a memory-mapped write to OSLAR_EL1 that is ignored.
• EDPCSR[63:32], EDCIDSR, and EDVIDSR are unchanged by a memory-mapped read from EDPCSR[31:0].

___ Note _______

Updating EDVIDSR, EDCIDSR, and EDPCSR[63:32] are side-effects of reading EDPCSR[31:0], such that these registers contain the matching context for EDPCSR. The process that updates EDPCSR with PC samples is not a side-effect of the access. Reads of EDPCSR[31:0] made when the Software Lock is locked can be used to profile software.

___ Note _______

• PMPCSR[63:32], PMCID1SR/PMCID2SR, and PMVIDSR are unchanged by a memory-mapped read from PMPCSR[31:0].

Updating PMVIDSR, PMCID1SR/PMCID2SR, and PMPCSR[31:0] are side-effects of reading PMPCSR[63:32], such that these registers contain the matching context for PMPCSR[63:32]. The process that updates PMPCSR[63:32] with PC samples is not a side-effect of the access. Reads of PMPCSR[63:32] made when the Software Lock is locked can be used to profile software.

___ Note _______

• EDPRSR.\{SDR, SPMAD, SDAD, SR, SPD\} are unchanged by a memory-mapped read from EDPRSR.
• EDPRSR.SDAD is not set if an error response is returned due to a memory-mapped read or write of any debug register as the result of the value of the EADAD field.
• The CLAIM tags are unchanged by memory-mapped writes to DBGCLAIMSET_EL1 and DBGCLAIMCLR_EL1 which are ignored.

Similarly, if PMLSR.SLK is set to 1, then EDPRSR.SPMAD is not set if an error response is returned to a memory-mapped read or write of any Performance Monitors register due to the value of the EPMAD field.

**Behavior of a not permitted memory-mapped access**

Where the architecture requires that an external debug interface access generates an error response, a memory-mapped access must also generate an error response. However, it is IMPLEMENTATION DEFINED how the error response is handled, as this depends on the system.

ARM recommends that the error is returned as either:

• A synchronous external Data Abort.
• An SError interrupt.

## H8.4.2 Synchronization of memory-mapped accesses to external debug registers

The synchronization requirements for memory-mapped accesses to the external debug interface is described in *Synchronization of changes to the external debug registers* on page H8-6540 and *Synchronization of memory-mapped registers* on page I1-6712.
The synchronization requirements between different routes to the external debug interface, that is, between Debug Access Port accesses and memory-mapped accesses are IMPLEMENTATION DEFINED.
H8.5 **External debug interface register access permissions**

Some external accesses to debug registers and Performance Monitor registers are not permitted and return an error response if:

- The Core power domain is powered down or is in low-power state where the registers cannot be accessed.
- `OSLSR.OSLK == 1`. The OS Lock is locked.
- The OS Double Lock is implemented and `DoubleLockStatus() == TRUE`. The OS Double Lock is locked.
- Access by the external debug interface is disabled by the authentication interface or secure monitor.

Not all registers are affected in all of these cases. For details, see *External debug interface register access permissions summary* on page H8-6549.

---

**Note**

OSLSR.OSLK is visible through EDPRSR.

---

If ARMv8.4-Debug is not implemented, authentication is controlled by the external authentication interface functions `ExternalSecureNoninvasiveDebugEnabled()` and `ExternalSecureInvasiveDebugEnabled()`, which may override `MDCR_EL3.{EPMAD, EDAD}`.

If ARMv8.4-Debug is implemented, authentication is controlled by the bus master. The bus master may be a Debug Access Port. The bus master uses `MDCR_EL3.{EPMAD, EDAD}` to indicate whether Secure and Non-secure accesses are permitted.

If ARMv8.4-Debug is implemented, an external read of `EDPRSR.{EDAD, EPMAD}` returns the values for a Non-secure view, whether a Secure or Non-secure view is accessed.

H8.5.1 **External debug over powerdown and locks**

Accessing registers using the external debug interface is not possible when the Debug power domain is off. In this case all accesses return an error.

External accesses to debug and Performance Monitors registers in the Core power domain are not permitted and return an error response if:

- The Core power domain is off or in low-power state where the registers cannot be accessed.
- `OSLSR.OSLK == 1`, meaning that the OS Lock is locked. This allows software to prevent external debugger modification of the registers while it saves and restores them over powerdown.
- The OS Double Lock is implemented and `DoubleLockStatus() == TRUE`. This means that the OS Double Lock is locked. The OS Double Lock ensures that it is safe to remove Core power by forcing the debug interface to be quiescent.

It is IMPLEMENTATION DEFINED whether the ID registers that describe the PE to the debugger are in the Debug power domain or the Core power domain.

---

**Note**

This applies only to the MIDR_EL1, EDPFR, EDDFR, and EDAA32PFR registers. It does not include the CoreSight ID registers in the management register address range.

---

The OS Lock condition does not apply to the following debug registers:

- `OSLR_EL1`. This means that an external debugger can override this lock.
- `EDESR`. This means that an external debugger can program a debug event for when software unlocks the OS Lock. See *OS Unlock Catch debug event* on page H3-6476.
- The ID registers that describe the PE to the debugger.

See also *Debug registers to save over powerdown* on page H6-6527.
H8.5.2   External access disabled

Accesses are further controlled by the external authentication interface. An untrusted external debugger cannot program the breakpoint and watchpoint registers to generate spurious debug exceptions. If external invasive debugging is not enabled, these external accesses to the registers are disabled. If EL3 is implemented, then SDCR provides additional external access controls for those registers.

The disable applies to:
• The DBGBVR<el1>, DBGBCR<el1>, DBGWVR<el1>, and DBGWCR<el1> registers.
• From ARMv8.2, the OSLAR_EL1 register.

In ARMv8.0 and ARMv8.1 implementations, it is IMPLEMENTATION DEFINED whether the disable applies to OSLAR_EL1.

If ARMv8.4-Debug is not implemented, the external debug interface cannot access these registers if any of the following are true:
• ExternalInvasiveDebugEnabled() == FALSE.
• ExternalSecureInvasiveDebugEnabled() == FALSE, EL3 is not implemented, and the PE behaves as if the Security state is Secure.
• ExternalSecureInvasiveDebugEnabled() == FALSE, EL3 is implemented and SDCR.EDAD == 1.

If ARMv8.4-Debug is implemented, Non-secure accesses to these registers are not permitted if any of the following are true:
• EL3 is not implemented and the PE behaves as if the Security state is Secure.
• EL3 is implemented and SDCR.EDAD == 1.

The AllowExternalDebugAccess() pseudocode function describes these accessibility rules.

PEs might also provide an OPTIONAL external debug interface to the Performance Monitor registers. The authentication interface and SDCR provide similar external access disable controls for those registers.

If ARMv8.4-Debug is not implemented, the external debug interface cannot access the Performance Monitor registers if any of the following are true:
• ExternalNoninvasiveDebugEnabled() == FALSE.
• ExternalSecureNoninvasiveDebugEnabled() == FALSE, EL3 is not implemented and the PE behaves as if the Security state is Secure.
• ExternalSecureNoninvasiveDebugEnabled() == FALSE, EL3 is implemented and SDCR.EPMAD == 1.

If ARMv8.4-Debug is implemented, Non-secure accesses to these registers are not permitted if any of the following are true:
• EL3 is not implemented and the PE behaves as if the Security state is Secure.
• EL3 is implemented and SDCR.EPMAD == 1.

The AllowExternalPMUAccess() pseudocode function describes these accessibility rules.

--- Note ---
• ARM recommends that secure software that is not making use of debug hardware does not lock out the external debug interface.
• ARMv8-A does not provide the equivalent control over access to Trace extension registers, which means if ARMv8.4-Debug is implemented, the Non-secure and Secure views are identical.

H8.5.3   Behavior of a not permitted access

For an external debug interface access by a Debug Access Port, the Debug Access Port receives the error response and must signal this to the external debugger. For an ADIV5 implementation of a Debug Access Port, the error sets a sticky error flag in the Debug Access Port that the debugger can poll, and that suppresses further accesses until it is explicitly cleared.
When an error is returned because external access is disabled, and this is the highest priority error condition, a sticky error flag in EDPRSR is indirectly written to 1 as a side-effect of the access:

- For a debug register access when AllowExternalPMUAccess() == FALSE, EDPRSR.SDAD is indirectly written to 1.
- For Performance Monitor register access when AllowExternalPMUAccess() == FALSE, EDPRSR.SPMAD is indirectly written to 1.

The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see Register access permissions for memory-mapped accesses on page H8-6544.

If no error is returned, or the error is returned because of a higher priority error condition, the flag in EDPRSR is unchanged.

See also Behavior of a not permitted memory-mapped access on page H8-6545.

For more information, see ARM® Debug Interface Architecture Specification.

**H8.5.4 External debug interface register access permissions summary**

For accesses to:

- IMPLEMENTATION DEFINED registers, see IMPLEMENTATION DEFINED registers.
- OPTIONAL registers for CoreSight compliance, see OPTIONAL CoreSight management registers.
- Reserved, unallocated, or unimplemented registers, writes to read-only registers, and reads of write-only registers, see Reserved and unallocated registers.

For all other external debug interface, CTI, and Performance Monitor registers, Table H8-3 on page H8-6554, Table H8-4 on page H8-6556 and Table I3-1 on page I3-6730, show the response of the PE to accesses by the external debug interface.

If ARMv8.4-Debug is implemented, each debug component has a Secure and a Non-secure view. Non-secure accesses are permitted only when AllowExternalDebugAccess() == TRUE or AllowExternalPMUAccess() == TRUE.

**H8.5.5 IMPLEMENTATION DEFINED registers**

For debug registers, Performance Monitors registers, CTI registers, IMPLEMENTATION DEFINED register access permissions are IMPLEMENTATION DEFINED. The power domain in which these registers are implemented is also IMPLEMENTATION DEFINED.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses to registers. These constraints must also apply to IMPLEMENTATION DEFINED registers. In particular, if the OPTIONAL Software Lock is locked, writes are ignored and accesses have no side-effects. For more information see Register access permissions for memory-mapped accesses on page H8-6544.

**H8.5.6 OPTIONAL CoreSight management registers**

Compliance with CoreSight architecture requires additional registers in the range 0xF00 - 0xFFF that are always accessible. See Management registers and CoreSight compliance on page K2-7237.

**H8.5.7 Reserved and unallocated registers**

The access requirements are described in Access requirements for reserved and unallocated registers on page I1-6714.

--- Note ---

Reads of WO and writes to RO refers to the default access permissions for a register. For example, when the SLK field is set, meaning that the relevant registers become RO, a memory-mapped write to a RW register is ignored, and not treated as a reserved access.
The following reserved registers are RES0 in all conditions, other than when debug power is off:

- If the implementation is CoreSight architecture compliant, all reserved registers in the range 0xF00 - 0xFFC.
  See Management register access permissions on page K2-7238.

- All reserved CTI registers.

Otherwise, the architecture defines that:

1. If debug power is off, all register accesses, including reserved accesses, return an error.

2. For reserved debug registers and Performance Monitors registers, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0, when any of the following hold:
   - **Off**: The Core power domain is either completely off or in a low-power state in which the Core power domain registers cannot be accessed.
   - **DLK**: The OS Double Lock is implemented and DoubleLockStatus() == TRUE. The OS Double Lock is locked.
   - **OSLK**: OSLR.OSLK == 1. The OS Lock is locked.

3. In addition, for reserved debug registers in the address ranges 0x400 - 0x4FC and 0x800 - 0x8FC, the response is a constrained unpredictable choice of error or RES0 when conditions 1 or 2 do not apply and:
   - **EDAD**: AllowExternalDebugAccess() == FALSE. External debug is disabled.

   See also Behavior of a not permitted access on page H8-6548.

4. In addition, for reserved Performance Monitors registers in the address ranges 0x000 - 0xEFC, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:
   - **EPMAD**: AllowExternalPMUAccess() == FALSE. External Performance Monitor access is disabled.

   See also Behavior of a not permitted access on page H8-6548.

5. For reads of WO locations, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when the architecture permits or requires a write to the location to return an error.

6. For writes of RO locations, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when the architecture permits or requires a read to the location to return an error.

7. For reads and writes of locations for features that are not implemented, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when the architecture permits or requires an access to the location to return an error if the feature is implemented.
H8.6 **External debug interface registers**

The external debug interface register map is described by:

- Performance Monitors external register views on page I5-6738.
- Cross-trigger interface registers on page H8-6556.
- External debug interface register map.

a. Supported only if the OPTIONAL PC Sample-Based Profiling is implemented but ARMv8.2-PCSample is not implemented. See Chapter H7 The PC Sample-based Profiling Extension.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented.

b. A 64-bit register mapped to a pair of 32-bit locations. Doubleword accesses to this register are not guaranteed to be 64-bit single copy atomic. See Endianness and supported access sizes on page H8-6539. Software must ensure a breakpoint or watchpoint is disabled before altering the value register.

c. Implemented breakpoints and watchpoints only. \( n \) is the breakpoint or the watchpoint number.

---

**Note**

All other locations are reserved.
H8.6.1 Access permissions for the External debug interface registers

Table H8-3 on page H8-6554 shows the access permissions for the external debug interface registers in an ARMv8-A Debug implementation. The terms are defined as follows:

**Domain**
This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

**Conditions**
This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.

The conditions are:

- **Off**
The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed, and EDPRSR.PU will read as 0.

  Note
  If debug power is off, then all external debug interface accesses return an error.

- **DLK**
The OS Double Lock is implemented and DoubleLockStatus() == TRUE. The OS Double Lock is locked.

- **OSLK**
  OSLR.OSLK == 1. The OS Lock is locked.

- **EDAD**
  AllowExternalDebugAccess() == FALSE. External debug access is disabled for the access. If ARMv8.4-Debug is implemented, this applies only for Non-secure accesses to the register. See also Behavior of a not permitted access on page H8-6548.

- **EPMAD**
  AllowExternalPMUAccess() == FALSE. Access to the external Performance Monitors is disabled for the access. If ARMv8.4-Debug is implemented, this applies only for Non-secure accesses to the register. See also Behavior of a not permitted access on page H8-6548.

- **SLK**
  SoftwareLockStatus() == TRUE. This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See Register access permissions for memory-mapped accesses on page H8-6544. For all other accesses, this column is ignored.

**Default**
This provides the default access permissions, if there are no conditions that prevent access to the register.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.

**RO**
This means that the register or field is read-only, and:

- Unless the register description states otherwise, a RO field in an RW register ignores writes.
- Where the SLK control makes a RW register RO, the register ignores writes.

**RW**
This means that the register or field is read/write. Individual fields within the register might be RO or WO. See the relevant register description for details.

**RC**
This means that a read of the register bit clears the field to 0.

**WO**
This means that the register or field is write-only. Unless the register description states otherwise, a WO field in a RW register returns an UNKNOWN value on a read of the register.

**WI**
This means that the register or field ignores writes.

**IMP DEF**
This means that the access permissions are IMPLEMENTATION DEFINED.
If OPTIONAL memory-mapped access to the external debug interface is supported, there might be additional constraints on memory-mapped accesses. See Register access permissions for memory-mapped accesses on page H8-6544.

- a. Implemented only if the PC Sample-based profiling Extension is implemented.
- b. In ARMv8.0 and ARMv8.1 implementations, it is IMPLEMENTATION DEFINED whether an error is returned. See External access disabled on page H8-6548. If no error is returned, the access is permitted.
- c. Some control bits are in the Core power domain. These bits ignore writes when Core power domain registers cannot be accessed as shown.
- d. Some status bits are fetched from the Core power domain. These bits read UNKNOWN when Core power domain registers cannot be accessed as shown.
- e. Implemented breakpoints and watchpoints only. *n* is the breakpoint or watchpoint number.
- f. It is IMPLEMENTATION DEFINED whether an error is returned. See External debug over powerdown and locks on page H8-6547. If no error is returned, the access is permitted.

For the reset values for the external debug interface registers, see Table H8-6 on page H8-6558.
H8.7 Cross-trigger interface registers

The embedded Cross-trigger Interface, CTI, is located within its own block of the external debug memory map. There must be one such block for each PE.

If the CTI of a PE does not implement the CTIDEVAFF0 or CTIDEVAFF1 registers it must be located 64KB above the debug registers in the external debug interface.

When ARMv8.4-Debug is implemented, each debug component has a Secure and Non-secure view. The Secure view of a debug component is mapped into Secure physical memory and the Non-secure view of a debug component is mapped into Non-secure memory. Apart from access conditions, the Non-secure and Secure views of the debug components are identical.

Table H8-4 shows the CTI register map.

a. Implemented triggers only (including triggers that are not connected). n is the trigger number.

For the reset values of the CTI registers, see Table H8-7 on page H8-6560.
H8.8 External debug register resets

Each register or field has a defined reset domain:

- Registers and fields in the Warm reset domain are also reset by a Cold reset and unchanged by an External Debug reset that is not coincident with a Cold reset or a Warm reset.

- Registers and fields in the Cold reset domain are unchanged by a Warm reset or an External Debug reset that is not coincident with a Cold reset.

- Registers and fields in the External Debug reset domain are unchanged by a Cold reset or a Warm reset that is not coincident with an External Debug reset.

A reset might change the value of a register. Specific rules apply to the observability of registers in the External Debug reset domain by indirect reads from the Core power domain when an External Debug reset is asserted without a coincident Cold reset. For more information, see Synchronization of changes to the external debug registers on page H8-6540.

Table H8-6 and Table H8-7 on page H8-6560 show the external debug register and CTI register resets. For other debug registers and Performance Monitors registers, see Management register resets on page K2-7242 and Power domains and Performance Monitors registers reset on page I3-6731.

Note
By reference to Figure H6-2 on page H6-6531 the power domain can be deduced from the reset domain. Table K2-7 on page K2-7242 also shows reset power domains.

Table H8-6 and Table H8-7 on page H8-6560 do not include:

- Read-only identification registers, such as Processor ID Registers and PMCFGR, that have a fixed value from reset.

- Read-only status registers, such as EDSCR.RW, that are evaluated each time the register is read and that have no meaningful reset value.

- Write-only registers, such as EDRCR, that only have an effect on writes, and have no meaningful reset value.

- Read/write registers, such as breakpoint and watchpoint registers, and EDPRCR.CORENPDRQ, that alias other registers. The reset values are described by the descriptions of those other registers.

- IMPLEMENTATION DEFINED registers. The reset values and reset domains of these registers are also IMPLEMENTATION DEFINED and might be UNKNOWN.

All other fields in the registers are set to an IMPLEMENTATION DEFINED value, that can be UNKNOWN. The register is in the specified reset domain.

Note
An IMPLEMENTATION DEFINED reset value, which can be UNKNOWN, means that hardware is not required to reset the register on the specified reset, but software must not rely on the register being preserved over reset.

---

^a. On a cold reset into AArch64 state, DBGPRCSR_EL1.CORENPRDRQ resets to the value of EDPFRC.COREPURQ. On a cold reset into AArch32 state, DBGPRCSR.CORENPRDRQ resets to the value of EDPFRC.COREPURQ. If an External Debug reset and a Cold reset coincide, both EDPFRC.COREPURQ and the CORENPRDRQ field of the appropriate System register are reset to 0.

Chapter H9
External Debug Register Descriptions

This chapter provides a description of the external debug registers.

It contains the following sections:

• About the debug registers on page H9-6562.
• External debug registers on page H9-6563.
• Cross-Trigger Interface registers on page H9-6665.
H9.1 About the debug registers

The following sections describe the registers that are accessible through the external debug interface:

- *External debug registers on page H9-6563.*
- *Cross-Trigger Interface registers on page H9-6665.*
H9.2 External debug registers

This section describes the debug registers that are accessible through the external debug interface and are used for external debug.

This section lists the registers that are accessible through the external debug interface.
H9.2.1   DBGAUTHSTATUS_EL1, Debug Authentication Status register

The DBGAUTHSTATUS_EL1 characteristics are:

**Purpose**

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

**Configurations**

External register DBGAUTHSTATUS_EL1[31:0] is architecturally mapped to AArch64 System register DBGAUTHSTATUS_EL1[31:0].

External register DBGAUTHSTATUS_EL1[31:0] is architecturally mapped to AArch32 System register DBGAUTHSTATUS[31:0].

It is IMPLEMENTATION DEFINED whether DBGAUTHSTATUS_EL1 is implemented in the Core power domain or in the Debug power domain.

**Attributes**

DBGAUTHSTATUS_EL1 is a 32-bit register.

**Field descriptions**

The DBGAUTHSTATUS_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>8-7</td>
<td>SNID</td>
</tr>
<tr>
<td>6-5</td>
<td>SID</td>
</tr>
<tr>
<td>4-3</td>
<td>NSID</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**SNID, bits [7:6]**

*When ARMv8.4-Debug is implemented:*

Secure non-invasive debug.

ExternalSecureNoninvasiveDebugEnabled() == ExternalSecureInvasiveDebugEnabled().

This field has the same value as DBGAUTHSTATUS_EL1.SID.

*Otherwise:*

Secure non-invasive debug.

- **0b00** Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 1.
- **0b10** Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.
- **0b11** Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

**SID, bits [5:4]**

Secure invasive debug.

- **0b00** Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 1.
- **0b10** Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.
- **0b11** Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

All other values are reserved.
NSNID, bits [3:2]

When ARMv8.4-Debug is implemented:

Non-secure non-invasive debug.

0b00  Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 0.
0b11  Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

If the Effective value of SCR_EL3.NS is 1, or if EL3 is implemented and EL2 is not implemented,
then this field reads as 0b11.
All other values are reserved.

Otherwise:

Non-secure non-invasive debug.

0b00  Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 0.
0b10  Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
0b11  Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.
All other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug.

0b00  Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 0.
0b10  Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
0b11  Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.
All other values are reserved.

Accessing the DBGAUTHSTATUS_EL1:

DBGAUTHSTATUS_EL1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFB8</td>
<td>DBGAUTHSTATUS_EL1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.2   DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n>_EL1 characteristics are:

Purpose
Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>_EL1.

Configurations
External register DBGBCR<n>_EL1[31:0] is architecturally mapped to AArch64 System register DBGBCR<n>_EL1[31:0].
External register DBGBCR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGBCR<n>[31:0].
DBGBCR<n>_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.
If breakpoint n is not implemented then this register is unallocated.

Attributes
DBGBCR<n>_EL1 is a 32-bit register.

Field descriptions
The DBGBCR<n>_EL1 bit assignments are:

| 31 | 24 | 23 | 20 | 19 | 16 | 15 | 14 | 13 | 12 | 9 | 8 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| RES0 | BT | LBN | SSC | RES0 | BAS | PMC | E |

When the E field is zero, all the other fields in the register are ignored.

Bits [31:24]
Reserved, RES0.

BT, bits [23:20]
Breakpoint Type. Possible values are:
0b0000  Unlinked instruction address match. DBGBVR<n>_EL1 is the address of an instruction.
0b0001  As 0b0000 but linked to a Context matching breakpoint.
0b0010  Unlinked Context ID match. When ARMv8.1-VHE is implemented, EL2 is using AArch64, and the Effective value of HCR_EL2.E2H is 1, if either the PE is executing at EL0 with HCR_EL2.TGE set to 1 or the PE is executing at EL2, then DBGBVR<n>_EL1.ContextID must match the CONTEXTIDR_EL2 value. Otherwise, DBGBVR<n>_EL1.ContextID must match the CONTEXTIDR_EL1 value.
0b0011  As 0b0010, with linking enabled.
0b0100  Unlinked instruction address mismatch. DBGBVR<n>_EL1 is the address of an instruction to be stepped.
0b0101  As 0b0100, with linking enabled.
0b0110  Unlinked CONTEXTIDR_EL1 match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1.
H9 External Debug Register Descriptions
H9.2 External debug registers

0b0111  As 0b0110, with linking enabled.
0b1000  Unlinked VMID match. DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.
0b1001  As 0b1000, with linking enabled.
0b1010  Unlinked VMID and Context ID match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.
0b1011  As 0b1010, with linking enabled.
0b1100  Unlinked CONTEXTIDR_EL2 match. DBGBVR<n>_EL1.ContextID2 is a Context ID compared against CONTEXTIDR_EL2.
0b1101  As 0b1100, with linking enabled.
0b1110  Unlinked Full Context ID match. DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.ContextID2 is compared against CONTEXTIDR_EL2.
0b1111  As 0b1110, with linking enabled.

Constraints on breakpoint programming mean some values are reserved under certain conditions. For more information on the operation of the SSC, HMC, and PMC fields, and on the effect of programming this field to a reserved value, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2293 and Reserved DBGBCR<n>_EL1.BT values on page D2-2297.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]
Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.
For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.
This field is ignored when the value of DBGBCR<n>_EL1.E is 0.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]
Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information, including the effect of programming the fields to a reserved set of values, see Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values on page D2-2298.
For more information on the operation of the SSC, HMC, and PMC fields, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2293.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]
Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see DBGBCR<n>_EL1.SSC description.
For more information on the operation of the SSC, HMC, and PMC fields, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2293.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [12:9]
Reserved, RES0.
BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless
of the instruction set and Execution state. In an AArch64 only implementation, this field is reserved,
RES1.

The permitted values depend on the breakpoint type.
For Address match breakpoints in either AArch32 or AArch64 state, the permitted values are:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b011</td>
<td>DBGBVR&lt;(n)&gt;_EL1</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBVR&lt;(n)&gt;_EL1 + 2</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBVR&lt;(n)&gt;_EL1</td>
<td>Use for A64 and A32 instructions</td>
</tr>
</tbody>
</table>

All other values are reserved.
For more information, see Using the BAS field in Address Match breakpoints on page G2-5387.
For Address mismatch breakpoints in an AArch32 stage 1 translation regime, the permitted values are:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>-</td>
<td>Use for a match anywhere breakpoint</td>
</tr>
<tr>
<td>0b0011</td>
<td>DBGBVR&lt;(n)&gt;_EL1</td>
<td>Use for stepping T32 instructions</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBVR&lt;(n)&gt;_EL1 + 2</td>
<td>Use for stepping T32 instructions</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBVR&lt;(n)&gt;_EL1</td>
<td>Use for stepping A64 and A32 instructions</td>
</tr>
</tbody>
</table>

For more information, see Using the BAS field in Address Match breakpoints on page G2-5387.
For Context matching breakpoints, this field is RES1 and ignored.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event
for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields,
and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more
information see the DBGBCR<\(n\)>_EL1.SSC description.
For more information on the operation of the SSC, HMC, and PMC fields, see Execution conditions
for which a breakpoint generates Breakpoint exceptions on page D2-2293.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable breakpoint DBGBVR<\(n\)>_EL1. Possible values are:

0b0 Breakpoint disabled.
0b1 Breakpoint enabled.
On a Cold reset, this field resets to an architecturally UNKNOWN value.
Accessing the DBGBCR<\texttt{n}>_EL1:

--- Note ---

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

DBGBCR<\texttt{n}>_EL1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x408 + 16n</td>
<td>DBGBCR&lt;\texttt{n}&gt;_EL1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
H9.2.3  DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n>_EL1 characteristics are:

**Purpose**

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register DBGBCR<n>_EL1.

**Configurations**

External register DBGBVR<n>_EL1[63:0] is architecturally mapped to AArch64 System register DBGBVR<n>_EL1[63:0].

External register DBGBVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGBVR<n>[31:0].

If the breakpoint is context-aware and EL2 is implemented then External register DBGBVR<n>_EL1[63:32] is architecturally mapped to AArch32 System register DBGBXVR<n>. Otherwise there is no External register access to DBGBVR<n>_EL1[63:32] from AArch32 state.

DBGBVR<n>_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

If breakpoint n is not implemented then this register is unallocated.

**Attributes**

How this register is interpreted depends on the value of DBGBCR<n>_EL1.BT.

- When DBGBCR<n>_EL1.BT is 0b0x0x, this register holds a virtual address.
- When DBGBCR<n>_EL1.BT is 0b001x, 0b011x, or 0b110x, this register holds a Context ID.
- When DBGBCR<n>_EL1.BT is 0b100x, this register holds a VMID.
- When DBGBCR<n>_EL1.BT is 0b101x, this register holds a VMID and a Context ID.
- When DBGBCR<n>_EL1.BT is 0b111x, this register holds two Context ID values.

For other values of DBGBCR<n>_EL1.BT, this register is RES0.

**Field descriptions**

The DBGBVR<n>_EL1 bit assignments are:

When DBGBCR<n>_EL1.BT == 0b0x0x:

<table>
<thead>
<tr>
<th>63</th>
<th>52</th>
<th>49</th>
<th>48</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

RESS[14:4], bits [63:53]

Reserved. Sign extended. Software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.
VA[52:49], bits [52:49]

From ARMv8.2, or if ARMv8.2-LVA is implemented:

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

VA[48:2], bits [48:2]

If the address is being matched in an AArch64 stage 1 translation regime:

- This field contains bits[48:2] of the address for comparison.
- When ARMv8.2-LVA is implemented, VA[52:49] forms the upper part of the address value.
  Otherwise, VA[52:49] are RESS.

If the address is being matched in an AArch32 stage 1 translation regime, the first 20 bits of this field are RES0, and the rest of the field contains bits[31:2] of the address for comparison.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT == 0b001x:

[Diagram]

Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison.
The value is compared against CONTEXTIDR_EL2 when ARMv8.1-VHE is implemented, EL2 is using AArch64, HCR_EL2.E2H is 1, and either:

- The PE is executing at EL2.
- HCR_EL2.TGE is 1, the PE is executing at EL0, and EL2 is enabled in the current Security state.

Otherwise, the value is compared against CONTEXTIDR when the PE is executing at AArch32, or CONTEXTIDR_EL1 when the PE is executing at AArch64.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT == 0b011x:

[Diagram]

Bits [63:32]

Reserved, RES0.
ContextID, bits [31:0]

From ARMv8.1, or if ARMv8.1-VHE is implemented:
Context ID value for comparison against CONTEXTIDR_EL1.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

When DBGBCR<n>_EL1.BT == 0b100x and HaveEL(EL2):

<table>
<thead>
<tr>
<th>Bits [63:48]</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
</tr>
<tr>
<td>VMID[15:8]</td>
</tr>
<tr>
<td>VMID[7:0]</td>
</tr>
<tr>
<td>RES0</td>
</tr>
</tbody>
</table>

VMID[15:8], bits [47:40]

From ARMv8.1, or if ARMv8.1-VHE is implemented:
Extension to VMID[7:0]. See VMID[7:0] for more details.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.
The VMID is 8 bits in the following cases.

- EL2 is using AArch32.
- ARMv8.1-VMID16 is not implemented.

When ARMv8.1-VMID16 is implemented and EL2 is using AArch64, it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

VMID[15:8] is RES0 if any of the following applies:

- The implementation has an 8-bit VMID.
- VTCR_EL2.VS has a value of 0.
- EL2 is using AArch32.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT == 0b101x and HaveEL(EL2):

<table>
<thead>
<tr>
<th>Bits [63:48]</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
</tr>
<tr>
<td>VMID[15:8]</td>
</tr>
<tr>
<td>VMID[7:0]</td>
</tr>
<tr>
<td>ContextID</td>
</tr>
</tbody>
</table>

Bits [63:48]

Reserved, RES0.
VMID[15:8], bits [47:40]

*From ARMv8.1:*

Extension to VMID[7:0]. See VMID[7:0] for more details.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits in the following cases.

- EL2 is using AArch32.
- ARMv8.1-VMID16 is not implemented.

When ARMv8.1-VMID16 is implemented and EL2 is using AArch64, it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

VMID[15:8] is RES0 if any of the following applies:

- The implementation has an 8-bit VMID.
- VTCR_EL2.VS has a value of 0.
- EL2 is using AArch32.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

*When DBGBCR<n>_EL1.BT == 0b110x and HaveEL(EL2):*

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>.ContextID2</td>
<td>ContextID2</td>
<td>RES0</td>
<td>RES0</td>
</tr>
</tbody>
</table>

ContextID2, bits [63:32]

*From ARMv8.1:*

Context ID value for comparison against CONTEXTIDR_EL2.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

Bits [31:0]

Reserved, RES0.

*When DBGBCR<n>_EL1.BT == 0b111x and HaveEL(EL2):*
ContextID2, bits [63:32]

*From ARMv8.1, or if ARMv8.1-VHE is implemented:*

Context ID value for comparison against CONTEXTIDR_EL2.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*
Reserved, RES0.

ContextID, bits [31:0]

*From ARMv8.1, or if ARMv8.1-VHE is implemented:*

Context ID value for comparison against CONTEXTIDR_EL1.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*
Reserved, RES0.

Accessing the DBGBVR<n>_EL1:

**Note**
SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

DBGBVR<n>_EL1[63:0] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x400 + 16n</td>
<td>DBGBVR&lt;n&gt;_EL1</td>
<td>63:0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
H9.2.4 DBGCLAIMCLR_EL1, Debug Claim Tag Clear register

The DBGCLAIMCLR_EL1 characteristics are:

**Purpose**

Used by software to read the values of the CLAIM tag bits, and to clear these bits to 0.

The architecture does not define any functionality for the CLAIM tag bits.

**Note**

CLAIM tags are typically used for communication between the debugger and target software.

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMSET_EL1 register.

**Configurations**

External register DBGCLAIMCLR_EL1[31:0] is architecturally mapped to AArch64 System register DBGCLAIMCLR_EL1[31:0].

External register DBGCLAIMCLR_EL1[31:0] is architecturally mapped to AArch32 System register DBGCLAIMCLR[31:0].

DBGCLAIMCLR_EL1 is in the Core power domain.

This register is not affected by a Warm reset, and is not affected by an External debug reset.

An implementation must include 8 CLAIM tag bits.

**Attributes**

DBGCLAIMCLR_EL1 is a 32-bit register.

**Field descriptions**

The DBGCLAIMCLR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:8</td>
<td>RAZ/SBZ</td>
</tr>
<tr>
<td>7:0</td>
<td>CLAIM</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

**CLAIM, bits [7:0]**

Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits. Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0.

Writing 0 to one of these bits has no effect.

On a Cold reset, this field resets to 0.

**Accessing the DBGCLAIMCLR_EL1:**

DBGCLAIMCLR_EL1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFA4</td>
<td>DBGCLAIMCLR_EL1</td>
</tr>
</tbody>
</table>
This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
H9.2.5 DBGCLAIMSET_EL1, Debug Claim Tag Set register

The DBGCLAIMSET_EL1 characteristics are:

Purpose

Used by software to set the CLAIM tag bits to 1.
The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMCLR_EL1 register.

Configurations

External register DBGCLAIMSET_EL1[31:0] is architecturally mapped to AArch64 System register DBGCLAIMSET_EL1[31:0].
External register DBGCLAIMSET_EL1[31:0] is architecturally mapped to AArch32 System register DBGCLAIMSET[31:0].
DBGCLAIMSET_EL1 is in the Core power domain.
An implementation must include 8 CLAIM tag bits.

Attributes

DBGCLAIMSET_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMSET_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAZ/SBZ</td>
<td>CLAIM</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Set CLAIM tag bits. RAO.
Writing a 1 to one of these bits sets the corresponding CLAIM tag bit to 1. This is an indirect write to the CLAIM tag bits. A single write operation can set multiple CLAIM tag bits to 1.
Writing 0 to one of these bits has no effect.

Accessing the DBGCLAIMSET_EL1:

DBGCLAIMSET_EL1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFA0</td>
<td>DBGCLAIMSET_EL1</td>
</tr>
</tbody>
</table>
This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
H9.2.6 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

**Purpose**

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communications Channel.

**Configurations**

External register DBGDTRRX_EL0[31:0] is architecturally mapped to AArch64 System register DBGDTRRX_EL0[31:0].

External register DBGDTRRX_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRRXInt[31:0].

DBGDTRRX_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

**Attributes**

DBGDTRRX_EL0 is a 32-bit register.

**Field descriptions**

The DBGDTRRX_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Update DTRRX</td>
</tr>
<tr>
<td>30-0</td>
<td>Write to this register:</td>
</tr>
<tr>
<td></td>
<td>• If RXfull is set to 1, set DTRRX to UNKNOWN.</td>
</tr>
<tr>
<td></td>
<td>• If RXfull is set to 0, update the value in DTRRX.</td>
</tr>
<tr>
<td></td>
<td>After the write, RXfull is set to 1.</td>
</tr>
<tr>
<td></td>
<td>Read from this register:</td>
</tr>
<tr>
<td></td>
<td>• If RXfull is set to 1, return the last value written to DTRRX.</td>
</tr>
<tr>
<td></td>
<td>• If RXfull is set to 0, return an UNKNOWN value.</td>
</tr>
<tr>
<td></td>
<td>After the read, RXfull remains unchanged.</td>
</tr>
</tbody>
</table>

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing the DBGDTRRX_EL0:**

If EDSCR.IE == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
• It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

DBGDTTRX_EL0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x080</td>
<td>DBGDTTRX_EL0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

• When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() access to this register is RO.

• When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() access to this register is RW.

• Otherwise access to this register returns an Error.
H9.2.7 DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communication Channel.

Configurations

External register DBGDTRTX_EL0[63:32] is architecturally mapped to AArch64 System register DBGDTRTX_EL0[31:0].

External register DBGDTRTX_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRTXint[31:0].

DBGDTRTX_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Attributes

DBGDTRTX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRTX_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Return DTRTX</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:0]

Return DTRTX.

Reads of this register:

- If TXfull is set to 1, return the last value written to DTRTX.
- If TXfull is set to 0, return an UNKNOWN value.

After the read, TXfull is cleared to 0.

Writes to this register:

- If TXfull is set to 1, set DTRTX to UNKNOWN.
- If TXfull is set to 0, update the value in DTRTX.

After the write, TXfull remains unchanged.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the DBGDTRTX_EL0:

If EDSCR ITE == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
• It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

DBGDTXTX_EL0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x08C</td>
<td>DBGDTXTX_EL0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

• When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() access to this register is RO.

• When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() access to this register is RW.

• Otherwise access to this register returns an Error.
H9.2.8   DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n>_EL1 characteristics are:

**Purpose**

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1.

**Configurations**

External register DBGWCR<n>_EL1[31:0] is architecturally mapped to AArch64 System register DBGWCR<n>_EL1[31:0].

External register DBGWCR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGWCR<n>[31:0].

DBGWCR<n>_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

If breakpoint n is not implemented then this register is unallocated.

**Attributes**

DBGWCR<n>_EL1 is a 32-bit register.

**Field descriptions**

The DBGWCR<n>_EL1 bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>29</th>
<th>28</th>
<th>24</th>
<th>23</th>
<th>21</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>12</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>MASK</td>
<td>RES0</td>
<td>LBN</td>
<td>SSC</td>
<td>BAS</td>
<td>LSC</td>
<td>PAC</td>
<td>E</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

When the E field is zero, all the other fields in the register are ignored.

**Bits [31:29]**

Reserved, RES0.

**MASK, bits [28:24]**

Address mask. Only objects up to 2GB can be watched using a single mask.

0b00000  No mask.

0b00001  Reserved.

0b00010  Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from 0b00001 masking 3 address bits (0x00000007 mask for address) to 0b11111 masking 31 address bits (0xffffffff mask for address).

On a Cold reset, this field resets to an architecturally UNKNOWN value.
Bits [23:21]
Reserved, RES0.

WT, bit [20]
Watchpoint type. Possible values are:
0b0 Unlinked data address match.
0b1 Linked data address match.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]
Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the
Context-matching breakpoint linked to.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]
Security state control. Determines the Security states under which a Watchpoint debug event for
watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.
For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions
for which a watchpoint generates Watchpoint exceptions on page D2-2304.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]
Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug
event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC
fields.
For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions
for which a watchpoint generates Watchpoint exceptions on page D2-2304.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

BAS, bits [12:5]
Byte address select. Each bit of this field selects whether a byte from within the word or
double-word addressed by DBGWVR<\text{n}> EL1 is being watched.

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxxx1xxxx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt; EL1</td>
</tr>
<tr>
<td>xxxx1xx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt; EL1 + 1</td>
</tr>
<tr>
<td>xxxx1xxx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt; EL1 + 2</td>
</tr>
<tr>
<td>xxxx1xxx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt; EL1 + 3</td>
</tr>
</tbody>
</table>

In cases where DBGWVR<\text{n}> EL1 addresses a double-word:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description, if DBGWVR&lt;\text{n}&gt; EL1[2] == 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxx1xxxx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt; EL1 + 4</td>
</tr>
<tr>
<td>xx1xxxxx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt; EL1 + 5</td>
</tr>
<tr>
<td>x1xxxxxx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt; EL1 + 6</td>
</tr>
<tr>
<td>lxxxxxxx</td>
<td>Match byte at DBGWVR&lt;\text{n}&gt; EL1 + 7</td>
</tr>
</tbody>
</table>

The valid values for BAS are non-zero binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software. See Reserved DBGWCR<EL1.BAS values on page G2-5409.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

- 0b01: Match instructions that load from a watchpointed address.
- 0b10: Match instructions that store to a watchpointed address.
- 0b11: Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-2304.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable watchpoint n. Possible values are:

- 0b0: Watchpoint disabled.
- 0b1: Watchpoint enabled.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing the DBGWCR<EL1:**

--- Note ---

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

DBGWCR<EL1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x808 + 16n</td>
<td>DBGWCR&lt;EL1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
H9.2.9  DBGWVR<\text{n}> _EL1, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<\text{n}> _EL1 characteristics are:

**Purpose**

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<\text{n}> _EL1.

**Configurations**

External register DBGWVR<\text{n}> _EL1[63:0] is architecturally mapped to AArch64 System register DBGWVR<\text{n}> _EL1[63:0].

External register DBGWVR<\text{n}> _EL1[31:0] is architecturally mapped to AArch32 System register DBGWVR<\text{n}>[31:0].

DBGWVR<\text{n}> _EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

If breakpoint n is not implemented then this register is unallocated.

**Attributes**

DBGWVR<\text{n}> _EL1 is a 64-bit register.

**Field descriptions**

The DBGWVR<\text{n}> _EL1 bit assignments are:

- **RESS[14:4], bits [63:53]**
  
  Reserved, Sign extended. Hardware and software must treat this field as RES0 if the most significant bit of VA is 0 or RES1 if the most significant bit of VA is 1.

  Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:
  - The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
  - The value held in those bits is ignored by hardware.

- **VA[52:49], bits [52:49]**
  
  When ARMv8.2-LVA is implemented:
  

  On a Cold reset, this field resets to an architecturally UNKNOWN value.

- **VA[48:2], bits [48:2]**
  
  Bits[48:2] of the address value for comparison.

  When ARMv8.2-LVA is implemented, VA[52:49] forms the upper part of the address value.

  Otherwise, VA[52:49] are RESSS.

On a Cold reset, this field resets to an architecturally **UNKNOWN** value.

**Bits [1:0]**

Reserved, RES0.

**Accessing the DBGWVR<n>_EL1:**

--- **Note** ---

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

---

DBGWVR<n>_EL1[63:0] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x800  + 16n</td>
<td>DBGWVR&lt;n&gt;_EL1</td>
<td>63:0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and SoftwareLockStatus() access to this register is RO.

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and !SoftwareLockStatus() access to this register is RW.

- Otherwise access to this register returns an Error.
H9.2.10   EDAA32PFR, External Debug AArch32 Processor Feature Register

The EDAA32PFR characteristics are:

**Purpose**

Provides information about implemented PE features.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D12-2668.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDAA32PFR is implemented in the Core power domain or in the Debug power domain.

EDAA32PFR is only accessible in an implementation that only supports execution in AA32 state. If AArch64 state is supported at any Exception level, EDAA32PFR is RES0.

**Attributes**

EDAA32PFR is a 64-bit register.

**Field descriptions**

The EDAA32PFR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-16</td>
<td>Reserved, RES0</td>
<td>0-255</td>
<td></td>
</tr>
<tr>
<td>15-12</td>
<td>EL3</td>
<td>0-2</td>
<td></td>
</tr>
<tr>
<td>11-8</td>
<td>EL2</td>
<td>0-2</td>
<td></td>
</tr>
<tr>
<td>7-4</td>
<td>PMSA</td>
<td>0-15</td>
<td></td>
</tr>
<tr>
<td>3-0</td>
<td>VMSA</td>
<td>0-31</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:16]**

Reserved, RES0.

**EL3, bits [15:12]**

AArch32 EL3 Exception level handling. Defined values are:

- **0b0000** EL3 is not implemented.
- **0b0001** EL3 can be executed in AArch32 state only.

When the value of EDPR.EL3 is non-zero, this field must be **0b0000**. All other values are reserved.

---

**Note**

EDPR. [EL1, EL0] indicate whether EL1 and EL0 can only be executed in AArch32 state.

---

**EL2, bits [11:8]**

AArch32 EL2 Exception level handling. Defined values are:

- **0b0000** EL2 is not implemented.
- **0b0001** EL2 can be executed in AArch32 state only.

When the value of EDPR.EL2 is non-zero, this field must be **0b0000**. All other values are reserved.

---

**Note**

EDPR. [EL1, EL0] indicate whether EL1 and EL0 can only be executed in AArch32 state.
PMSA, bits [7:4]
Indicates support for a PMSA. Defined values are:
- 0b0000  PMSA not supported.
- 0b0100  Support for an Armv8-R PMSA v8-32.
All other values are reserved. In Armv8-A, the only permitted value is 0b0000.

VMSA, bits [3:0]
Indicates support for a VMSA. When the PMSA field is nonzero, determines support for a VMSA. When the PMSA field is 0b0000, VMSA is supported. Defined values are:
- 0b0000  VMSA not supported.
All other values are reserved. In Armv8-A, the only permitted value is 0b0000.

Accessing the EDAA32PFR:

EDAA32PFR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xD60</td>
<td>EDAA32PFR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered() and !DoubleLockStatus() access to this register is RO.
- Otherwise access to this register is IMPDEF.
H9.2.11  EDACR, External Debug Auxiliary Control Register

The EDACR characteristics are:

**Purpose**

Allows implementations to support IMPLEMENTATION DEFINED controls.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDACR is implemented in the Core power domain or in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

Changing this register from its reset value causes IMPLEMENTATION DEFINED behavior, including possible deviation from the architecturally-defined behavior.

If the EDACR contains any control bits that must be preserved over power down, then these bits must be accessible by the external debug interface when the OS Lock is locked, OSLSR_EL1.OSLK == 1, and when the Core is powered off.

**Attributes**

EDACR is a 32-bit register.

**Field descriptions**

The EDACR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:0</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>
H9.2.12  EDCIDR0, External Debug Component Identification Register 0

The EDCIDR0 characteristics are:

**Purpose**

Provides information to identify an external debug component.

For more information see [About the Component Identification scheme on page K2-7245](#).

**Configurations**

It is IMPLEMENTATION DEFINED whether EDCIDR0 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

EDCIDR0 is a 32-bit register.

**Field descriptions**

The EDCIDR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:8 RES0</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>7:0 PRMBL_0</td>
<td>Preamble. Must read as 0x0D.</td>
</tr>
</tbody>
</table>

**Accessing the EDCIDR0:**

EDCIDR0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFFFF</td>
<td>EDCIDR0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.13   EDCIDR1, External Debug Component Identification Register 1

The EDCIDR1 characteristics are:

**Purpose**

Provides information to identify an external debug component.

For more information see *About the Component Identification scheme on page K2-7245*.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDCIDR1 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

EDCIDR1 is a 32-bit register.

**Field descriptions**

The EDCIDR1 bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>CLASS</td>
<td>PRMBL_1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:8]**

Reserved, RES0.

**CLASS, bits [7:4]**

Component class. Reads as 0x9, debug component.

**PRMBL_1, bits [3:0]**

Preamble. RAZ.

**Accessing the EDCIDR1:**

EDCIDR1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFF4</td>
<td>EDCIDR1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.14 EDCIDR2, External Debug Component Identification Register 2

The EDCIDR2 characteristics are:

**Purpose**

Provides information to identify an external debug component.

For more information see *About the Component Identification scheme on page K2-7245.*

**Configurations**

It is **IMPLEMENTATION DEFINED** whether EDCIDR2 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is **OPTIONAL**.

This register is required for CoreSight compliance.

**Attributes**

EDCIDR2 is a 32-bit register.

**Field descriptions**

The EDCIDR2 bit assignments are:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>8</td>
<td>7</td>
<td>0</td>
</tr>
<tr>
<td>RES0</td>
<td>PRMBL_2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**PRMBL_2, bits [7:0]**

Preamble. Must read as 0x05.

**Accessing the EDCIDR2:**

EDCIDR2 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFF8</td>
<td>EDCIDR2</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.

- Otherwise access to this register returns an Error.
H9.2.15 EDCIDR3, External Debug Component Identification Register 3

The EDCIDR3 characteristics are:

**Purpose**

Provides information to identify an external debug component.

For more information see *About the Component Identification scheme* on page K2-7245.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDCIDR3 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

EDCIDR3 is a 32-bit register.

**Field descriptions**

The EDCIDR3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>8-7</td>
<td>PRMBL_3, bits [7:0]</td>
</tr>
</tbody>
</table>

Preamble. Must read as 0xB1.

**Accessing the EDCIDR3**:

EDCIDR3 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFFC</td>
<td>EDCIDR3</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.16 EDCIDSR, External Debug Context ID Sample Register

The EDCIDSR characteristics are:

**Purpose**

Contains the sampled value of the Context ID, captured on reading EDPCSR[31:0].

**Configurations**

EDCIDSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented in the external debug registers space.

--- Note ---

ARMv8.2-PCSample implements the PC Sample-based Profiling Extension in the Performance Monitors registers space.

---

**Attributes**

EDCIDSR is a 32-bit register.

**Field descriptions**

The EDCIDSR bit assignments are:

*When ARMv8.2-PCSample is implemented:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:0</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

*Otherwise:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:0</td>
<td>CONTEXTIDR</td>
</tr>
</tbody>
</table>

**CONTEXTIDR, bits [31:0]**

Context ID. The value of CONTEXTIDR that is associated with the most recent EDPCSR sample.

- If EL1 is using AArch64, then the Context ID is held in CONTEXTIDR_EL1.
- If EL1 is using AArch32, then the Context ID is held in CONTEXTIDR.
- If EL3 is implemented and is using AArch32, then CONTEXTIDR is a banked register, and EDCIDSR samples the current banked copy of CONTEXTIDR for the Security state that is associated with the most recent EDPCSR sample.

Because the value written to EDCIDSR is an indirect read of CONTEXTIDR, therefore it is CONSTRAINED UNPREDICTABLE whether EDCIDSR is set to the original or new value if a read of EDPCSRlo samples:

- An instruction that writes to CONTEXTIDR_EL1.
• The next Context synchronization event.
• Any instruction executed between these two instructions.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing the EDCIDSR:**

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see *Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN* on page H7-6536.

EDCIDSR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x0A4</td>
<td>EDCIDSR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

• When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to this register is RO.

• Otherwise access to this register returns an Error.
H9.2.17   EDDEVAFF0, External Debug Device Affinity register 0

The EDDEVAFF0 characteristics are:

**Purpose**

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDDEVAFF0 is implemented in the Core power domain or in the Debug power domain.

**Attributes**

EDDEVAFF0 is a 32-bit register.

**Field descriptions**

The EDDEVAFF0 bit assignments are:

```
+---------+---------+
| 31      | 0       |
| MPIDR_EL1 low half |
```

**MPIDR_EL1 low half, bits [31:0]**

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

**Accessing the EDDEVAFF0:**

EDDEVAFF0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFA8</td>
<td>EDDEVAFF0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.18 EDDEVAFF1, External Debug Device Affinity register 1

The EDDEVAFF1 characteristics are:

**Purpose**

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDDEVAFF1 is implemented in the Core power domain or in the Debug power domain.

**Attributes**

EDDEVAFF1 is a 32-bit register.

**Field descriptions**

The EDDEVAFF1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPIDR_EL1 high half</td>
<td></td>
</tr>
</tbody>
</table>

**MPIDR_EL1 high half, bits [31:0]**

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

**Accessing the EDDEVAFF1:**

EDDEVAFF1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFAC</td>
<td>EDDEVAFF1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.19 EDDEVARCH, External Debug Device Architecture register

The EDDEVARCH characteristics are:

**Purpose**
Identifies the programmers’ model architecture of the external debug component.

**Configurations**
It is IMPLEMENTATION DEFINED whether EDDEVARCH is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

**Attributes**
EDDEVARCH is a 32-bit register.

**Field descriptions**
The EDDEVARCH bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCHITECT</td>
<td>[31:21]</td>
<td>Defines the architecture of the component. For debug, this is Arm Limited.</td>
</tr>
<tr>
<td>REVISION</td>
<td>[19:16]</td>
<td>Defines the architecture revision. For architectures defined by Arm this is the minor revision. For debug, the revision defined by Armv8-A is 0x0. All other values are reserved.</td>
</tr>
<tr>
<td>ARCHVER</td>
<td>[15:12]</td>
<td>Defines the architecture version of the component. This is the same value as ID_AA64FR0_EL1.DebugVer and DBGIDR.Version. The defined values of this field are: 0b0110 Armv8.0 Debug architecture. 0b0111 Armv8.0 Debug architecture with Virtualization Host Extensions. 0b1000 Armv8.2 Debug architecture. 0b1001 Armv8.4 Debug architecture. ARMv8.4-Debug adds the functionality indicated by the value 0b1001. ARMv8.2-Debug adds the functionality indicated by the value 0b1000. If ARMv8.1-VHE is not implemented, the only permitted value is 0b0110. The fields ARCHVER and ARCHPART together form the field ARCHID, so that ARCHVER is ARCHID[15:12].</td>
</tr>
<tr>
<td>ARCHPART</td>
<td>[11:0]</td>
<td></td>
</tr>
</tbody>
</table>

PRESENT, bit [20]
When set to 1, indicates that the DEVARCH is present.
This field is 1 in Armv8.
ARCHPART, bits [11:0]

0xA15  The part number of the Armv8-A debug component.

The fields ARCHVER and ARCHPART together form the field ARCHID, so that ARCHPART is ARCHID[11:0].

Accessing the EDDEVARCH:

EDDEVARCH can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFBC</td>
<td>EDDEVARCH</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.20 EDDEVID, External Debug Device ID register 0

The EDDEVID characteristics are:

**Purpose**

Provides extra information for external debuggers about features of the debug implementation.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDDEVID is implemented in the Core power domain or in the Debug power domain.

**Attributes**

EDDEVID is a 32-bit register.

**Field descriptions**

The EDDEVID bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Purpose</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:28</td>
<td>Reserved, RES0.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>27:24</td>
<td>AuxRegs</td>
<td></td>
<td></td>
</tr>
<tr>
<td>24:4</td>
<td>Reserved, RES0.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3:0</td>
<td>PCSample</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**AuxRegs, bits [27:24]**

Indicates support for Auxiliary registers. Permitted values for this field are:

- 0b0000: None supported.
- 0b0001: Support for External Debug Auxiliary Control Register, EDACR.

All other values are reserved.

**Bits [23:4]**

Reserved, RES0.

**PCSample, bits [3:0]**

Indicates the level of PC Sample-based Profiling support using external debug registers. Permitted values of this field are:

- 0b0000: PC Sample-based Profiling Extension is not implemented in the external debug registers space.
- 0b0010: Only EDPCSR and EDCIDSR are implemented. This option is only permitted if EL3 and EL2 are not implemented.
- 0b0011: EDPCSR, EDCIDSR, and EDVIDSR are implemented.

All other values are reserved.

When ARMv8.2-PCSample is implemented, the only permitted value is 0b0000.

**Note**

ARMv8.2-PCSample implements the PC Sample-based Profiling Extension in the Performance Monitors register space, as indicated by the value of PMDEVID.PCSample.
Accessing the EDDEVID:

EDDEVID can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFC8</td>
<td>EDDEVID</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.21   EDDEVID1, External Debug Device ID register 1

The EDDEVID1 characteristics are:

**Purpose**

Provides extra information for external debuggers about features of the debug implementation.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDDEVID1 is implemented in the Core power domain or in the Debug power domain.

**Attributes**

EDDEVID1 is a 32-bit register.

**Field descriptions**

The EDDEVID1 bit assignments are:

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>4</td>
<td>3</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>RES0</td>
<td>PCSROffset</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:4]**

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>RES0</td>
<td>PCSROffset</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Reserved, RES0.**

**PCSROffset, bits [3:0]**

This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in Armv8 are:

- **0b0000**  EDPCSR not implemented.
- **0b0010**  EDPCSR implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state.

When ARMv8.2-PCSample is implemented, the only permitted value is **0b0000**.

**Note**

ARMv8.2-PCSample implements the PC Sample-based Profiling Extension in the Performance Monitors register space, as indicated by the value of PMDEVID.PCSample.

**Accessing the EDDEVID1:**

EDDEVID1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFc4</td>
<td>EDDEVID1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.22 EDDEVID2, External Debug Device ID register 2

The EDDEVID2 characteristics are:

Purpose
Reserved for future descriptions of features of the debug implementation.

Configurations
It is IMPLEMENTATION DEFINED whether EDDEVID2 is implemented in the Core power domain or in the Debug power domain.

Attributes
EDDEVID2 is a 32-bit register.

Field descriptions
The EDDEVID2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

Accessing the EDDEVID2:
EDDEVID2 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFC0</td>
<td>EDDEVID2</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:
- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.23 EDDEVTYPE, External Debug Device Type register

The EDDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PEs debug logic.

Configurations

It is IMPLEMENTATION DEFINED whether EDDEVTYPE is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

Attributes

EDDEVTYPE is a 32-bit register.

Field descriptions

The EDDEVTYPE bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>7-4</td>
<td>Subtype, must read as 0x1</td>
</tr>
<tr>
<td>3-0</td>
<td>Major type, must read as 0x5</td>
</tr>
</tbody>
</table>

Accessing the EDDEVTYPE:

EDDEVTYPE can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFCC</td>
<td>EDDEVTYPE</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.24  EDDFR, External Debug Feature Register

The EDDFR characteristics are:

Purpose

Provides top level information about the debug system.

--- Note ---

Debuggers must use EDDEVARCH to determine the Debug architecture version.

---

For general information about the interpretation of the ID registers, see Principles of the ID scheme for fields in ID registers on page D12-2668.

Configurations

It is IMPLEMENTATION DEFINED whether EDDFR is implemented in the Core power domain or in the Debug power domain.

There are no configuration notes.

Attributes

EDDFR is a 64-bit register.

Field descriptions

The EDDFR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:44]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>TraceFilt, bits [43:40]</td>
<td>When ARMv8.4-Trace is implemented:</td>
</tr>
<tr>
<td></td>
<td>Armv8.4 Self-hosted Trace Extension version. The defined values of this field are:</td>
</tr>
<tr>
<td></td>
<td>0b0000  Armv8.4 Self-hosted Trace Extension is not implemented.</td>
</tr>
<tr>
<td></td>
<td>0b0001  Armv8.4 Self-hosted Trace Extension is implemented.</td>
</tr>
<tr>
<td></td>
<td>All other values are reserved.</td>
</tr>
<tr>
<td>Unknown, bits [39:32]</td>
<td>Reserved, UNKNOWN.</td>
</tr>
<tr>
<td>CTX_CMPs, bits [31:28]</td>
<td>Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints.</td>
</tr>
<tr>
<td></td>
<td>In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.CTX_CMPs.</td>
</tr>
<tr>
<td>Bits [27:24]</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
WRPs, bits [23:20]

Number of watchpoints, minus 1. The value of 0b0000 is reserved.
In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.WRPs.

Bits [19:16]

Reserved, RES0.

BRPs, bits [15:12]

Number of breakpoints, minus 1. The value of 0b0000 is reserved.
In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.BRPs.

PMUVer, bits [11:8]

Performance Monitors Extension version.
This field does not follow the standard ID scheme, but uses the Alternative ID scheme described in Alternative ID scheme used for the Performance Monitors Extension version on page D12-2670.
Defined values are:

0b0000 Performance Monitors Extension not implemented.
0b0001 Performance Monitors Extension implemented, PMUv3.
0b0100 PMUv3 for Armv8.1. As 0b0001, and also includes support for:
   • Extended 16-bit PMEVTYPER<n>_EL0.evtCount field.
   • If EL2 is implemented, the MDCR_EL2.HPMD control bit.
0b0101 PMUv3 for Armv8.4. As 0b0100 and also includes support for the PMMIR register.
0b1111 IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported. Arm does not recommend this value in new implementations.

ARMv8.1-PMU implements the functionality added by the value 0b0100.
ARMv8.4-PMU implements the functionality added by the value 0b0101.
All other values are reserved.
From Armv8.1, the value 0b0001 is not permitted.
From Armv8.4, the value 0b0100 is not permitted.
In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.PMUVer.

TraceVer, bits [7:4]

Trace support. Indicates whether System register interface to a PE trace unit is implemented.
Defined values are:

0b0000 PE trace unit System registers not implemented.
0b0001 PE trace unit System registers implemented.
All other values are reserved.
A value of 0b0000 only indicates that no System register interface to a PE trace unit is implemented. A PE trace unit might nevertheless be implemented without a System register interface.
In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.TraceVer.

UNKNOWN, bits [3:0]

Reserved, UNKNOWN.
Accessing the EDDFR:

EDDFR[31:0] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x028</td>
<td>EDDFR</td>
<td>31:0</td>
</tr>
</tbody>
</table>

EDDFR[63:32] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x02C</td>
<td>EDDFR</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- When IsCorePowered() and !DoubleLockStatus() access to EDDFR[31:0] is RO.
- Otherwise access to EDDFR[31:0] is IMPDEF.
- When IsCorePowered() and !DoubleLockStatus() access to EDDFR[63:32] is RO.
- Otherwise access to EDDFR[63:32] is IMPDEF.
H9.2.25 EDECCR, External Debug Exception Catch Control Register

The EDECCR characteristics are:

**Purpose**

Controls Exception Catch debug events.

**Configurations**

External register EDECCR[31:0] is architecturally mapped to AArch64 System register OSECCR_EL1[31:0].

External register EDECCR[31:0] is architecturally mapped to AArch32 System register DBGSECCR[31:0].

EDECCR is in the Core power domain. Some or all RW fields of this register have defined reset values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

**Attributes**

EDECCR is a 32-bit register.

**Field descriptions**

The EDECCR bit assignments are:

*When ARMv8.2-Debug is implemented:*

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:16</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>15:12</td>
<td>SE&lt;(n)&gt; bit ([n])</td>
</tr>
<tr>
<td>11:8</td>
<td>NSE&lt;(n)&gt; bit ([n+4])</td>
</tr>
<tr>
<td>7:4</td>
<td>SR&lt;(n)&gt; bit ([n+8])</td>
</tr>
<tr>
<td>3:0</td>
<td>NSR&lt;(n)&gt; bit ([n+12])</td>
</tr>
</tbody>
</table>

**Bits [31:16]**

Reserved, RES0.

**NSR<\(n\)> bit \([n+12]\), for \(n = 0 \text{ to } 3\)**

- \(0\)0: If the corresponding NSE<\(n\)> bit is 0, then Exception Catch debug events are disabled for Non-secure Exception level <\(n\)>.
- \(0\)1: If the corresponding NSE<\(n\)> bit is 1, then Exception Catch debug events are enabled for exception entry, reset entry and exception return to Non-secure Exception level <\(n\)>.
- \(1\)0: If the corresponding SE<\(n\)> bit is 0, then Exception Catch debug events are enabled for Non-secure Exception level <\(n\)>.
- \(1\)1: If the corresponding SE<\(n\)> bit is 1, then Exception Catch debug events are enabled for exception return to Non-secure Exception level <\(n\)>.

See the Table H3-5 on page H3-6473 for information.

If EL3 is not implemented and the PE behaves as if SCR_EL3.NS is set to 0, this field is reserved, RES0. Otherwise, possible values for this field are:

\(0\)0: If the corresponding NSE<\(n\)> bit is 0, then Exception Catch debug events are disabled for Non-secure Exception level <\(n\)>.

\(0\)1: If the corresponding NSE<\(n\)> bit is 1, then Exception Catch debug events are enabled for exception entry, reset entry and exception return to Non-secure Exception level <\(n\)>.

\(1\)0: If the corresponding SE<\(n\)> bit is 0, then Exception Catch debug events are enabled for Non-secure Exception level <\(n\)>.

\(1\)1: If the corresponding SE<\(n\)> bit is 1, then Exception Catch debug events are enabled for exception return to Non-secure Exception level <\(n\)>.
--- Note ---

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level is permitted to generate an Exception Catch debug event.

---

A value of the NSR field that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If the NSR field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for NSR by a read of EDECCR is UNKNOWN.

On a Cold reset, this field resets to 0.

SR<n>, bit [n+8], for n = 0 to 3

Controls Secure exception catch on exception return to EL<n> in conjunction with SE<n>. See the Table H3-5 on page H3-6473 for information.

If EL3 is not implemented and the PE behaves as if SCR_EL3.NS is set to 1, this field is reserved, RES0. Otherwise, possible values for this field are:

0b0  If the corresponding SE<n> bit is 0, then Exception Catch debug events are disabled for Secure Exception level <n>.
     If the corresponding SE<n> bit is 1, then Exception Catch debug events are enabled for exception entry, reset entry and exception return to Secure Exception level <n>.

0b1  If the corresponding SE<n> bit is 0, then Exception Catch debug events are enabled for exception return to Secure Exception level <n>.
     If the corresponding SE<n> bit is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure Exception level <n>.

--- Note ---

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level is permitted to generate an Exception Catch debug event.

---

A value of the SR field that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If the SR field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for SR by a read of EDECCR is UNKNOWN.

On a Cold reset, this field resets to 0.

NSE<n>, bit [n+4], for n = 0 to 3

Coarse-grained Non-secure exception catch for EL<n>. This controls whether Exception Catch debug events are enabled for Non-secure EL<n>. This also controls:

- The behavior of exception catch on exception entry to EL<n>.
- The behavior of exception catch on exception return to EL<n> in conjunction with NSR<n>.

If EL3 is not implemented and the PE behaves as if SCR_EL3.NS is set to 0, this field is reserved, RES0. Otherwise, possible values for this field are:

0b0  If the corresponding NSR<n> bit is 0, then Exception Catch debug events are disabled for Non-secure Exception level <n>.
     If the corresponding NSR<n> bit is 1, then Exception Catch debug events are enabled for exception returns to Non-secure Exception level <n>.

0b1  If the corresponding NSR<n> bit is 0, then Exception Catch debug events are enabled for exception entry, reset entry and exception return to Non-secure Exception level <n>.
     If the corresponding NSR<n> bit is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Non-secure Exception level <n>.
A value of the NSE field that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If the NSE field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for NSE by a read of EDECCR is UNKNOWN.

On a Cold reset, this field resets to 0.

**SE\(n\), bit [n], for n = 0 to 3**

Coarse-grained Secure exception catch for EL\(n\). This field controls whether Exception Catch debug events are enabled for Secure EL\(n\).

- The behavior of exception catch on exception entry to EL\(n\).
- The behavior of exception catch on exception return to EL\(n\) in conjunction with SR\(n\).

If EL3 is not implemented and the PE behaves as if SCR_EL3.NS is set to 1, this field is reserved, RES0. Otherwise, possible values for this field are:

- **0b0** If the corresponding SR\(n\) bit is 0, then Exception Catch debug events are disabled for Secure Exception level \(<n>\).
  
  If the corresponding SR\(n\) bit is 1, then Exception Catch debug events are enabled for exception returns to Secure Exception level \(<n>\).

- **0b1** If the corresponding SR\(n\) bit is 0, then Exception Catch debug events are enabled for exception entry, reset entry and exception return to Secure Exception level \(<n>\).
  
  If the corresponding SR\(n\) bit is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure Exception level \(<n>\).

A value of the SE field that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If the SE field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for SE by a read of EDECCR is UNKNOWN.

On a Cold reset, this field resets to 0.

**Otherwise:**

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**NSE\(n\), bit [n+4], for n = 0 to 3**

Coarse-grained Non-secure exception catch. If EL3 and EL2 are not implemented and the PE behaves as if SCR_EL3.NS is set to 0, this field is reserved, RES0. Otherwise, possible values for this field are:

- **0b0** Exception Catch debug events are disabled for Non-secure Exception level \(<n>\).
- **0b1** Exception Catch debug events are enabled for Non-secure Exception level \(<n>\).
A value of the NSE field that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If the NSE field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for NSE by a read of EDECCR is **UNKNOWN**.

**SE<\text{n}>, bit [n], for n = 0 to 3**

Coarse-grained Secure exception catch. If EL3 is not implemented and the PE behaves as if \text{SCR_EL3.NS} is set to 1, this field is reserved, RES0. Otherwise, possible values for this field are:

- \text{0b0} Exception Catch debug events are disabled for Secure Exception level \text{<\text{n}>}.
- \text{0b1} Exception Catch debug events are enabled for Secure Exception level \text{<\text{n}>}.

A value of the SE field that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If the SE field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for SE by a read of EDECCR is **UNKNOWN**.

**Accessing the EDECCR:**

EDECCR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x098</td>
<td>EDECCR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When \text{IsCorePowered()}, \text{!DoubleLockStatus()}, \text{!OSLockStatus()} and \text{SoftwareLockStatus()} access to this register is RO.
- When \text{IsCorePowered()}, \text{!DoubleLockStatus()}, \text{!OSLockStatus()} and \text{!SoftwareLockStatus()} access to this register is RW.
- Otherwise access to this register returns an Error.
### EDECR, External Debug Execution Control Register

The EDECR characteristics are:

**Purpose**

Controls Halting debug events.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDECR is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

**Attributes**

EDECR is a 32-bit register.

**Field descriptions**

The EDECR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>30</td>
<td>OSUCE</td>
</tr>
<tr>
<td>29</td>
<td>RCE</td>
</tr>
<tr>
<td>28</td>
<td>SS</td>
</tr>
<tr>
<td>31:3</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

**SS, bit [2]**

Halting step enable. Possible values of this field are:

- 0b0  Halting step debug event disabled.
- 0b1  Halting step debug event enabled.

If the value of EDECR.SS is changed when the PE is in Non-debug state, behavior is CONSTRAINED UNPREDICTABLE as described in Changing the value of EDECR.SS when not in Debug state on page H3-6467.

**RCE, bit [1]**

Reset Catch Enable.

- 0b0  Reset Catch debug event disabled.
- 0b1  Reset Catch debug event enabled.

On a External debug reset, this field resets to 0.

**OSUCE, bit [0]**

OS Unlock Catch Enable.

- 0b0  OS Unlock Catch debug event disabled.
- 0b1  OSUnlock Catch debug event enabled.

On a External debug reset, this field resets to 0.
**Accessing the EDECR:**

EDECR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x024</td>
<td>EDECR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When `SoftwareLockStatus()` access to this register is RO.
- When `!SoftwareLockStatus()` access to this register is RW.
- Otherwise access to this register returns an Error.
H9.2.27   EDESR, External Debug Event Status Register

The EDESR characteristics are:

**Purpose**
Indicates the status of internally pending Halting debug events.

**Configurations**
EDESR is in the Core power domain. Some or all RW fields of this register have defined reset values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

**Attributes**
EDESR is a 32-bit register.

**Field descriptions**
The EDESR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Halting step debug event pending</td>
<td>0b0 (not pending), 0b1 (pending)</td>
</tr>
<tr>
<td>2</td>
<td>Reset Catch debug event pending</td>
<td>0b0 (not pending), 0b1 (pending)</td>
</tr>
<tr>
<td>1</td>
<td>OS Unlock Catch debug event pending</td>
<td>0b0 (not pending), 0b1 (pending)</td>
</tr>
<tr>
<td>0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **RES0**
- **SS**
- **RC**
- **OSUC**

**Bits [31:3]**
Reserved, RES0.

**SS, bit [2]**
Halting step debug event pending. Possible values of this field are:
- 0b0: Reading this means that a Halting step debug event is not pending. Writing this means no action.
- 0b1: Reading this means that a Halting step debug event is pending. Writing this clears the pending Halting step debug event.

On a Warm reset, this field resets to the value in EDECR.SS.

**RC, bit [1]**
Reset Catch debug event pending. Possible values of this field are:
- 0b0: Reading this means that a Reset Catch debug event is not pending. Writing this means no action.
- 0b1: Reading this means that a Reset Catch debug event is pending. Writing this clears the pending Reset Catch debug event.

On a Warm reset, this field resets to the value in EDECR.RCE.

**OSUC, bit [0]**
OS Unlock Catch debug event pending. Possible values of this field are:
- 0b0: Reading this means that an OS Unlock Catch debug event is not pending. Writing this means no action.
- 0b1: Reading this means that an OS Unlock Catch debug event is pending. Writing this clears the pending OS Unlock Catch debug event.

On a Warm reset, this field resets to 0.
Accessing the EDESR:

If a request to clear a pending Halting debug event is received at or about the time when halting becomes allowed, it is CONstrained UNpredictable whether the event is taken.

If Core power is removed while a Halting debug event is pending, it is lost. However, it might become pending again when the Core is powered back on and Cold reset.

EDESR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x020</td>
<td>EDESR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
H9.2.28 EDITCTRL, External Debug Integration mode Control register

The EDITCTRL characteristics are:

Purpose

Enables the external debug to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Configurations

It is IMPLEMENTATION DEFINED whether EDITCTRL is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

Implementation of this register is OPTIONAL.

Attributes

EDITCTRL is a 32-bit register.

Field descriptions

The EDITCTRL bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

- 0b0 Normal operation.
- 0b1 Integration mode enabled.

On a Implementation reset, this field resets to 0.

Accessing the EDITCTRL:

EDITCTRL can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xF00</td>
<td>EDITCTRL</td>
</tr>
</tbody>
</table>
This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register is IMPDEF.
H9.2.29  EDITR, External Debug Instruction Transfer Register

The EDITR characteristics are:

Purpose

Used in Debug state for passing instructions to the PE for execution.

Configurations

EDITR is in the Core power domain.

There are no configuration notes.

Attributes

EDITR is a 32-bit register.

Field descriptions

The EDITR bit assignments are:

*When in AArch32 state:*

<table>
<thead>
<tr>
<th>31</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>T32Second</td>
<td></td>
<td>T32First</td>
</tr>
</tbody>
</table>

T32Second, bits [31:16]

Second halfword of the T32 instruction to be executed on the PE. When EDITR contains a 16-bit T32 instruction, this field is ignored. For more information, see Behavior in Debug state on page H2-6429.

T32First, bits [15:0]

First halfword of the T32 instruction to be executed on the PE.

*When in AArch64 state:*

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A64 instruction to be executed on the PE</td>
</tr>
</tbody>
</table>

Bits [31:0]

A64 instruction to be executed on the PE.

Accessing the EDITR:

If EDSCR.ITE == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any instruction issued through the ITR in Normal access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

EDITR ignores writes if the PE is in Non-debug state.
EDITR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x084</td>
<td>EDITR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() access to this register is WI.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() access to this register is WO.
- Otherwise access to this register returns an Error.
H9.2.30 EDLAR, External Debug Lock Access Register

The EDLAR characteristics are:

**Purpose**

Allows or disallows access to the external debug registers through a memory-mapped interface.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDLAR is implemented in the Core power domain or in the Debug power domain.

EDLAR ignores writes if the Software Lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses EDLAR to set or clear the lock, and EDLSR to check the current status of the lock.

**Attributes**

EDLAR is a 32-bit register.

**Field descriptions**

The EDLAR bit assignments are:

\[
\begin{array}{c|c}
31 & 0 \\
\hline
\end{array}
\]

KEY, bits [31:0]

Lock Access control. Writing the key value \(0xC5ACCE55\) to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

**Accessing the EDLAR:**

EDLAR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFB0</td>
<td>EDLAR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is WO.
- Otherwise access to this register returns an Error.
H9.2.31   EDLSR, External Debug Lock Status Register

The EDLSR characteristics are:

**Purpose**

Indicates the current status of the software lock for external debug registers.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDLSR is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

EDLSR is RAZ if the Software Lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses EDLAR to set or clear the lock, and EDLSR to check the current status of the lock.

**Attributes**

EDLSR is a 32-bit register.

**Field descriptions**

The EDLSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Location</th>
<th>Bit Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-3</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>2</td>
<td>nTT, not thirty-two bit access required. RAZ.</td>
</tr>
<tr>
<td>1</td>
<td>SLK, Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0. For memory-mapped accesses when the Software Lock is implemented, possible values of this field are: 0b0 Lock clear. Writes are permitted to this component's registers. 0b1 Lock set. Writes to this component's registers are ignored, and reads have no side effects. The following resets apply: This register is reset by External debug reset and not affected by Cold reset.</td>
</tr>
</tbody>
</table>

---

RES0

SLI

SLK

nTT
• On a reset, this field resets to 1.

**SLI, bit [0]**

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

- 0b0  Software Lock not implemented or not memory-mapped access.
- 0b1  Software Lock implemented and memory-mapped access.

**Accessing the EDLSR:**

EDLSR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFB4</td>
<td>EDLSR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
**H9.2.32 EDPCSR, External Debug Program Counter Sample Register**

The EDPCSR characteristics are:

**Purpose**

Holds a sampled instruction address value.

**Configurations**

EDPCSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset. Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented in the external debug registers space.

---

**Note**

ARMv8.2-PCSample implements the PC Sample-based Profiling Extension in the Performance Monitors registers space.

---

**Attributes**

EDPCSR is a pair of 32-bit registers.

If ARMv8.1-VHE is implemented, the format of this register differs depending on the value of EDCSR.SC2.

**Field descriptions**

The EDPCSR bit assignments are:

*When ARMv8.1-VHE is not implemented:*

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>PC Sample high word, EDPCSRhi</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>PC Sample low word, EDPCSRlo</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [63:32]**

PC Sample high word, EDPCSRhi. If EDVIDSR.HV == 0 then this field is RAZ, otherwise bits [63:32] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDSR.{NS,E2,E3}.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Bits [31:0]**

PC Sample low word. EDPCSRlo, bits[31:0] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDSR.{NS,E2,E3}.

- For a read of EDPCSR[31:0] from the memory-mapped interface, if EDLSR.SLK == 1, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.
- In any other cases, a read of EDPCSR[31:0] has the side-effect of indirectly writing to EDPCSRhi, EDCIDSR, and EDVIDSR:
  - If the PE is in Debug state, or PC Sample-based profiling is prohibited, EDPCSRlo reads as 0xFFFFFFFF, and EDPCSRhi, EDCIDSR, and EDVIDSR become unknown.
  - If the PE is in Reset state, the sampled value is unknown and EDPCSRhi, EDCIDSR, and EDVIDSR become unknown.
If no instruction has been sampled since the PE left Reset state, Debug state, or a state where PC Sample-based profiling is prohibited, the sampled value is `0xFFFFFFFF`, and EDPCSRhi, EDCIDSR, and EDVIDSR become **UNKNOWN**. Any subsequent read will return an instruction address value.

On a Cold reset, this field resets to an architecturally **UNKNOWN** value.

### When ARMv8.1-VHE is implemented and EDSCR.SC2 == 0:

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>32</td>
<td>PC Sample high word, EDPCSRhi</td>
<td>PC Sample low word</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

*When ARMv8.1-VHE is implemented:*

PC Sample high word, EDPCSRhi. If EDVIDSR.HV == 0 then this field is RAZ, otherwise bits [63:32] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDSR.{NS,E2,E3}.

On a Cold reset, this field resets to an architecturally **UNKNOWN** value.

*Otherwise:*

Reserved, RES0.

**Bits [31:0]**

*When ARMv8.1-VHE is implemented:*

PC Sample low word. EDPCSRlo, bits[31:0] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDSR.{NS,E2,E3}.

- For a read of EDPCSR[31:0] from the memory-mapped interface, if EDLSR.SLK == 1, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.
- In any other cases, a read of EDPCSR[31:0] has the side-effect of indirectly writing to EDPCSRhi, EDCIDSR, and EDVIDSR:
  - If the PE is in Debug state, or PC Sample-based profiling is prohibited, EDPCSRlo reads as `0xFFFFFFFF`, and EDPCSRhi, EDCIDSR, and EDVIDSR become **UNKNOWN**.
  - If the PE is in Reset state, the sampled value is **UNKNOWN** and EDPCSRhi, EDCIDSR, and EDVIDSR become **UNKNOWN**.
  - If no instruction has been retired since the PE left Reset state, Debug state, or a state where PC Sample-based profiling is prohibited, the sampled value is **UNKNOWN**, and EDPCSRhi, EDCIDSR, and EDVIDSR become **UNKNOWN**.

On a Cold reset, this field resets to an architecturally **UNKNOWN** value.

*Otherwise:*

Reserved, RES0.

### When ARMv8.1-VHE is implemented and EDSCR.SC2 == 1:

<table>
<thead>
<tr>
<th>63</th>
<th>62</th>
<th>61</th>
<th>60</th>
<th>56</th>
<th>55</th>
<th>32</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>NS</td>
<td>EL</td>
<td>RES0</td>
<td>PC Sample high word, EDPCSRhi</td>
<td>PC Sample low word</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**When ARMv8.1-VHE is implemented and EDSCR.SC2 == 1:**

- If no instruction has been sampled since the PE left Reset state, Debug state, or a state where PC Sample-based profiling is prohibited, the sampled value is `0xFFFFFFFF`, and EDPCSRhi, EDCIDSR, and EDVIDSR become **UNKNOWN**. Any subsequent read will return an instruction address value.

On a Cold reset, this field resets to an architecturally **UNKNOWN** value.
NS, bit [63]

When ARMv8.1-VHE is implemented:
Non-secure state sample. Indicates the Security state that is associated with the most recent EDPCSR sample or, when it is read as a single atomic 64-bit read, the current EDPCSR sample. The translation regime that EDPCSR samples can be determined from EDPCSR.\{NS,EL\}.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

EL, bits [62:61]

When ARMv8.1-VHE is implemented:
Exception level status sample. Indicates the Exception level that is associated with the most recent EDPCSR sample or, when it is read as a single atomic 64-bit read, the current EDPCSR sample. The translation regime that EDPCSR samples can be determined from EDPCSR.\{NS,EL\}.

\[0b00\] Sample is from EL0.
\[0b01\] Sample is from EL1.
\[0b10\] Sample is from EL2.
\[0b11\] Sample is from EL3.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [60:56]

Reserved, RES0.

Bits [55:32]

When ARMv8.1-VHE is implemented:
PC Sample high word, EDPCSRhi. Bits [55:32] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDPCSR.\{NS,EL\}.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [31:0]

When ARMv8.1-VHE is implemented:
PC Sample low word. EDPCSRlo, bits[31:0] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDS\{NS,E2,E3\}.

- For a read of EDPCSR[31:0] from the memory-mapped interface, if EDLSR.SLK == 1, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.
- In any other cases, a read of EDPCSR[31:0] has the side-effect of indirectly writing to EDPCSRhi, EDCIDS\{R\}, and EDVIDS:
  - If the PE is in Debug state, or PC Sample-based profiling is prohibited, EDPCSRlo reads as 0xFFFFFFFF, and EDPCSRhi, EDCIDS, and EDVIDS become UNKNOWN.
  - If the PE is in Reset state, the sampled value is UNKNOWN and EDPCSRhi, EDCIDS, and EDVIDS become UNKNOWN.
  - If no instruction has been retired since the PE left Reset state, Debug state, or a state where PC Sample-based profiling is prohibited, the sampled value is UNKNOWN, and EDPCSRhi, EDCIDS, and EDVIDS become UNKNOWN.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
**Otherwise:**
Reserved, RES0.

*When ARMv8.2-PCSample is implemented:*

```
63 0
RES0
```

Bits [63:0]
Reserved, RES0.

**Accessing the EDPCSR:**

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see *Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN* on page H7-6536

EDPCSR[31:0] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x0A0</td>
<td>EDPCSR</td>
<td>31:0</td>
</tr>
</tbody>
</table>

EDPCSR[63:32] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x0AC</td>
<td>EDPCSR</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to EDPCSR[31:0] is RO.
- Otherwise access to EDPCSR[31:0] returns an Error.
- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to EDPCSR[63:32] is RO.
- Otherwise access to EDPCSR[63:32] returns an Error.
H9.2.33   EDPFR, External Debug Processor Feature Register

The EDPFR characteristics are:

Purpose

Provides information about implemented PE features.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page D12-2668.

Configurations

It is IMPLEMENTATION DEFINED whether EDPFR is implemented in the Core power domain or in the Debug power domain.

There are no configuration notes.

Attributes

EDPFR is a 64-bit register.

Field descriptions

The EDPFR bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:52]</td>
<td>Reserved, RES0.</td>

<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

Bits [63:52]

Reserved, RES0.

UNKNOWN, bits [51:48]

*From ARMv8.4:*

Reserved, UNKNOWN.

*Otherwise:*

Reserved, RES0.

AMU, bits [47:44]

*From ARMv8.4:*

Activity Monitors Extension. Defined values are:

- 0b0000  Activity Monitors Extension is not implemented.
- 0b0001  Activity Monitors Extension version 1 is implemented.

All other values are reserved.

*AMUv1* implements the functionality identified by the value 0b0001.

In Armv8.0, Armv8.1, Armv8.2, and Armv8.3, the only permitted value is 0b0000.

From Armv8.4, the permitted values are 0b0000 and 0b0001.

*Otherwise:*

Reserved, RES0.

UNKNOWN, bits [43:40]

*From ARMv8.2:*

Reserved, UNKNOWN.
**Otherwise:**
Reserved, RES0.

**SEL2, bits [39:36]**

*From ARMv8.4:*
Secure EL2. Defined values are:
- 0b0000  Secure EL2 is not implemented.
- 0b0001  Secure EL2 is implemented.

All other values are reserved.

**Otherwise:**
Reserved, RES0.

**SVE, bits [35:32]**

*From ARMv8.2:*
Scalable Vector Extension. Defined values are:
- 0b0000  SVE is not implemented.
- 0b0001  SVE is implemented.

All other values are reserved.

**Otherwise:**
Reserved, RES0.

**UNKNOWN, bits [31:28]**

*When RAS is implemented:*
Reserved, UNKNOWN.

**Otherwise:**
Reserved, RES0.

**GIC, bits [27:24]**
System register GIC interface support. Defined values are:
- 0b0000  No System register interface to the GIC is supported.
- 0b0001  System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.

All other values are reserved.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.GIC.

**AdvSIMD, bits [23:20]**
Advanced SIMD. Defined values are:
- 0b0000  Advanced SIMD is implemented, including support for the following SISD and SIMD operations:
  - Integer byte, halfword, word and doubleword element operations.
  - Single-precision and double-precision floating-point arithmetic.
  - Conversions between single-precision and half-precision data types, and double-precision and half-precision data types.
- 0b0001  As for 0b0000, and also includes support for half-precision floating-point arithmetic.
- 0b1111  Advanced SIMD is not implemented.

All other values are reserved.
This field must have the same value as the FP field.
The permitted values are:

- \(0b0000\) in an implementation with Advanced SIMD support, that does not include the ARMv8.2-FP16 extension.
- \(0b0001\) in an implementation with Advanced SIMD support, that includes the ARMv8.2-FP16 extension.
- \(0b1111\) in an implementation without Advanced SIMD support.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.AdvSIMD.

**FP, bits [19:16]**

Floating-point. Defined values are:

- \(0b0000\) Floating-point is implemented, and includes support for:
  - Single-precision and double-precision floating-point types.
  - Conversions between single-precision and half-precision data types, and double-precision and half-precision data types.
- \(0b0001\) As for \(0b0000\), and also includes support for half-precision floating-point arithmetic.
- \(0b1111\) Floating-point is not implemented.

All other values are reserved.

This field must have the same value as the AdvSIMD field.

The permitted values are:

- \(0b0000\) in an implementation with floating-point support, that does not include the ARMv8.2-FP16 extension.
- \(0b0001\) in an implementation with floating-point support, that includes the ARMv8.2-FP16 extension.
- \(0b1111\) in an implementation without floating-point support.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.FP.

**EL3, bits [15:12]**

AArch64 EL3 Exception level handling. Defined values are:

- \(0b0000\) EL3 is not implemented or cannot be executed in AArch64 state.
- \(0b0001\) EL3 can be executed in AArch64 state only.
- \(0b0010\) EL3 can be executed in either AArch64 or AArch32 state.

When the value of EDAA32PFR.EL3 is non-zero, this field must be \(0b0000\).

All other values are reserved.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL3.

**EL2, bits [11:8]**

AArch64 EL2 Exception level handling. Defined values are:

- \(0b0000\) EL2 is not implemented or cannot be executed in AArch64 state.
- \(0b0001\) EL2 can be executed in AArch64 state only.
- \(0b0010\) EL2 can be executed in either AArch64 or AArch32 state.

When the value of EDAA32PFR.EL2 is non-zero, this field must be \(0b0000\).

All other values are reserved.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL2.
EL1, bits [7:4]  
AArch64 EL1 Exception level handling. Defined values are:
- 0b0000  EL1 can be executed in AArch32 state only.
- 0b0001  EL1 can be executed in AArch64 state only.
- 0b0010  EL1 can be executed in either AArch64 or AArch32 state.
All other values are reserved.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL1.

EL0, bits [3:0]  
AArch64 EL0 Exception level handling. Defined values are:
- 0b0000  EL0 can be executed in AArch32 state only.
- 0b0001  EL0 can be executed in AArch64 state only.
- 0b0010  EL0 can be executed in either AArch64 or AArch32 state.
All other values are reserved.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL0.

Accessing the EDPFR:
EDPFR[31:0] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xD20</td>
<td>EDPFR</td>
<td>31:0</td>
</tr>
</tbody>
</table>

EDPFR[63:32] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xD24</td>
<td>EDPFR</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:
- When IsCorePowered() and !DoubleLockStatus() access to EDPFR[31:0] is RO.
- Otherwise access to EDPFR[31:0] is IMPDEF.
- When IsCorePowered() and !DoubleLockStatus() access to EDPFR[63:32] is RO.
- Otherwise access to EDPFR[63:32] is IMPDEF.
H9.2.34 EDPIDR0, External Debug Peripheral Identification Register 0

The EDPIDR0 characteristics are:

**Purpose**

Provides information to identify an external debug component.

For more information see *About the Peripheral identification scheme* on page K2-7243.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDPIDR0 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

EDPIDR0 is a 32-bit register.

**Field descriptions**

The EDPIDR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>RESERVED, RES0</td>
</tr>
<tr>
<td>7-0</td>
<td>PART_0, part number</td>
</tr>
</tbody>
</table>

**Accessing the EDPIDR0:**

EDPIDR0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFE0</td>
<td>EDPIDR0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.35  EDPIDR1, External Debug Peripheral Identification Register 1

The EDPIDR1 characteristics are:

**Purpose**

Provides information to identify an external debug component.

For more information see *About the Peripheral identification scheme* on page K2-7243.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDPIDR1 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

EDPIDR1 is a 32-bit register.

**Field descriptions**

The EDPIDR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td>DES_0</td>
<td>PART_1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**DES_0, bits [7:4]**

Designer, least significant nibble of JEP106 ID code. For Arm Limited, this field is 0b1011.

**PART_1, bits [3:0]**

Part number, most significant nibble.

**Accessing the EDPIDR1:**

EDPIDR1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFE4</td>
<td>EDPIDR1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.36 EDPIDR2, External Debug Peripheral Identification Register 2

The EDPIDR2 characteristics are:

**Purpose**

Provides information to identify an external debug component. For more information see About the Peripheral identification scheme on page K2-7243.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDPIDR2 is implemented in the Core power domain or in the Debug power domain. Implementation of this register is OPTIONAL. This register is required for CoreSight compliance.

**Attributes**

EDPIDR2 is a 32-bit register.

**Field descriptions**

The EDPIDR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:8]</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>[7:4]</td>
<td>REVISION, Part major revision. Parts can also use this field to extend Part number to 16-bits.</td>
</tr>
<tr>
<td>[3]</td>
<td>JEDEC, RAO. Indicates a JEP106 identity code is used.</td>
</tr>
<tr>
<td>[2:0]</td>
<td>Designer, most significant bits of JEP106 ID code. For Arm Limited, this field is 0b011.</td>
</tr>
</tbody>
</table>

**Accessing the EDPIDR2:**

EDPIDR2 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFE8</td>
<td>EDPIDR2</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.37  EDPIDR3, External Debug Peripheral Identification Register 3

The EDPIDR3 characteristics are:

**Purpose**

Provides information to identify an external debug component.

For more information see *About the Peripheral identification scheme on page K2-7243*.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDPIDR3 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

EDPIDR3 is a 32-bit register.

**Field descriptions**

The EDPIDR3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit 31-8</th>
<th>Field Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved</td>
<td>RES0</td>
</tr>
<tr>
<td>REVAND</td>
<td>Part minor revision. Parts using EDPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.</td>
</tr>
<tr>
<td>CMOD</td>
<td>Customer modified. Indicates someone other than the Designer has modified the component.</td>
</tr>
</tbody>
</table>

**Accessing the EDPIDR3:**

EDPIDR3 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xFE</td>
<td>EDPIDR3</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.38   EDPIDR4, External Debug Peripheral Identification Register 4

The EDPIDR4 characteristics are:

**Purpose**

Provides information to identify an external debug component.
For more information see *About the Peripheral identification scheme* on page K2-7243.

**Configurations**

It is IMPLEMENTATION DEFINED whether EDPIDR4 is implemented in the Core power domain or in the Debug power domain.
Implementation of this register is OPTIONAL.
This register is required for CoreSight compliance.

**Attributes**

EDPIDR4 is a 32-bit register.

**Field descriptions**

The EDPIDR4 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Field description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:8</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>7:4</td>
<td>SIZE, bits</td>
</tr>
<tr>
<td>3:0</td>
<td>DES_2, bits</td>
</tr>
</tbody>
</table>

**Accessing the EDPIDR4:**

EDPIDR4 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0xF00</td>
<td>EDPIDR4</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
**H9.2.39 EDPRCR, External Debug Power/Reset Control Register**

The EDPRCR characteristics are:

**Purpose**

Controls the PE functionality related to powerup, reset, and powerdown.

**Configurations**

EDPRCR contains fields that are in the Core power domain and fields that are in the Debug power domain.

For RW fields see the field description for a description of the behavior of the field on a reset that applies to its power domain. However:

- Fields that are in the Core power domain are not affected by a warm reset and are not affected by an External debug reset.
- Fields that are in the Debug power domain reset to their defined reset values on an External debug reset, and are not affected by a Warm reset and are not affected by a Cold reset.

CORENPDRQ is the only field that is mapped between the EDPRCR and DBGPRCR and DBGPRCR_EL1.

**Attributes**

EDPRCR is a 32-bit register.

**Field descriptions**

The EDPRCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Bit Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31–4</td>
<td>Reserved, RES0</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>3</td>
<td>COREPURQ</td>
<td>Core powerup request. Allows a debugger to request that the power controller power up the core, enabling access to the debug register in the Core power domain, and that the power controller emulates powerdown. This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.</td>
</tr>
<tr>
<td>2</td>
<td>CWRR</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>CORENPDRQ</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>COREPURQ</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:4]**

Reserved, RES0.

**COREPURQ, bit [3]**

Core powerup request. Allows a debugger to request that the power controller power up the core, enabling access to the debug register in the Core power domain, and that the power controller emulates powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

- 0b0 Do not request power up of the Core power domain.
- 0b1 Request power up of the Core power domain, and emulation of powerdown.

In an implementation that includes the recommended external debug interface, this bit drives the DBGPWRUPREQ signal.

This field is in the Debug power domain and can be read and written when the Core power domain is powered off.
--- Note ---

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

On a External debug reset, this field resets to 0.

Accessing this field has the following behavior:
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RW.

**Bit [2]**

Reserved, RES0.

**CWRR, bit [1]**

Warm reset request. Write-only bit that reads as zero.

The extent of the reset is IMPLEMENTATION DEFINED, but must be one of:
- The request is ignored.
- Only this PE is Warm reset.
- This PE and other components of the system, possibly including other PEs, are Warm reset.

Arm deprecates use of this bit, and recommends that implementations ignore the request.

0b0 No action.

0b1 Request Warm reset.

This field is in the Core power domain

The PE ignores writes to this bit if any of the following are true:
- ExternalInvasiveDebugEnabled() == FALSE, EL3 is not implemented, and the implemented Security state is Non-secure state.
-ExternalSecureInvasiveDebugEnabled() == FALSE, EL3 is not implemented, and the implemented Security state is Secure state.
- ExternalSecureInvasiveDebugEnabled () == FALSE and EL3 is implemented.

In an implementation that includes the recommended external debug interface, this bit drives the DBGRSTREQ signal.

On a Warm reset, this field resets to 0.

Accessing this field has the following behavior:
- When !IsCorePowered(), or DoubleLockStatus(), or OSLockStatus() or SoftwareLockStatus(), access to this field is WI.
- Otherwise, access to this field is WO.

**CORENPDRQ, bit [0]**

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

0b0 If the system responds to a powerdown request, it powers down Core power domain.

0b1 If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

When this bit reads as UNKNOWN, the PE ignores writes to this bit.

This field is in the Core power domain, and permitted accesses to this field map to the DBGPRCR.CORENPDRQ and DBGPRCR_EL1.CORENPDRQ fields.

In an implementation that includes the recommended external debug interface, this bit drives the DBGNOPWRDWN signal.
It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see Core power domain power states on page H6-6522.

--- Note ---
Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

On a Cold reset, this field resets to the value in EDPRCR.COREPURQ.

Accessing this field has the following behavior:
- When !IsCorePowered(), or DoubleLockStatus() or OSLockStatus(), access to this field is UNKNOWN.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RW.

Accessing the EDPRCR:

On permitted accesses to the register, other access controls affect the behavior of some fields. See the field descriptions for more information.

EDPRCR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x310</td>
<td>EDPRCR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:
- When SoftwareLockStatus() access to this register is RO.
- When !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
H9.2.40  EDPRSR, External Debug Processor Status Register

The EDPRSR characteristics are:

**Purpose**

Holds information about the reset and powerdown state of the PE.

**Configurations**

EDPRSR contains fields that are in the Core power domain and fields that are in the Debug power domain.

Some of the fields in the Core power domain are in the Cold reset domain and others are in the Warm reset domain. See the field descriptions for more information. However:

- Fields that are in the Cold reset domain are not affected by a warm reset and are not affected by an External debug reset.
- Fields in the Warm reset domain are also reset by a Cold reset but are not affected by an External debug reset.
- Fields in the Debug power domain are not affected by a Warm reset and are not affected by a Cold reset.

**Attributes**

EDPRSR is a 32-bit register.

**Field descriptions**

The EDPRSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Permitted Values</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:12</td>
<td>Reserved, RES0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>SDR, Sticky debug restart</td>
<td></td>
<td>Sticky debug restart. Set to 1 when the PE exits Debug state.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>0b0</strong></td>
<td>The PE has not restarted since EDPRSR was last read.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>0b1</strong></td>
<td>The PE has restarted since EDPRSR was last read.</td>
</tr>
</tbody>
</table>

**Note**

If a reset occurs when the PE is in Debug state, the PE exits Debug state. SDR is **UNKNOWN** on Warm reset, meaning a debugger must also use the SR bit to determine whether the PE has left Debug state.
If the Core power domain is powered up, then following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or DoubleLockStatus() == FALSE this bit clears to 0.
- If ARMv8.0-DoubleLock is implemented and DoubleLockStatus() == TRUE, it is constrained unpredictable whether this bit clears to 0 or is unchanged.

This field is in the Core power domain and the Warm reset domain.

This field resets to an architecturally unknown value.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is unknown.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RC.

**SPMAD, bit [10]**

*When ARMv8.4-Debug is implemented:*

Sticky EPMAD error. Set to 1 if an external debug interface access to a Performance Monitors register returns an error because AllowExternalPMUAccess() == FALSE.

Permitted values are:

- **0b0**: No Non-secure external debug interface accesses to the external Performance Monitors registers have failed because AllowExternalPMUAccess() == FALSE for the access since EDPRSR was last read.
- **0b1**: At least one Non-secure external debug interface access to the external Performance Monitors register has failed and returned an error because AllowExternalPMUAccess() == FALSE for the access since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or DoubleLockStatus() == FALSE, this bit clears to 0.
- If ARMv8.0-DoubleLock is implemented, and DoubleLockStatus() == TRUE, it is constrained unpredictable whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

On a Cold reset, this field resets to 0.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is unknown.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RC.

**Otherwise:**

Sticky EPMAD error.

- **0b0**: No external debug interface accesses to the Performance Monitors registers have failed because AllowExternalPMUAccess() == FALSE since EDPRSR was last read.
- **0b1**: At least one external debug interface access to the Performance Monitors registers has failed and returned an error because AllowExternalPMUAccess() == FALSE since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or DoubleLockStatus() == FALSE, this bit clears to 0.
- If ARMv8.0-DoubleLock is implemented, and DoubleLockStatus() == TRUE, it is constrained unpredictable whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

On a Cold reset, this field resets to 0.
Accessing this field has the following behavior:

- When !IsCorePowered(), or OSLockStatus(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RC.

**EPMAD, bit [9]**

*When ARMv8.4-Debug is implemented:*

External Performance Monitors Access Disable status.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>External Non-secure Performance Monitors access enabled. AllowExternalPMUAccess() _== TRUE.</td>
</tr>
<tr>
<td>0b1</td>
<td>External Non-secure Performance Monitors access disabled. AllowExternalPMUAccess() _== FALSE.</td>
</tr>
</tbody>
</table>

This field is in the Core power domain.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

**Otherwise:**

External Performance Monitors access disable status.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>External Performance Monitors access enabled. AllowExternalPMUAccess() _== TRUE.</td>
</tr>
<tr>
<td>0b1</td>
<td>External Performance Monitors access disabled. AllowExternalPMUAccess() _== FALSE.</td>
</tr>
</tbody>
</table>

This field is in the Core power domain.

Accessing this field has the following behavior:

- When !IsCorePowered(), or OSLockStatus(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

**SDAD, bit [8]**

*When ARMv8.4-Debug is implemented:*

Sticky EDAD error. Set to 1 if an external debug interface access to a debug register returns an error because AllowExternalDebugAccess() == FALSE.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>No Non-secure external debug interface accesses to the debug registers have failed because AllowExternalDebugAccess() == FALSE for the access since EDPRSR was last read.</td>
</tr>
<tr>
<td>0b1</td>
<td>At least one Non-secure external debug interface access to the debug registers has failed and returned an error because AllowExternalDebugAccess() == FALSE for the access since EDPRSR was last read.</td>
</tr>
</tbody>
</table>

If the Core power domain is powered up, then, following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or DoubleLockStatus() == FALSE this bit clears to 0.
- If ARMv8.0-DoubleLock is implemented and DoubleLockStatus() == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

On a Cold reset, this field resets to 0.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.
Otherwise:

Sticky EDAD error. Set to 1 if an external debug interface access to a debug register returns an error because AllowExternalDebugAccess() == FALSE.

0b0 No external debug interface accesses to the debug registers have failed because AllowExternalDebugAccess() == FALSE since EDPRSR was last read.

0b1 At least one external debug interface access to the debug registers has failed and returned an error because AllowExternalDebugAccess() == FALSE since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or DoubleLockStatus() == FALSE this bit clears to 0.
- If ARMv8.0-DoubleLock is implemented and DoubleLockStatus() == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This bit is UNKNOWN on reads if OSLockStatus() == TRUE and external debug writes to OSLAR_EL1 do not return an error when AllowExternalDebugAccess() == FALSE.

This field is in the Core power domain.

On a Cold reset, this field resets to 0.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

EDAD, bit [7]

When ARMv8.4-Debug is implemented:

External debug access disable status.

0b0 External Non-secure access to breakpoint registers, watchpoint registers, and OSLAR_EL1 enabled. AllowExternalDebugAccess() == TRUE.

0b1 External Non-secure access to breakpoint registers, watchpoint registers, and OSLAR_EL1 disabled. AllowExternalDebugAccess() == FALSE.

This field is in the Core power domain.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

When ARMv8.2-Debug is implemented:

External debug access disable status.

0b0 External access to breakpoint registers, watchpoint registers, and OSLAR_EL1 enabled. AllowExternalDebugAccess() == TRUE.

0b1 External access to breakpoint registers, watchpoint registers, and OSLAR_EL1 disabled. AllowExternalDebugAccess() == FALSE.

This bit is not valid and reads UNKNOWN if OSLockStatus() == TRUE and external debug writes to OSLAR_EL1 do not return an error when AllowExternalDebugAccess() == FALSE.

This field is in the Core power domain.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.
**External debug access disable status.**

0b0 External access to breakpoint registers, watchpoint registers, and **OSLR_EL1** enabled. **AllowExternalDebugAccess()** == TRUE.

0b1 External access to breakpoint registers, watchpoint registers disabled. It is IMPLEMENTATION DEFINED whether accesses to **OSLR_EL1** are enabled or disabled. **AllowExternalDebugAccess()** == FALSE.

This field is in the Core power domain.

Accessing this field has the following behavior:

- When !IsCorePowered(), or **DoubleLockStatus()** or **EDPRSR.R** == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

**DLK, bit [6]**

*When ARMv8.4-Debug is implemented:*

This field is RES0.

*When ARMv8.2-Debug is implemented and ARMv8.0-DoubleLock is implemented:*

From Armv8.2, this field is deprecated.

This field is in the Core power domain.

Accessing this field has the following behavior:

- When IsCorePowered() and !DoubleLockStatus(), access to this field is RAZ.
- Otherwise, access to this field is UNKNOWN.

*When ARMv8.0-DoubleLock is implemented:*

This field returns the result of the pseudocode function **DoubleLockStatus()**.

If the Core power domain is powered up and **DoubleLockStatus()** == TRUE, it is IMPLEMENTATION DEFINED whether:

- **EDPRSR.PU** reads as 1, **EDPRSR.DLK** reads as 1, and **EDPRSR.SPD** is UNKNOWN.
- **EDPRSR.PU** reads as 0, **EDPRSR.DLK** is UNKNOWN, and **EDPRSR.SPD** reads as 0.

This field is in the Core power domain.

0b0 **DoubleLockStatus()** returns FALSE.

0b1 **DoubleLockStatus()** returns TRUE and the Core power domain is powered up.

Accessing this field has the following behavior:

- When !IsCorePowered(), access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

**Otherwise:**

Reserved, RES0.

**OSLK, bit [5]**

OS lock status bit.

A read of this bit returns the value of **OSLSR_EL1.OSLK**.

This field is in the Core power domain.

Accessing this field has the following behavior:

- When !IsCorePowered(), **DoubleLockStatus()** and **EDPRSR.R** == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

**HALTED, bit [4]**

Halted status bit.

0b0 PE is in Non-debug state.
0b1 PE is in Debug state.
This field is in the Core power domain.
Accessing this field has the following behavior:
• When !IsCorePowered(), access to this field is UNKNOWN.
• Otherwise, access to this field is RO.

SR, bit [3]
Sticky core reset status bit.
Permitted values are:
0b0 The non-debug logic of the PE is not in reset state and has not been reset since the last time EDPRSR was read.
0b1 The non-debug logic of the PE is in reset state or has been reset since the last time EDPRSR was read.

If EDPRSR.PU reads as 1 and EDPRSR.R reads as 0, which means that the Core power domain is in a powerup state and that the non-debug logic of the PE is not in reset state, then following a read of EDPRSR:
• If ARMv8.0-DoubleLock is not implemented or DoubleLockStatus() == FALSE this bit clears to 0.
• If ARMv8.0-DoubleLock is implemented and DoubleLockStatus() == TRUE, it is UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain and the Warm reset domain.
This field resets to 1.
Accessing this field has the following behavior:
• When !IsCorePowered() or DoubleLockStatus(), access to this field is UNKNOWN.
• When SoftwareLockStatus(), access to this field is RO.
• Otherwise, access to this field is RC.

R, bit [2]
PE reset status bit.
Permitted values are:
0b0 The non-debug logic of the PE is not in reset state.
0b1 The non-debug logic of the PE is in reset state.

If ARMv8.0-DoubleLock is implemented, the PE is in reset state, and the PE entered reset state with the OS Double Lock locked this bit has a CONSTRAINED UNPREDICTABLE value. For more information see EDPRSR.{DLK, R} and reset state on page H6-6524

This field is in the Core power domain.
Accessing this field has the following behavior:
• When !IsCorePowered() or DoubleLockStatus(), access to this field is UNKNOWN.
• Otherwise, access to this field is RO.

SPD, bit [1]
Sticky Core powerdown status bit.
0b0 If EDPRSR.PU is 0, it is not known whether the state of the debug registers in the Core power domain is lost.
If EDPRSR.PU is 1, the state of the debug registers in the Core power domain has not been lost.
0b1 The state of the debug registers in the Core power domain has been lost.

If the Core power domain is powered up, then, following a read of EDPRSR:
• If ARMv8.0-DoubleLock is not implemented or DoubleLockStatus() == FALSE this bit clears to 0.
**PU, bit [0]**

*When ARMv8.2-Debug is implemented:*

Core powerup status bit. Indicates whether the debug registers in the Core power domain can be accessed.

- **0b0**: Either the Core power domain is in a low-power or powerdown state, or **ARMv8.0-DoubleLock** is implemented and **DoubleLockStatus()** == TRUE, meaning the debug registers in the Core power domain cannot be accessed.

- **0b1**: The Core power domain is in a powerup state, and either **ARMv8.0-DoubleLock** is not implemented or **DoubleLockStatus()** == FALSE, meaning the debug registers in the Core power domain can be accessed.

If **ARMv8.0-DoubleLock** is implemented, the PE is in reset state, and the PE entered reset state with the OS Double Lock locked this bit has a CONSTRANDED UNPREDICATABLE value. For more information see **EDPRSR.\{DLK, R\} and reset state on page H6-6524**

**EDPRSR.\{DLK, SPD, PU\}** describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see **EDPRSR.\{DLK, SPD, PU\} and the Core power domain on page H6-6523**

Access to this field is RO.

*Otherwise:*

Core powerup status bit. Indicates whether the debug registers in the Core power domain can be accessed.

When the Core power domain is powered-up and **DoubleLockStatus()** == TRUE, then the value of **EDPRSR.PU** is IMPLEMENTATION DEFINED. See the description of the DLK bit for more information.

Otherwise, permitted values are:

- **0b0**: Core power domain is in a low-power or powerdown state where the debug registers in the Core power domain cannot be accessed.

- **0b1**: Core power domain is in a powerup state where the debug registers in the Core power domain can be accessed.

If **ARMv8.0-DoubleLock** is implemented, the Core power domain is powered up, and **DoubleLockStatus()** == TRUE, it is IMPLEMENTATION DEFINED whether this bit reads as 0 or 1.

If **ARMv8.0-DoubleLock** is implemented, the PE is in reset state, and the PE entered reset state with the OS Double Lock locked this bit has a CONSTRANDED UNPREDICATABLE value. For more information see **EDPRSR.\{DLK, R\} and reset state on page H6-6524**

**EDPRSR.\{DLK, SPD, PU\}** describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see **EDPRSR.\{DLK, SPD, PU\} and the Core power domain on page H6-6523**
Access to this field is RO.

**Accessing the EDPRSR:**

On permitted accesses to the register, other access controls affect the behavior of some fields. See the field descriptions for more information.

If the Core power domain is powered up (EDPRSR.PU == 1), then following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or DoubleLockStatus() == FALSE, then:
  - EDPRSR.{SDR, SPMAD, SDAD, SPD} are cleared to 0.
  - EDPRSR.SR is cleared to 0 if the non-debug logic of the PE is not in reset state (EDPRSR.R == 0).
- Otherwise it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

If the Core power domain is powered down (EDPRSR.PU == 0), then:

- EDPRSR.{SDR, SPMAD, SDAD, SR} are all UNKNOWN, and are either reset or restored on being powered up.
- EDPRSR.SPD is not cleared following a read of EDPRSR. See the SPD bit description for more information.

The clearing of bits is an indirect write to EDPRSR.

EDPRSR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x314</td>
<td>EDPRSR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
H9.2.41  EDRCR, External Debug Reserve Control Register

The EDRCR characteristics are:

**Purpose**

This register is used to allow imprecise entry to Debug state and clear sticky bits in EDSCR.

**Configurations**

EDRCR is in the Core power domain.

There are no configuration notes.

**Attributes**

EDRCR is a 32-bit register.

**Field descriptions**

The EDRCR bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:5]</th>
<th>RES0</th>
</tr>
</thead>
</table>

Reserved, RES0.

**CBRRQ, bit [4]**

Allow imprecise entry to Debug state. The actions on writing to this bit are:

- **0b0**: No action.
- **0b1**: Allow imprecise entry to Debug state, for example by canceling pending bus accesses.

Setting this bit to 1 allows a debugger to request imprecise entry to Debug state. An External Debug Request debug event must be pending before the debugger sets this bit to 1.

This feature is optional. If this feature is not implemented, writes to this bit are ignored.

**CSPA, bit [3]**

Clear Sticky Pipeline Advance. This bit is used to clear the EDSCR.PipeAdv bit to 0. The actions on writing to this bit are:

- **0b0**: No action.
- **0b1**: Clear the EDSCR.PipeAdv bit to 0.

**CSE, bit [2]**

Clear Sticky Error. Used to clear the EDSCR cumulative error bits to 0. The actions on writing to this bit are:

- **0b0**: No action.
- **0b1**: Clear the EDSCR. {TXU, RXO, ERR} bits, and, if the PE is in Debug state, the EDSCR.ITO bit, to 0.

**Bits [1:0]**

Reserved, RES0.
Accessing the EDRCR:

EDCR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x090</td>
<td>EDRCR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() access to this register is WI.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() access to this register is WO.
- Otherwise access to this register returns an Error.
H9.2.42 EDSCR, External Debug Status and Control Register

The EDSCR characteristics are:

**Purpose**

Main control register for the debug implementation.

**Configurations**

External register EDSCR[30:29] is architecturally mapped to AArch64 System register MDCCSR_EL0[30:29].

EDSCR is in the Core power domain. Some or all RW fields of this register have defined reset values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

**Attributes**

EDSCR is a 32-bit register.

**Field descriptions**

The EDSCR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 10 9 8 7 6 5 0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NS RW EL A STATUS</td>
</tr>
</tbody>
</table>

- **TFO**, bit [31]

  *When ARMv8.4-Trace is implemented:*

  Trace Filter Override. Overrides the Trace Filter controls allowing the external debugger to trace any visible Exception level.

  - **0** Trace Filter controls are not affected.
  - **1** Trace Filter controls in TRFCR_EL1, TRFCR_EL2, TRFCR, and HTRFCR are ignored.

  When OSLSR_EL1.OSLK == 1, this bit can be indirectly read and written through the MDSCR_EL1 and DBGDSCRExt System registers.

  This bit is ignored by the PE when `ExternalSecureNoninvasiveDebugEnabled()` == FALSE and the *Effective value on page Glossary-7462 of MDCR_EL3.STE == 1.*

  On a Cold reset, this field resets to 0.
**Otherwise:**

Reserved, RES0.

**RXfull, bit [30]**

DTRRX full. This bit is RO.

On a Cold reset, this field resets to 0.

**TXfull, bit [29]**

DTRTX full. This bit is RO.

On a Cold reset, this field resets to 0.

**ITO, bit [28]**

ITR overrun. This bit is RO.

If the PE is in Non-debug state, this bit is UNKNOWN. ITO is set to 0 on entry to Debug state.

**RXO, bit [27]**

DTRRX overrun. This bit is RO.

On a Cold reset, this field resets to 0.

**TXU, bit [26]**

DTRTX underrun. This bit is RO.

On a Cold reset, this field resets to 0.

**PipeAdv, bit [25]**

Pipeline advance. This bit is RO. Set to 1 every time the PE pipeline retires one or more instructions. Cleared to 0 by a write to `EDRCR.CSPA`.

The architecture does not define precisely when this bit is set to 1. It requires only that this happen periodically in Non-debug state to indicate that software execution is progressing.

**ITE, bit [24]**

ITR empty. This bit is RO.

If the PE is in Non-debug state, this bit is UNKNOWN. It is always valid in Debug state.

**INTdis, bits [23:22]**

When ARMv8.4-Debug is implemented:

Interrupt disable. Disables taking interrupts in Non-Debug state.

- **0b0** Masking of interrupts is controlled by `PSTATE` and interrupt routing controls.
- **0b1** If `ExternalSecureDebugEnabled() == TRUE`, then all interrupts, including virtual and SError interrupts, are masked.
  - If `ExternalSecureDebugEnabled() == FALSE`, then all interrupts targeting Non-secure state are masked.

When `OSLSR_EL1.OSLK == 1`, this field can be indirectly read and written through the `MDSCR_EL1` and `DBGDSCRext` System registers.

This field is ignored by the PE and treated as zero when `ExternalDebugEnabled() == FALSE`.

On a Cold reset, this field resets to 0.

Otherwise:

Interrupt disable.

When `OSLSR_EL1.OSLK == 1`, this field can be indirectly read and written through the `MDSCR_EL1` and `DBGDSCRext` System registers.

- **0b00** Do not disable interrupts.
- **0b01** Disable interrupts taken to Non-secure EL1.
0b10 Disable interrupts taken only to Non-secure EL1 and Non-secure EL2. If ExternalSecureInvasiveDebugEnabled() == TRUE, also disable interrupts taken to Secure EL1.

0b11 Disable interrupts taken only to Non-secure EL1 and Non-secure EL2. If ExternalSecureInvasiveDebugEnabled() == TRUE, also disable all other interrupts.

On a Cold reset, this field resets to 0.

**TDA, bit [21]**

Traps accesses to the following debug System registers:

- AArch64: DBGBCR<n>_EL1, DBGBVR<n>_EL1, DBGWCR<n>_EL1, DBGWVR<n>_EL1.
- AArch32: DBGBCR<n>, DBGBVR<n>, DBGXVR<n>, DBGWCR<n>, DBGWVR<n>.

The possible values of this field are:

- 0b0 Accesses to debug System registers do not generate a Software Access Debug event.
- 0b1 Accesses to debug System registers generate a Software Access Debug event, if OSLSR_EL1.OSLK is 0 and if halting is allowed.

On a Cold reset, this field resets to 0.

**MA, bit [20]**

Memory access mode. Controls the use of memory-access mode for accessing ITR and the DCC. This bit is ignored if in Non-debug state and set to zero on entry to Debug state.

Possible values of this field are:

- 0b0 Normal access mode.
- 0b1 Memory access mode.

On a Cold reset, this field resets to 0.

**SC2, bit [19]**

*When ARMv8.0-PCSample is implemented, ARMv8.1-VHE is implemented and ARMv8.2-PCSample is not implemented:*

Sample CONTEXTIDR_EL2. Controls whether the PC Sample-based Profiling Extension samples CONTEXTIDR_EL2 or VTTBR_EL2.VMID.

- 0b0 Sample VTTBR_EL2.VMID.
- 0b1 Sample CONTEXTIDR_EL2.

On a Cold reset, this field resets to 0.

**Otherwise:**

Reserved, RES0.

**NS, bit [18]**

Non-secure status. Read-only. When in Debug state, gives the current Security state:

- 0b0 Secure state, IsSecure() == TRUE.
- 0b1 Non-secure state, IsSecure() == FALSE.

In Non-debug state, this bit is UNKNOWN.

**Bit [17]**

Reserved, RES0.

**SDD, bit [16]**

Secure debug disabled. This bit is RO.

On entry to Debug state:

- If entering in Secure state, SDD is set to 0.
• If entering in Non-secure state, SDD is set to the inverse of
  ExternalSecureInvasiveDebugEnabled().

In Debug state, the value of the SDD bit does not change, even if
ExternalSecureInvasiveDebugEnabled() changes.

In Non-debug state:
• SDD returns the inverse of ExternalSecureInvasiveDebugEnabled(). If the authentication
  signals that control ExternalSecureInvasiveDebugEnabled() change, a context
  synchronization event is required to guarantee their effect.
• This bit is unaffected by the Security state of the PE.

If EL3 is not implemented and the implementation is Non-secure, this bit is RES1.

Bit [15]

Reserved, RES0.

HDE, bit [14]
Halting debug enable. The possible values of this field are:

00  Halting disabled for Breakpoint, Watchpoint and Halt Instruction debug events.
01  Halting enabled for Breakpoint, Watchpoint and Halt Instruction debug events.

On a Cold reset, this field resets to 0.

RW, bits [13:10]

Exception level Execution state status. Read-only. In Debug state, each bit gives the current
Execution state of each Exception level:

0111  All Exception levels are using AArch64 or the PE is in Non-debug state.
0110  The PE is in Debug state. EL0 is using AArch32. All other Exception levels are using
  AArch64. Only permitted if the PE is executing at EL0.
010x  The PE is in Debug state. EL0 and EL1 are using AArch32. EL2 and EL3 are using
  AArch64. Only permitted if EL2 is implemented and enabled in the current Security
  state.
01xx  The PE is in Debug state. EL0, EL1, and, if implemented in the current Security state,
  EL2 are using AArch32. EL3 is using AArch64. Only permitted if EL3 is implemented.
0bxx  The PE is in Debug state. All Exception levels are using AArch32.

In Non-debug state, this field is RAO.

EL, bits [9:8]

Exception level. Read-only. In Debug state, this gives the current EL of the PE.

In Non-debug state, this field is RAZ.

A, bit [7]

SErrOr interrupt pending. Read-only. In Debug state, indicates whether an SError interrupt is
pending:

• If HCR_EL2.AMO, TGE = {1, 0}, EL2 is enabled in the current Security state, and the PE
  is executing at EL0 or EL1, a virtual SError interrupt.
• Otherwise, a physical SError interrupt.
00  No SError interrupt pending.
01  SError interrupt pending.

A debugger can read EDSCR to check whether an SError interrupt is pending without having to
execute further instructions. A pending SError might indicate data from target memory is corrupted.
UNKNOWN in Non-debug state.
ERR, bit [6]
Cumulative error flag. This field is RO. It is set to 1 following exceptions in Debug state and on any
signaled overrun or underrun on the DTR or EDITR.
On a Cold reset, this field resets to 0.

STATUS, bits [5:0]
Debug status flags. This field is RO.
The possible values of this field are:
0b000001 PE is restarting, exiting Debug state.
0b000010 PE is in Non-debug state.
0b000111 Breakpoint.
0b010011 External debug request.
0b011011 Halting step, normal.
0b011111 Halting step, exclusive.
0b100011 OS Unlock Catch.
0b100111 Reset Catch.
0b101011 Watchpoint.
0b101111 HLT instruction.
0b110011 Software access to debug register.
0b110111 Exception Catch.
0b111011 Halting step, no syndrome.
All other values of STATUS are reserved.

Accessing the EDSCR:
EDSCR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x088</td>
<td>EDSCR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

• When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() access to this register is RO.
• When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() access to this register is RW.
• Otherwise access to this register returns an Error.
H9.2.43 EDVIDSR, External Debug Virtual Context Sample Register

The EDVIDSR characteristics are:

**Purpose**

Contains sampled values captured on reading EDPCSR[31:0].

**Configurations**

EDVIDSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented in the external debug registers space.

When the PC Sample-based Profiling Extension is implemented in the external debug registers space, if EL2 is not implemented and EL3 is not implemented, it is IMPLEMENTATION DEFINED whether EDVIDSR is implemented.

--- Note ---

ARMv8.2-PCSample implements the PC Sample-based Profiling Extension in the Performance Monitors registers space.

--- Attributes ---

If ARMv8.1-VHE is implemented, the format of this register differs depending on the value of EDSR.SC2.

**Field descriptions**

The EDVIDSR bit assignments are:

*When ARMv8.2-PCSample is implemented:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

*When ARMv8.1-VHE is not implemented:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Non-secure state sample. Indicates the Security state associated with the most recent EDPCSR sample.</td>
</tr>
<tr>
<td>29</td>
<td>E2</td>
</tr>
<tr>
<td>28</td>
<td>E3</td>
</tr>
<tr>
<td>27</td>
<td>HV</td>
</tr>
<tr>
<td>8</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>7</td>
<td>VMID</td>
</tr>
</tbody>
</table>

NS, bit [31]

Non-secure state sample. Indicates the Security state associated with the most recent EDPCSR sample.

If EL3 is not implemented, this bit indicates the *Effective value on page Glossary-7462* of SCR.NS.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

**E2, bit [30]**

Exception level 2 status sample. Indicates whether the most recent EDPCSR sample was associated with EL2.

If EL2 is not implemented, this bit is RES0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**E3, bit [29]**

Exception level 3 status sample. Indicates whether the most recent EDPCSR sample was associated with EL3 using AArch64.

If EDVIDSR.NS == 1 or the PE was in AArch32 state when EDPCSRlo (EDPCSR[31:0]) was read, this bit is 0.

If EL3 is not implemented, this bit is RES0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**HV, bit [28]**

EDPCSRhi (EDPCSR[63:32]) valid. Indicates whether bits [63:32] of the most recent EDPCSR sample might be nonzero:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Bits[63:32] of the most recent EDPCSR sample are zero.</td>
</tr>
<tr>
<td>0b1</td>
<td>Bits[63:32] of the most recent EDPCSR sample might be nonzero.</td>
</tr>
</tbody>
</table>

An EDVIDSR.HV value of 1 does not mean that the value of EDPCSRhi is nonzero.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Bits [27:8]**

Reserved, RES0.

**VMID, bits [7:0]**

VMID sample. The VMID associated with the most recent EDPCSRlo (EDPCSR[31:0]) sample.

If EL2 is using AArch64 and the value of EDVIDSR.NS is 0 or the value of EDVIDSR.E2 is 1 this field is RES0.

If EL2 is not implemented and this field is RES0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**When ARMv8.1-VHE is implemented and ESCR.SC2 == 0:**

<table>
<thead>
<tr>
<th>NS</th>
<th>RES0</th>
<th>VMID</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>30</td>
<td>29</td>
</tr>
<tr>
<td>NS</td>
<td>28</td>
<td>27</td>
</tr>
<tr>
<td>E2</td>
<td>16</td>
<td>15</td>
</tr>
<tr>
<td>E3</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

This format applies in all Armv8.0 implementations.

**NS, bit [31]**

*From ARMv8.1:*

Non-secure state sample. Indicates the Security state associated with the most recent EDPCSR sample.

If EL3 is not implemented, this bit indicates the *Effective value on page Glossary-7462* of SCR.NS.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**E2, bit [30]**

*From ARMv8.1:*

Exception level 2 status sample. Indicates whether the most recent EDPCSR sample was associated with EL2.

If EL2 is not implemented, this bit is RES0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**E3, bit [29]**

*From ARMv8.1:*

Exception level 3 status sample. Indicates whether the most recent EDPCSR sample was associated with EL3 using AArch64.

If EDVIDSR.NS == 1 or the PE was in AArch32 state when EDPCSRlo (EDPCSR[31:0]) was read, this bit is 0.

If EL3 is not implemented, this bit is RES0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**HV, bit [28]**

*From ARMv8.1:*

EDPCSRhi (EDPCSR[63:32]) valid. Indicates whether bits [63:32] of the most recent EDPCSR sample might be nonzero:

- 0b0  Bits[63:32] of the most recent EDPCSR sample are zero.
- 0b1  Bits[63:32] of the most recent EDPCSR sample might be nonzero.

An EDVIDSR.HV value of 1 does not mean that the value of EDPCSRhi is nonzero. An EDVIDSR.HV value of 0 is a hint that EDPCSRhi (EDPCSR[63:32]) does not need to be read.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Otherwise:**
Reserved, RES0.

**Bits [27:16]**

Reserved, RES0.

**VMID, bits [15:0]**

*From ARMv8.1:*

VMID sample. The VMID associated with the most recent EDPCSRlo (EDPCSR[31:0]) sample.

- If EL2 is using AArch64 and the value of EDVIDSR.NS is 0 or the value of EDVIDSR.E2 is 1 this field is RES0.
- If EL2 is not implemented, this field is RES0.
- If EL2 is implemented and is using AArch64, the VMID is held in VTTBR_EL2.VMID.
- If EL2 is implemented and is using AArch32, the VMID is held in VTTBR.VMID.
- If 16-bit VMIDs are not supported, EDVIDSR.VMID[15:8] is RES0.
• If 16-bit VMIDs are supported, but VTTBRx.VMID[15:8] are not used, EDVIDSR.VMID[15:8] is set to 0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

**When ARMv8.1-VHE is implemented and EDSCR.SC2 == 1:**

<table>
<thead>
<tr>
<th>CONTEXTIDR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
</tr>
</tbody>
</table>

**CONTEXTIDR_EL2**, bits [31:0]

*From ARMv8.1:*
Context ID.

• If EL2 is using AArch64 and if the value of EDPCSR.NS is 0, the value of CONTEXTIDR_EL2 as associated with the most recent EDPCSR sample.

• If the value of EDPCSR.NS is 0, then this field is set to an UNKNOWN value.

• If neither of the above conditions are true, this field is set to an UNKNOWN value.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

**Accessing the EDVIDSR:**

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see *Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN* on page H7-6536

EDVIDSR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x0A8</td>
<td>EDVIDSR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

• When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to this register is RO.

• Otherwise access to this register returns an Error.
H9.2.44   EDWAR, External Debug Watchpoint Address Register

The EDWAR characteristics are:

Purpose
Returns the virtual data address being accessed when a Watchpoint Debug Event was triggered.

Configurations
EDWAR is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Attributes
EDWAR is a 64-bit register.

Field descriptions
The EDWAR bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Watchpoint address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Watchpoint address. The data virtual address being accessed when a Watchpoint Debug Event was triggered and caused entry to Debug state. This address must be within a naturally-aligned block of memory of power-of-two size no larger than the DC ZVA block size.</td>
<td></td>
</tr>
<tr>
<td>The value of this register is UNKNOWN if the PE is in Non-debug state, or if Debug state was entered other than for a Watchpoint debug event.</td>
<td></td>
</tr>
<tr>
<td>The value of EDWAR[63:32] is UNKNOWN if Debug state was entered for a Watchpoint debug event taken from AArch32 state.</td>
<td></td>
</tr>
<tr>
<td>The EDWAR is subject to the same alignment rules as the reporting of a watchpointed address in the FAR. See Determining the memory location that caused a Watchpoint exception on page D2-2310</td>
<td></td>
</tr>
<tr>
<td>On a Cold reset, this field resets to an architecturally UNKNOWN value.</td>
<td></td>
</tr>
</tbody>
</table>

Accessing the EDWAR:
EDWAR[31:0] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x030</td>
<td>EDWAR</td>
<td>31:0</td>
</tr>
</tbody>
</table>

EDWAR[63:32] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x034</td>
<td>EDWAR</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to EDWAR[31:0] is RO.
• Otherwise access to EDWAR[31:0] returns an Error.

• When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to EDWAR[63:32] is RO.

• Otherwise access to EDWAR[63:32] returns an Error.
H9.2.45  MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

**Purpose**

Provides identification information for the PE, including an implementer code for the device and a device ID number.

**Configurations**

External register MIDR_EL1[31:0] is architecturally mapped to AArch64 System register MIDR_EL1[31:0].

External register MIDR_EL1[31:0] is architecturally mapped to AArch32 System register MIDR[31:0].

It is IMPLEMENTATION DEFINED whether MIDR_EL1 is implemented in the Core power domain or in the Debug power domain.

**Attributes**

MIDR_EL1 is a 32-bit register.

**Field descriptions**

The MIDR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implementer</td>
<td>Variant</td>
<td>Architecture</td>
<td>PartNum</td>
<td>Revision</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Implementer, bits [31:24]**

The Implementer code. This field must hold an implementer code that has been assigned by Arm. Assigned codes include the following:

<table>
<thead>
<tr>
<th>Hex representation</th>
<th>Implementer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>Reserved for software use</td>
</tr>
<tr>
<td>0xC0</td>
<td>Ampere Computing</td>
</tr>
<tr>
<td>0x41</td>
<td>Arm Limited</td>
</tr>
<tr>
<td>0x42</td>
<td>Broadcom Corporation</td>
</tr>
<tr>
<td>0x43</td>
<td>Cavium Inc.</td>
</tr>
<tr>
<td>0x44</td>
<td>Digital Equipment Corporation</td>
</tr>
<tr>
<td>0x49</td>
<td>Infineon Technologies AG</td>
</tr>
<tr>
<td>0x4D</td>
<td>Motorola or Freescale Semiconductor Inc.</td>
</tr>
<tr>
<td>0x4E</td>
<td>NVIDIA Corporation</td>
</tr>
<tr>
<td>0x50</td>
<td>Applied Micro Circuits Corporation</td>
</tr>
</tbody>
</table>
Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

**Variant, bits [23:20]**

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

**Architecture, bits [19:16]**

The permitted values of this field are:

- 0b0001: Armv4.
- 0b0010: Armv4T.
- 0b0011: Armv5 (obsolete).
- 0b0100: Armv5T.
- 0b0101: Armv5TE.
- 0b0110: Armv5TEJ.
- 0b0111: Armv6.
- 0b1111: Architectural features are individually identified in the ID_* registers, see Table K13-9 on page K13-7410

All other values are reserved.

**PartNum, bits [15:4]**

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

**Revision, bits [3:0]**

An IMPLEMENTATION DEFINED revision number for the device.

**Accessing the MIDR_EL1:**

MIDR_EL1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x0</td>
<td>MIDR_EL1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered() and !DoubleLockStatus() access to this register is RO.
- Otherwise access to this register is IMPDEF.
H9.2.46  OSLAR_EL1, OS Lock Access Register

The OSLAR_EL1 characteristics are:

**Purpose**

Used to lock or unlock the OS lock.

**Configurations**

- External register OSLAR_EL1[31:0] is architecturally mapped to AArch64 System register OSLAR_EL1[31:0].
- External register OSLAR_EL1[31:0] is architecturally mapped to AArch32 System register DBGOSLAR[31:0].
- OSLAR_EL1 is in the Core power domain.
- If ARMv8.2-Debug is not implemented, it is IMPLEMENTATION DEFINED whether external debug accesses to OSLAR_EL1 are ignored and return an error when AllowExternalDebugAccess() returns FALSE for the access.
- If ARMv8.2-Debug is implemented, external debug accesses to OSLAR_EL1 are ignored and return an error when AllowExternalDebugAccess() returns FALSE for the access.

**Attributes**

OSLAR_EL1 is a 32-bit register.

**Field descriptions**

The OSLAR_EL1 bit assignments are:

```
31  1  0
RES0  OSLK
```

**Bits [31:1]**

Reserved, RES0.

**OSLK, bit [0]**

On writes to OSLAR_EL1, bit[0] is copied to the OS lock.

Use EDPRSR.OSLK to check the current status of the lock.

**Accessing the OSLAR_EL1:**

**Note**

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

OSLAR_EL1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>0x300</td>
<td>OSLAR_EL1</td>
</tr>
</tbody>
</table>
This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), AllowExternalDebugAccess() and SoftwareLockStatus() access to this register is WI.

- When IsCorePowered(), !DoubleLockStatus(), AllowExternalDebugAccess() and !SoftwareLockStatus() access to this register is WO.

- When IsCorePowered(), !DoubleLockStatus(), !AllowExternalDebugAccess() and ARMv8.2-Debug is not implemented access to this register is IMPDEF.

- Otherwise access to this register returns an Error.
H9.3 Cross-Trigger Interface registers

This section lists the Cross-Trigger Interface registers.
H9.3.1 ASICCTL, CTI External Multiplexer Control register

The ASICCTL characteristics are:

Purpose

Can be used to provide implementation defined controls for the CTI. For example, the register might be used to control multiplexors for additional implementation defined triggers. The implementation defined controls provided by this register might modify the architecturally defined behavior of the CTI.

Note

The architecturally-defined triggers must not be multiplexed.

Configurations

It is implementation defined whether ASICCTL is implemented in the Core power domain or in the Debug power domain.

If it is implemented in the Core power domain then it is implementation defined whether it is in the Cold reset domain or the Warm reset domain.

This register must reset to a value that supports the architecturally-defined behavior of the CTI. Changing the value of the register from its reset value causes implementation defined behavior that might differ from the architecturally-defined behavior of the CTI.

Other than the requirements listed in this register description, all aspects of the reset behavior of the ASICCTL are implementation defined.

Attributes

ASICCTL is a 32-bit register.

Field descriptions

The ASICCTL bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
</tr>
</tbody>
</table>

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the ASICCTL:

ASICCTL can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x144</td>
<td>ASICCTL</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and SoftwareLockStatus() access to this register is RO.
- Otherwise access to this register is IMPDEF.
H9.3.2 CTIAPPCLEAR, CTI Application Trigger Clear register

The CTIAPPCLEAR characteristics are:

**Purpose**

Clears bits of the Application Trigger register.

**Configurations**

CTIAPPCLEAR is in the Debug power domain.

There are no configuration notes.

**Attributes**

CTIAPPCLEAR is a 32-bit register.

**Field descriptions**

The CTIAPPCLEAR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPCLEAR&lt;31&gt;, bit [x]</td>
<td></td>
</tr>
</tbody>
</table>

**APPCLEAR<31>, bit [x], for x = 0 to 31**

Application trigger <x> disable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Writing to this bit has the following effect:

- **0b0**: No effect.
- **0b1**: Clear corresponding bit in CTIAPPTRIG to 0 and clear the corresponding channel event.

If the ECT does not support multicycle channel events, use of CTIAPPCLEAR is deprecated and the debugger must only use CTIAPPULSE.

**Accessing the CTIAPPCLEAR:**

CTIAPPCLEAR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x818</td>
<td>CTIAPPCLEAR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When SoftwareLockStatus() access to this register is WI.
- When !SoftwareLockStatus() access to this register is WO.
H9.3.3 CTIAPPPULSE, CTI Application Pulse register

The CTIAPPPULSE characteristics are:

**Purpose**

- Causes event pulses to be generated on ECT channels.

**Configurations**

- CTIAPPPULSE is in the Debug power domain.
- There are no configuration notes.

**Attributes**

- CTIAPPPULSE is a 32-bit register.

**Field descriptions**

The CTIAPPPULSE bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPPULSE&lt;(x)&gt; , bit [(x)]</td>
<td></td>
</tr>
</tbody>
</table>

**APPPULSE<\(x\)> , bit [\(x\)], for \(x = 0\) to \(31\)**

- Generate event pulse on ECT channel \(<x>\).
- Bits [31:N] are RAZ/WI. \(N\) is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.
- Writing to this bit has the following effect:
  - 0b0: No effect.
  - 0b1: Channel \(<x>\) event pulse generated.

**Note**

- The CTIAPPPULSE operation does not affect the state of the Application Trigger register, CTIAPPTTRIG. If the channel is active, either because of an earlier event or from the application trigger, then the value written to CTIAPPPULSE might have no effect.
- Multiple pulse events that occur close together might be merged into a single pulse event.

**Accessing the CTIAPPPULSE:**

It is CONstrained UNPREDICTABLE whether a write to CTIAPPPULSE generates an event on a channel if CTICONTROL.GLBEN is 0.

CTIAPPPULSE can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x01C</td>
<td>CTIAPPPULSE</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When SoftwareLockStatus() access to this register is WI.
- When !SoftwareLockStatus() access to this register is WO.
H9.3.4  CTIAPPSET, CTI Application Trigger Set register

The CTIAPPSET characteristics are:

**Purpose**
Sets bits of the Application Trigger register.

**Configurations**
CTIAPPSET is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

**Attributes**
CTIAPPSET is a 32-bit register.

**Field descriptions**
The CTIAPPSET bit assignments are:

<table>
<thead>
<tr>
<th>APPSET&lt;x&gt;, bit [x]</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
</table>

APPSET<x>, bit [x], for x = 0 to 31
Application trigger <x> enable.
Bit [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.
Possible values of this bit are:
- 0b0: Reading this means the application trigger is inactive. Writing this has no effect.
- 0b1: Reading this means the application trigger is active. Writing this sets the corresponding bit in CTIAPPPTRIG to 1 and generates a channel event.

If the ECT does not support multicycle channel events, use of CTIAPPSET is deprecated and the debugger must only use CTIAPPPULSE.

On a External debug reset, this field resets to an architecturally UNKNOWN value.

**Accessing the CTIAPPSET:**
CTIAPPSET can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x014</td>
<td>CTIAPPSET</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:
- When SoftwareLockStatus() access to this register is RO.
- When !SoftwareLockStatus() access to this register is RW.
H9.3.5 CTIAUTHSTATUS, CTI Authentication Status register

The CTIAUTHSTATUS characteristics are:

**Purpose**

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for CTI.

**Configurations**

CTIAUTHSTATUS is in the Debug power domain.

This register is OPTIONAL, and is required for CoreSight compliance.

**Attributes**

CTIAUTHSTATUS is a 32-bit register.

**Field descriptions**

The CTIAUTHSTATUS bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>7-4</td>
<td>Reserved, RAZ.</td>
</tr>
<tr>
<td>3-2</td>
<td>NSNID, bits [3:2]</td>
</tr>
<tr>
<td>1-0</td>
<td>NSID, bits [1:0]</td>
</tr>
</tbody>
</table>

**NSNID, bits [3:2]**

If EL3 is not implemented and the implemented Security state is Secure state, holds the same value as DBGAUTHSTATUS_EL1.SNID.

Otherwise, holds the same value as DBGAUTHSTATUS_EL1.NSNID.

**NSID, bits [1:0]**

If EL3 is not implemented and the implemented Security state is Secure state, holds the same value as DBGAUTHSTATUS_EL1.SID.

Otherwise, holds the same value as DBGAUTHSTATUS_EL1.NSID.

**Accessing the CTIAUTHSTATUS:**

CTIAUTHSTATUS can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFB8</td>
<td>CTIAUTHSTATUS</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
**H9.3.6 CTICHINSTATUS, CTI Channel In Status register**

The CTICHINSTATUS characteristics are:

**Purpose**

Provides the raw status of the ECT channel inputs to the CTI.

**Configurations**

CTICHINSTATUS is in the Debug power domain.

There are no configuration notes.

**Attributes**

CTICHINSTATUS is a 32-bit register.

**Field descriptions**

The CTICHINSTATUS bit assignments are:

<table>
<thead>
<tr>
<th>CHIN&lt;n&gt;, bit [n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

CHIN<n>, bit [n], for n = 0 to 31

Input channel <n> status.

Bits [31:N] are RAZ. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

- 0b0 Input channel <n> is inactive.
- 0b1 Input channel <n> is active.

If the ECT channels do not support multicycle events then it is IMPLEMENTATION DEFINED whether an input channel can be observed as active.

**Accessing the CTICHINSTATUS:**

CTICHINSTATUS can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x138</td>
<td>CTICHINSTATUS</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.7 CTICHOUTSTATUS, CTI Channel Out Status register

The CTICHOUTSTATUS characteristics are:

**Purpose**

Provides the status of the ECT channel outputs from the CTI.

**Configurations**

CTICHOUTSTATUS is in the Debug power domain.

There are no configuration notes.

**Attributes**

CTICHOUTSTATUS is a 32-bit register.

**Field descriptions**

The CTICHOUTSTATUS bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>CHOUT&lt;n&gt;, bit [n]</td>
</tr>
</tbody>
</table>
```

**CHOUT<n>, bit [n], for n = 0 to 31**

Output channel <n> status.

Bits [31:N] are RAZ. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

- 0b0 Output channel <n> is inactive.
- 0b1 Output channel <n> is active.

If the ECT channels do not support multicycle events then it is IMPLEMENTATION DEFINED whether an output channel can be observed as active.

**Note**

The value in CTICHOUTSTATUS is after gating by the channel gate. For more information, see CTIGATE.

**Accessing the CTICHOUTSTATUS:**

CTICHOUTSTATUS can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x13C</td>
<td>CTICHOUTSTATUS</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.8 CTICIDR0, CTI Component Identification Register 0

The CTICIDR0 characteristics are:

**Purpose**

Provides information to identify a CTI component.

For more information see *About the Component Identification scheme on page K2-7245.*

**Configurations**

CTICIDR0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

CTICIDR0 is a 32-bit register.

**Field descriptions**

The CTICIDR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [31:8]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>PRMBL_0, bits [7:0]</td>
<td>Preamble. Must read as 0x0D.</td>
</tr>
</tbody>
</table>

**Accessing the CTICIDR0:**

CTICIDR0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFF0</td>
<td>CTICIDR0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

* Access to this register is RO.
H9.3.9 CTICIDR1, CTI Component Identification Register 1

The CTICIDR1 characteristics are:

**Purpose**

Provides information to identify a CTI component.

For more information see *About the Component Identification scheme on page K2-7245*.

**Configurations**

CTICIDR1 is in the Debug power domain.

Implementation of this register is *OPTIONAL*.

This register is required for CoreSight compliance.

**Attributes**

CTICIDR1 is a 32-bit register.

**Field descriptions**

The CTICIDR1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>RES0</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>7-4</td>
<td>CLASS</td>
<td>Component class. Reads as 0x9, debug component.</td>
</tr>
<tr>
<td>3-0</td>
<td>PRMBL_1</td>
<td>Preamble. RAZ.</td>
</tr>
</tbody>
</table>

**Accessing the CTICIDR1:**

CTICIDR1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFF4</td>
<td>CTICIDR1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.10 CTICIDR2, CTI Component Identification Register 2

The CTICIDR2 characteristics are:

**Purpose**
Provides information to identify a CTI component.
For more information see *About the Component Identification scheme on page K2-7245*.

**Configurations**
CTICIDR2 is in the Debug power domain.
Implementation of this register is OPTIONAL.
This register is required for CoreSight compliance.

**Attributes**
CTICIDR2 is a 32-bit register.

**Field descriptions**
The CTICIDR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Field Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>RES0</td>
</tr>
<tr>
<td>7-0</td>
<td>PRMBL_2</td>
</tr>
</tbody>
</table>

**Bits [31:8]**
Reserved, RES0.

**PRMBL_2, bits [7:0]**
Preamble. Must read as 0x05.

**Accessing the CTICIDR2:**
CTICIDR2 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFF8</td>
<td>CTICIDR2</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.11  CTICIDR3, CTI Component Identification Register 3

The CTICIDR3 characteristics are:

**Purpose**

Provides information to identify a CTI component.

For more information see About the Component Identification scheme on page K2-7245.

**Configurations**

CTICIDR3 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

CTICIDR3 is a 32-bit register.

**Field descriptions**

The CTICIDR3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>7-0</td>
<td>PRMBL_3, bits [7:0]</td>
</tr>
</tbody>
</table>

Preamble. Must read as 0xB1.

**Accessing the CTICIDR3:**

CTICIDR3 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFFC</td>
<td>CTICIDR3</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
**H9.3.12 CTICLAIMCLR, CTI Claim Tag Clear register**

The CTICLAIMCLR characteristics are:

**Purpose**

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

**Configurations**

CTICLAIMCLR is in the Debug power domain.

This register is not affected by a Warm reset, and is not affected by a Cold reset.

Implementation of this register is **OPTIONAL**.

**Attributes**

CTICLAIMCLR is a 32-bit register.

**Field descriptions**

The CTICLAIMCLR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLAIM[&lt;x&gt;], bit [x]</td>
<td></td>
</tr>
</tbody>
</table>

**CLAIM[<x>], bit [x], for x = 0 to 31**

CLAIM tag clear bit.

For values of x greater than or equal to the IMPLEMENTATION DEFINED number of CLAIM tags, this bit is RAZ/SBZ. Software can rely on these bits reading as zero, and must use a Should-Be-Zero policy on writes. Implementations must ignore writes.

For other values of x, reads return the value of CLAIM[x] and the behavior on writes is:

- 0b0  No action.
- 0b1  Indirectly clear CLAIM[x] to 0.

A single write to CTICLAIMCLR can clear multiple tags to 0.

An External Debug reset clears the CLAIM tag bits to 0.

An External Debug reset clears the CLAIM tag bits to 0.

**Accessing the CTICLAIMCLR:**

CTICLAIMCLR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFA4</td>
<td>CTICLAIMCLR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When SoftwareLockStatus() access to this register is RO.
- When !SoftwareLockStatus() access to this register is RW.
H9.3.13 CTICLAIMSET, CTI Claim Tag Set register

The CTICLAIMSET characteristics are:

**Purpose**
Used by software to set CLAIM bits to 1.

**Configurations**
CTICLAIMSET is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

Implementation of this register is OPTIONAL.

**Attributes**
CTICLAIMSET is a 32-bit register.

**Field descriptions**
The CTICLAIMSET bit assignments are:

<table>
<thead>
<tr>
<th>Claim Tag Set Bit Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLAIM[&lt;x&gt;], bit [x]</td>
</tr>
<tr>
<td>31 0</td>
</tr>
</tbody>
</table>

**CLAIM[<x>], bit [x], for x = 0 to 31**
CLAIM tag set bit.

For values of x greater than or equal to the IMPLEMENTATION DEFINED number of CLAIM tags, this bit is RAZ/SBZ. Software can rely on these bits reading as zero, and must use a Should-Be-Zero policy on writes. Implementations must ignore writes.

For other values of x, the bit is RAO and the behavior on writes is:

- **0b0** No action.
- **0b1** Indirectly set CLAIM[x] tag to 1.

A single write to CTICLAIMSET can set multiple tags to 1.

An External Debug reset clears the CLAIM tag bits to 0.

**Accessing the CTICLAIMSET:**
CTICLAIMSET can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFA0</td>
<td>CTICLAIMSET</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When SoftwareLockStatus() access to this register is RO.
- When !SoftwareLockStatus() access to this register is RW.
H9.3.14 CTICONTROL, CTI Control register

The CTICONTROL characteristics are:

**Purpose**

Controls whether the CTI is enabled.

**Configurations**

CTICONTROL is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

**Attributes**

CTICONTROL is a 32-bit register.

**Field descriptions**

The CTICONTROL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>0</td>
<td>GLBEN, bit [0] Enables or disables the CTI mapping functions. Possible values of this field are: 0b0 CTI mapping functions and application trigger disabled. 0b1 CTI mapping functions and application trigger enabled. When GLBEN is 0, the input channel to output trigger, input trigger to output channel, and application trigger functions are disabled and do not signal new events on either output triggers or output channels. If a previously asserted output trigger has not been acknowledged, it remains asserted after the mapping functions are disabled. All output triggers are disabled by CTI reset. If the ECT supports multicycle channel events any existing output channel events will be terminated. On a External debug reset, this field resets to 0.</td>
</tr>
</tbody>
</table>

**Accessing the CTICONTROL:**

CTICONTROL can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x00</td>
<td>CTICONTROL</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When SoftwareLockStatus() access to this register is RO.
- When !SoftwareLockStatus() access to this register is RW.
H9.3.15 CTIDEVAFF0, CTI Device Affinity register 0

The CTIDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

If the CTI is CTIv1, this register is optional. If the CTI is CTIv2, this register is mandatory.

Arm recommends that the CTI is CTIv2.

If this register is implemented, then CTIDEVAFF1 must also be implemented. If the CTI of a PE does not implement the CTI Device Affinity registers, the CTI block of the external debug memory map must be located 64KB above the debug registers in the external debug interface.

Configurations

CTIDEVAFF0 is in the Debug power domain.

Implementation of this register is optional.

Attributes

CTIDEVAFF0 is a 32-bit register.

Field descriptions

The CTIDEVAFF0 bit assignments are:

31

| 31:0 | MPIDR_EL1 low half |

MPIDR_EL1 low half, bits [31:0]

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the CTIDEVAFF0:

CTIDEVAFF0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFA8</td>
<td>CTIDEVAFF0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.16  CTIDEVAFF1, CTI Device Affinity register 1

The CTIDEVAFF1 characteristics are:

Purpose
Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

If the CTI is CTIv1, this register is optional. If the CTI is CTIv2, this register is mandatory.

Arm recommends that the CTI is CTIv2.

If this register is implemented, then CTIDEVAFF0 must also be implemented. If the CTI of a PE does not implement the CTI Device Affinity registers, the CTI block of the external debug memory map must be located 64KB above the debug registers in the external debug interface.

Configurations
CTIDEVAFF1 is in the Debug power domain.
Implementation of this register is optional.

Attributes
CTIDEVAFF1 is a 32-bit register.

Field descriptions
The CTIDEVAFF1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPIDR_EL1 high half</td>
<td></td>
</tr>
</tbody>
</table>

MPIDR_EL1 high half, bits [31:0]

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the CTIDEVAFF1:
CTIDEVAFF1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFA1</td>
<td>CTIDEVAFF1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.17 CTIDEVARC, CTI Device Architecture register

The CTIDEVARC characteristics are:

**Purpose**

Identifies the programmers’ model architecture of the CTI component.

If the CTI is CTIv1, this register is **optional**. If the CTI is CTIv2, this register is mandatory.

Arm recommends that the CTI is CTIv2.

If this register is not implemented, CTIDEVAFF0 and CTIDEVAFF1 are also not implemented.

**Configurations**

CTIDEVARC is in the Debug power domain.

Implementation of this register is **optional**.

**Attributes**

CTIDEVARC is a 32-bit register.

**Field descriptions**

The CTIDEVARC bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>21 20 19</th>
<th>16 15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ARCHITECT</td>
<td>REVISION</td>
<td>ARCHID</td>
</tr>
<tr>
<td>PRESENT</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ARCHITECT, bits [31:21]**

Defines the architecture of the component. For CTI, this is Arm Limited.

Bits [31:28] are the JEP106 continuation code, 0x4.

Bits [27:21] are the JEP106 ID code, 0x3B.

**PRESENT, bit [20]**

When set to 1, indicates that the DEVARCH is present.

This field is 1 in Armv8.

**REVISION, bits [19:16]**

Revision.

Defines the architecture revision of the component.

0b0000 First revision.

All other values are reserved.

**ARCHID, bits [15:0]**

Defines this part to be an Armv8 debug component. For architectures defined by Arm this is further subdivided.

For CTI:

- Bits [15:12] are the architecture version, 0x1.
- Bits [11:0] are the architecture part number, 0xA14.

This corresponds to CTI architecture version CTIv2.
Accessing the CTIDEVARCH:

CTIDEVARCH can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFBc</td>
<td>CTIDEVARCH</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.18   CTIDEVID, CTI Device ID register 0

The CTIDEVID characteristics are:

**Purpose**

Describes the CTI component to the debugger.

**Configurations**

CTIDEVID is in the Debug power domain. There are no configuration notes.

**Attributes**

CTIDEVID is a 32-bit register.

**Field descriptions**

The CTIDEVID bit assignments are:

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>26-22</td>
<td>NUMCHAN</td>
</tr>
<tr>
<td>16-13</td>
<td>NUMTRIG, RES0</td>
</tr>
<tr>
<td>8</td>
<td>EXTMUXNUM</td>
</tr>
<tr>
<td>25-24</td>
<td>INOUT</td>
</tr>
<tr>
<td>23-22</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>15-14</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>13-8</td>
<td>NUMTRIG</td>
</tr>
<tr>
<td>7</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>6</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

**Bits [31:26]**

Reserved, RES0.

**INOUT, bits [25:24]**

Input/output options. Indicates presence of the input gate. If the CTM is not implemented or CTIv2 is not implemented, this field is RAZ.

- **0b00**  CTIGATE does not mask propagation of input events from external channels.
- **0b01**  CTIGATE masks propagation of input events from external channels.

All other values are reserved.

**Bits [23:22]**

Reserved, RES0.

**NUMCHAN, bits [21:16]**

Number of ECT channels implemented. IMPLEMENTATION DEFINED. For Armv8, valid values are:

- **0b000011**  3 channels (0..2) implemented.
- **0b000100**  4 channels (0..3) implemented.
- **0b000101**  5 channels (0..4) implemented.
- **0b000110**  6 channels (0..5) implemented.

and so on up to **0b100000**, 32 channels (0..31) implemented.

All other values are reserved.

**Bits [15:14]**

Reserved, RES0.

**NUMTRIG, bits [13:8]**

Number of triggers implemented. IMPLEMENTATION DEFINED. This is one more than the index of the largest trigger, rather than the actual number of triggers.
For Armv8, valid values are:
- `0b000011` Up to 3 triggers (0..2) implemented.
- `0b001000` Up to 8 triggers (0..7) implemented.
- `0b001001` Up to 9 triggers (0..8) implemented.
- `0b001010` Up to 10 triggers (0..9) implemented.
and so on up to `0b100000`, 32 triggers (0..31) implemented.

All other values are reserved. If the contains a Trace extension, this field must be at least `0b001000`. There is no guarantee that any of the implemented triggers, including the highest numbered, are connected to any components.

**Bits [7:5]**

Reserved, RES0.

**EXTMUXNUM, bits [4:0]**

Number of multiplexors available on triggers. This value is used in conjunction with External Control register, ASICCTL.

**Accessing the CTIDEVID:**

CTIDEVID can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFC8</td>
<td>CTIDEVID</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.19  CTIDEVID1, CTI Device ID register 1

The CTIDEVID1 characteristics are:

**Purpose**

Reserved for future information about the CTI component to the debugger.

**Configurations**

CTIDEVID1 is in the Debug power domain.
There are no configuration notes.

**Attributes**

CTIDEVID1 is a 32-bit register.

**Field descriptions**

The CTIDEVID1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:0]</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

**Accessing the CTIDEVID1:**

CTIDEVID1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFC4</td>
<td>CTIDEVID1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.20 CTIDEVID2, CTI Device ID register 2

The CTIDEVID2 characteristics are:

**Purpose**
Reserved for future information about the CTI component to the debugger.

**Configurations**
CTIDEVID2 is in the Debug power domain.
There are no configuration notes.

**Attributes**
CTIDEVID2 is a 32-bit register.

**Field descriptions**
The CTIDEVID2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Bit Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>RES0</td>
</tr>
</tbody>
</table>

**Bits [31:0]**
Reserved, RES0.

**Accessing the CTIDEVID2:**
CTIDEVID2 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFC0</td>
<td>CTIDEVID2</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:
- Access to this register is RO.
H9.3.21  CTIDEVTYPE, CTI Device Type register

The CTIDEVTYPE characteristics are:

**Purpose**

Indicates to a debugger that this component is part of a PE's cross-trigger interface.

**Configurations**

CTIDEVTYPE is in the Debug power domain.

Implementation of this register is OPTIONAL.

**Attributes**

CTIDEVTYPE is a 32-bit register.

**Field descriptions**

The CTIDEVTYPE bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SUB</td>
<td>MAJOR</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**SUB, bits [7:4]**

Subtype. Must read as 0x1 to indicate this is a component within a PE.

**MAJOR, bits [3:0]**

Major type. Must read as 0x4 to indicate this is a cross-trigger component.

**Accessing the CTIDEVTYPE:**

CTIDEVTYPE can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFCC</td>
<td>CTIDEVTYPE</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.22 CTIGATE, CTI Channel Gate Enable register

The CTIGATE characteristics are:

**Purpose**

Determines whether events on channels propagate through the CTM to other ECT components, or from the CTM into the CTI.

**Configurations**

CTIGATE is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

**Attributes**

CTIGATE is a 32-bit register.

**Field descriptions**

The CTIGATE bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GATE&lt;x&gt;, bit [x]</td>
<td>Channel &lt;x&gt; gate enable.</td>
</tr>
</tbody>
</table>

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

- b0: Disable output and, if CTIDEVID.INOUT == b01, input channel <x> propagation.
- b1: Enable output and, if CTIDEVID.INOUT == b01, input channel <x> propagation.

If GATE[x] is set to 0, no new events will be propagated to the ECT, and if the ECT supports multicycle channel events any existing output channel events will be terminated.

On a External debug reset, this field resets to an architecturally UNKNOWN value.

**Accessing the CTIGATE:**

CTIGATE can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x140</td>
<td>CTIGATE</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When SoftwareLockStatus() access to this register is RO.
- When !SoftwareLockStatus() access to this register is RW.
H9.3.23  CTIINEN<n>, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31

The CTIINEN<n> characteristics are:

**Purpose**

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

**Configurations**

CTIINEN<n> is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

If input trigger n is not connected, the behavior of CTIINEN<n> is IMPLEMENTATION DEFINED.

**Attributes**

CTIINEN<n> is a 32-bit register.

**Field descriptions**

The CTIINEN<n> bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>INEN&lt;x&gt;, bit [x]</td>
<td></td>
</tr>
</tbody>
</table>

**INEN<x>, bit [x], for x = 0 to 31**

Input trigger <n> to output channel <x> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

- 0b0: Input trigger <n> will not generate an event on output channel <x>.
- 0b1: Input trigger <n> will generate an event on output channel <x>.

On a External debug reset, this field resets to an architecturally UNKNOWN value.

**Accessing the CTIINEN<n>:**

CTIINEN<n> can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x820 + 4n</td>
<td>CTIINEN&lt;n&gt;</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When SoftwareLockStatus() access to this register is RO.
- When !SoftwareLockStatus() access to this register is RW.
H9.3.24 CTIINTACK, CTI Output Trigger Acknowledge register

The CTIINTACK characteristics are:

**Purpose**

Can be used to deactivate the output triggers.

**Configurations**

CTIINTACK is in the Debug power domain.

There are no configuration notes.

**Attributes**

CTIINTACK is a 32-bit register.

**Field descriptions**

The CTIINTACK bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACK&lt;n&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

**ACK<n>, bit [n], for n = 0 to 31**

Acknowledge for output trigger <n>.

Bits [31:N] are RAZ/WI. N is the number of CTI triggers implemented as defined by the CTIDEVID.NUMTRIG field.

If any of the following is true, writes to ACK<n> are ignored:

- \( n >= \text{CTIDEVID.NUMTRIG} \), the number of implemented triggers.
- Output trigger n is not active.
- The channel mapping function output, as controlled by CTIOUTEN<n>, is still active.

Otherwise, if any of the following are true, it is IMPLEMENTATION DEFINED whether writes to ACK<n> are ignored:

- Output trigger n is not implemented.
- Output trigger n is not connected.
- Output trigger n is self-acknowledging and does not require software acknowledge.

Otherwise, the behavior on writes to ACK<n> is as follows:

- \( 0b0 \) No effect
- \( 0b1 \) Deactivate the trigger.

**Accessing the CTIINTACK:**

A debugger must read CTITRIGOUTSTATUS to confirm that the output trigger has been acknowledged before generating any event that must be ordered after the write to CTIINTACK, such as a write to CTIAPPPULSE to activate another trigger.

CTIINTACK can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x010</td>
<td>CTIINTACK</td>
</tr>
</tbody>
</table>
This interface is accessible as follows:

- When SoftwareLockStatus() access to this register is WI.
- When !SoftwareLockStatus() access to this register is WO.
H9.3.25 CTITCTRL, CTI Integration mode Control register

The CTITCTRL characteristics are:

**Purpose**

Enables the CTI to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

**Configurations**

It is IMPLEMENTATION DEFINED whether CTITCTRL is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

Implementation of this register is OPTIONAL.

**Attributes**

CTITCTRL is a 32-bit register.

**Field descriptions**

The CTITCTRL bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:1 RES0</td>
<td>Reserved</td>
</tr>
<tr>
<td>0 IME</td>
<td>Integration mode enable</td>
</tr>
</tbody>
</table>

**Bits [31:1]**

Reserved, RES0.

**IME, bit [0]**

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

- **0b0** Normal operation.
- **0b1** Integration mode enabled.

On a Implementation reset, this field resets to 0.

**Accessing the CTITCTRL:**

CTITCTRL can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xF00</td>
<td>CTITCTRL</td>
</tr>
</tbody>
</table>
This interface is accessible as follows:

- When `IsCorePowered()`, `!DoubleLockStatus()`, `!OSLockStatus()` and `SoftwareLockStatus()` access to this register is RO.
- When `IsCorePowered()`, `!DoubleLockStatus()`, `!OSLockStatus()` and `!SoftwareLockStatus()` access to this register is RW.
- Otherwise access to this register is IMPDEF.
H9.3.26 CTILAR, CTI Lock Access Register

The CTILAR characteristics are:

**Purpose**

Allows or disallows access to the CTI registers through a memory-mapped interface.

**Configurations**

CTILAR is in the Debug power domain.

CTILAR ignores writes if the Software lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses CTILAR to set or clear the lock, and CTILSR to check the current status of the lock.

**Attributes**

CTILAR is a 32-bit register.

**Field descriptions**

The CTILAR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEY</td>
<td></td>
</tr>
</tbody>
</table>

**KEY, bits [31:0]**

Lock Access control. Writing the key value 0xC5ACEE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

**Accessing the CTILAR:**

CTILAR can be accessed through a memory-mapped interface access to the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFB0</td>
<td>CTILAR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is WO.
H9.3.27 CTILSR, CTI Lock Status Register

The CTILSR characteristics are:

**Purpose**

Indicates the current status of the Software Lock for CTI registers.

**Configurations**

CTILSR is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

CTILSR is RAZ if the Software Lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses CTILAR to set or clear the lock, and CTILSR to check the current status of the lock.

**Attributes**

CTILSR is a 32-bit register.

**Field descriptions**

The CTILSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-3</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>2</td>
<td>Not thirty-two bit access required. RAZ.</td>
</tr>
<tr>
<td>1</td>
<td>Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0. For memory-mapped accesses when the Software Lock is implemented, possible values of this field are: 0b0 Lock clear. Writes are permitted to this component's registers. 0b1 Lock set. Writes to this component's registers are ignored, and reads have no side effects. On a External debug reset, this field resets to 1.</td>
</tr>
</tbody>
</table>

nTT, bit [2]

SLK, bit [1]
SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

\[0b0\] Software Lock not implemented or not memory-mapped access.
\[0b1\] Software Lock implemented and memory-mapped access.

Accessing the CTILSR:

CTILSR can be accessed through a memory-mapped interface access to the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFB4</td>
<td>CTILSR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.28  CTIOUTEN<n>, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31

The CTIOUTEN<n> characteristics are:

**Purpose**

Defines which input channels generate output trigger n.

**Configurations**

CTIOUTEN<n> is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

If output trigger n is not connected, the behavior of CTIOUTEN<n> is IMPLEMENTATION DEFINED.

**Attributes**

CTIOUTEN<n> is a 32-bit register.

**Field descriptions**

The CTIOUTEN<n> bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>OUTEN&lt;x&gt;, bit [x]</td>
<td></td>
</tr>
</tbody>
</table>
```

**OUTEN<x>, bit [x], for x = 0 to 31**

Input channel <x> to output trigger <n> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

- 0b0  An event on input channel <x> will not cause output trigger <n> to be asserted.
- 0b1  An event on input channel <x> will cause output trigger <n> to be asserted.

On a External debug reset, this field resets to an architecturally UNKNOWN value.

**Accessing the CTIOUTEN<n>:**

CTIOUTEN<n> can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x8A0 + 4n</td>
<td>CTIOUTEN&lt;n&gt;</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When SoftwareLockStatus() access to this register is RO.
- When !SoftwareLockStatus() access to this register is RW.
H9.3.29   CTIPIDR0, CTI Peripheral Identification Register 0

The CTIPIDR0 characteristics are:

**Purpose**

Provides information to identify a CTI component.
For more information see *About the Peripheral identification scheme* on page K2-7243.

**Configurations**

CTIPIDR0 is in the Debug power domain.
Implementation of this register is OPTIONAL.
This register is required for CoreSight compliance.

**Attributes**

CTIPIDR0 is a 32-bit register.

**Field descriptions**

The CTIPIDR0 bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>PART_0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:8]**

Reserved, RES0.

**PART_0, bits [7:0]**

Part number, least significant byte.

**Accessing the CTIPIDR0:**

CTIPIDR0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFE0</td>
<td>CTIPIDR0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.30 CTIPIDR1, CTI Peripheral Identification Register 1

The CTIPIDR1 characteristics are:

**Purpose**

Provides information to identify a CTI component.

For more information see *About the Peripheral identification scheme* on page K2-7243.

**Configurations**

CTIPIDR1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

CTIPIDR1 is a 32-bit register.

**Field descriptions**

The CTIPIDR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>DES_0</td>
<td>PART_1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**DES_0, bits [7:4]**

Designer, least significant nibble of JEP106 ID code. For Arm Limited, this field is 0b1011.

**PART_1, bits [3:0]**

Part number, most significant nibble.

**Accessing the CTIPIDR1:**

CTIPIDR1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFE4</td>
<td>CTIPIDR1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.31 CTIPIDR2, CTI Peripheral Identification Register 2

The CTIPIDR2 characteristics are:

**Purpose**

Provides information to identify a CTI component.

For more information see About the Peripheral identification scheme on page K2-7243.

**Configurations**

CTIPIDR2 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

CTIPIDR2 is a 32-bit register.

**Field descriptions**

The CTIPIDR2 bit assignments are:

| Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 09 | Bit 08 |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| RES0   | REVISION | DES_1  | JEDEC  |

**Bits [31:8]**

Reserved, RES0.

**REVISION, bits [7:4]**

Part major revision. Parts can also use this field to extend Part number to 16-bits.

**JEDEC, bit [3]**

RAO. Indicates a JEP106 identity code is used.

**DES_1, bits [2:0]**

Designer, most significant bits of JEP106 ID code. For Arm Limited, this field is 0b011.

**Accessing the CTIPIDR2:**

CTIPIDR2 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFE8</td>
<td>CTIPIDR2</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.32  CTIPIDR3, CTI Peripheral Identification Register 3

The CTIPIDR3 characteristics are:

**Purpose**

Provides information to identify a CTI component.
For more information see *About the Peripheral identification scheme on page K2-7243*.

**Configurations**

CTIPIDR3 is in the Debug power domain.
Implementation of this register is OPTIONAL.
This register is required for CoreSight compliance.

**Attributes**

CTIPIDR3 is a 32-bit register.

**Field descriptions**

The CTIPIDR3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>Bit 8</th>
<th>Bit 7</th>
<th>Bit 4</th>
<th>Bit 3</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>REVAND</td>
<td>CMOD</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**REVAND, bits [7:4]**

Part minor revision. Parts using CTIPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

**CMOD, bits [3:0]**

Customer modified. Indicates someone other than the Designer has modified the component.

**Accessing the CTIPIDR3:**

CTIPIDR3 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xFE0</td>
<td>CTIPIDR3</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
H9.3.33 CTIPIDR4, CTI Peripheral Identification Register 4

The CTIPIDR4 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see About the Peripheral identification scheme on page K2-7243.

Configurations

CTIPIDR4 is in the Debug power domain.
Implementation of this register is OPTIONAL.
This register is required for CoreSight compliance.

Attributes

CTIPIDR4 is a 32-bit register.

Field descriptions

The CTIPIDR4 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SIZE</td>
<td>DES_2</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. Log2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For Arm Limited, this field is 0b0100.

Accessing the CTIPIDR4:

CTIPIDR4 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0xF00</td>
<td>CTIPIDR4</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

• Access to this register is RO.
H9.3.34   CTITRIGINSTATUS, CTI Trigger In Status register

The CTITRIGINSTATUS characteristics are:

Purpose
Provides the status of the trigger inputs.

Configurations
CTITRIGINSTATUS is in the Debug power domain.
There are no configuration notes.

Attributes
CTITRIGINSTATUS is a 32-bit register.

Field descriptions
The CTITRIGINSTATUS bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>TRIN&lt;n&gt;, bit [n]</td>
</tr>
</tbody>
</table>

TRIN<n>, bit [n], for n = 0 to 31
Trigger input <n> status.
Bits [31:N] are RAZ. N is the number of CTI triggers implemented as defined by the CTIDEVID.NUMTRIG field.
Possible values of this bit are:
- 0b0  Input trigger n is inactive.
- 0b1  Input trigger n is active.
Not implemented and not-connected input triggers are always inactive.
It is IMPLEMENTATION DEFINED whether an input trigger that does not support multicycle events can be observed as active.

Accessing the CTITRIGINSTATUS:
CTITRIGINSTATUS can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x130</td>
<td>CTITRIGINSTATUS</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:
- Access to this register is RO.
H9.3.35  CTITRIGOUTSTATUS, CTI Trigger Out Status register

The CTITRIGOUTSTATUS characteristics are:

Purpose

Provides the raw status of the trigger outputs, after processing by any IMPLEMENTATION DEFINED trigger interface logic. For output triggers that are self-acknowledging, this is only meaningful if the CTI implements multicycle channel events.

Configurations

CTITRIGOUTSTATUS is in the Debug power domain.

There are no configuration notes.

Attributes

CTITRIGOUTSTATUS is a 32-bit register.

Field descriptions

The CTITRIGOUTSTATUS bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>TROUT&lt;n&gt;, bit [n]</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

TROUT<n>, bit [n], for n = 0 to 31

Trigger output <n> status.

Bits [31:N] are RAZ. N is the value in CTIDEVID.NUMTRIG.

If n < N, and output trigger <n> is implemented and connected, and either the trigger is not self-acknowledging or the CTI implements multicycle channel events, then permitted values for TROUT<n> are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Output trigger n is inactive.</td>
</tr>
<tr>
<td>0b1</td>
<td>Output trigger n is active.</td>
</tr>
</tbody>
</table>

Otherwise when n < N it is IMPLEMENTATION DEFINED whether TROUT<n> behaves as described here or is RAZ.

Accessing the CTITRIGOUTSTATUS:

CTITRIGOUTSTATUS can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTI</td>
<td>0x134</td>
<td>CTITRIGOUTSTATUS</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
Part I

Memory-mapped Components of the ARMv8 Architecture
Chapter 11
Requirements for Memory-mapped Components

This chapter provides some additional information about memory-mapped components. It contains the following sections:

- Supported access sizes on page 11-6710.
- Synchronization of memory-mapped registers on page 11-6712.
- Access requirements for reserved and unallocated registers on page 11-6714.
I1.1 Supported access sizes

The information in this section applies to all accesses to memory-mapped components of the ARMv8 architecture, unless a register or component description explicitly states otherwise.

The memory access sizes that are supported by any peripheral are IMPLEMENTATION DEFINED by the peripheral.

When \texttt{HaveSecureExtDebugView()} == TRUE, each debug component has a Secure and Non-secure view. The Secure view of a debug component is mapped into Secure physical memory and the Non-secure view of a debug component is mapped into Non-secure memory. Apart from access conditions, the Non-secure and Secure views of the debug components are identical.

An implementation of a memory-mapped component that is compatible with the ARMv8 architecture must support the following:

- **Word-aligned 32-bit accesses to access 32-bit registers.**

- If any PE in the system implements AArch32, word-aligned 32-bit accesses to either half of a 64-bit register that is mapped to a doubleword-aligned pair of adjacent 32-bit locations.

**Note**  
Some memory-mapped components of the ARMv8 architecture require support for word-aligned 32-bit accesses to either half of a 64-bit memory mapped register regardless of whether any PE in the system implements AArch32. These include:

- The memory-mapped interface to the external debug and CTI registers that are described in Chapter H9 External Debug Register Descriptions.

- The memory-mapped interfaces to the Generic Timer registers that are described in Chapter I2 System Level Implementation of the Generic Timer.

- The memory-mapped interfaces to the Performance Monitors registers that are described in Chapter I3 Recommended External Interface to the Performance Monitors.

- **Doubleword-aligned 64-bit accesses to access 64-bit registers that are mapped to a doubleword-aligned pair of adjacent 32-bit locations.**

All registers are only single-copy atomic at word granularity. This means that for 64-bit accesses to a 64-bit register, the system might generate a pair of 32-bit accesses. The order in which the two halves are accessed is not specified.

The following accesses are not supported:

- **Byte accesses.**

- **Halfword accesses.**

- **Unaligned word accesses.** These accesses are not word single-copy atomic.

- **Unaligned doubleword accesses.** These accesses are not doubleword single-copy atomic.

- **Doubleword accesses to a pair of 32-bit locations that are not a doubleword-aligned pair that forms a 64-bit register.**

- **Quadword accesses or higher accesses.**

- **Exclusive accesses.**

For unsupported accesses, it is CONSTRAINED UNPREDICTABLE whether:

- The access generates an External abort or not.
- The defined side-effects of a read occur or not. A read returns UNKNOWN values.
- A write is ignored or sets the accessed register or registers to UNKNOWN.
- The access generates a fault handling interrupt or not. A read returns UNKNOWN data.
For memory-mapped accesses from a PE that complies with an ARM architecture, the single-copy atomicity rules for the instruction, the type of instruction, and the type of memory that is accessed, determine the size of the access that is made by an instruction. Example I1-1 shows this.

Example I1-1  Access sizes for memory-mapped accesses

Two Load Doubleword instructions that are made to consecutive doubleword-aligned locations generate a pair of single-copy atomic doubleword reads. However, if the accesses are made to Normal memory or Device-GRE memory they might appear as a single quadword access that is not supported by the peripheral.

The ARMv8 architecture does not require the size of each element that is accessed by a multi-register load or store instruction to be identifiable by the memory system beyond the PE. Unless otherwise specified by the component, any access to a memory-mapped component of the ARMv8 architecture is defined to be beyond the PE.

Software must use a Device-nGRE or stronger memory type, and only single register load and store instructions, to create memory accesses that are supported by the peripheral. For more information, see Memory types and attributes on page B2-122.
I1.2 Synchronization of memory-mapped registers

This section describes the synchronization requirements for the memory-mapped accesses to System registers.

This section refers to accesses to external system control registers as external reads and external writes. It refers to accesses to System registers as direct reads, direct writes, indirect reads and indirect writes.

Note

Synchronization requirements for AArch64 System registers on page D12-2663 and Synchronization of changes to AArch32 System registers on page G8-5640 define direct read, direct write, indirect read, and indirect write, and classifies external reads as indirect reads and external writes as indirect writes.

Writes to the same register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes. Unless otherwise stated, external writes to different registers are not necessarily observed in the same order by all observers as the order in which they complete.

Explicit synchronization is not required for an external read or an external write by an external agent to be observable to a following external read or external write by that agent to the same register using the same address, and so is never required for registers that are accessible as external system control registers.

Unless required to be observable to all observers in finite time, without explicit synchronization, explicit synchronization is normally required following an external write to any register for that write to be observable by:

• A direct access.
• An indirect read by an instruction.
• An external read of the register using a different address.

This means that an external write by an external agent is guaranteed to have an effect on subsequent instructions executed by the PE only if all of the following are true:

• The write has completed.
• The PE has executed a Context synchronization event.
• The Context synchronization event was executed after the write completed.

The order and synchronization of direct reads and direct writes of System registers is defined by:

• Synchronization requirements for AArch64 System registers on page D12-2663
• Synchronization of changes to AArch32 System registers on page G8-5640

The external agent must be able to guarantee completion of a write. For example, the agent can:

• Mark the memory as Device-nGnRnE and executing a DSB barrier, if the system supports this property.
• If the register is read/write and reads are not destructive, read back the value written.
• Use some guaranteed property of the connection between the PE and the external agent.

The external agent and PE can guarantee ordering by, for example, passing messages in an ordered way with respect to the external write and the Context synchronization event, and relying on the memory ordering rules provided by the memory model.

External reads and external write complete in the order in which they arrive at the PE. For accesses to different register locations the external agent must create this order. The agent can:

• Mark the memory as Device-nGnRnE or Device-nGnRE.
• Use the appropriate memory barriers.
• Rely on some guaranteed property of the connection between the PE and the external agent.

However, the external agent cannot force the synchronization of completed writes.
In a simple sequential execution, an indirect write that occurs as a side-effect of an access happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

Without explicit synchronization to guarantee the order of the accesses, where the same register is accessed by two or more of a System register access instruction, and external agent, and autonomous asynchronous event, or as a result of a memory-mapped access, the behavior must be as if the accesses occurred atomically and in any order. This applies even if the accesses occur simultaneously.

For example, some registers have the property that for certain bits a write of 0 is ignored and a write of 1 has an effect. This means the simultaneous writes must be merged.
I1.3 Access requirements for reserved and unallocated registers

This section describes the access requirements for reserved and unallocated memory-mapped components.

The following information relates to certain types of reserved accesses:

• Reads and writes of unallocated locations. These accesses are reserved for the architecture.

• Reads and writes of locations for features that are not implemented, including:
  — OPTIONAL features that are not implemented.
  — Breakpoints and watchpoints that are not implemented.
  — Performance Monitors counters that are not implemented.
  — CTI triggers that are not implemented.
  — Error records that are not implemented.

  These accesses are reserved.

• Reads of WO locations. These accesses are reserved for the architecture.

• Writes to RO locations. These accesses are reserved for the architecture.

Reserved accesses are normally RAZ/WI. However, software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture. Software must treat reserved accesses as RES0.
Chapter I2
System Level Implementation of the Generic Timer

This chapter defines the system level implementation of the Generic Timer. It contains the following sections:

- About the Generic Timer specification on page I2-6716.
- Memory-mapped counter module on page I2-6718.
- Memory-mapped timer components on page I2-6722.

Note

- Generic Timer memory-mapped register descriptions on page I5-6852 describes the System level Generic Timer registers. These registers are memory-mapped.

- Appendix K5 Additional Information for Implementations of the Generic Timer gives additional information, that does not form part of the architectural definition of a system level implementation of the Generic Timer,

- Chapter D10 The Generic Timer in AArch64 state gives a general description of the AArch64 state view of the Generic Timer, and describes the AArch64 System register interface to the Generic Timer.

- Chapter G6 The Generic Timer in AArch32 state gives a general description of the AArch32 state view of the Generic Timer, and describes the AArch32 System register interface to the Generic Timer.
I2.1 About the Generic Timer specification

Chapter D10 The Generic Timer in AArch64 state describes the ARM Generic Timer and its implementation as seen from AArch64 state. Chapter G6 The Generic Timer in AArch32 state describes the ARM Generic Timer and its implementation as seen from AArch32 state. These chapters include the definition of the low-latency System register interface to the Generic Timer. However, the ARM Generic Timer architecture also defines a memory-mapped component, that comprises:

- A memory-mapped counter module, that controls the generation of the Count value used by the Generic Timer.
  This memory-mapped counter module is required in any ARM Generic Timer implementation that requires software control of the Count value of the Generic Timer.
- Optional memory-mapped timer modules. These give a standardized way of providing timers for programmable system components other than PEs that implement the ARM architecture.

The full set of Generic Timer components on page D10-2635 summarizes these components as seen from AArch64 state, and The full set of Generic Timer components on page G6-5603 summarizes them as seen from AArch32 state. The system level components of the Generic Timer on page I2-6717 summarizes the system level components.

I2.1.1 Registers in the system level implementation of the Generic Timer

Registers that control components of the system level implementation of the Generic Timer are grouped into frames. This specification defines the registers in each frame, and their offsets within the frame. The system defines the position of each frame in the memory map. This means the base addresses for each frame is IMPLEMENTATION DEFINED.

Note
The final 12 words of the first or only 4KB block of a register memory frame is an ID block.

Each frame must be in its own memory page, or memory protection region, and must be aligned to the size of the translation granule or protection granule.

Note
When a system level implementation of the Generic Timer is accessed by a PE:

- Using a VMSA, each frame is in its own memory page, aligned to the size of the translation granule.
- Using a PMSA, each frame is in its own memory protection region, aligned to the size of the memory protection granule.

The following sections give more information about the requirements for the system level Generic Timer component:

- Endianness and supported access sizes.
- Power and reset domains for the system level implementation of the Generic Timer on page I2-6717.

Endianness and supported access sizes

All memory-mapped peripherals defined in the ARM architecture must be little-endian. This means the system-level Generic Timer registers, and the register frames, are little-endian.

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the memory-mapped Generic Timer registers implementations must:

- Comply with the requirements of Supported access sizes on page I1-6710.
- Support word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations, even if no PE in the system implements AArch32.
Power and reset domains for the system level implementation of the Generic Timer

The power and reset domains of the system level implementation of the Generic Timer are IMPLEMENTATION DEFINED as part of the system implementation. These domains can be outside the PE power and reset domains defined by the remainder of this manual.

The ARM architecture requires that the CNTCR.{FCREQ, EN} and CNTSR.FCACK fields reset to 0. These reset values apply only on powerup of the power domain in which the registers are implemented or a reset of the reset domain in which they are implemented.

Every other register, or register field, of a system level implementation of the Generic Timer resets to a value that is architecturally UNKNOWN if it has a meaningful reset value. This applies on powerup of the power domain in which the register is implemented, and on a reset of the reset domain in which it is implemented.

I2.1.2 The system level components of the Generic Timer

Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required

This module controls the system counter. It has two frames:

• A control frame, CNTControlBase.
• A status frame, CNTReadBase.

Memory-mapped counter module on page I2-6718 describes this component.

The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

• Which timers are implemented.
• The features of each implemented timer.

This module has a single frame, CNTCTLBase.

The CNTCTLBase frame on page I2-6723 describes this frame.

Memory-mapped timers, optional

An implemented memory-mapped timer:

• Must provide a privileged view of the timer, in the CNTBaseN frame.
• Optionally provides an unprivileged view of the timer in the CNTEL0BaseN frame.

N is the timer number, and the corresponding frame number, in the range 0-7.

The CNTBaseN and CNTEL0BaseN frames on page I2-6724 describes these frames.
I2.2 Memory-mapped counter module

The memory-mapped counter module provides top-level control of the system counter. The CNTControlBase frame holds the registers for the memory-mapped counter, and provides:

- An RW control register CNTCR, that provides:
  — An enable bit for the system counter.
  — An enable bit for Halt-on-debug. For more information, see Halt-on-debug on page I2-6720.
  — A field that can be written to request a change to the update frequency of the system counter, with a corresponding change to the increment made at each update. This mechanism means that, for example, if the update frequency is halved, the increment at each update is doubled.
    For more information, see Control of counter operating frequency and increment on page I2-6719.

  Writes to this register are rare. In a system that supports two Security states, this register is writable only by Secure writes.

- A RO status register, CNTSR, that provides:
  — A bit that indicates whether the system counter is halted because of an asserted Halt-on-debug signal.
  — A field that indicates the current update frequency of the system counter. This field can be polled to determine when a requested change to the update frequency has been made.

- Two contiguous 32-bit RW registers that hold the current system counter value, CNTCV. If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

  The system counter must be disabled before writing to these registers, otherwise the effect of the write is UNPREDICTABLE.

  Writes to these registers are rare. In a system that supports two Security states, these registers are writable only by Secure writes.

- A Frequency modes table of one or more 32-bit entries, where:
  — The first entry in the table defines the base frequency of the system counter. This is the maximum frequency at which the counter updates.
  — Each subsequent entry in the table defines an alternative frequency of the system counter, that must be an exact divisor of the base frequency.

  A 32-bit zero entry immediately follows the last table entry.

  This table can be RO or RW. For more information, see The Frequency modes table on page I2-6719.

In addition, the CNTReadBase frame includes a read-only copy of the system counter value, CNTCV, as two contiguous 32-bit RO registers. If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

Counter module control and status register summary on page I2-6720 describes CNTReadBase and CNTControlBase memory maps, and the registers in each frame.
I2.2.1 Control of counter operating frequency and increment

The system counter has a fixed base frequency, and must maintain the required counter accuracy, meaning ARM recommends that it does not gain or lose more than ten seconds in a 24-hour period, see The system counter on page D10-2636. However, the counter can increment at a lower frequency than the base frequency, using a correspondingly larger increment. For example, it can increment by four at a quarter of the base frequency. Any lower-frequency operation, and any switching between operating frequencies, must not reduce the accuracy of the counter.

Control of the system counter frequency and increment is provided only through the memory-mapped counter module. The following sections describe this control:

- The Frequency modes table.
- Changing the system counter and increment.

The Frequency modes table

The Frequency modes table starts at offset 0x20 in the CNTControlBase frame. Table entries are 32-bits, and each entry specifies a system counter update frequency, in Hz. The first entry in the table specifies the base frequency of the system counter.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

\[
\text{increment} = \frac{\text{base\_frequency}}{\text{selected\_frequency}}
\]

A 32-bit word of zero value marks the end of the table. That is, the word of memory immediately after the last entry in the table must be zero.

The only required entry in the table is the entry for the base frequency.

Typically, the Frequency modes table is in RO memory. However, a system implementation might use RW memory for the table, and initialize the table entries as part of its startup sequence. Therefore, the CNTControlBase memory map shows the table region as RO or RW.

ARM strongly recommends that the Frequency modes table is not updated once the system is running.

The architecture can support up to 1004 entries in the Frequency modes table, including the zero-word end marker, and the maximum number of entries is IMPLEMENTATION DEFINED, up to this limit.

--- Note ---

- ARM considers it likely that implementations will require significantly fewer entries than the architectural limit.
- In the CNTControlBase frame, the offset range 0x0C0-0x0FC can be used for IMPLEMENTATION DEFINED registers. If any registers are defined in this space, then the Frequency modes table cannot extend beyond offset 0x088, with a zero word at offset 0x08C. This means that if any IMPLEMENTATION DEFINED registers are defined the maximum number of entries in the table is 40, including the zero-word end marker.

---

Changing the system counter and increment

The value of the CNTCR.FCREQ field specifies which entry in the Frequency modes table specifies the system counter update frequency.

Changing the value of CNTCR.FCREQ requests a change to the system counter update frequency. To ensure the frequency change does not affect the overall accuracy of the counter, a change is made as follows:

- When changing from a higher frequency to a lower frequency, the counter:
  1. Continues running at the higher frequency until the count reaches an integer multiple of the required lower frequency.
  2. Switches to operating at the lower frequency.
• When changing from a lower frequency to a higher frequency, the counter:
  1. Waits until the end of the current lower-frequency cycle.
  2. Makes the counter increment required for operation at that lower frequency.
  3. Switches to operating at the higher frequency.

When the frequency has changed, CNTSR is updated to indicate the new frequency. Therefore, a system component that is waiting for a frequency change can poll CNTSR to detect the change.

### I2.2.2 Halt-on-debug

The CNTCR register provides an enable bit for an OPTIONAL Halt-on-debug signal.

When the CNTCR.HDBG bit is set to 1, and the Halt-on-debug signal is implemented and asserted, the system counter is halted. Otherwise, the system counter ignores the state of this signal.

ARM recommends that a system counter implements a Halt-on-debug signal that can be controlled by a debugger using the Embedded Cross-Trigger (ECT) using a system-level cross-trigger interface that includes:

- A debug request output trigger event that asserts the Halt-on-debug signal.
- A restart request output trigger event that deasserts the Halt-on-debug signal.

For more information, see About the Embedded Cross-Trigger (ECT) on page H5-6504.

--- Note ---

Software must use the Halt-on-debug enable bit to ensure that the timers cannot be halted maliciously in an attempt to prohibit progress.

---

For more information about Halt-on-debug, contact ARM.

### I2.2.3 Counter module control and status register summary

The Counter module control and status registers are memory-mapped registers in the following register memory frames:

- A control frame, with base address CNTControlBase.
- A status frame, with base address CNTReadBase.

Each of these register memory frames is in its own memory page or memory protection region, and the frame base address points to the start of this region. Each base address must be aligned to the size of the translation granule or protection granule.

--- Note ---

Each frame of a memory-mapped Generic Timer takes the name of its base address.

---

In each register memory frame, the memory at offset 0xF00-0xFFF is reserved for twelve 32-bit IMPLEMENTATION DEFINED ID registers, see the CounterID<n> register descriptions for more information.

--- Note ---

The ARM architecture requires memory-mapped peripherals to be little-endian, and therefore the counter is little-endian.

---

In an implementation that supports Secure and Non-secure memory maps, CNTControlBase is accessible only by Secure accesses.

Table I2-1 on page I2-6721 shows the CNTControlBase control registers, in order of their offsets from the CNTControlBase base address, for an implementation that includes registers in the implementation defined register space 0xC0-0xFFC, and also has fewer than 39 CNTFID<n> registers. The Frequency modes table on page I2-6719 describes how this memory map differs if more CNTFID<n> registers are implemented.
Generic Timer memory-mapped register descriptions on page I5-6852 describes each of these registers.

I2.3 Memory-mapped timer components

This part of the ARM Generic Timer specification defines an optional memory-mapped timer component. This can be implemented as part of any programmable system component that does not incorporate a System register mapped ARM Generic Timer, to provide that system component with the timer functionality of an ARM Generic Timer.

The memory map consists of up to eight timer frames. The base address of a frame is CNTBaseN, where N numbers from 0 up to a maximum permitted value of 7.

Each CNTBaseN timer frame:

• Provides its own set of timers and associated interrupts.
• Is implemented in its own memory page or memory protection region.
• Is implemented at a base address, identified as CNTBaseN, that is aligned to the size of the translation granule or memory protection region.

For each implemented CNTBaseN frame the system can optionally provide an unprivileged view of the frame, described as the EL0 view of the frame. The base address of this second view of the CNTBaseN frame is CNTEL0BaseN.

Note

In the naming of the registers associated with a CNTBaseN or CNTEL0BaseN frame, the value of N is represented as \(<n>\), for example CNTACR<\(<n>\).

If a CNTEL0BaseN frame is implemented:

• Is implemented in its own memory page or memory protection region and is aligned to the size of the translation granule or memory protection region.
• All registers visible in CNTBaseN, except for CNTVOFF<\(<n>\> and CNTEL0ACR, can be visible in CNTEL0BaseN.
  — Control fields in CNTEL0ACR determine whether each register is visible.
• The offsets of all visible registers are the same as their offsets in the CNTBaseN frame.

In addition to the implemented CNTBaseN and CNTEL0BaseN frames, the system must provide a single control frame at base address CNTCTLBase. CNTCTLBase must be implemented in its own memory page or memory protection region and is aligned to the size of the translation granule or memory protection region.

The system defines the position of each frame in the memory map. This means the values of each of the CNTBaseN, CNTEL0BaseN, and CNTCTLBase base addresses is IMPLEMENTATION DEFINED.

Note

The ARM architecture requires memory-mapped peripherals to be little-endian, and therefore the memory-mapped timers are little-endian.

The following sections describe the implementation of a memory-mapped view of the counter and timer:

• The CNTCTLBase frame on page I2-6723.
• The CNTBaseN and CNTEL0BaseN frames on page I2-6724.

Note

Providing a complete set of features in a system level implementation on page K5-7268 gives an implementation example for a system level Generic Timer implementation that provides equivalent features to a System registers Generic Timer implementation in a PE that includes all of the Exception levels.
## I2.3.1 The CNTCTLBase frame

The CNTCTLBase frame contains:

- An identification register for the features of the memory-mapped counter and timer implementation.
- Access controls for each CNTBaseN frame.
- A virtual offset register for frames that implement a virtual timer.

Table I2-3 shows the CNTCTLBase registers, in order of their offsets from the CNTCTLBase base address.

**Note**

CNTFRQ and CNTVOFF\(<n>\) registers are also implemented in a System register interface to the Generic Timer.

*Generic Timer memory-mapped register descriptions on page I5-6852* describes each of these registers.

</tr>
</tbody>
</table>

\(^a\) Access security requirement in an implementation that supports two Security states. In an implementation that does not support multiple Security states all registers are accessible as shown in the Type column.

\(^b\) These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in *Generic Timer registers on page D12-3444* and *Generic Timer registers on page G8-6342*. The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.

\(^c\) Implemented for each value of \(N\) from 0 to 7 for which a CNTBaseN frame is implemented.

\(^d\) The CNTNSAR determines the Non-secure accessibility of the CNTACR\(<n>\)'s and the CNTVOFF\(<n>\) in the CNTCTLBase frame. For more information, see the register descriptions.

\(^e\) Address is reserved, RAZ/WI if register not implemented.

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the CNTVOFF\(<n>\) register that defines the virtual offset between the physical count and the virtual count. If a memory-mapped Generic Timer component does not distinguish between real time and virtual time, then it can implement CNTVOFF\(<n>\) as RAZ/WI. Otherwise CNTVOFF\(<n>\) is an RW register, and ARM strongly recommends that the system only permits access to CNTVOFF\(<n>\) from EL2 or higher.
### I2.3.2 The CNTBaseN and CNTEL0BaseN frames

Each CNTBaseN frame, or {CNTBaseN, CNTEL0BaseN} pair of frames, provides a memory-mapped counter and timer, see:

- *The CNTBaseN frame.*
- *The CNTEL0BaseN frame on page I2-6725.*
- *CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-6725.*

#### The CNTBaseN frame

Table I2-4 shows the CNTBaseN registers, in order of their offsets from the CNTBaseN base address. Whether a frame includes a virtual timer is IMPLEMENTATION DEFINED. If it does not, then memory at offsets 0x030–0x03C is RAZ/WI. Except for CNTEL0ACR and the CounterID<11> registers, equivalent registers are also implemented in a System register interface to the timer component of a Generic Timer.

*Generic Timer memory-mapped register descriptions on page I5-6852 describes each of these registers.*

a. These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in *Generic Timer registers on page D12-3444* and *Generic Timer registers on page G8-6342*. The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.

b. Address is reserved, RAZ/WI if register not implemented.

c. The CNTCTLBase frame includes an RW view of this register.
The CNTEL0BaseN frame

For any value of N, the layout of the registers in the CNTEL0BaseN frame is identical to the CNTBaseN frame, except that, in the CNTEL0BaseN frame:

- CNTVOFF<\text{n}> is never visible, and the memory at 0x018-0x01C is RAZ/WI.
- CNTEL0ACR is never visible, and the memory at 0x014 is RAZ/WI.
- If implemented in the CNTBaseN frame, CNTEL0ACR controls whether CNTPCT, CNTVCT, CNTFRQ, the Physical Timer, and the Virtual Timer registers are visible in the CNTEL0BaseN frame.

If CNTEL0ACR is not implemented then these registers are not visible in the CNTEL0BaseN frame, and their addresses in that frame are RAZ/WI.

If an implementation supports 64-bit atomic accesses, then CNTPCT, CNTVCT, CNTVOFF<\text{n}>, CNTP_CVAL, and CNTV_CVAL must be accessible as atomic 64-bit values.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames

In the CNTCTLBase frame:

**CNTTIDR controls:**

- Whether each CNTBaseN frame is implemented.
- If a CNTBaseN frame is implemented, whether:
  - That CNTBaseN frame has virtual timer capability.
  - A corresponding CNTEL0BaseN frame is implemented.

**CNTNSAR controls:**

In an implementation that recognizes two Security states, determines whether each implemented CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

This control also determines whether, in the CNTCTLBase frame, the CNTACR<\text{n}> and CNTVOFF<\text{n}><\text{n}> registers are accessible by Non-secure accesses.

The CNTACR<\text{n}> registers control:

For each implemented CNTBaseN frame, the accessibility of the following registers in that frame:

- CNTP_CTL, CNTP_CVAL, and CNTP_TVAL.
- CNTV_CTL, CNTV_CVAL, and CNTV_TVAL.
- CNTVOFF<\text{n}>.
- CNTFRQ.
- CNTPCT.
- CNTVCT.

For CNTACR<\text{n}>, the value of <\text{n}> corresponds to the value of N for the controlled CNTBaseN frame.

The CNTVOFF<\text{n}><\text{n}> registers provide:

For each implemented CNTBaseN frame that has virtual capability, the RW copy of the CNTVOFF<\text{n}> register for that frame.

--- *Note* ---

In a CNTBaseN frame that has virtual timer capability the CNTVOFF<\text{n}> register is RO.

---

For CNTVOFF<\text{n}><\text{n}>, the value of <\text{n}> corresponds to the value of N for the controlled CNTBaseN frame.
I2 System Level Implementation of the Generic Timer
I2.3 Memory-mapped timer components
Chapter I3
Recommended External Interface to the Performance Monitors

This chapter describes the recommended external interface to the Performance Monitors. It contains the following section:

- About the external interface to the Performance Monitors registers on page I3-6728.

Note

Performance Monitors external register descriptions on page I5-6741 describes the external view of the Performance Monitors registers.
I3.1 About the external interface to the Performance Monitors registers

ARM recommends that:

• An implementation provides the OPTIONAL external debug interface to the Performance Monitors registers.

  — **Note** —

  A debugger can use this interface to access counters in the Performance Monitors.

• The implementation includes the OPTIONAL support for memory-mapped access to the External debug interface.

  — **Note** —

  — Software running on any PE in a system can use this interface to access counters in the Performance Monitors.
  — Privileged software should use the MMU to control access to this interface.

• The external debug interface is implemented as defined in Appendix K2 Recommended External Debug Interface.

The following sections describe the memory-mapped views of the Performance Monitors registers:

• Differences in the external views of the Performance Monitors registers.
• Synchronization of changes to the memory-mapped views on page I3-6729.
• Access permissions for external views of the Performance Monitors on page I3-6729.

In this section, unless the context explicitly indicates otherwise, any reference to a memory-mapped view applies equally to a register view using:

• An access through an external debug interface.
• A memory-mapped access.

I3.1.1 Endianness and supported access sizes

When an implementation supports memory-mapped access to the external debug interface the interface is accessed as a little-endian memory-mapped peripheral. External Performance Monitors registers summary on page I5-6738 gives the memory map of these registers.

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the external interface to the Performance Monitors registers implementations must:

• Comply with the requirements of Supported access sizes on page I1-6710.
• Support word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations, even if no PE in the system implements AArch32.

I3.1.2 Differences in the external views of the Performance Monitors registers

An external view of the Performance Monitors registers accesses the same registers as the System registers interface described in Performance Monitors Extension registers on page D6-2573, except that:

1. The PMSELR is accessible only in the System registers interface.
2. The following registers are accessible only in external views:
   • PMCFGR
   • PMDEVAFF0
   • PMDEVAFF1
   • PMLAR
   • PMLSR
• PMAUTHSTATUS
• PMDEVAARCH
• PMDEVTYPE
• PMPIDR0
• PMPIDR1
• PMPIDR2
• PMPIDR3
• PMPIDR4
• PMCIDR0
• PMCIDR1
• PMCIDR2
• PMCIDR3

*Performance Monitors external register descriptions on page I5-6741* describes these registers.

3. The following controls do not affect the external views:
   • PMSELR.
   • PMUSERENR.
   • HDCR.{TPM, TPMCR, HPMN}.

Instead, see the register descriptions in *Chapter I5 External System Control Register Descriptions*.

### I3.1.3 Synchronization of changes to the memory-mapped views

Synchronization must comply with *Synchronization of memory-mapped registers on page I1-6712*.

In particular, if a Performance Monitor is visible in both System register and an external view, and is accessed simultaneously through these two mechanisms, the behavior must be as if the access occurred atomically in any order. For more information, see *Synchronization of changes to the external debug registers on page H8-6540*.

### I3.1.4 Access permissions for external views of the Performance Monitors

For more information, see *External debug interface register access permissions on page H8-6547*.

Table I3-1 on page I3-6730 shows the access permissions for the Performance Monitors registers in a v8 Debug implementation. This table uses the following terms:

**DLK**
When the OS Double Lock is implemented and locked, `DoubleLockStatus()` == TRUE, accesses to some registers produce an error. Applies to both interfaces.

**EPMAD**
When `AllowExternalPMUAccess()` == FALSE, external debug access is disabled for the access. If ARMv8.4-Debug is implemented, this applies only for Non-secure access to the register. See also *Behavior of a not permitted memory-mapped access on page H8-6545*.

**Error**
Indicates that the access gives an error response.

**Default**
This shows the default access permissions, if none of the conditions in this list prevent access to the register.

**Off**
The Core power domain is completely off, or in a low-power state where the Core power domain registers cannot be accessed, and `EDPRSR.PU` will read as zero.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>If debug power is off, then all external debug interface accesses return an error.</td>
</tr>
</tbody>
</table>

**OSLK**
When the OS Lock is locked, `OSLR_EL1.OSLK` == 1, accesses to some registers produces an error. This column shows the effect of this control on accesses using the external debug interface.
This indicates the modified default access permissions for optional memory-mapped accesses to the external debug interface if the optional Software Lock is locked. See Register access permissions for memory-mapped accesses on page H8-6544.

For all other accesses, this column is ignored.

- Indicates that the control has no effect on the behavior of the access:
  • If no other control affects the behavior, the Default access behavior applies.
  • However, another control might determine the behavior.

I3.1 About the external interface to the Performance Monitors registers

For ARMv8-A implementations, ARM recommends that Performance Monitors are implemented as part of the core power domain, not as part of a separate debug power domain. There is no interface to access the Performance Monitors registers when the core power domain is powered down.

A Warm or Cold reset sets the Performance Monitors registers to their reset values. An External Debug reset does not change the values of the Performance Monitors registers.

For more information about the reset scheme recommended for a v8 Debug implementation see Chapter H6 Debug Reset and Powerdown Support.

Table I3-2 on page I3-6732 shows the Performance Monitors register resets for writable register fields. The column headings use the following terms:

- **64** This is the architectural reset value when resetting into AArch64 state.
- **32** This is the architectural reset value when resetting into AArch32 state.
- **-** This indicates an IMPLEMENTATION DEFINED reset value on the specified reset. This might be UNKNOWN.

**Note**

This table does not include:

- Read-only identification registers and fields that have a fixed value. In this case, the reset value is that fixed value. An example of this is PMCR_EL0.N.
- Write-only registers and fields that only have an effect on writes. These do not have a reset value. An example of this is PMSWINC_EL0.
- IMPLEMENTATION DEFINED registers. In this case, the reset domains are IMPLEMENTATION DEFINED. The reset values are IMPLEMENTATION DEFINED and might be UNKNOWN.

Chapter I4
Recommended External Interface to the Activity Monitors

This chapter describes the optional external interface to the Activity Monitors Extension registers. It contains the following section:

• About the external interface to the Activity Monitors Extension registers on page I4-6734

--- Note ---
Activity Monitors external register descriptions on page I5-6816 describes the external view of the Activity Monitors Extension registers.
I4.1 About the external interface to the Activity Monitors Extension registers

If an implementation supports the Activity Monitors Extension, it may optionally support an external memory-mapped interface to the Activity Monitors Extension, and, if so, may further optionally support CoreSight device registers and ID registers.

The memory access sizes supported by the memory-mapped interface are IMPLEMENTATION DEFINED and comply with the requirements of Supported access sizes on page I1-6710.

The base address of the memory-mapped view are aligned to a 4KB boundary, but is otherwise IMPLEMENTATION DEFINED. The address offsets for the memory-mapped view are given in Table I5-2 on page I5-6814.

I4.1.1 Differences in the external views of the Activity Monitors Extension registers

The external memory-mapped interface view of the Activity Monitors Extension registers accesses the same registers as the System registers interface to the registers, except that:

• AMUSERENR is accessible only in the System registers interface.
• If implemented, the following registers are accessible only in the memory-mapped view:
  — AMIIDR.
  — AMDEVAFF0.
  — AMDEVAFF1.
  — AMDEVARCH.
  — AMDEVTYPE.
  — AMPIDR0.
  — AMPIDR1.
  — AMPIDR2.
  — AMPIDR3.
  — AMPIDR4.
  — AMCIDR0.
  — AMCIDR1.
  — AMCIDR2.
  — AMCIDR3.

Activity Monitors external register descriptions on page I5-6816 describes these registers.

I4.1.2 Access during reset and power transitions

As described in Power and reset domains on page D7-2577, the power and reset domains of the activity monitoring unit are IMPLEMENTATION DEFINED, and when a Cold reset of the power domain of the activity monitoring unit occurs, the activity monitoring unit is reset and the counters are reset to zero.

If the power domain of the activity monitoring unit is an always-on power domain, while the PE is reset or powered down counter values may be preserved and might be accessible by memory-mapped access.

If the power domain of the activity monitoring unit is the Core power domain, while the PE is reset or powered down and when a memory-mapped access occurs, the access reads as zero and the bus access completes without an error.
Chapter 15
External System Control Register Descriptions

This chapter describes the external system control registers. It excludes the External debug registers that are described in Chapter H9 External Debug Register Descriptions. It contains the following sections:

- About the external system control register descriptions on page I5-6736.
- External Performance Monitors registers summary on page I5-6738.
- Performance Monitors external register descriptions on page I5-6741.
- External Activity Monitors Extension registers summary on page I5-6814.
- Activity Monitors external register descriptions on page I5-6816.
- Generic Timer memory-mapped registers overview on page I5-6851.
- Generic Timer memory-mapped register descriptions on page I5-6852.
I5.1 About the external system control register descriptions

This chapter describes the external system control registers other than the external debug registers. That is, it describes:

An external view of the Performance Monitors registers

ARM recommends that implementations provide access to the Performance Monitors registers through the OPTIONAL External debug interface, and provide the OPTIONAL memory-mapped interface to this interface:

- External Performance Monitors registers summary on page I5-6738 lists the registers that are accessible in this view of the Performance Monitors, and describes their memory map.
- Performance Monitors external register descriptions on page I5-6741 describes each of the memory-mapped registers.

Chapter I3 Recommended External Interface to the Performance Monitors describes the recommended interface to these registers.

Note

Chapter D6 The Performance Monitors Extension describes the Performance Monitors. The following sections describe the System register interfaces to the Performance Monitors:

- Performance Monitors registers on page D12-3290, for accesses from an Exception level that is using AArch64.
- Performance Monitors registers on page G8-6204, for accesses from an Exception level that is using AArch32.

An external view of the Activity Monitors Extension registers

An implementation which supports the Activity Monitors Extension may support an optional external memory-mapped interface to the Activity Monitors Extension registers.

- External Activity Monitors Extension registers summary on page I5-6814 lists the registers that are accessible in this view of the Performance Monitors, and describes their memory map.
- Activity Monitors external register descriptions on page I5-6816 describes each of the memory-mapped registers.

Chapter I3 Recommended External Interface to the Performance Monitors describes the recommended interface to these registers.

Note

Chapter D7 The Activity Monitors Extension describes the Activity Monitors. The following sections describe the System register interfaces to the Activity Monitors:

- Activity Monitors registers on page D12-3344, for accesses from an Exception level that is using AArch64.
- Activity Monitors registers on page G8-6264, for accesses from an Exception level that is using AArch32.

The registers for the system level Generic Timer component

Any implementation that includes the Generic Timer must include the memory-mapped system level component described in Chapter I2 System Level Implementation of the Generic Timer. In this chapter:

- Generic Timer memory-mapped registers overview on page I5-6851 gives an overview of the registers, referring to Chapter I2 for more information.
- Generic Timer memory-mapped register descriptions on page I5-6852 describes each of the memory-mapped registers.
Note

Chapter D10 The Generic Timer in AArch64 state describes the Generic Timer component that is accessible using the System registers. The following sections describe the System register interfaces to that component:

- Generic Timer registers on page D12-3444, for accesses from an Exception level that is using AArch64.
- Generic Timer registers on page G8-6342, for accesses from an Exception level that is using AArch32.

Note

Chapter H9 External Debug Register Descriptions describes the external debug registers.
# 5.2 External Performance Monitors registers summary

When an implementation provides access to the Performance Monitors registers through the External debug interface, that interface provides access to:

- Performance Monitors System registers.
- A read-only configuration register, PMCFGR.
- The optional CoreSight registers for the Performance Monitors, if they are implemented.

The locations of the registers are defined as offsets from a system-defined base address. *Performance Monitors external register views* defines this memory map.

## 5.2.1 Performance Monitors external register views

Table I5-1 shows the external view of the Performance Monitors registers. All other entries are reserved.

### Note

- Counters that are reserved because HDCR.HPMN has been changed from its reset value remain visible in any external view.
- The registers that relate to an implemented event counter, PMN<sub>x</sub>, are PMEVCNTR<sub>n</sub> and PMEVTYPE<sub>n</sub>.
- The mapping of the *Performance Monitors Event Counter Registers*, at offsets 0x000-0x0F4, has changed compared to the mappings of the equivalent registers in ARMv7.

Each entry in the Name column links to the register description in *Performance Monitors external register descriptions* on page I5-6741, and:

- If the System register? column of the table shows that the register is a System register, the memory-mapped interface provides a view of the System register described in:
  - *Performance Monitors registers* on page D12-3290, for the AArch64 System register.
  - *Performance Monitors registers* on page G8-6204, for the AArch32 System register.
- Otherwise, the register is accessible only using the external interface.

</tbody>
</table>

a. The interface must support at least single-copy atomic 32-bit accesses. If single-copy atomic 64-bit access to the registers is not possible, software must use a high-low-high read access to read the counter value if the counter is enabled.

b. PC Sample-based Profiling Extension registers. Implemented only when ARMv8.2-PCSample is implemented, except that PMDEVIDt is required regardless of whether ARMv8.2-PCSample is implemented.

Before ARMv8.2, the PC Sample-based Profiling Extension can, instead, be implemented in the memory-mapped debug registers space, see Chapter H7 The PC Sample-based Profiling Extension.

c. CoreSight interface registers, see Management registers and CoreSight compliance on page K2-7237.

d. The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.
I5.3 Performance Monitors external register descriptions

This section describes the external view of the Performance Monitors registers. *External Performance Monitors registers summary* on page I5-6738 lists these registers in offset order.
I5.3.1 PMAUTHSTATUS, Performance Monitors Authentication Status register

The PMAUTHSTATUS characteristics are:

**Purpose**

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for Performance Monitors.

**Configurations**

It is IMPLEMENTATION DEFINED whether PMAUTHSTATUS is implemented in the Core power domain or in the Debug power domain.

This register is OPTIONAL, and is required for CoreSight compliance. Arm recommends that this register is implemented.

**Attributes**

PMAUTHSTATUS is a 32-bit register.

**Field descriptions**

The PMAUTHSTATUS bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:8</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
<tr>
<td>7:6</td>
<td>SNID, bits</td>
<td>Holds the same value as DBGAUTHSTATUS_EL1.SNID.</td>
</tr>
<tr>
<td>5:4</td>
<td>SID, bits</td>
<td>Secure invasive debug. Possible values of this field are: 0b00 Not implemented. All other values are reserved.</td>
</tr>
<tr>
<td>3:2</td>
<td>NSNID, bits</td>
<td>Holds the same value as DBGAUTHSTATUS_EL1.NSNID.</td>
</tr>
<tr>
<td>1:0</td>
<td>NSID, bits</td>
<td>Non-secure invasive debug. Possible values of this field are: 0b00 Not implemented. All other values are reserved.</td>
</tr>
</tbody>
</table>

**Accessing the PMAUTHSTATUS:**

PMAUTHSTATUS can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xF88</td>
<td>PMAUTHSTATUS</td>
</tr>
</tbody>
</table>
This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
### I5.3.2 PMCCFILTR_EL0, Performance Monitors Cycle Counter Filter Register

The PMCCFILTR_EL0 characteristics are:

**Purpose**

Determines the modes in which the Cycle Counter, PMCCNTR_EL0, increments.

**Configurations**

- External register PMCCFILTR_EL0[31:0] is architecturally mapped to AArch64 System register PMCCFILTR_EL0[31:0].
- External register PMCCFILTR_EL0[31:0] is architecturally mapped to AArch32 System register PMCCFILTR[31:0].
- PMCCFILTR_EL0 is in the Core power domain.

On a Warm or Cold reset RW fields in this register reset:

- To architecturally UNKNOWN values if the reset is to an Exception level that is using AArch64.
- To 0 if the reset is to an Exception level that is using AArch32.

The register is not affected by an External debug reset.

**Attributes**

PMCCFILTR_EL0 is a 32-bit register.

**Field descriptions**

The PMCCFILTR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>P</td>
<td>Privileged filtering bit</td>
<td>0b0, 0b1</td>
</tr>
<tr>
<td>U</td>
<td>User filtering bit</td>
<td>0b0, 0b1</td>
</tr>
<tr>
<td>NSK</td>
<td>Non-secure EL1 (kernel) modes filtering bit</td>
<td>RES0</td>
</tr>
<tr>
<td>NSU</td>
<td>Non-secure EL0 filtering bit</td>
<td>RES0</td>
</tr>
<tr>
<td>NSH</td>
<td>Non-secure EL0 filtering bit</td>
<td>RES0</td>
</tr>
<tr>
<td>RES0</td>
<td></td>
<td>RES0</td>
</tr>
<tr>
<td>SH</td>
<td></td>
<td>RES0</td>
</tr>
</tbody>
</table>

- **P, bit [31]**
  
  Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the PMCCFILTR_EL0.NSK bit. The possible values of this bit are:
  
  - 0b0: Count cycles in EL1.
  - 0b1: Do not count cycles in EL1.

- **U, bit [30]**
  
  User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the PMCCFILTR_EL0.NSU bit. The possible values of this bit are:
  
  - 0b0: Count cycles in EL0.
  - 0b1: Do not count cycles in EL0.

- **NSK, bit [29]**
  
  Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.
If the value of this bit is equal to the value of the PMCCFILTR_EL0.P bit, cycles in Non-secure EL1 are counted.
Otherwise, cycles in Non-secure EL1 are not counted.

NSU, bit [28]
Non-secure EL0 (Unprivileged) filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.
If the value of this bit is equal to the value of the PMCCFILTR_EL0.U bit, cycles in Non-secure EL0 are counted.
Otherwise, cycles in Non-secure EL0 are not counted.

NSH, bit [27]
EL2 (Hypervisor) filtering bit. Controls counting in EL2. If EL2 is not implemented, this bit is RES0.
If Secure EL2 is implemented, counting in Secure EL2 is further controlled by the PMCCFILTR_EL0.SH bit.
0b0  Do not count cycles in EL2.
0b1  Count cycles in EL2.

M, bit [26]
Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.
If the value of this bit is equal to the value of the PMCCFILTR_EL0.P bit, cycles in Secure EL3 are counted.
Otherwise, cycles in Secure EL3 are not counted.
Most applications can ignore this field and set its value to 0.

Note
This field is not visible in the AArch32 PMCCFILTR System register.

Bit [25]
Reserved, RES0.

SH, bit [24]
When ARMv8.4-SecEL2 is implemented:
Secure EL2 filtering.
If the value of this bit is not equal to the value of the PMCCFILTR_EL0.NSH bit, cycles in Secure EL2 are counted.
Otherwise, cycles in Secure EL2 are not counted.
If Secure EL2 is not implemented or is disabled, this field is RES0.

Note
This field is not visible in the AArch32 PMCCFILTR System register.

Otherwise:
Reserved, RES0.

Bits [23:0]
Reserved, RES0.
Accessing the PMCCFILTR_EL0:

Note
SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCCFILTR_EL0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0x47C</td>
<td>PMCCFILTR_EL0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
I5.3.3 PMCCNTR_EL0, Performance Monitors Cycle Counter

The PMCCNTR_EL0 characteristics are:

**Purpose**

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See *Time as measured by the Performance Monitors cycle counter* on page D6-2527 for more information. PMCCFILTR_EL0 determines the modes and states in which the PMCCNTR_EL0 can increment.

**Configurations**

External register PMCCNTR_EL0[63:0] is architecturally mapped to AArch64 System register PMCCNTR_EL0[63:0].

External register PMCCNTR_EL0[63:0] is architecturally mapped to AArch32 System register PMCCNTR[63:0].

PMCCNTR_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

**Attributes**

PMCCNTR_EL0 is a 64-bit register.

**Field descriptions**

The PMCCNTR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>62</th>
<th>61</th>
<th>...</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CCNT</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**CCNT, bits [63:0]**

Cycle count. Depending on the values of PMCR_EL0.{LC,D}, the cycle count increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR_EL0.C sets this field to 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing the PMCCNTR_EL0:**

--- **Note** ---

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

---

PMCCNTR_EL0[31:0] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0x0F8</td>
<td>PMCCNTR_EL0</td>
<td>31:0</td>
</tr>
</tbody>
</table>
PMCCNTR_EL0[63:32] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xF0C</td>
<td>PMCCNTR_EL0</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to PMCCNTR_EL0[31:0] is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() access to PMCCNTR_EL0[63:32] is RW.
- Otherwise access to PMCCNTR_EL0[31:0] returns an Error.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to PMCCNTR_EL0[63:32] is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() access to PMCCNTR_EL0[63:32] is RW.
- Otherwise access to PMCCNTR_EL0[63:32] returns an Error.
I5.3.4 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

**Purpose**

- Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range 0x0000 to 0x001F.
- When the value of a bit in the register is 1 the corresponding common event is implemented and counted.
- For more information about the common events and the use of the PMCEIDn registers see *The PMU event number space and common events* on page D6-2545.

--- Note ---

- Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.
- This view of the register was previously called PMCEID0_EL0.

**Configurations**

- External register PMCEID0[31:0] is architecturally mapped to AArch64 System register PMCEID0_EL0[31:0].
- External register PMCEID0[31:0] is architecturally mapped to AArch32 System register PMCEID0[31:0].
- PMCEID0 is in the Core power domain.

**Attributes**

- PMCEID0 is a 32-bit register.

**Field descriptions**

The PMCEID0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID[n], bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

**ID<n>, bit [n], for n = 0 to 31**

- ID[n] corresponds to common event n.
- For each bit:
  - 0b0: The common event is not implemented, or not counted.
  - 0b1: The common event is implemented.
- A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

--- Note ---

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.
Accessing the PMCEID0:

--- Note ---
AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCEID0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xE20</td>
<td>PMCEID0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and AllowExternalPMUAccess() access to this register is RO.
- Otherwise access to this register returns an Error.
PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

**Purpose**

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range 0x020 to 0x03f.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

For more information about the common events and the use of the PMCEIDn registers see *The PMU event number space and common events on page D6-2545*.

--- Note ---

- Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.
- This view of the register was previously called PMCEID1_EL0.

**Configurations**

External register PMCEID1[31:0] is architecturally mapped to AArch64 System register PMCEID1_EL0[31:0].

External register PMCEID1[31:0] is architecturally mapped to AArch32 System register PMCEID1[31:0].

PMCEID1 is in the Core power domain.

**Attributes**

PMCEID1 is a 32-bit register.

**Field descriptions**

The PMCEID1 bit assignments are:

<table>
<thead>
<tr>
<th>ID&lt;n&gt;, bit [n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

ID<n>, bit [n], for n = 0 to 31

ID[n] corresponds to common event (0x0020 + n).

For each bit:

- 0b0 The common event is not implemented, or not counted.
- 0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

--- Note ---

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.
Accessing the PMCEID1:

--- Note ---
AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCEID1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xE24</td>
<td>PMCEID1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and AllowExternalPMUAccess() access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.6 **PMCEID2, Performance Monitors Common Event Identification register 2**

The PMCEID2 characteristics are:

**Purpose**

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range 0x4000 to 0x401F.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

**Note**

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEIDn registers see *The PMU event number space and common events* on page D6-2545.

**Configurations**

External register PMCEID2[31:0] is architecturally mapped to AArch64 System register PMCEID0_EL0[63:32].

External register PMCEID2[63:32] is architecturally mapped to AArch32 System register PMCEID2[31:0].

PMCEID2 is in the Core power domain.

This register is present only from ARMv8.1. Otherwise, direct accesses to PMCEID2 are RES0.

This register is introduced in ARMv8.1.

**Attributes**

PMCEID2 is a 32-bit register.

**Field descriptions**

The PMCEID2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDhi&lt;n&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

**IDhi<n>, bit [n], for n = 0 to 31**

*From ARMv8.1:*

IDhi[n] corresponds to common event (0x4000 + n).

For each bit:

0b0 The common event is not implemented, or not counted.

0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

**Note**

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.
Otherwise:

Reserved, RES0.

Accessing the PMCEID2:

Note

AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCEID2 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xE28</td>
<td>PMCEID2</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and AllowExternalPMUAccess() access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.7 PMCEID3, Performance Monitors Common Event Identification register 3

The PMCEID3 characteristics are:

**Purpose**

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range 0x4020 to 0x403F.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

--- **Note** ---

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

---

For more information about the common events and the use of the PMCEIDn registers see *The PMU event number space and common events on page D6-2545.*

**Configurations**

External register PMCEID3[31:0] is architecturally mapped to AArch64 System register PMCEID1_EL0[63:32].

External register PMCEID3[63:32] is architecturally mapped to AArch32 System register PMCEID3[31:0].

PMCEID3 is in the Core power domain.

This register is present only from ARMv8.1. Otherwise, direct accesses to PMCEID3 are RES0.

This register is introduced in ARMv8.1.

**Attributes**

PMCEID3 is a 32-bit register.

**Field descriptions**

The PMCEID3 bit assignments are:

<table>
<thead>
<tr>
<th>IDhi&lt;n&gt;</th>
<th>bit [n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0</td>
</tr>
</tbody>
</table>

**IDhi<n>, bit [n], for n = 0 to 31**

*From ARMv8.1:*

IDhi[n] corresponds to common event (0x4020 + n).

For each bit:

- **0b0** The common event is not implemented, or not counted.
- **0b1** The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

--- **Note** ---

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.
Otherwise:

Reserved, RES0.

Accessing the PMCEID3:

--- Note ---
AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCEID3 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xE2C</td>
<td>PMCEID3</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and AllowExternalPMUAccess() access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.8 PMCFGR, Performance Monitors Configuration Register

The PMCFGR characteristics are:

**Purpose**
Contains PMU-specific configuration data.

**Configurations**
PMCFGR is in the Core power domain.
There are no configuration notes.

**Attributes**
PMCFGR is a 32-bit register.

**Field descriptions**
The PMCFGR bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
<th>15</th>
<th>14</th>
<th>13</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>NCG</td>
<td>RES0</td>
<td>SIZE</td>
<td>N</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**NCG, bits [31:28]**
This feature is not supported, so this field is RAZ.

**Bits [27:20]**
Reserved, RES0.

**UEN, bit [19]**
User-mode Enable Register supported. PMUSERENR_EL0 is not visible in the external debug interface, so this bit is RAZ.

**WT, bit [18]**
This feature is not supported, so this bit is RAZ.

**NA, bit [17]**
This feature is not supported, so this bit is RAZ.

**EX, bit [16]**
Export supported. Value is IMPLEMENTATION DEFINED.
0b0 PMCR_EL0.X is RES0.
0b1 PMCR_EL0.X is read/write.

**CCD, bit [15]**
Cycle counter has prescale. This is RES1 if AArch32 is supported at any EL, and RAZ otherwise.
0b0 PMCR_EL0.D is RES0.
0b1 PMCR_EL0.D is read/write.
CC, bit [14]
Dedicated cycle counter (counter 31) supported. This bit is RAO.

SIZE, bits [13:8]
Size of counters, minus one. This field defines the size of the largest counter implemented by the Performance Monitors Unit. In Armv8, the largest counter is 64-bits, so the value of this field is 0b111111. This field is used by software to determine the spacing of the counters in the memory-map. In Armv8, the counters are a doubleword-aligned addresses.

N, bits [7:0]
Number of counters implemented in addition to the cycle counter, PMCCNTR_EL0. The maximum number of event counters is 31.

- 0x00 Only PMCCNTR_EL0 implemented.
- 0x01 PMCCNTR_EL0 plus one event counter implemented.

and so on up to 0b00011111, which indicates PMCCNTR_EL0 and 31 event counters implemented.

### Accessing the PMCFGR:

**Note**
AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCFGR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xE0</td>
<td>PMCFGR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and AllowExternalPMUAccess() access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.9   PMCIDR0, Performance Monitors Component Identification Register 0

The PMCIDR0 characteristics are:

**Purpose**

Provides information to identify a Performance Monitor component.
For more information see *About the Component Identification scheme on page K2-7245*.

**Configurations**

It is IMPLEMENTATION DEFINED whether PMCIDR0 is implemented in the Core power domain or in the Debug power domain.
Implementation of this register is OPTIONAL.
This register is required for CoreSight compliance.

**Attributes**

PMCIDR0 is a 32-bit register.

**Field descriptions**

The PMCIDR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>8:0</td>
<td>PRMBL_0</td>
</tr>
</tbody>
</table>

Bits [31:8]

- Reserved, RES0.
- **PRMBL_0, bits [7:0]**
  - Preamble. Must read as 0x0D.

**Accessing the PMCIDR0:**

PMCIDR0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFF0</td>
<td>PMCIDR0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.10 PMCIDR1, Performance Monitors Component Identification Register 1

The PMCIDR1 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see About the Component Identification scheme on page K2-7245.

Configurations

It is IMPLEMENTATION DEFINED whether PMCIDR1 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

PMCIDR1 is a 32-bit register.

Field descriptions

The PMCIDR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>CLASS</td>
<td>PRMBL_1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as 0x9, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the PMCIDR1:

PMCIDR1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFF4</td>
<td>PMCIDR1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.11 PMCIDR2, Performance Monitors Component Identification Register 2

The PMCIDR2 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.
For more information see About the Component Identification scheme on page K2-7245.

Configurations

It is IMPLEMENTATION DEFINED whether PMCIDR2 is implemented in the Core power domain or in the Debug power domain.
Implementation of this register is OPTIONAL.
This register is required for CoreSight compliance.

Attributes

PMCIDR2 is a 32-bit register.

Field descriptions

The PMCIDR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>8</td>
<td>PRMBL_2</td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as 0x05.

Accessing the PMCIDR2:

PMCIDR2 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFF8</td>
<td>PMCIDR2</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.12 PMCIDR3, Performance Monitors Component Identification Register 3

The PMCIDR3 characteristics are:

**Purpose**

Provides information to identify a Performance Monitor component.

For more information see *About the Component Identification scheme on page K2-7245*.

**Configurations**

It is IMPLEMENTATION DEFINED whether PMCIDR3 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

PMCIDR3 is a 32-bit register.

**Field descriptions**

The PMCIDR3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>8-7</td>
<td>PRMBL_3</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**PRMBL_3, bits [7:0]**

Preamble. Must read as 0xB1.

**Accessing the PMCIDR3:**

PMCIDR3 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFFF</td>
<td>PMCIDR3</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.13 PMCID1SR, CONTEXTIDR_EL1 Sample Register

The PMCID1SR characteristics are:

**Purpose**

Contains the sampled value of CONTEXTIDR_EL1, captured on reading PMPCSR[31:0].

**Configurations**

PMCID1SR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

This register is present only from ARMv8.2. Otherwise, direct accesses to PMCID1SR are RES0.

Implemented only when ARMv8.2-PCSample is implemented.

--- Note ---

Before Armv8.2, the PC Sample-based Profiling Extension can be implemented in the external debug register space, as indicated by the value of EDDEVID.PCSample.

---

This register is introduced in ARMv8.2.

**Attributes**

PMCID1SR is a 32-bit register.

**Field descriptions**

The PMCID1SR bit assignments are:

```
31 0
```

**CONTEXTIDR_EL1, bits [31:0]**

*From ARMv8.2:*

Context ID. The value of CONTEXTIDR that is associated with the most recent PMPCSR sample.

- If EL1 is using AArch64, then the Context ID is sampled from CONTEXTIDR_EL1.
- If EL1 is using AArch32, then the Context ID is sampled from CONTEXTIDR.
- If EL3 is implemented and is using AArch32, then CONTEXTIDR is a banked register and PMCID1SR samples the current banked copy of CONTEXTIDR for the Security state that is associated with the most recent PMPCSR sample.

Because the value written to PMCID1SR is an indirect read of CONTEXTIDR, therefore it is CONstrained UnPredictable whether PMCID1SR is set to the original or new value if a read of PMPCSR samples:

- An instruction that writes to CONTEXTIDR_EL1.
- The next Context synchronization event.
- Any instruction executed between these two instructions.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.
Accessing the PMCID1SR:

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN on page H7-6536

PMCID1SR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0x208</td>
<td>PMCID1SR</td>
</tr>
<tr>
<td>PMU</td>
<td>0x228</td>
<td>PMCID1SR</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to PMCID1SR[:] is RO.
- Otherwise access to PMCID1SR[:] returns an Error.
- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to PMCID1SR[:] is RO.
- Otherwise access to PMCID1SR[:] returns an Error.
I5.3.14 PMCID2SR, CONTEXTIDR_EL2 Sample Register

The PMCID2SR characteristics are:

Purpose

Contains the sampled value of CONTEXTIDR_EL2, captured on reading PMPCSR[31:0].

Configurations

PMCID2SR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

This register is present only from ARMv8.2. Otherwise, direct accesses to PMCID2SR are RES0.

Implemented only when ARMv8.2-PCSample is implemented.

Note

Before Armv8.2, the PC Sample-based Profiling Extension can be implemented in the external debug register space, as indicated by the value of EDDEVID.PCSample.

If EL2 is not implemented, this register is RES0.

This register is introduced in ARMv8.2.

Attributes

PMCID2SR is a 32-bit register.

Field descriptions

The PMCID2SR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CONTEXTIDR_EL2</td>
</tr>
</tbody>
</table>

CONTEXTIDR_EL2, bits [31:0]

From ARMv8.2:

Context ID. The value of CONTEXTIDR that is associated with the most recent PMPCSR sample.

• If EL2 is using AArch64, then the Context ID sampled from CONTEXTIDR_EL2.
• If EL2 is using AArch32, then this field is set to an UNKNOWN value.

Because the value written to PMCID2SR is an indirect read of CONTEXTIDR, therefore it is CONSTRAINED UNPREDICTABLE whether PMCID2SR is set to the original or new value if a read of PMPCSR samples:

• An instruction that writes to CONTEXTIDR_EL2.
• The next Context synchronization event.
• Any instruction executed between these two instructions.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the PMCID2SR:

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN on page H7-6536.
PMCID2SR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0x22C</td>
<td>PMCID2SR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.15 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register

The PMCNTENCLR_EL0 characteristics are:

**Purpose**

Disables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<n>. Reading this register shows which counters are enabled.

**Configurations**

External register PMCNTENCLR_EL0[31:0] is architecturally mapped to AArch64 System register PMCNTENCLR_EL0[31:0].

External register PMCNTENCLR_EL0[31:0] is architecturally mapped to AArch32 System register PMCNTENCLR[31:0].

PMCNTENCLR_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

**Attributes**

PMCNTENCLR_EL0 is a 32-bit register.

**Field descriptions**

The PMCNTENCLR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>PMCCNTR_EL0 disable bit. Disables the cycle counter register. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>0b0  When read, means the cycle counter is disabled. When written, has no effect.</td>
</tr>
<tr>
<td></td>
<td>0b1  When read, means the cycle counter is enabled. When written, disables the cycle counter.</td>
</tr>
<tr>
<td></td>
<td>On a Warm reset, this field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>0n</td>
<td>Event counter disable bit for PMEVCNTR&lt;n&gt;_EL0.</td>
</tr>
<tr>
<td></td>
<td>If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are RAZ/WI.</td>
</tr>
<tr>
<td></td>
<td>0b0  When read, means that PMEVCNTR&lt;n&gt;_EL0 is disabled. When written, has no effect.</td>
</tr>
<tr>
<td></td>
<td>0b1  When read, means that PMEVCNTR&lt;n&gt;_EL0 is enabled. When written, disables PMEVCNTR&lt;n&gt;_EL0.</td>
</tr>
<tr>
<td></td>
<td>On a Warm reset, this field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the PMCNTENCLR_EL0:**

--- **Note** ---

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.
PMCNTENCLR_EL0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xC20</td>
<td>PMCNTENCLR_EL0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
I5.3.16 PMCNTENSET_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET_EL0 characteristics are:

**Purpose**

Enables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<->. Reading this register shows which counters are enabled.

**Configurations**

External register PMCNTENSET_EL0[31:0] is architecturally mapped to AArch64 System register PMCNTENSET_EL0[31:0].

External register PMCNTENSET_EL0[31:0] is architecturally mapped to AArch32 System register PMCNTENSET[31:0].

PMCNTENSET_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

**Attributes**

PMCNTENSET_EL0 is a 32-bit register.

**Field descriptions**

The PMCNTENSET_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;n&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

**C**, bit [31]

PMCCNTR_EL0 enable bit. Enables the cycle counter register. Possible values are:

- 0b0 When read, means the cycle counter is disabled. When written, has no effect.
- 0b1 When read, means the cycle counter is enabled. When written, enables the cycle counter.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**P<n>, bit [n], for n = 0 to 30**

Event counter enable bit for PMEVCNTR<->_EL0.

If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are RAZ/WI.

- 0b0 When read, means that PMEVCNTR<->_EL0 is disabled. When written, has no effect.
- 0b1 When read, means that PMEVCNTR<->_EL0 event counter is enabled. When written, enables PMEVCNTR<->_EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing the PMCNTENSET_EL0:**

--- Note ---

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

---
PMCNTENSET_EL0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xC00</td>
<td>PMCNTENSET_EL0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
## 5.3.17 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

**Purpose**

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

**Configurations**

External register PMCR_EL0[7:0] is architecturally mapped to AArch32 System register PMCR[7:0].

External register PMCR_EL0[7:0] is architecturally mapped to AArch64 System register PMCR_EL0[7:0].

PMCR_EL0 is in the Core power domain. Some or all RW fields of this register have defined reset values. The field descriptions identify when the reset values apply.

This register is only partially mapped to the internal PMCR System register. An external agent must use other means to discover the information held in PMCR[31:11], such as accessing PMCFGR and the ID registers.

**Attributes**

PMCR_EL0 is a 32-bit register.

**Field descriptions**

The PMCR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>RAZ/WI</td>
</tr>
<tr>
<td>1</td>
<td>RES0</td>
</tr>
<tr>
<td>2</td>
<td>LC</td>
</tr>
<tr>
<td>3</td>
<td>DP</td>
</tr>
</tbody>
</table>

### Bits [31:11]

Reserved, RAZ/WI.

Hardware must implement this field as RAZ/WI. Software must not rely on the register reading as zero, and must use a read-modify-write sequence to write to the register.

### Bits [10:7]

Reserved, RES0.

### LC, bit [6]

Long cycle counter enable. Determines when unsigned overflow is recorded by the cycle counter overflow bit.

- 0: Cycle counter overflow on increment that causes unsigned overflow of PMCCNTR_EL0[31:0].
- 1: Cycle counter overflow on increment that causes unsigned overflow of PMCCNTR_EL0[63:0].

Arm deprecates use of PMCR_EL0.LC = 0.

In an AArch64 only implementation, this field is RES1.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

### DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

- 0: Cycle counting by PMCCNTR_EL0 is not affected by this bit.
When event counting for counters in the range [0..(MDCR_EL2.HPMN-1)] is prohibited, cycle counting by PMCCNTR_EL0 is disabled.

For more information about the interaction between the Performance Monitors and EL3, see *Effect of EL3 and EL2* on page D6-2533.

When EL3 is not implemented, this field is RES0:
- When ARMv8.1-PMU is not implemented.
- When ARMv8.1-PMU is implemented, only if EL2 is not implemented.

Otherwise this field is RW.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field it resets to:
- A value that is architecturally UNKNOWN if the reset is into an Exception level that is using AArch64.
- 0 if the reset is into an Exception level that is using AArch32.

**X, bit [4]**

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:
- 0b0  Do not export events.
- 0b1  Export events where not prohibited.

This field enables the exporting of events over an event bus to another device, for example to an OPTIONAL PE trace unit. If the implementation does not include such an event bus then this field is RAZ/WI, otherwise it is an RW field.

In an implementation that includes an event bus, no events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field it resets to:
- A value that is architecturally UNKNOWN if the reset is into an Exception level that is using AArch64.
- 0 if the reset is into an Exception level that is using AArch32.

**D, bit [3]**

Clock divider. The possible values of this bit are:
- 0b0  When enabled, PMCCNTR_EL0 counts every clock cycle.
- 0b1  When enabled, PMCCNTR_EL0 counts once every 64 clock cycles.

In an AArch64 only implementation this field is RES0, otherwise it is an RW field. If PMCR_EL0.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

Arm deprecates use of PMCR_EL0.D = 1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field it resets to:
- A value that is architecturally UNKNOWN if the reset is into an Exception level that is using AArch64.
- 0 if the reset is into an Exception level that is using AArch32.

**C, bit [2]**

Cycle counter reset. This bit is WO. The effects of writing to this bit are:
- 0b0  No action.
- 0b1  Reset PMCCNTR_EL0 to zero.

This bit is always RAZ.
--- Note ---
Resetting PMCCNTR_EL0 does not change the cycle counter overflow bit.

---

**P, bit [1]**

Event counter reset. This bit is WO. The effects of writing to this bit are:

0b0  No action.
0b1  Reset all event counters, not including PMCCNTR_EL0, to zero.

This bit is always RAZ.

--- Note ---
Resetting the event counters does not change the event counter overflow bits.

---

**E, bit [0]**

Enable.

0b0  All event counters in the range [0:(PMN-1)] and PMCCNTR_EL0, are disabled.
0b1  All event counters in the range [0:(PMN-1)] and PMCCNTR_EL0, are enabled by PMCNTENSET_EL0.

This bit is RW.

If EL2 is implemented then:

- If EL2 is using AArch32, PMN is HDCR.HPMN.
- If EL2 is using AArch64, PMN is MDCR_EL2.HPMN.
- If PMN is less than PMCR_EL0.N, this bit does not affect the operation of event counters in the range [PMN:(PMN:(PMCR_EL0.N-1)].

If EL2 is not implemented, PMN is PMCR_EL0.N.

--- Note ---
The effect of MDCR_EL2.HPMN or HDCR.HPMN on the operation of this bit applies if EL2 is implemented regardless of whether EL2 is enabled in the current Security state. For more information, see the description of MDCR_EL2.HPMN or HDCR.HPMN.

---

On a Warm reset, this field resets to 0.

**Accessing the PMCR_EL0:**

--- Note ---
SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

---

PMCR_EL0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xE04</td>
<td>PMCR_EL0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() access to this register is RW.
• Otherwise access to this register returns an Error.
I5.3.18 PMDEVAFF0, Performance Monitors Device Affinity register 0

The PMDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

Configurations

It is IMPLEMENTATION DEFINED whether PMDEVAFF0 is implemented in the Core power domain or in the Debug power domain. This register is required if the external interface to the PMU is implemented.

Attributes

PMDEVAFF0 is a 32-bit register.

Field descriptions

The PMDEVAFF0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>MPIDR_EL1 low half</td>
</tr>
</tbody>
</table>

MPIDR_EL1 low half, bits [31:0]

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the PMDEVAFF0:

PMDEVAFF0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFA8</td>
<td>PMDEVAFF0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.19   PMDEVAFF1, Performance Monitors Device Affinity register 1

The PMDEVAFF1 characteristics are:

Purpose
Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

Configurations
It is IMPLEMENTATION DEFINED whether PMDEVAFF1 is implemented in the Core power domain or in the Debug power domain.
This register is required if the external interface to the PMU is implemented.

Attributes
PMDEVAFF1 is a 32-bit register.

Field descriptions
The PMDEVAFF1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>MPIDR_EL1 high half</td>
</tr>
</tbody>
</table>

MPIDR_EL1 high half, bits [31:0]
MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the PMDEVAFF1:
PMDEVAFF1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xfAC</td>
<td>PMDEVAFF1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.20 PMDEVARCH, Performance Monitors Device Architecture register

The PMDEVARCH characteristics are:

Purpose

Identifies the programmers’ model architecture of the Performance Monitor component.

Configurations

It is IMPLEMENTATION DEFINED whether PMDEVARCH is implemented in the Core power domain or in the Debug power domain.

Attributes

PMDEVARCH is a 32-bit register.

Field descriptions

The PMDEVARCH bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCHITECT</td>
<td>REVISION</td>
<td>ARCHID</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

PRESENT

ARCHITECT, bits [31:21]

Defines the architecture of the component. For Performance Monitors, this is Arm Limited.

Bits [31:28] are the JEP106 continuation code, 0x4.

Bits [27:21] are the JEP106 ID code, 0x3B.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in Armv8.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by Arm this is the minor revision.

For Performance Monitors, the revision defined by Armv8 is 0x0.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be an Armv8 debug component. For architectures defined by Arm this is further subdivided.

For Performance Monitors:

- Bits [15:12] are the architecture version, 0x2.
- Bits [11:0] are the architecture part number, 0xA16.

This corresponds to Performance Monitors architecture version PMUv3.

Note

The PMUv3 memory-mapped programmers' model can be used by devices other than Armv8 processors. Software must determine whether the PMU is attached to an Armv8 processor by using the PMDEVAFF0 and PMDEVAFF1 registers to discover the affinity of the PMU to any Armv8 processors.
**Accessing the PMDEVARCH:**

PMDEVARCH can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xF8C</td>
<td>PMDEVARCH</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
### PMDEVID, Performance Monitors Device ID register

The PMDEVID characteristics are:

**Purpose**

Provides information about features of the Performance Monitors implementation.

**Configurations**

It is **IMPLEMENTATION DEFINED** whether PMDEVID is implemented in the Core power domain or in the Debug power domain.

This register is required from Armv8.2 and in any implementation that includes **ARMv8.2-PCSample**. Otherwise, its location is **RES0**.

--- **Note** ---

Before Armv8.2, the PC Sample-based Profiling Extension can be implemented in the external debug register space, as indicated by the value of **EDDEVID.PCSample**.

**Attributes**

PMDEVID is a 32-bit register.

**Field descriptions**

The PMDEVID bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:4</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

**PCSample, bits [3:0]**

Indicates the level of PC Sample-based Profiling support using Performance Monitors registers. Permitted values of this field are:

- `0b0000` PC Sample-based Profiling Extension is not implemented in the Performance Monitors register space.
- `0b0001` PC Sample-based Profiling Extension is implemented in the Performance Monitors register space.

All other values are reserved.

**ARMv8.2-PCSample** implements the functionality identified by the value `0b0001`.

**Accessing the PMDEVID:**

PMDEVID can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFc8</td>
<td>PMDEVID</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
• Otherwise access to this register returns an Error.
I5.3.22 PMDEVTYPE, Performance Monitors Device Type register

The PMDEVTYPE characteristics are:

**Purpose**
Indicates to a debugger that this component is part of a PEs performance monitor interface.

**Configurations**
It is IMPLEMENTATION DEFINED whether PMDEVTYPE is implemented in the Core power domain or in the Debug power domain.
Implementation of this register is OPTIONAL.

**Attributes**
PMDEVTYPE is a 32-bit register.

**Field descriptions**
The PMDEVTYPE bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SUB</td>
<td>MAJOR</td>
</tr>
</tbody>
</table>

**Bits [31:8]**
Reserved, RES0.

**SUB, bits [7:4]**
Subtype. Must read as 0x1 to indicate this is a component within a PE.

**MAJOR, bits [3:0]**
Major type. Must read as 0x6 to indicate this is a performance monitor component.

**Accessing the PMDEVTYPE:**
PMDEVTYPE can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFCC</td>
<td>PMDEVTYPE</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.23 PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>_EL0 characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

Configurations

External register PMEVCNTR<n>_EL0[31:0] is architecturally mapped to AArch64 System register PMEVCNTR<n>_EL0[31:0].

External register PMEVCNTR<n>_EL0[31:0] is architecturally mapped to AArch32 System register PMEVCNTR<n>[31:0].

PMEVCNTR<n>_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. The field descriptions identify when the reset values apply.

Attributes

PMEVCNTR<n>_EL0 is a 32-bit register.

Field descriptions

The PMEVCNTR<n>_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Event counter n</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Event counter n</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Accessing the PMEVCNTR<n>_EL0:

External accesses to the performance monitors ignore PMUSERENR_EL0 and, if implemented, MDCR_EL2. {TPM, TPMCR, HPMN} and MDCR_EL3.TPM. This means that all counters are accessible regardless of the current Exception level or privilege of the access.

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMEVCNTR<n>_EL0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0x000 + 8n</td>
<td>PMEVCNTR&lt;n&gt;_EL0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() access to this register is RW.
• Otherwise access to this register returns an Error.
I5.3.24 PMEVTYPER<\(n\)>_EL0, Performance Monitors Event Type Registers, \(n = 0 - 30\)

The PMEVTYPER<\(n\)>_EL0 characteristics are:

**Purpose**

Configures event counter \(n\), where \(n\) is 0 to 30.

**Configurations**

External register PMEVTYPER<\(n\)>_EL0[31:0] is architecturally mapped to AArch64 System register PMEVTYPER<\(n\)>_EL0[31:0].

External register PMEVTYPER<\(n\)>_EL0[31:0] is architecturally mapped to AArch32 System register PMEVTYPER<\(n\)>[31:0].

PMEVTYPER<\(n\)>_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

**Attributes**

PMEVTYPER<\(n\)>_EL0 is a 32-bit register.

**Field descriptions**

The PMEVTYPER<\(n\)>_EL0 bit assignments are:

```
  P  U  M  RES0  \(\text{evtCount}\)[15:10]  \(\text{evtCount}\)[9:0]
```

**P, bit [31]**

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the PMEVTYPER<\(n\)>_EL0.NSK bit. The possible values of this bit are:

- \(0b0\): Count events in EL1.
- \(0b1\): Do not count events in EL1.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**U, bit [30]**

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the PMEVTYPER<\(n\)>_EL0.NSU bit. The possible values of this bit are:

- \(0b0\): Count events in EL0.
- \(0b1\): Do not count events in EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**NSK, bit [29]**

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.
If the value of this bit is equal to the value of the PMEVTYPER<\text{n}>_EL0.P bit, events in Non-secure EL1 are counted.
Otherwise, events in Non-secure EL1 are not counted.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**NSU, bit [28]**

Non-secure EL0 (Unprivileged) filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.
If the value of this bit is equal to the value of the PMEVTYPER<\text{n}>_EL0.U bit, events in Non-secure EL0 are counted.
Otherwise, events in Non-secure EL0 are not counted.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**NSH, bit [27]**

EL2 (Hypervisor) filtering bit. Controls counting in EL2. If EL2 is not implemented, this bit is RES0.
If Secure EL2 is implemented, counting in Secure EL2 is further controlled by the PMEVTYPER<\text{n}>_EL0.SH bit.
0b0 Do not count events in EL2.
0b1 Count events in EL2.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**M, bit [26]**

Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.
If the value of this bit is equal to the value of the PMEVTYPER<\text{n}>_EL0.P bit, cycles in Secure EL3 are counted.
Otherwise, cycles in Secure EL3 are not counted.
Most applications can ignore this field and set its value to 0b0.

--- **Note**

This field is not visible in the AArch32 PMEVTYPER<\text{n}> System register.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**MT, bit [25]**

Multithreading. When the implementation is multi-threaded, the valid values for this bit are:
0b0 Count events only on controlling PE.
0b1 Count events from any PE with the same affinity at level 1 and above as this PE.
When the implementation is not multi-threaded, this bit is RES0.

--- **Note**

- When the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach, an implementation is described as multi-threaded. That is, the performance of PEs at the lowest affinity level is highly interdependent. On such an implementation, the value of the MPIDR_EL1.MT bit, when read at the highest implemented Exception level, is 0b1.
- Events from a different thread of a multithreaded implementation are not Attributable to the thread counting the event.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**SH, bit [24]**

*When ARMv8.4-SecEL2 is implemented:*

Secure EL2 filtering.
If the value of this bit is not equal to the value of the PMEVTYPEPERNEL0.NSH bit, events in Secure EL2 are counted.
Otherwise, events in Secure EL2 are not counted.
If Secure EL2 is not implemented or is disabled, this field is RES0.

--- Note ---
This field is not visible in the AArch32 PMEVTYPEPERN System register.

---
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [23:16]
Reserved, RES0.

evCount[15:10], bits [15:10]

From ARMv8.1:
On a Warm reset, this field resets to an architecturally UNKNOWN value.

 Otherwise:
Reserved, RES0.

evCount[9:0], bits [9:0]
Event to count. The event number of the event that is counted by event counter PMEVCNTERNEL0.
Software must program this field with an event that is supported by the PE being programmed.
There are three types of event:
• Common architectural and microarchitectural events.
• Arm recommended common architectural and microarchitectural events.
• IMPLEMENTATION DEFINED events.
The ranges of event numbers allocated to each type of event are shown in Table D6-6 on page D6-2545.
If evCount is programmed to an event that is reserved or not supported by the PE, the behavior depends on the event type:
• For the range 0x000 to 0x03F, no events are counted, and the value returned by a direct or external read of the evCount field is the value written to the field.
• For IMPLEMENTATION DEFINED events, it is UNPREDICTABLE what event, if any, is counted, and the value returned by a direct or external read of the evCount field is UNKNOWN.

--- Note ---
UNPREDICTABLE means the event must not expose privileged information.

---
Arm recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evCount is the value written.
On a Warm reset, this field resets to an architecturally UNKNOWN value.
Accessing the PMEVTYPER<n>_EL0:

—— Note ————
SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new
definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMEVTYPER<n>_EL0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0x400 + 4n</td>
<td>PMEVTYPER&lt;n&gt;_EL0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and
  SoftwareLockStatus() access to this register is RO.

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and
  !SoftwareLockStatus() access to this register is RW.

- Otherwise access to this register returns an Error.
I5.3.25 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR_EL1 characteristics are:

**Purpose**
Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

**Configurations**
External register PMINTENCLR_EL1[31:0] is architecturally mapped to AArch64 System register PMINTENCLR_EL1[31:0].
External register PMINTENCLR_EL1[31:0] is architecturally mapped to AArch32 System register PMINTENCLR[31:0].
PMINTENCLR_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

**Attributes**
PMINTENCLR_EL1 is a 32-bit register.

**Field descriptions**
The PMINTENCLR_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C, bit [31]</td>
<td>PMCCNTR_EL0 overflow interrupt request disable bit. Possible values are:</td>
</tr>
<tr>
<td>0b0</td>
<td>When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.</td>
</tr>
<tr>
<td>0b1</td>
<td>When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.</td>
</tr>
<tr>
<td>P&lt;n&gt;, bit [n], for n = 0 to 30</td>
<td>Event counter overflow interrupt request disable bit for PMEVCNTR&lt;n&gt;_EL0.</td>
</tr>
<tr>
<td>0b0</td>
<td>When read, means that the PMEVCNTR&lt;n&gt;_EL0 event counter interrupt request is disabled. When written, has no effect.</td>
</tr>
<tr>
<td>0b1</td>
<td>When read, means that the PMEVCNTR&lt;n&gt;_EL0 event counter interrupt request is enabled. When written, disables the PMEVCNTR&lt;n&gt;_EL0 interrupt request.</td>
</tr>
</tbody>
</table>

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing the PMINTENCLR_EL1:**

--- Note ---
SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.
PMINTENCLR_EL1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xC60</td>
<td>PMINTENCLR_EL1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
I5.3.26 PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register

The PMINTENSET_EL1 characteristics are:

**Purpose**

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

**Configurations**

External register PMINTENSET_EL1[31:0] is architecturally mapped to AArch64 System register PMINTENSET_EL1[31:0].

External register PMINTENSET_EL1[31:0] is architecturally mapped to AArch32 System register PMINTENSET[31:0].

PMINTENSET_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

**Attributes**

PMINTENSET_EL1 is a 32-bit register.

**Field descriptions**

The PMINTENSET_EL1 bit assignments are:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>30</td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>P&lt;n&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

**C, bit [31]**

PMCCNTR_EL0 overflow interrupt request enable bit. Possible values are:

- **0b0** When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- **0b1** When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**P<n>, bit [n], for n = 0 to 30**

Event counter overflow interrupt request enable bit for PMEVCNTR<n>_EL0.

If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are RAZ/WI.

- **0b0** When read, means that the PMEVCNTR<n>_EL0 event counter interrupt request is disabled. When written, has no effect.
- **0b1** When read, means that the PMEVCNTR<n>_EL0 event counter interrupt request is enabled. When written, enables the PMEVCNTR<n>_EL0 interrupt request.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Accessing the PMINTENSET_EL1:**

--- **Note** ---

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.
PMINTENSET_EL1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xC40</td>
<td>PMINTENSET_EL1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
I5.3.27 PMITCTRL, Performance Monitors Integration mode Control register

The PMITCTRL characteristics are:

Purpose

Enables the Performance Monitors to switch from default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Configurations

It is IMPLEMENTATION DEFINED whether PMITCTRL is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

Implementation of this register is OPTIONAL.

Attributes

PMITCTRL is a 32-bit register.

Field descriptions

The PMITCTRL bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 1 0</td>
<td>RES0   IME</td>
</tr>
</tbody>
</table>

Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

0b0 Normal operation.

0b1 Integration mode enabled.

On a Implementation reset, this field resets to 0.

Accessing the PMITCTRL:

PMITCTRL can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xF00</td>
<td>PMITCTRL</td>
</tr>
</tbody>
</table>
This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() access to this register is RO.

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() access to this register is RW.

- Otherwise access to this register is IMPDEF.
I5.3.28   PMLAR, Performance Monitors Lock Access Register

The PMLAR characteristics are:

**Purpose**

Allows or disallows access to the Performance Monitors registers through a memory-mapped interface.

**Configurations**

It is IMPLEMENTATION DEFINED whether PMLAR is implemented in the Core power domain or in the Debug power domain.

PMLAR ignores writes if the Software Lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses PMLAR to set or clear the lock, and PMLSR to check the current status of the lock.

**Attributes**

PMLAR is a 32-bit register.

**Field descriptions**

The PMLAR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEY</td>
<td></td>
</tr>
</tbody>
</table>

**KEY, bits [31:0]**

Lock Access control. Writing the key value \( \text{0xC5ACCE55} \) to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory-mapped interface.

**Accessing the PMLAR:**

PMLAR can be accessed through its memory-mapped interface:

```
<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFB0</td>
<td>PMLAR</td>
</tr>
</tbody>
</table>
```

This interface is accessible as follows:

- Access to this register is WO.
- Otherwise access to this register returns an Error.
5.3.29 PMLSR, Performance Monitors Lock Status Register

The PMLSR characteristics are:

**Purpose**

Indicates the current status of the software lock for Performance Monitors registers.

**Configurations**

It is IMPLEMENTATION DEFINED whether PMLSR is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

PMLSR is RAZ if the Software Lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses PMLAR to set or clear the lock, and PMLSR to check the current status of the lock.

**Attributes**

PMLSR is a 32-bit register.

**Field descriptions**

The PMLSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>30</td>
<td>nTT, bit [2]</td>
</tr>
<tr>
<td>29</td>
<td>SLK, bit [1]</td>
</tr>
</tbody>
</table>

Reserved, RES0.

Not thirty-two bit access required. RAZ.

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:
- 0b0 Lock clear. Writes are permitted to this component's registers.
- 0b1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.

The following resets apply:
- This register is reset by External debug reset and not affected by Cold reset.
• On a reset, this field resets to 1.

**SLI, bit [0]**

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

- 0b0  Software Lock not implemented or not memory-mapped access.
- 0b1  Software Lock implemented and memory-mapped access.

**Accessing the PMLSR:**

PMLSR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFB4</td>
<td>PMLSR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

• Access to this register is RO.

• Otherwise access to this register returns an Error.
I5.3.30 PMMIR, Performance Monitors Machine Identification Register

The PMMIR characteristics are:

**Purpose**

Describes Performance Monitors parameters specific to the implementation.

**Configurations**

PMMIR is in the Core power domain.

This register is present only when ARMv8.4-PMU is implemented. Otherwise, direct accesses to PMMIR are RES0.

**Attributes**

PMMIR is a 32-bit register.

**Field descriptions**

The PMMIR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:8]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>[7:0]</td>
<td>SLOTS, Operation width. The largest value by which the STALL_SLOT event might increment by in a single cycle. If the STALL_SLOT event is implemented, this field must not be zero.</td>
</tr>
</tbody>
</table>

**Accessing the PMMIR:**

If the Core power domain is off or in a low-power state, access on this interface returns an Error.

PMMIR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xE40</td>
<td>PMMIR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When !IsCorePowered(), or DoubleLockStatus(), or OSLockStatus() or !AllowExternalPmuAccess() access to this register returns an Error.
- Otherwise access to this register is RO.
I5.3.31 PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear register

The PMOVSCLR_EL0 characteristics are:

**Purpose**

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<n>. Writing to this register clears these bits.

**Configurations**

External register PMOVSCLR_EL0[31:0] is architecturally mapped to AArch64 System register PMOVSCLR_EL0[31:0].

External register PMOVSCLR_EL0[31:0] is architecturally mapped to AArch32 System register PMOVSR[31:0].

PMOVSCLR_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

**Attributes**

PMOVSCLR_EL0 is a 32-bit register.

**Field descriptions**

The PMOVSCLR_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;n&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

**C, bit [31]**

Cycle counter overflow clear bit.

- **0b0**: When read, means the cycle counter has not overflowed since this bit was last cleared. When written, has no effect.
- **0b1**: When read, means the cycle counter has overflowed since this bit was last cleared. When written, clears the cycle counter overflow bit to 0.

PMCR_EL0.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR_EL0[31:0] or unsigned overflow of PMCCNTR_EL0[63:0].

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**P<n>, bit [n], for n = 0 to 30**

Event counter overflow clear bit for PMEVCNTR<n>_EL0.

If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are RAZ/WI.

- **0b0**: When read, means that PMEVCNTR<n>_EL0 has not overflowed since this bit was last cleared. When written, has no effect.
- **0b1**: When read, means that PMEVCNTR<n>_EL0 has overflowed since this bit was last cleared. When written, clears the PMEVCNTR<n>_EL0 overflow bit to 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.
Accessing the PMOVSCLR_EL0:

--- Note ---
SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMOVSCLR_EL0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xC80</td>
<td>PMOVSCLR_EL0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
I5.3.32  PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register

The PMOVSSET_EL0 characteristics are:

**Purpose**

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<n>.

**Configurations**

External register PMOVSSET_EL0[31:0] is architecturally mapped to AArch64 System register PMOVSSET_EL0[31:0].

External register PMOVSSET_EL0[31:0] is architecturally mapped to AArch32 System register PMOVSSET[31:0].

PMOVSSET_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

**Attributes**

PMOVSSET_EL0 is a 32-bit register.

**Field descriptions**

The PMOVSSET_EL0 bit assignments are:

<table>
<thead>
<tr>
<th>C, bit [31]</th>
<th>P&lt;n&gt;, bit [n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>When read, means the cycle counter has not overflowed since this bit was last cleared. When written, has no effect.</td>
</tr>
<tr>
<td>0b1</td>
<td>When read, means the cycle counter has overflowed since this bit was last cleared. When written, sets the cycle counter overflow bit to 1.</td>
</tr>
<tr>
<td>PMCR_EL0.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR_EL0[31:0] or unsigned overflow of PMCCNTR_EL0[63:0].</td>
<td></td>
</tr>
<tr>
<td>On a Warm reset, this field resets to an architecturally UNKNOWN value.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>P&lt;n&gt;, bit [n], for n = 0 to 30</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event counter overflow set bit for PMEVCNTR&lt;n&gt;_EL0.</td>
</tr>
<tr>
<td>If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are RAZ/WI.</td>
</tr>
<tr>
<td>0b0</td>
</tr>
<tr>
<td>0b1</td>
</tr>
<tr>
<td>On a Warm reset, this field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>
Accessing the PMOVSET_EL0:

--- Note ---
SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMOVSET_EL0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xCC0</td>
<td>PMOVSET_EL0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to this register is RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() access to this register is RW.
- Otherwise access to this register returns an Error.
I5.3.33 PMPCSR, Program Counter Sample Register

The PMPCSR characteristics are:

**Purpose**

Holds a sampled instruction address value.

**Configurations**

PMPCSR is in the Core power domain.

Fields in this register reset to architecturally **UNKNOWN** values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

This register is present only when ARMv8.2-PCSample is implemented. Otherwise, direct accesses to PMPCSR are **UNDEFINED**.

**Note**

Before Armv8.2, the PC Sample-based Profiling Extension can be implemented in the external debug register space, as indicated by the value of **EDDEVID.PCSample**.

Support for 64-bit atomic reads is **IMPLEMENTATION DEFINED**. If 64-bit atomic reads are implemented, a 64-bit read of PMPCSR has the same side-effect as a 32-bit read of PMCSR[31:0] followed by a 32-bit read of PMPCSR[63:32], returning the combined value. For example, if the PE is in Debug state then a 64-bit atomic read returns bits[31:0] == 0xFFFFFFFF and bits[63:32] **UNKNOWN**.

**Attributes**

PMPCSR is a 64-bit register.

**Field descriptions**

The PMPCSR bit assignments are:

<table>
<thead>
<tr>
<th>63 62 61 60 56 55</th>
<th>32 31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>NS</td>
<td>EL</td>
<td>RES0</td>
</tr>
</tbody>
</table>

**NS, bit [63]**

Non-secure state sample. Indicates the Security state that is associated with the most recent PMPCSR sample or, when it is read as a single atomic 64-bit read, the current PMPCSR sample.

On a Cold reset, this field resets to an architecturally **UNKNOWN** value.

**EL, bits [62:61]**

Exception level status sample. Indicates the Exception level that is associated with the most recent PMPCSR sample or, when it is read as a single atomic 64-bit read, the current PMPCSR sample.

- **0b00**: Sample is from EL0.
- **0b01**: Sample is from EL1.
- **0b10**: Sample is from EL2.
- **0b11**: Sample is from EL3.

On a Cold reset, this field resets to an architecturally **UNKNOWN** value.

**Bits [60:56]**

Reserved, **RES0**.
PC Sample[55:32], bits [55:32]

Bits[55:32] of the sampled instruction address value. The translation regime that PMPCSR samples can be determined from PMPCSR.{NS,EL}.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

PC Sample[31:0], bits [31:0]

Bits[31:0] of the sampled instruction address value. The translation regime that PMPCSR samples can be determined from PMPCSR.{NS,EL}.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

For a read of PMPCSR[31:0] from the memory-mapped interface, if PMLSR.SLK == 1, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.

In any other cases, a read of PMPCSR[31:0] has the side-effect of indirectly writing to PMPCSR[63:32], PMCID1SR, PMCID2SR, and PMVIDSR:

- If the PE is in Debug state, or PC Sample-based profiling is prohibited, PMPCSR[31:0] reads as 0xFFFFFFFF, and PMPCSR[63:32], PMCID1SR, PMCID2SR, and PMVIDSR become UNKNOWN.
- If the PE is in Reset state, the sampled value is UNKNOWN and PMPCSR[63:32], PMCID1SR, PMCID2SR, and PMVIDSR become UNKNOWN.
- If no instruction has been sampled since the PE left Reset state, Debug state, or a state where PC Sample-based Profiling is prohibited, the sampled value is 0xFFFFFFFF, and PMPCSR[63:32], PMCID1SR, PMCID2SR, and PMVIDSR become UNKNOWN. Any subsequent read will return an instruction address value.

Accessing the PMPCSR:

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN on page H7-6536.

PMPCSR[31:0] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0x200</td>
<td>PMPCSR</td>
<td>31:0</td>
</tr>
<tr>
<td>PMU</td>
<td>0x220</td>
<td>PMPCSR</td>
<td>31:0</td>
</tr>
</tbody>
</table>

PMPCSR[63:32] can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0x204</td>
<td>PMPCSR</td>
<td>63:32</td>
</tr>
<tr>
<td>PMU</td>
<td>0x224</td>
<td>PMPCSR</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to PMPCSR[31:0] is RO.
- Otherwise access to PMPCSR[31:0] returns an Error.
- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to PMPCSR[63:32] is RO.
- Otherwise access to PMPCSR[63:32] returns an Error.
- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to PMPCSR[31:0] is RO.
• Otherwise access to PMPCSR[31:0] returns an Error.
• When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to PMPCSR[63:32] is RO.
• Otherwise access to PMPCSR[63:32] returns an Error.
I5.3.34 PMPIDR0, Performance Monitors Peripheral Identification Register 0

The PMPIDR0 characteristics are:

**Purpose**

Provides information to identify a Performance Monitor component.

For more information see *About the Peripheral identification scheme on page K2-7243.*

**Configurations**

It is IMPLEMENTATION DEFINED whether PMPIDR0 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

PMPIDR0 is a 32-bit register.

**Field descriptions**

The PMPIDR0 bit assignments are:

```
+-------+-------+
| 31    | 8 7   |
| RES0  | PART_0|
+-------+-------+
```

**Bits [31:8]**

Reserved, RES0.

**PART_0, bits [7:0]**

Part number, least significant byte.

**Accessing the PMPIDR0:**

PMPIDR0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFE0</td>
<td>PMPIDR0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.35 PMPIDR1, Performance Monitors Peripheral Identification Register 1

The PMPIDR1 characteristics are:

**Purpose**
Provides information to identify a Performance Monitor component.
For more information see About the Peripheral identification scheme on page K2-7243.

**Configurations**
It is IMPLEMENTATION DEFINED whether PMPIDR1 is implemented in the Core power domain or in the Debug power domain.
Implementation of this register is OPTIONAL.
This register is required for CoreSight compliance.

**Attributes**
PMPIDR1 is a 32-bit register.

**Field descriptions**
The PMPIDR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>DES_0</td>
<td>PART_1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**
Reserved, RES0.

**DES_0, bits [7:4]**
Designer, least significant nibble of JEP106 ID code. For Arm Limited, this field is 0b1011.

**PART_1, bits [3:0]**
Part number, most significant nibble.

**Accessing the PMPIDR1:**
PMPIDR1 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFE4</td>
<td>PMPIDR1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.36  PMPIDR2, Performance Monitors Peripheral Identification Register 2

The PMPIDR2 characteristics are:

**Purpose**

Provides information to identify a Performance Monitor component.
For more information see *About the Peripheral identification scheme* on page K2-7243.

**Configurations**

It is IMPLEMENTATION DEFINED whether PMPIDR2 is implemented in the Core power domain or in the Debug power domain.
Implementation of this register is OPTIONAL.
This register is required for CoreSight compliance.

**Attributes**

PMPIDR2 is a 32-bit register.

**Field descriptions**

The PMPIDR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>8</td>
<td>REVISION</td>
</tr>
<tr>
<td>7-4</td>
<td>Part major revision</td>
</tr>
<tr>
<td>3</td>
<td>JEDEC, bit [3]</td>
</tr>
<tr>
<td>2-0</td>
<td>Designer, bits [2:0]</td>
</tr>
</tbody>
</table>

Bits [31:8]: Reserved, RES0.

REVISION, bits [7:4]: Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]: RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]: Designer, most significant bits of JEP106 ID code. For Arm Limited, this field is 0b011.

**Accessing the PMPIDR2:**

PMPIDR2 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFE8</td>
<td>PMPIDR2</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.37 PMPIDR3, Performance Monitors Peripheral Identification Register 3

The PMPIDR3 characteristics are:

**Purpose**

Provides information to identify a Performance Monitor component.

For more information see About the Peripheral identification scheme on page K2-7243.

**Configurations**

It is IMPLEMENTATION DEFINED whether PMPIDR3 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

**Attributes**

PMPIDR3 is a 32-bit register.

**Field descriptions**

The PMPIDR3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>8</td>
<td>REVAND</td>
</tr>
<tr>
<td>4</td>
<td>C MOD</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**REVAND, bits [7:4]**

Part minor revision. Parts using PMPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

**CMOD, bits [3:0]**

Customer modified. Indicates someone other than the Designer has modified the component.

**Accessing the PMPIDR3:**

PMPIDR3 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFEC</td>
<td>PMPIDR3</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.38 PMPIDR4, Performance Monitors Peripheral Identification Register 4

The PMPIDR4 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.
For more information see About the Peripheral identification scheme on page K2-7243.

Configurations

It is IMPLEMENTATION DEFINED whether PMPIDR4 is implemented in the Core power domain or in
the Debug power domain.
Implementation of this register is OPTIONAL.
This register is required for CoreSight compliance.

Attributes

PMPIDR4 is a 32-bit register.

Field descriptions

The PMPIDR4 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [31:8]</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
| SIZE, bits [7:4]| Size of the component. RAZ. Log2 of the number of 4KB pages from the start of the component to
|                 | the end of the component ID registers. |
| DES_2, bits [3:0]| Designer, JEP106 continuation code, least significant nibble. For Arm Limited, this field is 0b0100. |

Accessing the PMPIDR4:

PMPIDR4 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xFD0</td>
<td>PMPIDR4</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
- Otherwise access to this register returns an Error.
I5.3.39  **PMSWINC_EL0, Performance Monitors Software Increment register**

The PMSWINC_EL0 characteristics are:

**Purpose**

Increments a counter that is configured to count the Software increment event, event 0x0. For more information, see SW_INCR.

**Configurations**

External register PMSWINC_EL0[31:0] is architecturally mapped to AArch64 System register PMSWINC_EL0[31:0].

External register PMSWINC_EL0[31:0] is architecturally mapped to AArch32 System register PMSWINC[31:0].

PMSWINC_EL0 is in the Core power domain.

Implementation of this register is OPTIONAL.

If this register is implemented, use of it is deprecated.

If 1 is written to bit [n] from the external debug interface, it is CONSTRAINED UNPREDICTABLE whether or not a SW_INCR event is created for counter n. This is consistent with not implementing the register in the external debug interface.

**Attributes**

PMSWINC_EL0 is a 32-bit register.

**Field descriptions**

The PMSWINC_EL0 bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| RES0 |

**Bit [31]**

Reserved, RES0.

**P<\text{n}>, bit [n], for n = 0 to 30**

Event counter software increment bit for PMEVCNTR<\text{n}>_EL0.

If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are W1.

- **0b0**: No action. The write to this bit is ignored.
- **0b1**: It is CONSTRAINED UNPREDICTABLE whether a SW_INCR event is generated for event counter n.

**Accessing the PMSWINC_EL0:**

--- **Note** ---

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.
PMSWINC_EL0 can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0xCA0</td>
<td>PMSWINC_EL0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() access to this register is WI.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() access to this register is WO.
- Otherwise access to this register returns an Error.
**I5.3.40 PMVIDSR, VMID Sample Register**

The PMVIDSR characteristics are:

**Purpose**

Contains the sampled VMID value that is captured on reading PMPCSR[31:0].

**Configurations**

PMVIDSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

This register is present only from ARMv8.2. Otherwise, direct accesses to PMVIDSR are RES0.

 Implemented only when ARMv8.2-PCSample is implemented.

--- **Note** ---

Before Armv8.2, the PC Sample-based Profiling Extension can be implemented in the external debug register space, as indicated by the value of EDDEVID.PCSample.

---

If EL2 is not implemented, this register is RES0.

This register is introduced in ARMv8.2.

**Attributes**

PMVIDSR is a 32-bit register.

**Field descriptions**

The PMVIDSR bit assignments are:

`RES0` | `VMID`
--- | ---
0  | 31 16 15

**Bits [31:16]**

Reserved, RES0.

**VMID, bits [15:0]**

From **ARMv8.2**:

VMID sample. The VMID associated with the most recent PMPCSR sample.

- If EL2 is implemented and is using AArch64, then the VMID is held in VTTBR_EL2.VMID.
- If EL2 is implemented and is using AArch32, then the VMID is held in VTTBR.VMID.
- This field is set to an UNKNOWN value if any of the following apply:
  - PMPCSR.NS == 0.
  - PMPCSR.EL == 0b10.
  - PMPCSR.NS == 1, PMPCSR.EL == 0b00, EL2 is using AArch64, HCR_EL2.E2H == 1, and HCR_EL2.TGE == 1.
- If EL2 is not implemented, then this field is RES0.
- If 16-bit VMIDs are not supported, PMVIDSR.VMID[15:8] is RES0.
- If 16-bit VMIDs are supported, but VTTBRx.VMID[15:8] are not used, PMVIDSR.VMID[15:8] is set to RES0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

Accessing the PMVIDSR:

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN on page H7-6536

PMVIDSR can be accessed through the external debug interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMU</td>
<td>0x20C</td>
<td>PMVIDSR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() access to this register is RO.
- Otherwise access to this register returns an Error.
I5.4 External Activity Monitors Extension registers summary

The memory-mapped interface to the Activity Monitors Extension registers provides read-only access to:

- Read-only copies of the Activity Monitors Extension System registers, with the exception of AMUSERENR.
- An implementation identification register, AMIIDR.
- If they are implemented, the OPTIONAL Activity Monitors CoreSight and ID registers.

The locations of the registers are defined as offsets from a base address. The base address of the memory-mapped view must be aligned to a 4KB boundary, but is otherwise IMPLEMENTATION DEFINED. Activity Monitors external register views defines this memory map.

I5.4.1 Activity Monitors external register views

Table I5-2 shows the external view of the Activity Monitors registers. All implemented registers are RO. Offsets within the 4KB region not defined in this table are RAZ/WI.

Each entry in the Name column links to the register description in Activity Monitors external register descriptions on page I5-6816, and:

- If the System register? on page I5-6738 column of the table shows that the register is a System register, the memory-mapped interface provides a view of the System register described in:
  - Activity Monitors registers on page D12-3344, for the AArch64 System register.
  - Activity Monitors registers on page G8-6264, for the AArch32 System register.
- Otherwise, the register is accessible only using the external memory-mapped interface.

Table I5-2 Activity Monitors external register views

a. CoreSight interface registers, see *Management registers and CoreSight compliance* on page K2-7237.
I5.5 Activity Monitors external register descriptions

This section lists the external Activity Monitors registers.
### I5.5.1 AMCFGR, Activity Monitors Configuration Register

The AMCFGR characteristics are:

**Purpose**

Global configuration register for the activity monitors.

Provides information on supported features, the number of counter groups implemented, the total number of activity monitor event counters implemented, and the size of the counters. AMCFGR is applicable to both the architected and the auxiliary counter groups.

**Configurations**

External register AMCFGR[31:0] is architecturally mapped to AArch64 System register AMCFGR_EL0[31:0].

External register AMCFGR[31:0] is architecturally mapped to AArch32 System register AMCFGR[31:0].

The power domain of AMCFGR is IMPLEMENTATION DEFINED.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCFGR are RES0.

**Attributes**

AMCFGR is a 32-bit register.

**Field descriptions**

The AMCFGR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NCG</td>
<td>Defines the number of counter groups. Its number of implemented counter groups is defined as [AMCFGR.NCG + 1]. If the number of implemented auxiliary activity monitor event counters is zero, this field has a value of 0b0000. Otherwise, this field has a value of 0b0001.</td>
</tr>
<tr>
<td>RES0</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>RAZ</td>
<td>Reserved, RAZ.</td>
</tr>
<tr>
<td>SIZE</td>
<td>Defines the size of activity monitor event counters.</td>
</tr>
<tr>
<td>N</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>HDBG, bit 24</td>
<td>Halt-on-debug supported. In Armv8, this feature must be supported, and so this bit is 0b1. 0b0 AMCR.HDBG is RES0. 0b1 AMCR.HDBG is read/write.</td>
</tr>
<tr>
<td>Bits 23:14</td>
<td>Reserved, RAZ.</td>
</tr>
</tbody>
</table>

![AMCFGR Bit Assignments](image-url)
The size of the activity monitor event counters implemented by the Activity Monitors Extension is defined as \([\text{AMCFGR.SIZE} + 1]\).

In Armv8, the counters are 64-bit, and so this field is \(0b111111\).

--- Note ---
Software also uses this field to determine the spacing of counters in the memory-map. In Armv8, the counters are at doubleword-aligned addresses.

\(N, \text{bits } [7:0]\)
Defines the number of activity monitor event counters.

The total number of counters implemented in all groups by the Activity Monitors Extension is defined as \([\text{AMCFGR.N} + 1]\).

**Accessing the AMCFGR:**
AMCFGR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xE0</td>
<td>AMCFGR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
### I5.5.2 AMCGCR, Activity Monitors Counter Group Configuration Register

The AMCGCR characteristics are:

**Purpose**

Provides information on the number of activity monitor event counters implemented within each counter group.

**Configurations**

External register AMCGCR[31:0] is architecturally mapped to AArch64 System register AMCGCR_EL0[31:0].

External register AMCGCR[31:0] is architecturally mapped to AArch32 System register AMCGCR[31:0].

The power domain of AMCGCR is IMPLEMENTATION DEFINED.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCGCR are RES0.

**Attributes**

AMCGCR is a 32-bit register.

**Field descriptions**

The AMCGCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-16</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>15-8</td>
<td>Counter Group 1 Number of Counters. The number of counters in the auxiliary counter group. The permitted range of values is 0 to 16.</td>
</tr>
<tr>
<td>7-0</td>
<td>Counter Group 0 Number of Counters. The number of counters in the architected counter group. In AMUv1, the value of this field is 4.</td>
</tr>
</tbody>
</table>

**Accessing the AMCGCR:**

AMCGCR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xCE0</td>
<td>AMCGCR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.3 AMCIDR0, Activity Monitors Component Identification Register 0

The AMCIDR0 characteristics are:

Purpose

Provides information to identify an activity monitors component.

For more information, see About the Component Identification scheme on page K2-7245 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

The power domain of AMCIDR0 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCIDR0 are RES0.

Attributes

AMCIDR0 is a 32-bit register.

Field descriptions

The AMCIDR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>8</td>
<td>7</td>
</tr>
<tr>
<td>0</td>
<td>PRMBL_0</td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as 0x0D.

Accessing the AMCIDR0:

AMCIDR0 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xFFF0</td>
<td>AMCIDR0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.4 **AMCIDR1, Activity Monitors Component Identification Register 1**

The AMCIDR1 characteristics are:

**Purpose**

Provides information to identify an activity monitors component.

For more information, see *About the Component Identification scheme* on page K2-7245 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

**Configurations**

The power domain of AMCIDR1 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCIDR1 are RES0.

**Attributes**

AMCIDR1 is a 32-bit register.

**Field descriptions**

The AMCIDR1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [31:8]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>CLASS, bits [7:4]</td>
<td>Component class. Reads as 0x9, CoreSight component.</td>
</tr>
<tr>
<td>PRMBL_1, bits [3:0]</td>
<td>Preamble. Reads as 0x0.</td>
</tr>
</tbody>
</table>

**Accessing the AMCIDR1:**

AMCIDR1 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xFF4</td>
<td>AMCIDR1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.5 AMCIDR2, Activity Monitors Component Identification Register 2

The AMCIDR2 characteristics are:

Purpose

Provides information to identify an activity monitors component.

For more information, see About the Component Identification scheme on page K2-7245 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

The power domain of AMCIDR2 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCIDR2 are RES0.

Attributes

AMCIDR2 is a 32-bit register.

Field descriptions

The AMCIDR2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td>PRMBL_2</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Reads as 0x05.

Accessing the AMCIDR2:

AMCIDR2 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xFF8</td>
<td>AMCIDR2</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.6 AMCIDR3, Activity Monitors Component Identification Register 3

The AMCIDR3 characteristics are:

Purpose
Provides information to identify an activity monitors component.
For more information, see About the Component Identification scheme on page K2-7245 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations
The power domain of AMCIDR3 is IMPLEMENTATION DEFINED.
Implementation of this register is OPTIONAL.
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCIDR3 are RES0.

Attributes
AMCIDR3 is a 32-bit register.

Field descriptions
The AMCIDR3 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>PRMBL_3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]
Reserved, RES0.

PRMBL_3, bits [7:0]
Preamble. Reads as 0xB1.

Accessing the AMCIDR3:
AMCIDR3 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xFFC</td>
<td>AMCIDR3</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

• Access to this register is RO.
I5.5.7 AMCNTENCLR0, Activity Monitors Count Enable Clear Register 0

The AMCNTENCLR0 characteristics are:

**Purpose**

Disable control bits for the architected event counters, AMEVCNTR0<n>.

**Configurations**

External register AMCNTENCLR0[31:0] is architecturally mapped to AArch64 System register AMCNTENCLR0_EL0[31:0].

External register AMCNTENCLR0[31:0] is architecturally mapped to AArch32 System register AMCNTENCLR0[31:0].

The power domain of AMCNTENCLR0 is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR0 are RES0.

**Attributes**

AMCNTENCLR0 is a 32-bit register.

**Field descriptions**

The AMCNTENCLR0 bit assignments are:

<table>
<thead>
<tr>
<th>Field: P&lt;n&gt;, bit [n]</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
</table>

P<n>, bit [n], for n = 0 to 31

Activity monitor event counter disable bit for AMEVCNTR0<n>. Bits [31:N] are RAZ/WI. N is the value in AMCGCR.CG0NC.

Possible values of each bit are:

- **0b0**: When read, means that AMEVCNTR0<n> is disabled. When written, has no effect.
- **0b1**: When read, means that AMEVCNTR0<n> is enabled. When written, disables AMEVCNTR0<n>.

On a Cold reset, this field resets to 0.

**Accessing the AMCNTENCLR0**

AMCNTENCLR0 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xC20</td>
<td>AMCNTENSET0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.8 AMCNTENCLR1, Activity Monitors Count Enable Clear Register 1

The AMCNTENCLR1 characteristics are:

**Purpose**

Disable control bits for the auxiliary activity monitors event counters, AMEVCNTR1<n>.

**Configurations**

External register AMCNTENCLR1[31:0] is architecturally mapped to AArch64 System register AMCNTENCLR1_EL0[31:0].
External register AMCNTENCLR1[31:0] is architecturally mapped to AArch32 System register AMCNTENCLR1[31:0].

The power domain of AMCNTENCLR1 is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR1 are RES0.

**Attributes**

AMCNTENCLR1 is a 32-bit register.

**Field descriptions**

The AMCNTENCLR1 bit assignments are:

\[
\begin{array}{c|c}
31 & 0 \\
\hline
P<n>, \text{ bit } [n] & \\
\end{array}
\]

**P<n>, bit [n], for n = 0 to 31**

Activity monitor event counter disable bit for AMEVCNTR1<n>.

Bits [31:N] are RAZ/WI. N is the value in AMCGCR.CG1NC.

Possible values of each bit are:

- **0b0**: When read, means that AMEVCNTR1<n> is disabled. When written, has no effect.
- **0b1**: When read, means that AMEVCNTR1<n> is enabled. When written, disables AMEVCNTR1<n>.

On a Cold reset, this field resets to 0.

**Accessing the AMCNTENCLR1:**

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENCLR1 are CONSTRAINED UNPREDICTABLE, and accesses to the register behave as RAZ/WI.

--- **Note** ---

The number of auxiliary activity monitor event counters implemented is zero exactly when AMCFGR.NCG == 0b0000.

AMCNTENCLR1 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xC24</td>
<td>AMCNTENCLR1</td>
</tr>
</tbody>
</table>
This interface is accessible as follows:

- Access to this register is RO.
### I5.5.9 AMCNTENSET0, Activity Monitors Count Enable Set Register 0

The AMCNTENSET0 characteristics are:

**Purpose**

Enable control bits for the architected activity monitors event counters, AMEVCNTR0<\(n\)>.

**Configurations**

- External register AMCNTENSET0[31:0] is architecturally mapped to AArch64 System register AMCNTENSET0_EL0[31:0].
- External register AMCNTENSET0[31:0] is architecturally mapped to AArch32 System register AMCNTENSET0[31:0].

The power domain of AMCNTENSET0 is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENSET0 are RES0.

**Attributes**

AMCNTENSET0 is a 32-bit register.

**Field descriptions**

The AMCNTENSET0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>P&lt;(n)&gt;, bit [n]</td>
<td>Activity monitor event counter enable bit for AMEVCNTR0&lt;(n)&gt;</td>
</tr>
</tbody>
</table>

- Bits [31:N] are RAZ/WI. N is the value in AMCGCR.CG0NC.
- Possible values of each bit are:
  - 0b0: When read, means that AMEVCNTR0<\(n\)> is disabled. When written, has no effect.
  - 0b1: When read, means that AMEVCNTR0<\(n\)> is enabled. When written, enables AMEVCNTR0<\(n\)>.

On a Cold reset, this field resets to 0.

**Accessing the AMCNTENSET0:**

AMCNTENSET0 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xC0</td>
<td>AMCNTENSET0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.10 AMCNTENSET1, Activity Monitors Count Enable Set Register 1

The AMCNTENSET1 characteristics are:

**Purpose**
Enable control bits for the auxiliary activity monitors event counters, AMEVCNTR1<n>.

**Configurations**
- External register AMCNTENSET1[31:0] is architecturally mapped to AArch64 System register AMCNTENSET1_EL0[31:0].
- External register AMCNTENSET1[31:0] is architecturally mapped to AArch32 System register AMCNTENSET1[31:0].
- The power domain of AMCNTENSET1 is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.
- This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENSET1 are RES0.

**Attributes**
AMCNTENSET1 is a 32-bit register.

**Field descriptions**
The AMCNTENSET1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
</table>

P<n>, bit [n], for n = 0 to 31
- Activity monitor event counter enable bit for AMEVCNTR1<n>.
- Bits [31:N] are RAZ/WI. N is the value in AMCGCR.CG1NC.
- Possible values of each bit are:
  - 0b0: When read, means that AMEVCNTR1<n> is disabled. When written, has no effect.
  - 0b1: When read, means that AMEVCNTR1<n> is enabled. When written, enables AMEVCNTR1<n>.
- On a Cold reset, this field resets to 0.

**Accessing the AMCNTENSET1:**
If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENSET1 are CONSTRAINED UNPREDICTABLE, and accesses to the register behave as RAZ/WI.

**Note**
The number of auxiliary activity monitor counters implemented is zero exactly when AMCFGR.NCG == 0b0000.

AMCNTENSET1 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xC04</td>
<td>AMCNTENSET1</td>
</tr>
</tbody>
</table>
This interface is accessible as follows:

- Access to this register is RO.
I5.5.11 AMCR, Activity Monitors Control Register

The AMCR characteristics are:

**Purpose**

Global control register for the activity monitors implementation. AMCR is applicable to both the architected and the auxiliary counter groups.

**Configurations**

External register AMCR[31:0] is architecturally mapped to AArch64 System register AMCR_EL0[31:0].

External register AMCR[31:0] is architecturally mapped to AArch32 System register AMCR[31:0].

The power domain of AMCR is IMPLEMENTATION DEFINED.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCR are RES0.

**Attributes**

AMCR is a 32-bit register.

**Field descriptions**

The AMCR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RAZ/WI</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>HDBG</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:11]**

Reserved, RES0.

**HDBG, bit [10]**

This bit controls whether activity monitor counting is halted when the PE is halted in Debug state.

- **0b0** Activity monitors do not halt counting when the PE is halted in Debug state.
- **0b1** Activity monitors halt counting when the PE is halted in Debug state.

**Bits [9:0]**

Reserved, RAZ/WI.

**Accessing the AMCR:**

AMCR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xE04</td>
<td>AMCR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.12 AMDEVAFF0, Activity Monitors Device Affinity Register 0

The AMDEVAFF0 characteristics are:

**Purpose**

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the AMU component relates to.

**Configurations**

The power domain of AMDEVAFF0 is IMPLEMENTATION DEFINED. Implementation of this register is OPTIONAL. This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMDEVAFF0 are RES0.

**Attributes**

AMDEVAFF0 is a 32-bit register.

**Field descriptions**

The AMDEVAFF0 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>MPIDR_EL1 low half</td>
</tr>
</tbody>
</table>

**MPIDR_EL1 low half, bits [31:0]**

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

**Accessing the AMDEVAFF0:**

AMDEVAFF0 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xFA8</td>
<td>AMDEVAFF0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.13 AMDEVAFF1, Activity Monitors Device Affinity Register 1

The AMDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the AMU component relates to.

Configurations

The power domain of AMDEVAFF1 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMDEVAFF1 are RES0.

Attributes

AMDEVAFF1 is a 32-bit register.

Field descriptions

The AMDEVAFF1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>MPIDR_EL1 high half</td>
</tr>
</tbody>
</table>

MPIDR_EL1 high half, bits [31:0]

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the AMDEVAFF1:

AMDEVAFF1 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xFAC</td>
<td>AMDEVAFF1</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
### 5.5.14 AMDEVARCH, Activity Monitors Device Architecture Register

The AMDEVARCH characteristics are:

**Purpose**

Identifies the programmers’ model architecture of the AMU component.

**Configurations**

The power domain of AMDEVARCH is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMDEVARCH are RES0.

**Attributes**

AMDEVARCH is a 32-bit register.

**Field descriptions**

The AMDEVARCH bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>ARCHITECT</td>
</tr>
<tr>
<td>20</td>
<td>PRESENT</td>
</tr>
<tr>
<td>19</td>
<td>REVISION</td>
</tr>
<tr>
<td>15</td>
<td>ARCHID</td>
</tr>
</tbody>
</table>

**ARCHITECT, bits [31:21]**

Defines the architecture of the component. For AMU, this is Arm Limited.

- Bits [31:28] are the JEP106 continuation code, 0x4.
- Bits [27:21] are the JEP106 ID code, 0x3B.

**PRESENT, bit [20]**

When set to 1, indicates that the DEVARCH is present.

This field is 1 in Armv8.

**REVISION, bits [19:16]**

Defines the architecture revision. For architectures defined by Arm this is the minor revision.

- 0b0000: Architecture revision is AMUv1.
- All other values are reserved.

**ARCHID, bits [15:0]**

Defines this part to be an AMU component. For architectures defined by Arm this is further subdivided.

For AMU:

- Bits [15:12] are the architecture version, 0x0.
- Bits [11:0] are the architecture part number, 0xA66.

This corresponds to AMU architecture version AMUv1.
Accessing the AMDEVARCH:

AMDEVARCH can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xFBC</td>
<td>AMDEVARCH</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.15 AMDEVTYPE, Activity Monitors Device Type Register

The AMDEVTYPE characteristics are:

**Purpose**

Indicates to a debugger that this component is part of a PE's performance monitor interface.

**Configurations**

The power domain of AMDEVTYPE is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMDEVTYPE are RES0.

**Attributes**

AMDEVTYPE is a 32-bit register.

**Field descriptions**

The AMDEVTYPE bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>7-4</td>
<td>Subtype. Reads as 0x1, to indicate this is a component within a PE.</td>
</tr>
<tr>
<td>3-0</td>
<td>Major type. Reads as 0x6, to indicate this is a performance monitor component.</td>
</tr>
</tbody>
</table>

**Accessing the AMDEVTYPE:**

AMDEVTYPE can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xFCC</td>
<td>AMDEVTYPE</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.16 AMEVCNTR0<n>, Activity Monitors Event Counter Registers 0, n = 0 - 15

The AMEVCNTR0<n> characteristics are:

**Purpose**

Provides access to the architected activity monitor event counters.

**Configurations**

External register AMEVCNTR0<n>[63:0] is architecturally mapped to AArch64 System register AMEVCNTR0<n>_EL0[63:0].

External register AMEVCNTR0<n>[63:0] is architecturally mapped to AArch32 System register AMEVCNTR0<n>[63:0].

The power domain of AMEVCNTR0<n> is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVCNTR0<n> are RES0.

**Attributes**

AMEVCNTR0<n> is a 64-bit register.

**Field descriptions**

The AMEVCNTR0<n> bit assignments are:

### ACNT, bits [63:0]

Architected activity monitor event counter n.

Value of architected activity monitor event counter n, where n is the number of this register and is a number from 0 to 15.

If the counter is enabled, writes to this register have UNPREDICTABLE results.

On a Cold reset, this field resets to 0.

**Accessing the AMEVCNTR0<n>**

If <n> is greater than or equal to the number of architected activity monitor event counters, reads and writes of AMEVCNTR0<n> are CONSTRAINED UNPREDICTABLE, and accesses to the register behave as RAZ/WI.

**Note**

AMEVCNTR0<n>[31:0] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0x000 + 8n</td>
<td>AMEVCNTR0&lt;n&gt;</td>
<td>31:0</td>
</tr>
</tbody>
</table>
AMEVCNTR0\(n\)[63:32] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0x004 + 8n</td>
<td>AMEVCNTR0(n)</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- Access to AMEVCNTR0\(n\)[31:0] is RO.
- Access to AMEVCNTR0\(n\)[63:32] is RO.
I5.5.17 AMEVCNTR1\(<n>\), Activity Monitors Event Counter Registers 1, \(n = 0 - 15\)

The AMEVCNTR1\(<n>\) characteristics are:

**Purpose**

Provides access to the auxiliary activity monitor event counters.

**Configurations**

External register AMEVCNTR1\(<n>\)[63:0] is architecturally mapped to AArch64 System register AMEVCNTR1\(<n>_EL0[63:0]\).

External register AMEVCNTR1\(<n>_EL0[63:0]\) is architecturally mapped to AArch32 System register AMEVCNTR1\(<n>_EL0[63:0]\).

The power domain of AMEVCNTR1\(<n>_EL0[63:0]\) is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVCNTR1\(<n>_EL0[63:0]\) are RES0.

**Attributes**

AMEVCNTR1\(<n>\) is a 64-bit register.

**Field descriptions**

The AMEVCNTR1\(<n>\) bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 (\ldots) 0</td>
<td>ACNT</td>
</tr>
</tbody>
</table>

ACNT, bits [63:0]

Auxiliary activity monitor event counter \(n\).

Value of auxiliary activity monitor event counter \(n\), where \(n\) is the number of this register and is a number from 0 to 15.

If the counter is enabled, writes to this register have UNPREDICTABLE results.

On a Cold reset, this field resets to 0.

**Accessing the AMEVCNTR1\(<n>:**

If \(<n>\) is greater than or equal to the number of auxiliary activity monitor event counters, reads and writes of AMEVCNTR1\(<n>\) are CONSTRAINED UNPREDICTABLE, and accesses to the register behave as RAZ/WI.

---

**Note**

AMEVCNTR1\(<n>\)[31:0] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0x100 + 8n</td>
<td>AMEVCNTR1(&lt;n&gt;_EL0[31:0])</td>
<td>31:0</td>
</tr>
</tbody>
</table>
AMEVCNTR1<n>[63:32] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0x104 + 8n</td>
<td>AMEVCNTR1&lt;n&gt;</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- Access to AMEVCNTR1<n>[31:0] is RO.
- Access to AMEVCNTR1<n>[63:32] is RO.
AMEVTYPE0<n>, Activity Monitors Event Type Registers 0, n = 0 - 15

The AMEVTYPE0<n> characteristics are:

**Purpose**
Provides information on the events that an architected activity monitor event counter AMEVCNTR0<n> counts.

**Configurations**
- External register AMEVTYPE0<n>[31:0] is architecturally mapped to AArch64 System register AMEVTYPE0<n>_EL0[31:0].
- External register AMEVTYPE0<n>[31:0] is architecturally mapped to AArch32 System register AMEVTYPE0<n>[31:0].
- The power domain of AMEVTYPE0<n> is IMPLEMENTATION DEFINED.
- This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVTYPE0<n> are RES0.

**Attributes**
AMEVTYPE0<n> is a 32-bit register.

**Field descriptions**
The AMEVTYPE0<n> bit assignments are:

<table>
<thead>
<tr>
<th>31 25 24 16 15 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAZ</td>
</tr>
</tbody>
</table>

**Bits [31:25]**
Reserved, RAZ.

**Bits [24:16]**
Reserved, RES0.

**evtCount, bits [15:0]**
Event to count. The event number of the event that is counted by the architected activity monitor event counter AMEVCNTR0<n>. The value of this field is architecturally mandated for each architected counter.

The following table shows the mapping between required event numbers and the corresponding counters:

- 0x0011 When n == 0 Processor frequency cycles
- 0x4004 When n == 1 Constant frequency cycles
- 0x0008 When n == 2 Instructions retired
- 0x4005 When n == 3 Memory stall cycles

**Accessing the AMEVTYPE0<n>:**
If <n> is greater than or equal to the number of architected activity monitor event counters, reads and writes of AMEVTYPE0<n> are CONSTRAINED UNPREDICTABLE, and accesses to the register behave as RAZ/WI.

---

**Note**
AMCGCR.CG0NC identifies the number of architected activity monitor event counters.
AMEVTYPER0<\text{n}> can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0x400 + 4n</td>
<td>AMEVTYPER0&lt;\text{n}&gt;</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.19 AMEVTYPE1<\textit{n}>, Activity Monitors Event Type Registers 1, \textit{n} = 0 - 15

The AMEVTYPE1<\textit{n}> characteristics are:

**Purpose**

Provides information on the events that an auxiliary activity monitor event counter AMEVCNTR1<\textit{n}> counts.

**Configurations**

External register AMEVTYPE1<\textit{n}>[31:0] is architecturally mapped to AArch64 System register AMEVTYPE1<\textit{n}>_EL0[31:0].

External register AMEVTYPE1<\textit{n}>[31:0] is architecturally mapped to AArch32 System register AMEVTYPE1<\textit{n}>[31:0].

The power domain of AMEVTYPE1<\textit{n}> is IMPLEMENTATION DEFINED.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVTYPE1<\textit{n}> are RES0.

**Attributes**

AMEVTYPER1<\textit{n}> is a 32-bit register.

**Field descriptions**

The AMEVTYPE1<\textit{n}> bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>25 24</th>
<th>16 15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAZ</td>
<td>RES0</td>
<td>evtCount</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:25]**

Reserved, RAZ.

**Bits [24:16]**

Reserved, RES0.

**evtCount, bits [15:0]**

Event to count. The event number of the event that is counted by the auxiliary activity monitor event counter AMEVCNTR1<\textit{n}>.

It is IMPLEMENTATION DEFINED what values are supported by each counter.

If software writes a value to this field which is not supported by the corresponding counter AMEVCNTR1<\textit{n}>, then:

- It is UNPREDICTABLE which event will be counted.
- The value read back is UNKNOWN.

**Note**

The event counted by AMEVCNTR1<\textit{n}> might be fixed at implementation. In this case, the field is read-only and writes are UNDEFINED.

If the corresponding counter AMEVCNTR1<\textit{n}> is enabled, writes to this register have UNPREDICTABLE results.

**Accessing the AMEVTYPE1<\textit{n}>:**

If \textit{n} is greater than or equal to the number of auxiliary activity monitor event counters, reads and writes of AMEVTYPE1<\textit{n}> are CONSTRAINED UNPREDICTABLE, and accesses to the register behave as RAZ/WI.
— Note —

AMCGCR.CG1NC identifies the number of auxiliary activity monitor event counters.

AMEVTYPER1<n> can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0x480 + 4n</td>
<td>AMEVTYPER1&lt;n&gt;</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.20 AMIIDR, Activity Monitors Implementation Identification Register

The AMIIDR characteristics are:

**Purpose**

Defines the implementer and revisions of the AMU.

**Configurations**

The power domain of AMIIDR is IMPLEMENTATION DEFINED.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMIIDR are RES0.

**Attributes**

AMIIDR is a 32-bit register.

**Field descriptions**

The AMIIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ProductID</td>
<td>Variant</td>
<td>Revision</td>
<td>Implementer</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ProductID, bits [31:20]**

This field is an AMU part identifier.

The value of this field is IMPLEMENTATION DEFINED.

If AMPIDR0 is implemented, AMPIDR0.PART_0 matches bits [27:20] of this field.

If AMPIDR1 is implemented, AMPIDR1.PART_1 matches bits [31:28] of this field.

**Variant, bits [19:16]**

This field distinguishes product variants or major revisions of the product.

The value of this field is IMPLEMENTATION DEFINED.

If AMPIDR2 is implemented, AMPIDR2.REVISION matches AMIIDR.Variant.

**Revision, bits [15:12]**

This field distinguishes minor revisions of the product.

The value of this field is IMPLEMENTATION DEFINED.

If AMPIDR3 is implemented, AMPIDR3.REVAND matches AMIIDR.Revision.

**Implementer, bits [11:0]**

Contains the JEP106 code of the company that implemented the AMU.

For an Arm implementation, this field reads as 0x43B.

Bits [11:8] contain the JEP106 continuation code of the implementer.

Bit 7 is RES0

Bits [6:0] contain the JEP106 identity code of the implementer.

If AMPIDR4 is implemented, AMPIDR4.DES_2 matches bits [11:8] of this field.

If AMPIDR2 is implemented, AMPIDR2.DES_1 matches bits [6:4] of this field.

If AMPIDR1 is implemented, AMPIDR1.DES_0 matches bits [3:0] of this field.
Accessing the AMIIDR:

AMIIDR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xE08</td>
<td>AMIIDR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.21 AMPIDR0, Activity Monitors Peripheral Identification Register 0

The AMPIDR0 characteristics are:

**Purpose**

Provides information to identify an activity monitors component.

For more information, see *About the Peripheral identification scheme on page K2-7243* in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

**Configurations**

The power domain of AMPIDR0 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMPIDR0 are RES0.

**Attributes**

AMPIDR0 is a 32-bit register.

**Field descriptions**

The AMPIDR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>8</td>
<td>PART_0, Part number, least significant byte. The value of this field is IMPLEMENTATION DEFINED.</td>
</tr>
</tbody>
</table>

**Accessing the AMPIDR0:**

AMPIDR0 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xFE0</td>
<td>AMPIDR0</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.22  AMPIDR1, Activity Monitors Peripheral Identification Register 1

The AMPIDR1 characteristics are:

**Purpose**

Provides information to identify an activity monitors component.

For more information, see *About the Peripheral identification scheme* on page K2-7243 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

**Configurations**

The power domain of AMPIDR1 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMPIDR1 are RES0.

**Attributes**

AMPIDR1 is a 32-bit register.

**Field descriptions**

The AMPIDR1 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>Reserved, RES0</td>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.23 AMPIDR2, Activity Monitors Peripheral Identification Register 2

The AMPIDR2 characteristics are:

**Purpose**

Provides information to identify an activity monitors component.

For more information, see About the Peripheral identification scheme on page K2-7243 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

**Configurations**

The power domain of AMPIDR2 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMPIDR2 are RES0.

**Attributes**

AMPIDR2 is a 32-bit register.

**Field descriptions**

The AMPIDR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>8-7</td>
<td>Revision</td>
</tr>
<tr>

</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xFE8</td>
<td>AMPIDR2</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.24 AMPIDR3, Activity Monitors Peripheral Identification Register 3

The AMPIDR3 characteristics are:

**Purpose**

Provides information to identify an activity monitors component.

For more information, see *About the Peripheral identification scheme* on page K2-7243 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

**Configurations**

The power domain of AMPIDR3 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMPIDR3 are RES0.

**Attributes**

AMPIDR3 is a 32-bit register.

**Field descriptions**

The AMPIDR3 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>REVAND</td>
<td>CMOD</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**REVAND, bits [7:4]**

Part minor revision. Parts using AMPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

The value of this field is IMPLEMENTATION DEFINED.

**CMOD, bits [3:0]**

Customer modified. Indicates someone other than the Designer has modified the component.

The value of this field is IMPLEMENTATION DEFINED.

**Accessing the AMPIDR3:**

AMPIDR3 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xEFEC</td>
<td>AMPIDR3</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.5.25 AMPIDR4, Activity Monitors Peripheral Identification Register 4

The AMPIDR4 characteristics are:

**Purpose**

Provides information to identify an activity monitors component.

For more information, see About the Peripheral identification scheme on page K2-7243 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

**Configurations**

The power domain of AMPIDR4 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMPIDR4 are RES0.

**Attributes**

AMPIDR4 is a 32-bit register.

**Field descriptions**

The AMPIDR4 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
<td>0</td>
</tr>
<tr>
<td>8</td>
<td>SIZE</td>
<td>0</td>
</tr>
<tr>
<td>4</td>
<td>DES_2</td>
<td>0</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**SIZE, bits [7:4]**

Size of the component. Log₂ of the number of 4KB pages from the start of the component to the end of the component ID registers.

This field reads as 0b0000.

**DES_2, bits [3:0]**

Designer. JEP106 continuation code, least significant nibble.

The value of this field is IMPLEMENTATION DEFINED. For Arm Limited, this field is 0b0100.

**Accessing the AMPIDR4:**

AMPIDR4 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMU</td>
<td>0xFD0</td>
<td>AMPIDR4</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.6 Generic Timer memory-mapped registers overview

The Generic Timer memory-mapped registers are implemented as multiple register frames, with each register frame having its own base address, as follows:

- A single CNTCTLBase register frame, at base address CNTCTLBase.
- Between one and seven CNTBaseN register frames, each with its own base address CNTBaseN.
- For each CNTBaseN register frame, if required, a CNTEL0BaseN register frame, at base address CNTEL0BaseN, that provides an EL0 view of the CNTBaseN register frame.

For more information, see:

- Memory-mapped timer components on page I2-6722.
- The CNTBaseN and CNTEL0BaseN frames on page I2-6724. This section includes the memory map of the CNTBaseN and CNTBaseN register frames.
- The CNTCTLBase frame on page I2-6723. This section includes the memory map of the CNTCTLBase register frame.

Note

Providing a complete set of features in a system level implementation on page K5-7268 gives an implementation example for a system level implementation of the Generic Timer.
I5.7 Generic Timer memory-mapped register descriptions

This section describes the Generic Timer registers. *Generic Timer memory-mapped registers overview on page I5-6851* gives an overview of these registers, and includes links to their memory maps.
I5.7.1 CNTACR<n>, Counter-timer Access Control Registers, n = 0 - 7

The CNTACR<n> characteristics are:

Purpose

Provides top-level access controls for the elements of a timer frame. CNTACR<n> provides the controls for frame CNTBaseN.

In addition to the CNTACR<n> control:
- CNTNSAR controls whether CNTACR<n> is accessible by Non-secure accesses.
- If frame CNTEL0BaseN is implemented, the CNTEL0ACR in frame CNTBaseN provides additional control of accesses to frame CNTEL0BaseN.

Configurations

The power domain of CNTACR<n> is IMPLEMENTATION DEFINED. On a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see Power and reset domains for the system level implementation of the Generic Timer on page I2-6717. Implemented only if the value of CNTTIDR.Frame<n> is 1. An implementation of the counters might not provide configurable access to some or all of the features. In this case, the associated field in the CNTACR<n> register is:
- RAZ/WI if access is always denied.
- RAO/WI if access is always permitted.

Attributes

CNTACR<n> is a 32-bit register.

Field descriptions

The CNTACR<n> bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>6</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>5</td>
<td>RWPT, bit [5]</td>
</tr>
<tr>
<td>4</td>
<td>Reserved.</td>
</tr>
<tr>
<td>3</td>
<td>Reserved.</td>
</tr>
<tr>
<td>2</td>
<td>Reserved.</td>
</tr>
<tr>
<td>1</td>
<td>Reserved.</td>
</tr>
<tr>
<td>0</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

Bits [31:6]

Reserved, RES0.

RWPT, bit [5]

Read/write access to the EL1 Physical Timer registers CNTP_CVAL, CNTP_TVAL, and CNTP_CTL, in frame <n>. The possible values of this bit are:
- 0: No access to the EL1 Physical Timer registers in frame <n>. The registers are RES0.
- 1: Read/write access to the EL1 Physical Timer registers in frame <n>.

This field resets to an architecturally UNKNOWN value.
### RWVT, bit [4]
Read/write access to the Virtual Timer register CNTV_CVAL, CNTV_TVAL, and CNTV_CTL, in frame `<n>`. The possible values of this bit are:
- **0b0**: No access to the Virtual Timer registers in frame `<n>`. The registers are RES0.
- **0b1**: Read/write access to the Virtual Timer registers in frame `<n>.
This field resets to an architecturally UNKNOWN value.

### RVOFF, bit [3]
Read-only access to CNTVOFF<`n`>, in frame `<n>`. The possible values of this bit are:
- **0b0**: No access to CNTVOFF<`n`> in frame `<n>`. The register is RES0.
- **0b1**: Read-only access to CNTVOFF<`n`> in frame `<n>.
This field resets to an architecturally UNKNOWN value.

### RFRQ, bit [2]
Read-only access to CNTFRQ, in frame `<n>`. The possible values of this bit are:
- **0b0**: No access to CNTFRQ in frame `<n>`. The register is RES0.
- **0b1**: Read-only access to CNTFRQ in frame `<n>.
This field resets to an architecturally UNKNOWN value.

### RVCT, bit [1]
Read-only access to CNTVCT, in frame `<n>`. The possible values of this bit are:
- **0b0**: No access to CNTVCT in frame `<n>`. The register is RES0.
- **0b1**: Read-only access to CNTVCT in frame `<n>.
This field resets to an architecturally UNKNOWN value.

### RPCT, bit [0]
Read-only access to CNTPCT, in frame `<n>`. The possible values of this bit are:
- **0b0**: No access to CNTPCT in frame `<n>`. The register is RES0.
- **0b1**: Read-only access to CNTPCT in frame `<n>.
This field resets to an architecturally UNKNOWN value.

### Accessing the CNTACR<`n`>:
In a system that recognizes two Security states:
- **CNTACR<`n`>** is always accessible by Secure accesses.
- **CNTNSAR.NS<`n`>** determines whether CNTACR<`n`> is accessible by Non-secure accesses.

CNTACR<`n`> can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTCTLBase</td>
<td>0x040 + 4<code>n</code></td>
<td>CNTACR&lt;<code>n</code>&gt;</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:
- Access to this register is RW.
I5.7.2 CNTCR, Counter Control Register

The CNTCR characteristics are:

Purpose

Enables the counter, controls the counter frequency setting, and controls counter behavior during debug.

Configurations

The power domain of CNTCR is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

Attributes

CNTCR is a 32-bit register.

Field descriptions

The CNTCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:18]</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>[17:8]</td>
<td>FREQ, bits</td>
</tr>
<tr>
<td>[7:3]</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>[2]</td>
<td>SCEN, bit</td>
</tr>
</tbody>
</table>

Bits [31:18]

Reserved, RES0.

FCREQ, bits [17:8]

Frequency change request. Indicates the number of the entry in the Frequency modes table to select. Selecting an unimplemented entry, or an entry that contains 0, has no effect on the counter.

The maximum number of entries in the Frequency modes table is IMPLEMENTATION DEFINED up to a maximum of 1004 entries, see The Frequency modes table on page I2-6719. An implementation is only required to implement an FCREQ field that can hold values from 0 to the highest supported Frequency modes table entry. Any unrequired most-significant bits of FCREQ can be implemented as RES0.

This field resets to 0.

Bits [7:3]

Reserved, RES0.

SCEN, bit [2]

When ARMv8.4-CNTSC is implemented:

Scale Enable.

000 Scaling is not enabled. The counter value is incremented by 0x1.0000000 for each counter tick.

01 Scaling is enabled. The counter is incremented by CNTSCR.ScaleVal for each counter tick.

The SCEN bit can only be changed when the counter is disabled, when CNTCR.EN == 0.
If the value of CNTCR.SCEN changes when CNTCR.EN == 1 then:
- The counter value becomes UNKNOWN.
- The counter value remains UNKNOWN on future ticks of the clock.

When the CNTCV register in the CNTControlBase frame of the memory mapped counter module is written to, the accumulated fraction information is reset to zero.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HDBG, bit [1]
Halt-on-debug. Controls whether a Halt-on-debug signal halts the system counter:
- 0b0: System counter ignores Halt-on-debug.
- 0b1: Asserted Halt-on-debug signal halts system counter update.
This field resets to an architecturally UNKNOWN value.

EN, bit [0]
Enables the counter:
- 0b0: System counter disabled.
- 0b1: System counter enabled.
This field resets to 0.

Accessing the CNTCR:

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

CNTCR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTControlBase</td>
<td>0x000</td>
<td>CNTCR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:
- Access to this register is RW.
I5.7.3 CNTCV, Counter Count Value register

The CNTCV characteristics are:

**Purpose**
Indicates the current count value.

**Configurations**
The power domain of CNTCV is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-6717.

**Attributes**
CNTCV is a 64-bit register.

**Field descriptions**
The CNTCV bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CountValue</td>
<td></td>
</tr>
</tbody>
</table>

**CountValue, bits [63:0]**
Indicates the counter value.
This field resets to an architecturally UNKNOWN value.

**Accessing the CNTCV:**

<table>
<thead>
<tr>
<th>Frame</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>CNTControlBase</td>
<td>RW</td>
</tr>
<tr>
<td>CNTReadBase</td>
<td>RO</td>
</tr>
</tbody>
</table>

A write to CNTCV must be visible in the CNTPCT register of each running processor in a finite time.

For the instance of the register in the CNTControlBase frame:

- In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, and therefore this register instance, is implemented only in the Secure memory map.
- If the counter is enabled, the effect of writing to the register is UNKNOWN.

In an implementation that supports 64-bit atomic memory accesses, this register must be accessible using a 64-bit atomic access.

CNTCV[63:0] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTControlBase</td>
<td>0x008</td>
<td>CNTCV</td>
<td>63:0</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTReadBase</td>
<td>0x000</td>
<td>CNTCV</td>
<td>63:0</td>
</tr>
</tbody>
</table>
These interfaces are accessible as follows:

- Access to CNTCV[63:0] is RW.
- Access to CNTCV[63:0] is RO.
I5.7.4 CNTEL0ACR, Counter-timer EL0 Access Control Register

The CNTEL0ACR characteristics are:

**Purpose**

An implementation of CNTEL0ACR in the frame at CNTBaseN controls whether the CNTPCT, CNTVCT, CNTFRQ, EL1 Physical Timer, and Virtual Timer registers are visible in the frame at CNTEL0BaseN.

**Configurations**

The power domain of CNTEL0ACR is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-6717.

Implementation of this register is OPTIONAL.

**Attributes**

CNTEL0ACR is a 32-bit register.

**Field descriptions**

The CNTEL0ACR bit assignments are:

![Bit assignments diagram]

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-10</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>9</td>
<td>EL0PTEN, bit [9]</td>
</tr>
<tr>
<td>8</td>
<td>EL0VTEN, bit [8]</td>
</tr>
</tbody>
</table>

**Bits [31:10]**

Reserved, RES0.

**EL0PTEN, bit [9]**

Second view read/write access control for the EL1 Physical Timer registers. This bit controls whether the CNTP_CV, CNTP_TV, and CNTP_CTL registers in the current CNTBaseN frame are also accessible in the corresponding CNTEL0BaseN frame. The possible values of this bit are:

0b0 No access. Registers are RES0 in the second view.

0b1 Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

This field resets to an architecturally UNKNOWN value.

**EL0VTEN, bit [8]**

Second view read/write access control for the Virtual Timer registers. This bit controls whether the CNTV_CV, CNTV_TV, and CNTV_CTL registers in the current CNTBaseN frame are also accessible in the corresponding CNTEL0BaseN frame. The possible values of this bit are:

0b0 No access. Registers are RES0 in the second view.

0b1 Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.
The definition of this bit means that, if the Virtual Timer registers are not implemented in the current CNTBaseN frame, then the Virtual Timer register addresses are RES0 in the corresponding CNTEL0FrameN frame, regardless of the value of this bit.

This field resets to an architecturally UNKNOWN value.

**Bits [7:2]**

Reserved, RES0.

**EL0VCTEN, bit [1]**

Second view read access control for CNTVCT and CNTFRQ. The possible values of this bit are:

0b0  
  CNTVCT is not visible in the second view.
  If EL0PCTEN is set to 0, CNTFRQ is not visible in the second view.

0b1  
  Access permitted. If CNTVCT and CNTFRQ are visible in the current frame then they are visible in the second view.

This field resets to an architecturally UNKNOWN value.

**EL0PCTEN, bit [0]**

Second view read access control for CNTPCT and CNTFRQ. The possible values of this bit are:

0b0  
  CNTPCT is not visible in the second view.
  If EL0VCTEN is set to 0, CNTFRQ is not visible in the second view.

0b1  
  Access permitted. If CNTPCT and CNTFRQ are visible in the current frame then they are visible in the second view.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTEL0ACR:**

CNTEL0ACR can be implemented in any implemented CNTBaseN frame.

*CNTCTRLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page 12-6725* describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

If CNTEL0ACR is not implemented in an implemented CNTBaseN frame:

- The register location in that frame is RAZ/WI.
- If the corresponding CNTEL0BaseN frame is implemented, the registers CNTFRQ, CNTP_CTL, CNTP_CVAL, CNTP_TVAL, CNTPCT, CNTV_CTL, CNTV_CVAL, CNTV_TVAL, and CNTVCT are not visible in that frame.

CNTEL0ACR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x814</td>
<td>CNTEL0ACR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RW.
I5.7.5 CNTFID0, Counter Frequency ID

The CNTFID0 characteristics are:

**Purpose**

Indicates the base frequency of the system counter.

**Configurations**

The power domain of CNTFID0 is IMPLEMENTATION DEFINED.

If this register is implemented as an RW register, on a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page 12-6717.

The possible frequencies for the system counter are stored in the Frequency modes table as 32-bit words starting with the base frequency, CNTFID0. For more information see *The Frequency modes table* on page 12-6719.

The final entry in the Frequency modes table must be followed by a 32-bit word of zero value, to mark the end of the table.

Typically, the Frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialize the table entries as part of its start-up sequence.

If the Frequency modes table is in read/write memory, Arm strongly recommends that the table is not updated once the system is running.

**Attributes**

CNTFID0 is a 32-bit register.

**Field descriptions**

The CNTFID0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Frequency</td>
<td></td>
</tr>
</tbody>
</table>

**Frequency, bits [31:0]**

The base frequency of the system counter, in Hz.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTFID0:**

It is IMPLEMENTATION DEFINED whether this register is RO or RW

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

CNTFID0 can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTControlBase</td>
<td>0x020</td>
<td>CNTFID0</td>
</tr>
</tbody>
</table>
This interface is accessible as follows:

- Access to this register is RO or RW.
### CNTFID\(<n>\), Counter Frequency IDs, \(n > 0\)

The CNTFID\(<n>\) characteristics are:

#### Purpose

Indicates alternative system counter update frequencies.

#### Configurations

The power domain of CNTFID\(<n>\) is IMPLEMENTATION DEFINED.

If this register is implemented as an RW register, on a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see Power and reset domains for the system level implementation of the Generic Timer on page I1-6717.

The possible frequencies for the system counter are stored in the Frequency modes table as 32-bit words starting with the base frequency, CNTFID0, see The Frequency modes table on page I2-6719.

The number of CNTFID\(<n>\) registers is IMPLEMENTATION DEFINED, and the only required CNTFID\(<n>\) register is CNTFID0.

The final entry in the Frequency modes table must be followed by a 32-bit word of zero value, to mark the end of the table.

Typically, the Frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialize the table entries as part of its start-up sequence.

If the Frequency modes table is in read/write memory, Arm strongly recommends that the table is not updated once the system is running.

#### Attributes

CNTFID\(<n>\) is a 32-bit register.

#### Field descriptions

The CNTFID\(<n>\) bit assignments are:

#### Frequency, bits [31:0]

A system counter update frequency, in Hz. Must be an exact divisor of the base frequency. Arm strongly recommends that all frequency values in the Frequency modes table are integer power-of-two divisors of the base frequency.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

\[
\text{increment} = \frac{\text{base frequency}}{\text{selected frequency}}
\]

This field resets to an architecturally UNKNOWN value.

#### Accessing the CNTFID\(<n>\):

It is IMPLEMENTATION DEFINED whether this register is RO or RW

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes these registers, is implemented only in the Secure memory map.
CNTFID<\text{n}> can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>

</tr>
</tbody>
</table>
### 5.7.7 CNTFRQ, Counter-timer Frequency

The CNTFRQ characteristics are:

**Purpose**

This register is provided so that software can discover the frequency of the system counter. The instance of the register in the CNTCTLB frame must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

**Configurations**

The power domain of CNTFRQ is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-6717.

**Attributes**

CNTFRQ is a 32-bit register.

**Field descriptions**

The CNTFRQ bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clock frequency</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

- Clock frequency. Indicates the system counter clock frequency, in Hz.
- This field resets to an architecturally UNKNOWN value.

**Accessing the CNTFRQ:**

CNTFRQ must be implemented as an RW register in the CNTCTLB frame.

In a system that recognizes two Security states, the instance of the register in the CNTCTLB frame is only accessible by Secure accesses.

CNTFRQ can be implemented as a RO register in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

*CNTCTLB status and control fields for the CNTBaseN and CNTEL0BaseN frames* on page I2-6725 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTFRQ is accessible in that frame, as a RO register, if the value of CNTACR<ref>.RFRQ is 1.
- Otherwise, the CNTFRQ address in that frame is RAZ/WI.
For an implemented CNTEL0BaseN frame:

- CNTFRQ is accessible as a RO register in that frame if both:
  
  - CNTFRQ is accessible in the corresponding CNTBaseN frame.
  
  - Either the value of CNTEL0ACR.EL0VCTEN is 1 or the value of CNTEL0ACR.EL0PCTEN is 1.

- Otherwise, the CNTFRQ address in that frame is RAZ/WI.

CNTFRQ can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x010</td>
<td>CNTFRQ</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x010</td>
<td>CNTFRQ</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTCTLBase</td>
<td>0x000</td>
<td>CNTFRQ</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- Access to CNTFRQ[:] is RO.

- Access to CNTFRQ[:] is RO.

- Access to CNTFRQ[:] is RO.
I5.7.8 CNTID, Counter Identification Register

The CNTID characteristics are:

**Purpose**
Indicates whether counter scaling is implemented.

**Configurations**
The power domain of CNTID is IMPLEMENTATION DEFINED.
This register is present only when ARMv8.4-CNTSC is implemented. Otherwise, direct accesses to CNTID are RES0.

**Attributes**
CNTID is a 32-bit register.

**Field descriptions**
The CNTID bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:4</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>3:0</td>
<td>CNTSC</td>
</tr>
</tbody>
</table>

**CNTSC, bits [3:0]**
Indicates whether Counter Scaling is implemented
- 0b0000 Counter scaling is not implemented.
- 0b0001 Counter scaling is implemented.
All other values are reserved.

**Accessing the CNTID:**
In a system that supports Secure and Non-secure memory maps, the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.
CNTID can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTControlBase</td>
<td>0x1C</td>
<td>CNTID</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:
- Access to this register is RO.
### I5.7.9 CNTNSAR, Counter-timer Non-secure Access Register

The CNTNSAR characteristics are:

**Purpose**

Provides the highest-level control of whether frames CNTBaseN and CNTEL0BaseN are accessible by Non-secure accesses.

**Configurations**

The power domain of CNTNSAR is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I5-6717.

**Attributes**

CNTNSAR is a 32-bit register.

**Field descriptions**

The CNTNSAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>8...0</td>
<td>NS0, NS1, NS2, NS3, NS4, NS5, NS6, NS7</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**NS<\(n\)> bit [n], for \(n = 0\) to \(7\)**

Non-secure access to frame \(n\). The possible values of this bit are:

- 0b0 Secure access only. Behaves as RES0 to Non-secure accesses.
- 0b1 Secure and Non-secure accesses permitted.

This bit also determines whether, in the CNTCTLBase frame, CNTACR<\(n\)> and CNTVOFF<\(n\)> are accessible to Non-secure accesses.

If frame CNTBase<\(n\)>:

- Is not implemented, then NS<\(n\)> is RES0.
- Is not Configurable access, and is accessible only by Secure accesses, then NS<\(n\)> is RES0.
- Is not Configurable access, and is accessible by both Secure and Non-secure accesses, then NS<\(n\)> is RES1.

This field resets to an architecturally UNKNOWN value.
Accessing the CNTNSAR:

In a system that recognizes two Security states, this register is only accessible by Secure accesses.

CNTNSAR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTCTLBase</td>
<td>0x004</td>
<td>CNTNSAR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RW.
I5.7.10   CNTP_CTL, Counter-timer Physical Timer Control

The CNTP_CTL characteristics are:

Purpose

Control register for the EL1 physical timer.

Configurations

The power domain of CNTP_CTL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see Power and reset domains for the system level implementation of the Generic Timer on page I2-6717.

Attributes

CNTP_CTL is a 32-bit register.

Field descriptions

The CNTP_CTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>31</td>
<td></td>
</tr>
<tr>
<td>32</td>
<td>ENABLE</td>
</tr>
<tr>
<td>31</td>
<td>IMASK</td>
</tr>
<tr>
<td>31</td>
<td>ISTATUS</td>
</tr>
</tbody>
</table>

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0b0: Timer condition is not met.
- 0b1: Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see Operation of the CompareValue views of the timers on page D10-2641 and Operation of the TimerValue views of the timers on page D10-2641.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0b0: Timer interrupt is not masked by the IMASK bit.
- 0b1: Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.
ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0b0  Timer disabled.
- 0b1  Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTP_TV_AL continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTP_CTL:

CNTP_CTL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page 12-6725 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTP_CTL is accessible in that frame if the value of CNTACR<?>.RWPT is 1.
- Otherwise, the CNTP_CTL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTP_CTL is accessible in that frame if both:
  - CNTP_CTL is accessible in the corresponding CNTBaseN frame:
  - The value of CNTEL0ACR.EL0PTEN is 1.
- Otherwise, the CNTP_CTL address in that frame is RAZ/WI.

CNTP_CTL can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x02C</td>
<td>CNTP_CTL</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x02C</td>
<td>CNTP_CTL</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- Access to CNTP_CTL[:] is RW.
- Access to CNTP_CTL[:] is RW.
I5.7.11 CNTP_CVAL, Counter-timer Physical Timer CompareValue

The CNTP_CVAL characteristics are:

**Purpose**

Holds the 64-bit compare value for the EL1 physical timer.

**Configurations**

The power domain of CNTP_CVAL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-6717.

**Attributes**

CNTP_CVAL is a 64-bit register.

**Field descriptions**

The CNTP_CVAL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>CompareValue, bits [63:0]</td>
</tr>
<tr>
<td>0</td>
<td>Holds the EL1 physical timer CompareValue.</td>
</tr>
</tbody>
</table>

When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer.

When the timer condition is met:

- CNTP_CTL.ISTATUS is set to 1.
- An interrupt is generated if CNTP_CTL.IMASK is 0.

When CNTP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count. This field resets to an architecturally UNKNOWN value.

**Accessing the CNTP_CVAL:**

CNTP_CVAL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

*CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames* on page I2-6725 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTP_CVAL is accessible in that frame if the value of CNTACR<n>.RWPT is 1.
- Otherwise, the CNTP_CVAL address in that frame is RAZ/WI.
For an implemented CNTEL0BaseN frame:

- CNTP_CV AL is accessible in that frame if both:
  - CNTP_CV AL is accessible in the corresponding CNTBaseN frame:
  - The value of CNTEL0ACR.EL0PTEN is 1.
- Otherwise, the CNTP_CV AL address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTP_CV AL register must be accessible as an atomic 64-bit value.

CNTP_CV AL[31:0] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x020</td>
<td>CNTP_CV AL</td>
<td>31:0</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x020</td>
<td>CNTP_CV AL</td>
<td>31:0</td>
</tr>
</tbody>
</table>

CNTP_CV AL[63:32] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x024</td>
<td>CNTP_CV AL</td>
<td>63:32</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x024</td>
<td>CNTP_CV AL</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- Access to CNTP_CV AL[31:0] is RW.
- Access to CNTP_CV AL[63:32] is RW.
- Access to CNTP_CV AL[31:0] is RW.
- Access to CNTP_CV AL[63:32] is RW.
I5.7.12  CNTP_TVAL, Counter-timer Physical Timer TimerValue

The CNTP_TVAL characteristics are:

**Purpose**

Holds the timer value for the EL1 physical timer.

**Configurations**

The power domain of CNTP_TVAL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-6717.

**Attributes**

CNTP_TVAL is a 32-bit register.

**Field descriptions**

The CNTP_TVAL bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimerValue</td>
<td></td>
</tr>
</tbody>
</table>

**TimerValue, bits [31:0]**

The TimerValue view of the EL1 physical timer.

On a read of this register:
- If CNTP_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTP_CTL.ENABLE is 1, the value returned is (CompareValue - CNTPCT).

On a write of this register, CompareValue is set to (CNTPCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CompareValue) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:
- CNTP_CTL.ISTATUS is set to 1.
- If CNTP_CTL.IMASK is 0, an interrupt is generated.

When CNTP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count, so the TimerValue view appears to continue to count down. This field resets to an architecturally UNKNOWN value.

**Accessing the CNTP_TVAL:**

CNTP_TVAL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

*CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames* on page I2-6725 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
• For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:
• CNTP_TV AL is accessible in that frame if the value of CNTACR<n>.RWPT is 1.
• Otherwise, the CNTP_TV AL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:
• CNTP_TV AL is accessible in that frame if both:
  — CNTP_TV AL is accessible in the corresponding CNTBaseN frame:
  — The value of CNTEL0ACR.EL0PTEN is 1.
• Otherwise, the CNTP_TV AL address in that frame is RAZ/WI.

CNTP_TV AL can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x028</td>
<td>CNTP_TV AL</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x028</td>
<td>CNTP_TV AL</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:
• Access to CNTP_TV AL[:] is RW.
• Access to CNTP_TV AL[:] is RW.
CNTPCT, Counter-timer Physical Count

The CNTPCT characteristics are:

**Purpose**

Holds the 64-bit physical count value.

**Configurations**

The power domain of CNTPCT is IMPLEMENTATION DEFINED.

For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-6717.

**Attributes**

CNTPCT is a 64-bit register.

**Field descriptions**

The CNTPCT bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>

<td></td>
</tr>
</tbody>
</table>
```

**Accessing the CNTPCT:**

CNTPCT can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame, as a RO register.

*CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames* on page I2-6725 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTPCT is accessible in that frame, as a RO register, if the value of CNTACR<n>.RPCT is 1.
- Otherwise, the CNTPCT address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTPCT is accessible in that frame if both:
  - CNTPCT is accessible in the corresponding CNTBaseN frame.
  - The value of CNTEL0ACR.EL0PCTEN is 1.
- Otherwise, the CNTPCT address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTPCT register must be accessible as an atomic 64-bit value.
CNTPCT[31:0] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x000</td>
<td>CNTPCT</td>
<td>31:0</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x000</td>
<td>CNTPCT</td>
<td>31:0</td>
</tr>
</tbody>
</table>

CNTPCT[63:32] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x004</td>

<td>63:32</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x004</td>
<td>CNTPCT</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- Access to CNTPCT[31:0] is RO.
- Access to CNTPCT[63:32] is RO.
- Access to CNTPCT[31:0] is RO.
- Access to CNTPCT[63:32] is RO.
I5.7.14  CNTSCR, Counter Scale Register

The CNTSCR characteristics are:

**Purpose**

Enables the counter, controls the counter frequency setting, and controls counter behavior during debug.

**Configurations**

The power domain of CNTSCR is IMPLEMENTATION DEFINED.

Some or all fields in this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain. For more information see Power and reset domains for the system level implementation of the Generic Timer on page I2-6717.

This register is present only from ARMv8.4, when ARMv8.4-CNTSC is implemented. Otherwise, direct accesses to CNTSCR are RES0.

This register is introduced in ARMv8.4.

**Attributes**

CNTSCR is a 32-bit register.

**Field descriptions**

The CNTSCR bit assignments are:

### ScaleVal, bits [31:0]

Scale Value

When counter scaling is enabled, ScaleVal is the amount added to the counter value for every counter tick.

Counter tick is defined as one period of the current operating frequency of the Generic counter.

ScaleVal is expressed as an unsigned fixed point number with an 8-bit integer value and a 24-bit fractional value.

CNTSCR.ScaleVal can only be changed when **CNTCR.EN == 0**. If the value of this field is changed when **CNTCR.EN == 1**:

- The counter value becomes **UNKNOWN**.
- The counter value remains **UNKNOWN** on future ticks of the clock.

This field resets to an architecturally **UNKNOWN** value.

**Accessing the CNTSCR:**

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

CNTSCR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTControlBase</td>
<td>0x10</td>
<td>CNTSCR</td>
</tr>
</tbody>
</table>
This interface is accessible as follows:

- Access to this register is RW.
### 5.7.15 CNTSR, Counter Status Register

The CNTSR characteristics are:

**Purpose**

Provides counter frequency status information.

**Configurations**

The power domain of CNTSR is IMPLEMENTATION DEFINED.

Some or all fields in this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain. For more information see Power and reset domains for the system level implementation of the Generic Timer on page I2-6717.

**Attributes**

CNTSR is a 32-bit register.

**Field descriptions**

The CNTSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>FCACK</td>
<td>Frequency change acknowledge. Indicates the currently selected entry in the Frequency modes table, see The Frequency modes table on page I2-6719. This field resets to 0.</td>
</tr>
<tr>
<td>7:2</td>
<td>Reserved, RES0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**Accessing the CNTSR:**

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.
CNTSR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTControlBase</td>
<td>0x004</td>
<td>CNTSR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

- Access to this register is RO.
I5.7.16 CNTTIDR, Counter-timer Timer ID Register

The CNTTIDR characteristics are:

**Purpose**

Indicates the implemented timers in the memory map, and their features. For each value of N from 0 to 7 it indicates whether:

- Frame CNTBaseN is a view of an implemented timer.
- Frame CNTBaseN has a second view, CNTEL0BaseN.
- Frame CNTBaseN has a virtual timer capability.

**Configurations**

The power domain of CNTTIDR is IMPLEMENTATION DEFINED.

For more information see Power and reset domains for the system level implementation of the Generic Timer on page I2-6717.

**Attributes**

CNTTIDR is a 32-bit register.

**Field descriptions**

The CNTTIDR bit assignments are:

<table>
<thead>
<tr>
<th>Frame7</th>
<th>Frame6</th>
<th>Frame5</th>
<th>Frame4</th>
<th>Frame3</th>
<th>Frame2</th>
<th>Frame1</th>
<th>Frame0</th>
</tr>
</thead>
</table>

Frame<\(n\)>, bits [4n+3:4n], for \(n = 0 \) to 7

A 4-bit field indicating the features of frame CNTBase<\(n\)>.

Bit[3] of the field is RES0.

Bit[2], the FEL0 subfield, indicates whether frame CNTBase<\(n\)> has a second view, CNTEL0Base<\(n\)>.

The possible values of this bit are:

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Frame&lt;(n)&gt; does not have a second view. The CNTEL0ACR register in the first view of the frame is RES0</td>
</tr>
<tr>
<td>0b1</td>
<td>Frame&lt;(n)&gt; has a second view, CNTEL0Base&lt;(n)&gt;</td>
</tr>
</tbody>
</table>

If bit[0] is 0, bit[2] is RES0.

Bit[1], the FVI subfield, indicates whether both:

- Frame CNTBase<\(n\)> implements the virtual timer registers CNTV_CVAL, CNTV_TVAL, and CNTV_CTL.
- This CNTCTLBase frame implements the virtual timer offset register CNTVOFF<\(n\)>.

The possible values of bit[1] are:

<table>
<thead>
<tr>
<th>Bit[1]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Frame&lt;(n)&gt; does not have virtual capability. The virtual time and offset registers are RES0</td>
</tr>
<tr>
<td>0b1</td>
<td>Frame&lt;(n)&gt; has virtual capability. The virtual time and offset registers are implemented</td>
</tr>
</tbody>
</table>
If bit[0] is 0, bit[1] is RES0. Bit[0], the FI subfield, indicates whether frame CNTBase<′n′> is implemented. The possible values of this bit are:

<table>
<thead>
<tr>
<th>Bit[0]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Frame&lt;′n′&gt; is not implemented. All registers associated with the frame are RES0.</td>
</tr>
<tr>
<td>0b1</td>
<td>Frame&lt;′n′&gt; is implemented</td>
</tr>
</tbody>
</table>

### Accessing the CNTTIDR:

In a system that recognizes two Security states this register is accessible by both Secure and Non-secure accesses. CNTTIDR can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTCTLBase</td>
<td>0x08</td>
<td>CNTTIDR</td>
</tr>
</tbody>
</table>

This interface is accessible as follows:

* Access to this register is RO.
I5.7.17 CNTV_CTL, Counter-timer Virtual Timer Control

The CNTV_CTL characteristics are:

**Purpose**

Control register for the virtual timer.

**Configurations**

The power domain of CNTV_CTL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see Power and reset domains for the system level implementation of the Generic Timer on page I2-6717.

**Attributes**

CNTV_CTL is a 32-bit register.

**Field descriptions**

The CNTV_CTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>3</td>
<td>ENABLE</td>
</tr>
<tr>
<td>2</td>
<td>IMASK</td>
</tr>
<tr>
<td>1</td>
<td>ISTATUS</td>
</tr>
<tr>
<td>0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**Bits [31:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is met:

- **0b0** Timer condition is not met.
- **0b1** Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see Operation of the CompareValue views of the timers on page D10-2641 and Operation of the TimerValue views of the timers on page D10-2641.

This bit is read-only.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

- **0b0** Timer interrupt is not masked by the IMASK bit.
- **0b1** Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.
ENABLE, bit [0]

Enables the timer. Permitted values are:

0b0  Timer disabled.
0b1  Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTV_TV AL continues to count down.

--- Note ---

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTV_CTL:

CNTV_CTL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-6725 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

• Whether the CNTBaseN frame has virtual timer capability.
• Whether the corresponding CNTEL0BaseN frame is implemented.
• For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

• CNTV_CTL is accessible in that frame if the value of CNTACR<n>.RWVT is 1.
• Otherwise, the CNTV_CTL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

• CNTV_CTL is accessible in that frame if both:
  — CNTV_CTL is accessible in the corresponding CNTBaseN frame:
  — The value of CNTEL0ACR.EL0VTEN is 1.
• Otherwise, the CNTV_CTL address in that frame is RAZ/WI.

CNTV_CTL can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x03C</td>
<td>CNTV_CTL</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x03C</td>
<td>CNTV_CTL</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

• Access to CNTV_CTL[:] is RW.
• Access to CNTV_CTL[:] is RW.
I5.7.18 CNTV_CVAL, Counter-timer Virtual Timer CompareValue

The CNTV_CVAL characteristics are:

**Purpose**

Holds the 64-bit compare value for the virtual timer.

**Configurations**

The power domain of CNTV_CVAL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see Power and reset domains for the system level implementation of the Generic Timer on page I2-6717.

**Attributes**

CNTV_CVAL is a 64-bit register.

**Field descriptions**

The CNTV_CVAL bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:0</td>
<td>CompareValue</td>
</tr>
</tbody>
</table>

**CompareValue, bits [63:0]**

Holds the virtual timer CompareValue.

When CNTV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTV_CTL.ISTATUS is set to 1.
- An interrupt is generated if CNTV_CTL.IMASK is 0.

When CNTV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count. This field resets to an architecturally UNKNOWN value.

**Accessing the CNTV_CVAL:**

CNTV_CVAL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-6725 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV_CVAL is accessible in that frame if the value of CNTACR<n>.RWVT is 1.
- Otherwise, the CNTV_CVAL address in that frame is RAZ/WI.
For an implemented CNTEL0BaseN frame:

- CNTV_CVAL is accessible in that frame if both:
  - CNTV_CVAL is accessible in the corresponding CNTBaseN frame:
  - The value of CNTEL0ACR.EL0VTEN is 1.
- Otherwise, the CNTV_CVAL address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTV_CVAL register must be accessible as an atomic 64-bit value.

CNTV_CVAL[31:0] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x030</td>
<td>CNTV_CVAL</td>
<td>31:0</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x030</td>
<td>CNTV_CVAL</td>
<td>31:0</td>
</tr>
</tbody>
</table>

CNTV_CVAL[63:32] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x034</td>
<td>CNTV_CVAL</td>
<td>63:32</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x034</td>
<td>CNTV_CVAL</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- Access to CNTV_CVAL[31:0] is RW.
- Access to CNTV_CVAL[63:32] is RW.
I5.7.19 CNTV_TVAL, Counter-timer Virtual Timer TimerValue

The CNTV_TVAL characteristics are:

**Purpose**

Holds the timer value for the virtual timer.

**Configurations**

The power domain of CNTV_TVAL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page 12-6717.

**Attributes**

CNTV_TVAL is a 32-bit register.

**Field descriptions**

The CNTV_TVAL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>TimerValue</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**TimerValue, bits [31:0]**

The TimerValue view of the virtual timer.

On a read of this register:

- If CNTV_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTV_CTL.ENABLE is 1, the value returned is (CompareValue - CNTVCT).

On a write of this register, CompareValue is set to (CNTVCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CompareValue) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTV_CTL.ISTATUS is set to 1.
- If CNTV_CTL.IMASK is 0, an interrupt is generated.

When CNTV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count, so the TimerValue view appears to continue to count down. This field resets to an architecturally UNKNOWN value.

**Accessing the CNTV_TVAL:**

CNTV_TVAL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

*CNTCTLBBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page 12-6725* describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV_TVAL is accessible in that frame if the value of CNTACR<\text{n}>.RWVT is 1.
- Otherwise, the CNTV_TVAL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTV_TVAL is accessible in that frame if both:
  - CNTV_TVAL is accessible in the corresponding CNTBaseN frame:
  - The value of CNTEL0ACR.EL0VTEN is 1.
- Otherwise, the CNTV_TVAL address in that frame is RAZ/WI.

CNTV_TVAL can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x038</td>
<td>CNTV_TVAL</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x038</td>
<td>CNTV_TVAL</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- Access to CNTV_TVAL[:\text{]} is RW.
- Access to CNTV_TVAL[:\text{]} is RW.
I5.7.20  CNTVCT, Counter-timer Virtual Count

The CNTVCT characteristics are:

**Purpose**

Holds the 64-bit virtual count value.

**Configurations**

The power domain of CNTVCT is **IMPLEMENTATION DEFINED**.

For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-6717.

**Attributes**

CNTVCT is a 64-bit register.

**Field descriptions**

The CNTVCT bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual count value</th>
</tr>
</thead>
</table>

**Accessing the CNTVCT:**

CNTVCT can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame, as a RO register.

*CNTCTRLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames* on page I2-6725 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTVCT is accessible in that frame, as a RO register, if the value of CNTACR<n>.RVCT is 1.
- Otherwise, the CNTVCT address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTVCT is accessible in that frame if both:
  - CNTVCT is accessible in the corresponding CNTBaseN frame.
  - The value of CNTEL0ACR.EL0VCTEN is 1.
- Otherwise, the CNTVCT address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTVCT register must be accessible as an atomic 64-bit value.
CNTVCT[31:0] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x008</td>
<td>CNTVCT</td>
<td>31:0</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x008</td>
<td>CNTVCT</td>
<td>31:0</td>
</tr>
</tbody>
</table>

CNTVCT[63:32] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x00C</td>
<td>CNTVCT</td>
<td>63:32</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTEL0BaseN</td>
<td>0x00C</td>
<td>CNTVCT</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- Access to CNTVCT[31:0] is RO.
- Access to CNTVCT[63:32] is RO.
- Access to CNTVCT[31:0] is RO.
- Access to CNTVCT[63:32] is RO.
I5.7.21 CNTVOFF{<n>}, Counter-timer Virtual Offset

The CNTVOFF{<n>} characteristics are:

**Purpose**

Holds the 64-bit virtual offset.

**Configurations**

Implementation of CNTVOFF{<n>} is OPTIONAL.

The power domain of CNTVOFF{<n>} is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see Power and reset domains for the system level implementation of the Generic Timer on page I2-6717.

**Attributes**

CNTVOFF{<n>} is a 64-bit register.

**Field descriptions**

The CNTVOFF{<n>} bit assignments are:

<table>
<thead>
<tr>
<th>Bit Index</th>
<th>Bit Assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Virtual offset</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTVOFF{<n>}:**

In the CNTCTLBase frame a CNTVOFF{<n>} register must be implemented, as a RW register, for each CNTBaseN frame that has virtual timer capability.

--- Note ---

The value of <n> in an instance of CNTVOFF{<n>} specifies the value of N for the associated CNTBaseN frame.

In a system that recognizes two Security states, for any CNTVOFF{<n>} register in the CNTCTLBase frame:

- CNTVOFF{<n>} is always accessible by Secure accesses.
- CNTNSAR.NS{<n>} determines whether CNTVOFF{<n>} is accessible by Non-secure accesses.

The register location of any unimplemented CNTVOFF{<n>} register in the CNTCTLBase frame is RAZ/WI.

CNTVOFF is implemented, as a RO register, in any implemented CNTBaseN frame that has virtual timer capability. CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-6725 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.
For an implemented CNTBaseN frame that has virtual timer capability:

- CNTVOFF is accessible in that frame, as a RO register, if the value of CNTACR<n>.RVOFF is 1.
- Otherwise, the CNTVOFF address in that frame is RAZ/WI.

**Note**

CNTVOFF is never visible in any CNTELOBaseN frame. This means that the CNTVOFF address in any implemented CNTELOBaseN frame is RAZ/WI.

In an implementation that supports 64-bit atomic accesses, a CNTVOFF{<n>} register must be accessible as an atomic 64-bit value.

CNTVOFF[31:0] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x018</td>
<td>31:0</td>
</tr>
</tbody>
</table>

CNTVOFF[63:32] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTBaseN</td>
<td>0x01C</td>
<td>63:32</td>
</tr>
</tbody>
</table>

CNTVOFF<n>[31:0] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTCTLBase</td>
<td>0x80 + 8n</td>
<td>31:0</td>
</tr>
</tbody>
</table>

CNTVOFF<n>[63:32] can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTCTLBase</td>
<td>0x84 + 8n</td>
<td>63:32</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- Access to CNTVOFF[31:0] is RO.
- Access to CNTVOFF[63:32] is RO.
- Access to CNTVOFF<n>[31:0] is RW.
- Access to CNTVOFF<n>[63:32] is RW.
I5.7.22 CounterID<n>, Counter ID registers, n = 0 - 11

The CounterID<n> characteristics are:

Purpose
IMPLEMENTATION DEFINED identification registers 0 to 11 for the memory-mapped Generic Timer.

Configurations
The power domain of CounterID<n> is IMPLEMENTATION DEFINED.

For more information see Power and reset domains for the system level implementation of the Generic Timer on page I2-6717.

These registers are implemented independently in each of the implemented Generic Timer memory-mapped frames.

If the implementation of the Counter ID registers requires an architecture version, the value for this version of the Arm Generic Timer is version 0.

The Counter ID registers can be implemented as a set of CoreSight ID registers, comprising Peripheral ID Registers and Component ID Registers. An implementation of these registers for the Generic Timer must use a Component class value of 0xF.

Attributes
CounterID<n> is a 32-bit register.

Field descriptions
The CounterID<n> bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
</tbody>
</table>

IMPLEMENTATION DEFINED, bits [31:0]
IMPLEMENTATION DEFINED.

Accessing the CounterID<n>:

These registers must be implemented, as RO registers, in every implemented Generic Timer memory-mapped frame.

For the CNTCTLBase frame, in a system that recognizes two Security states these registers are accessible by both Secure and Non-secure accesses.

For theCNTControlBase frame, in a system that supports Secure and Non-secure memory maps the frame is implemented only in the Secure memory map, meaning these registers are implemented only in the Secure memory map.

For theCNTBaseN frames,CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-6725 describes the status fields that identify whether a frame is implemented, and for an implemented frame:

• Whether the CNTBaseN frame has virtual timer capability.
• Whether the corresponding CNTEL0BaseN frame is implemented.
• For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.
CounterID<n> can be accessed through its memory-mapped interface:

<table>
<thead>
<tr>
<th>Component</th>
<th>Frame</th>
<th>Offset</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timer</td>
<td>CNTControlBase</td>
<td>0xF00 + 4n</td>
<td>CounterID&lt;n&gt;</td>
</tr>
<tr>
<td>Timer</td>
<td>CNTReadBase</td>
<td>0xF00 + 4n</td>
<td>CounterID&lt;n&gt;</td>
</tr>
<tr>

</tr>
<tr>
<td>Timer</td>
<td>CNTCTLBase</td>
<td>0xF00 + 4n</td>
<td>CounterID&lt;n&gt;</td>
</tr>
</tbody>
</table>

These interfaces are accessible as follows:

- Access to CounterID<n>[:], is RO.
- Access to CounterID<n>[:], is RO.
- Access to CounterID<n>[:], is RO.
- Access to CounterID<n>[:], is RO.
- Access to CounterID<n>[:], is RO.
I5 External System Control Register Descriptions
I5.7 Generic Timer memory-mapped register descriptions
Part J

Architectural Pseudocode
Chapter J1
ARMv8 Pseudocode

This chapter contains pseudocode that describes many features of the ARMv8 architecture. It contains the following sections:

- *Pseudocode for AArch64 operations* on page J1-6900.
- *Pseudocode for AArch32 operation* on page J1-7006.
- *Shared pseudocode* on page J1-7082.
J1 ARMv8 Pseudocode
J1.1 Pseudocode for AArch64 operations

This section holds the pseudocode for execution in AArch64 state. Functions that are listed in this section are identified as AArch64.FunctionName. Some of these functions have an equivalent AArch32 function, AArch32.FunctionName. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example aarch64/debug/breakpoint.

The top-level sections of the AArch64 pseudocode hierarchy are:

• aarch64/debug
• aarch64/exceptions on page J1-6910.
• aarch64/functions on page J1-6928.

J1.2 Pseudocode for AArch32 operation

This section holds the pseudocode for execution in AArch32 state. Functions that are listed in this section are identified as AArch32.FunctionName. Some of these functions have an equivalent AArch64 function, AArch64.FunctionName. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example aarch32/debug/breakpoint.

--- Note ---

Many AArch32 pseudocode functions have not been updated to show the constraints on the ARMv7 UNPREDICTABLE behaviors that are described in Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors. Where AArch32 pseudocode shows something to be UNPREDICTABLE, check Appendix K1 for possible constraints on the permitted behavior.

The top-level sections of the AArch32 pseudocode hierarchy are:

- aarch32/debug.
- aarch32/exceptions on page J1-7014.
- aarch32/functions on page J1-7033.
- aarch32/translation on page J1-7061.

J1.2.1 aarch32/debug

This section includes the following pseudocode functions:

- aarch32/debug/VCRMatch/AArch32.VCRMatch.
- aarch32/debug/breakpoint/AArch32.StateMatch.
- aarch32/debug/pmu/AArch32.CheckForPMUOverflow.
- aarch32/debug/takeexceptiondbg/AArch32.EnterHypModeInDebugState.
- aarch32/debug/takeexceptiondbg/AArch32.EnterModeInDebugState.
- aarch32/debug/takeexceptiondbg/AArch32.EnterMonitorModeInDebugState.
- aarch32/debug/watchpoint/AArch32.WatchpointByteMatch.

aarch32/functions/aborts/AArch32.CreateFaultRecord

    // AArch32.CreateFaultRecord()
    // =========================

    FaultRecord AArch32.CreateFaultRecord(Fault statuscode, bits(40) ipaddress, bits(4) domain,
                                        integer level, AccType acctype, boolean write, bit extflag,
                                        bits(4) debugmoe, bits(2) errortype, boolean secondstage, boolean
                                        s2fs1walk)

        FaultRecord fault;
        fault.statuscode = statuscode;
        if (statuscode != Fault_None && PSTATE.EL != EL2 && TTBCR.EAE == '0' && !secondstage && !s2fs1walk

            &&
            AArch32.DomainValid(statuscode, level)) then
            fault.domain = domain;
            else
            fault.domain = bits(4) UNKNOWN;

            fault.debugmoe = debugmoe;
            fault.errortype = errortype;
            fault.ipaddress.NS = bit UNKNOWN;
            fault.ipaddress.address = ZeroExtend(ipaddress);
            fault.level = level;
            fault.acctype = acctype;
            fault.write = write;
            fault.extflag = extflag;
            fault.secondstage = secondstage;
            fault.s2fs1walk = s2fs1walk;

        return fault;

aarch32/functions/aborts/AArch32.DomainValid

    // AArch32.DomainValid()
    // =====================

    // Returns TRUE if the Domain is valid for a Short-descriptor translation scheme.

    boolean AArch32.DomainValid(Fault statuscode, integer level)

        assert statuscode != Fault_None;

        case statuscode of
        when Fault_Domain
            return TRUE;
        when Fault_Translation, Fault_AccessFlag, Fault_SyncExternalOnWalk, Fault_SyncParityOnWalk
            return level == 2;
        otherwise
            return FALSE;

aarch32/functions/aborts/AArch32.FaultStatusLD

    // AArch32.FaultStatusLD()
    // =======================

    // Creates an exception fault status value for Abort and Watchpoint exceptions taken
    // to Abort mode using AArch32 and Long-descriptor format.
The code snippet provided is a pseudocode for AArch32 operation that deals with exception handling. Here's a breakdown of the code:

```plaintext
bits(32) AArch32.FaultStatusLD(boolean d_side, FaultRecord fault)
assert fault.statuscode != Fault_None;

bits(32) fsr = Zeros();
if HaveRASExt() & IsAsyncAbort(fault) then fsr<15:14> = fault.errortype;
if d_side then
  if fault.acctype IN {AccType_DC, AccType_IC, AccType_AT} then
    fsr<13> = '1'; fsr<11> = '1';
  else
    fsr<11> = if fault.write then '1' else '0';
if IsExternalAbort(fault) then fsr<12> = fault.extflag;
fsr<9> = '1';
fsr<5:0> = EncodeLDFSC(fault.statuscode, fault.level);
return fsr;
```

The `aaarch32/functions/aborts/AArch32.FaultStatusSD` function is a similar implementation for creating an exception fault status value for Abort and Watchpoint exceptions taken to Abort mode using AArch32 and Short-descriptor format.

```plaintext
bits(32) AArch32.FaultStatusSD(boolean d_side, FaultRecord fault)
assert fault.statuscode != Fault_None;

bits(32) fsr = Zeros();
if HaveRASExt() & IsAsyncAbort(fault) then fsr<15:14> = fault.errortype;
if d_side then
  if fault.acctype IN {AccType_DC, AccType_IC, AccType_AT} then
    fsr<13> = '1'; fsr<11> = '1';
  else
    fsr<11> = if fault.write then '1' else '0';
if IsExternalAbort(fault) then fsr<12> = fault.extflag;
fsr<9> = '0';
fsr<10,3:0> = EncodeSDFSC(fault.statuscode, fault.level);
if d_side then
  fsr<7:4> = fault.domain;               // Domain field (data fault only)
return fsr;
```

The `aaarch32/functions/aborts/AArch32.FaultSyndrome` function creates an exception syndrome value for Abort and Watchpoint exceptions taken to AArch32 Hyp mode.

```plaintext
bits(25) AArch32.FaultSyndrome(boolean d_side, FaultRecord fault)
assert fault.statuscode != Fault_None;

bits(25) iss = Zeros();
if HaveRASExt() & IsAsyncAbort(fault) then iss<11:10> = fault.errortype; // AET
if d_side then
  if IsSecondStage(fault) & !fault.c2fs1walk then iss<24:14> = LSSecondStageSyndrome();
  if fault.acctype IN {AccType_DC, AccType_DC_UNPRIV, AccType_IC, AccType_AT} then
    iss<8> = '1'; iss<6> = '1';
  else
    iss<6> = if fault.write then '1' else '0';
if IsExternalAbort(fault) then iss<9> = fault.extflag;
iss<7> = if fault.c2fs1walk then '1' else '0';
iss<5:0> = EncodeLDFSC(fault.statuscode, fault.level);
return iss;
```
aarch32/functions/aborts/EncodeSDFSC

// EncodeSDFSC()
// =============
// Function that gives the Short-descriptor FSR code for different types of Fault

bits(5) EncodeSDFSC(Fault statuscode, integer level)

    bits(5) result;

J1.3 Shared pseudocode

This section holds the pseudocode that is common to execution in AArch64 state and in AArch32 state. Functions listed in this section are identified only by a FunctionName, without an AArch64. or AArch32. prefix. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example shared/debug/DebugTarget.

The top-level sections of the shared pseudocode hierarchy are:

- shared/debug
- shared/exceptions on page J1-7101.
- shared/functions on page J1-7103.
- shared/translation on page J1-7180.

J1.3.1 shared/debug

This section includes the following pseudocode functions:

- shared/debug/DebugTarget/DebugTarget on page J1-7083.
- shared/debug/DebugTarget/DebugTargetFrom on page J1-7084.
- shared/debug/authentication/AllowExternalDebugAccess on page J1-7084.
- shared/debug/authentication/AllowExternalPMUAccess on page J1-7085.
- shared/debug/authentication/Debug_authentication on page J1-7085.
- shared/debug/authentication/ExternalNoninvasiveDebugAllowed on page J1-7085.
- shared/debug/authentication/ExternalNoninvasiveDebugEnabled on page J1-7086.
- shared/debug/cti/CTI_SetEventLevel on page J1-7086.
- shared/debug/cti/CTI_SignalEvent on page J1-7086.
- shared/debug/cti/CrossTrigger on page J1-7087.
- shared/debug/dccanditr/CheckForDCCInterrupts on page J1-7087.
- shared/debug/dccanditr/DBGDTRRX_EL0 on page J1-7087.
- shared/debug/dccanditr/DBGDTRTX_EL0 on page J1-7088.
- shared/debug/dccanditr/DBGDTR_EL0 on page J1-7089.

Architectural Constraints on UNPREDICTABLE behaviors

This chapter describes the architectural constraints on UNPREDICTABLE behaviors in the ARMv8 architecture. It contains the following sections:

- AArch32 CONSTRAINED UNPREDICTABLE behaviors on page K1-7190.
- AArch64 CONSTRAINED UNPREDICTABLE behaviors on page K1-7214.
K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

ARMv8 defines architecturally-required constraints on many behaviors that are UNPREDICTABLE in ARMv7. The following sections define those constraints:

- **Overview of the constraints on ARMv7 UNPREDICTABLE behaviors** on page K1-7191.
- **Using R13** on page K1-7191.
- **Using R15** on page K1-7191.
- **Branching into an IT block** on page K1-7192.
- **Branching to an unaligned PC** on page K1-7192.
- **Loads and Stores to unaligned locations** on page K1-7192.
- **CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT** on page K1-7192.
- **Unallocated System register access instructions** on page K1-7193.
- **SBZ or SBO fields T32 and A32 in instructions** on page K1-7194.
- **UNPREDICTABLE cases in immediate constants in T32 data-processing instructions** on page K1-7194.
- **UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions** on page K1-7195.
- **CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values** on page K1-7195.
- **CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization** on page K1-7196.
- **Translation Table Base Address alignment** on page K1-7196.
- **Handling of System register control fields for Advanced SIMD and floating-point operation** on page K1-7196.
- **The Performance Monitors Extension** on page K1-7197.
- **The Activity Monitors Extension** on page K1-7198.
- **Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED** on page K1-7199.
- **Out of range VA** on page K1-7199.
- **Instruction fetches from Device memory** on page K1-7200.
- **Multi-access instructions that load the PC from Device memory** on page K1-7200.
- **Programming CSSELR.Level for a cache level that is not implemented** on page K1-7200.
- **Crossing a page boundary with different memory types or Shareability attributes** on page K1-7200.
- **Crossing a 4KB boundary with a Device access** on page K1-7201.
- **UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs** on page K1-7201.
- **CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings** on page K1-7202.
- **Out of range values of the Set/Way/Index fields in cache maintenance instructions** on page K1-7202.
- **CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set** on page K1-7203.
- **CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions** on page K1-7205.
K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

•  CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR on page K1-7209.
•  CONSTRAINED UNPREDICTABLE behavior of EL2 features on page K1-7209.
•  Reserved values in System and memory-mapped registers and translation table entries on page K1-7212.
•  CONSTRAINED UNPREDICTABLE behavior in Debug state on page K1-7213.

K1.1.1 Overview of the constraints on ARMv7 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch32 state, where previous versions of the architecture define behavior as UNPREDICTABLE, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Note
Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases.

K1.1.2 Using R13

In prior versions of the architecture, the use of R13 as a named register specifier was described as UNPREDICTABLE in the pseudocode. In the ARMv8-A architecture, the use of R13 as a named register specifier is not UNPREDICTABLE, unless this is specifically stated, and R13 can be used in the regular form. Bits[1:0] of R13 are not treated as RES0, but can hold any values programmed into them.

K1.1.3 Using R15

All uses of R15 as a named register specifier for a source register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this Manual must do one of the following:
•  Cause the instruction to be treated as UNDEFINED.
•  Cause the instruction to execute as a NOP.
•  Read or return an UNKNOWN value for the source register specified as R15.

All uses of R15 as a named register specifier for a destination register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual must do one of the following:
•  Cause the instruction to be treated as UNDEFINED.
•  Cause the instruction to execute as a NOP.
•  Ignore the write.
•  Branch to an UNKNOWN location in either A32 or T32 state.

The choice between these behaviors might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Instructions that are CONSTRAINED UNPREDICTABLE when the base register is R15 and the instruction specifies a writeback of the base register, are treated as having R15 as both a source register and a destination register.

For instructions that have two destination registers, for example LDRD, MRRC, and many of the multiply instructions, if Rt, Rt2, RdLo, or RdHi is R15, then the other destination register of the pair is UNKNOWN, if the CONSTRAINED UNPREDICTABLE behavior for the write to R15 is either to ignore the write or to branch to an UNKNOWN location.

For instructions that affect any or all of PSTATE.{N, Z, C, V}, PSTATE.Q, and PSTATE.GE when the register specifier is not R15, any flags affected by an instruction that is CONSTRAINED UNPREDICTABLE when the register specifier is R15 become UNKNOWN.

In addition, for MRC instructions that use R15 as the destination register descriptor, and therefore target APSR.nzcv where these are described as being CONSTRAINED UNPREDICTABLE, PSTATE.{N, Z, C, V} becomes UNKNOWN.
K1.1.4 Branching into an IT block

Branching into an IT block leads to CONSTRAINED UNPREDICTABLE behavior. Execution starts from the address determined by the branch, but each instruction in the IT block is:

- Executed as if it were not in an IT block. This means that it is executed unconditionally.
- Executed as if it had passed its Condition code check within an IT block.
- Executed as a NOP. That is, it behaves as if it had failed the Condition code check.

K1.1.5 Branching to an unaligned PC

In A32 state, when branching to an address that is not word aligned and is defined to be CONSTRAINED UNPREDICTABLE, one of the following behaviors must occur:

- The unaligned location is forced to be aligned.
- The unaligned address generates an exception on the first instruction using the unaligned PC value.

If that instruction is executed at EL0 and either of the following applies, the exception is taken to EL2:

- EL2 is using AArch32 and the value of HCR.TGE is 1.
- EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.

If the instruction is executed at EL0 when the applicable TGE bit is 0 the exception is taken to EL1.

If the instruction is executed at an Exception level that is higher than EL0 the exception is taken to the Exception level at which the instruction was executed.

In all cases, the exception is generated only if the first instruction using the unaligned PC value is architecturally executed.

If the exception that results from a branch to an unaligned PC value:

- Is taken to an Exception level that is using AArch64, it is reported as a PC alignment fault exception, see ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault on page D12-2774.
- Is taken to an Exception level that is using AArch32, it is reported as a Prefetch Abort exception, see Prefetch Abort exception reporting a PC alignment fault exception on page G1-5290.

Note

Because bit[0] is used for interworking, it is impossible to specify a branch to A32 state when the bottom bit of the target address is 1. Therefore the bottom bit of IFAR, HIFAR, or FAR_ELx is 0 for all these cases.

K1.1.6 Loads and Stores to unaligned locations

Some unaligned loads and stores in the ARMv7 architecture are described as UNPREDICTABLE. These are defined in the ARMv8-A architecture to do one of the following:

- Take an alignment fault.
- Perform the specified load or store to the unaligned memory location.

K1.1.7 CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT

A number of instructions in the architecture are described as being CONSTRAINED UNPREDICTABLE either:

- Anywhere within an IT block.
- As an instruction within an IT block, other than the last instruction within an IT block.

Unless otherwise stated in this manual, when these instructions are committed for execution, one of the following occurs:

- An UNDEFINED exception results.
- The instructions are executed as if they had passed the Condition code check.
- The instructions execute as NOPs. This means that they behave as if they had failed the Condition code check.
The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Many instructions that are CONSTRAINED UNPREDICTABLE in an IT block are branch instructions or other non-sequential instructions that change the PC. Where these instructions are not treated as UNDEFINED within an IT block, the remaining iterations of the PSTATE.IT state machine must be treated in one of the following ways:

- **PSTATE.IT** is cleared to 0.
- **PSTATE.IT** advances for either a sequential or a nonsequential change of the PC in the same way as it does for instructions that are not CONSTRAINED UNPREDICTABLE that cause a sequential change of the PC.

---

**Note**

This does not apply to an instruction that is the last instruction in an IT block.

---

The instructions addressed by the updated PC must do one of the following:

- Execute as if they had passed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as **NOP**s. That is, they behave as if they had failed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as if they were unconditional, or, if the instructions are part of another IT block, in accordance with the behavior described in *Branching into an IT block on page K1-7192*.

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

For exception returns or Debug state exits that cause PSTATE.IT to be set to a reserved value in T32 state or that return to A32 state with a nonzero value in PSTATE.IT, the PSTATE.IT bits are forced to ‘00000000’. The reserved values are:

- **PSTATE.IT[7:4]** != ‘0000’ && **PSTATE.IT[3:0]** = ‘0000’
- **PSTATE.IT[2:0]** != ‘000’ when SCTLR/SCTLR_EL_1.ITD == ‘1’

Exception returns or Debug state exits that set PSTATE.IT to a non-reserved value in T32 state can occur when the flow of execution returns to a point:

- Outside an IT block, but with the PSTATE.IT bits set to a value other than ‘00000000’.
- Inside an IT block, but with a different value of the PSTATE.IT bits than if the IT block had been executed without an exception return or Debug state exit.

In this case the instructions at the target of the exception return or Debug state exit must do one of the following:

- Execute as if they passed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as **NOP**s. That is, they behave as if they failed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as if they were unconditional, or as if the instruction were part of another IT block, in accordance with the behavior in *Branching into an IT block on page K1-7192*.

The remaining iterations of the PSTATE.IT state machine must behave in one of the following ways:

- The PSTATE.IT state machine advances as if it were in an IT block.
- The PSTATE.IT bits are ignored.
- The PSTATE.IT bits are forced to ‘00000000’.

**K1.1.8 Unallocated System register access instructions**

In ARMv8-A, accesses to unallocated System register encodings are UNDEFINED.
This includes:
- Reads using encodings that are defined as WO.
- Writes using encodings that are defined as RO.
- MCR or MRC accesses to using a set of \{coproc, Crn, opc1, Crm, opc2\} values that the ARMv7 architecture defined as UNPREDICTABLE.
- Accesses to System registers in the \(\text{coproc}==0\text{b111x}\) encoding space that the ARMv7 architecture defined as UNPREDICTABLE when particular functionality was not implemented, when an ARMv8 implementation does not include the Exception level that provides that functionality.

### K1.1.9 SBZ or SBO fields T32 and A32 in instructions

Many of the A32 and T32 instructions have (0) or (1) in the instruction decode to indicate should-be-zero, SBZ, or should-be-one, SBO. If the instruction bit pattern of an instruction is executed with these fields not having the should be values, one of the following must occur:
- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the should-be value.
- Any destination registers of the instruction become UNKNOWN.

The exceptions to this rule are:
- \textit{LDM, LDMIA, LDMFD} on page F5-3972.

- \textit{UDIV} on page F5-4459.

### K1.1.10 UNPREDICTABLE cases in immediate constants in T32 data-processing instructions

The description of immediate constants in T32 data processing \textit{Modified immediate constants in T32 instructions} on page F2-3675 include constant values that were UNPREDICTABLE in ARMv7. Instruction encodings on page F2-3656 describes 32-bit T32 instructions as \(\{\text{hw1}, \text{hw2}\}\), where \text{hw1} is the left-hand halfword in the 32-bit encoding diagram for the instruction. The UNPREDICTABLE cases are those where both:
- \(\text{hw2}[7:0] == 0\text{b00000000}\).
- \(\text{hw1}[10] == 0\) and either:
  - \(\text{hw2}[14:12] == 0\text{b001}\).
  - \(\text{hw2}[14:12] == 0\text{b010}\).
  - \(\text{hw2}[14:12] == 0\text{b011}\).

In ARMv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce the value \text{0b00000000}.
K1.1.11 UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions

The description of immediate constants in *Modified immediate constants in T32 and A32 Advanced SIMD instructions* on page F2-3677 include constant values that were UNPREDICTABLE in ARMv7. The UNPREDICTABLE cases are those where:

- The bits that the encoding diagram shows as `abcd` are all 0.
  - In the A32 encoding these are bits[24, 18:6, 3:0]. In the T32 encoding they are bits `{hw1[12, 2:0], hw2[3:0]}`.
- The bits that the encoding diagram shows as `cmode[3:1]` are one of `{0b001, 0b010, 0b011, 0b101, 0b110}`.
  - In the A32 encoding these are bits[11:9]. In the T32 encoding they are bits `hw2[11:9]`.

In ARMv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce an immediate constant value of zero.

K1.1.12 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to CONSTRAINED UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes ARMv8.2-TTCNP, this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting `TTBR.CnP` to 1, as identified in the descriptions of the `TTBR.CnP` field. In this case, for a particular `TTBR`, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that `TTBR` on one of the PEs within the Inner Shareable domain for which both the value of `TTBR.CnP` is 1 and the other conditions for sharing translation table entries pointed to by that `TTBR` are met.
- An amalgamation of the values of the translation table entries pointed to by that `TTBR` on two or more of the PEs within the Inner Shareable domain for which both the value of `TTBR.CnP` is 1 and the other conditions for sharing translation table entries pointed to by that `TTBR` are met.

Note

If the Effective value of a control or data value that determines the behavior of the PE results from the amalgamation of two or more values then that Effective value must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.
- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a `TTBR.CnP` value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that `TTBR` and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits within a TLB might generate an exception, reporting the exception using the TLB Conflict fault code, see *TLB conflict aborts on page G5-5535*.

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.
### K1.1.13  CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The ARM architecture requires that changes to System registers must be synchronized before they take effect. This can lead to CONSTRAINED UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

### K1.1.14  Translation Table Base Address alignment

A misaligned Translation Table Base Address can occur if:

- The VMSAv8-32 Short-descriptor translation table format is enabled and TTBR0[13-N:7], which is defined to be RES0, contains one or more nonzero values.
- The VMSAv8-32 Long-descriptor translation table format is enabled, and TTBR0[x-1:3], TTBR1[x-1:3], HTTBR[x-1:3], or VTTBR[x-1:3], which are defined to be RES0, contain one or more nonzero values.

In the event of a misaligned Translation Table Base Address, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all bits were zero:
  - The value that is read back might be the value written or it might be zero.

- The calculation of an address for a translation table walk using that register might be corrupted in those bits that are nonzero.

### K1.1.15  Handling of System register control fields for Advanced SIMD and floating-point operation

For historical reasons described in Background to the System register interface on page G1-5314, each of the CPACR, HCPTR, and NSACR has a pair of control fields that were defined to have identical functionality for controlling Advanced SIMD and floating-point operation. These fields are:

- CPACR.{cp10, cp11}.
- HCPTR.{TCP10, TCP11}.
- NSACR.{cp10, cp11}.

The architecture requires that both fields in one of these pairs are programmed to the same value. If this is not done, then the CONSTRAINED UNPREDICTABLE behavior is that behavior is the same as if the cp11, or TCP11, control field was equal to the cp10, or TCP10, field in all respects other than the value read back by a direct read of the register. After a register write that writes different values to the two fields of a pair, a direct read of the register might return an UNKNOWN value for the cp11 or TCP11 field.

**Note**

This means that, when different values are written to the {cp10, cp11} fields in a single register, the architecture permits but does not require that a read of that register returns the value written to the cp11 field.

**CONSTRAINED UNPREDICTABLE CPACR and NSACR settings**

If CPACR.cp<n> contains the encoding ‘10’, then one of the following behaviors must occur:

- The encoding maps onto any of the allocated values, but otherwise does not cause UNPREDICTABLE behavior.
• The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.

Note

In ARMv7, CPACR had a D32DIS bit, and NSACR had an NSD32DIS bit. There is no CPACR.D32DIS or NSACR.NSD32DIS in ARMv8-A, and the corresponding bits in the two registers are RES0.

K1.1.16 The Performance Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Performance Monitors Extension in AArch32 state:

• CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXEVCNTR.
• CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n> and PMEVTYPER<n> on page K1-7198.
• CONSTRAINED UNPREDICTABLE behavior caused by HDCR.HPMN on page K1-7198.

CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXEVCNTR

The following cases can cause CONSTRAINED UNPREDICTABLE behavior:

• If PMSELR.SEL is not equal to 31, and PMSELR.SEL is greater than or equal to PMCR.N, and the PE is executing in Secure state or in Non-secure Hyp mode.
• If PMSELR.SEL is not 31, and PMSELR.SEL is greater than or equal to HDCR.HPMN, and the PE is executing in a Non-secure mode other than Hyp mode.

In these UNPREDICTABLE cases, one of the following behaviors must occur:

• Accesses to PMXEVTYPER or PMXEVCNTR from that mode are UNDEFINED.
• Accesses to PMXEVTYPER or PMXEVCNTR from that mode behave as RAZ/WI.
• Accesses to PMXEVTYPER or PMXEVCNTR from that mode execute as NOPs.
• Accesses to PMXEVTYPER or PMXEVCNTR from that mode behave as if PMSELR.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
• Accesses to PMXEVTYPER or PMXEVCNTR behave as if PMSELR.SEL is 31.
• In Non-secure state, for an access to PMXEVTYPER or PMXEVCNTR from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  — EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  — EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

If PMSELR.SEL is equal to 31, then one of the following behaviors must occur:

• Accesses to PMXEVCNTR are UNDEFINED.
• Accesses to PMXEVCNTR behave as RAZ/WI.
• Accesses to PMXEVCNTR execute as NOPs.
• Accesses to PMXEVCNTR behave as if PMSELR.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
• In Non-secure state, for an access to PMXEVCNTR from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  — EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
--- EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

Note

In an implementation that includes EL2, in Non-secure state at PL0 and PL1, HDCR.HPMN, or MDCR_EL2.HPMN, identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

CONSTRANDED UNPREDICTABLE accesses to PMEVCNTR<n> and PMEVTYPER<n>

If <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVCNTR<n> and PMEVTYPER<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- In Non-secure state, for an access to PMEVCNTR<n> or PMEVTYPER<n> from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  - EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

Note

In an implementation that includes EL2, in Non-secure state at PL0 and PL1, HDCR.HPMN, or MDCR_EL2.HPMN, identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

CONSTRANDED UNPREDICTABLE behavior caused by HDCR.HPMN

If HDCR.HPMN is set to 0 or to a value greater than PMCR.N, then the CONSTRAINED UNPREDICTABLE behavior is:

- The value returned by a direct read of HDCR.HPMN is UNKNOWN.
- Either:
  - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if HDCR.HPMN is set to an UNKNOWN non-zero value less than PMCR.N.
  - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

K1.1.17 The Activity Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Activity Monitors registers in AArch32 state:

- CONSTRAINED UNPREDICTABLE accesses to AMEVCNTR0<n> and AMEVTYPER0<n>.
- CONSTRAINED UNPREDICTABLE accesses to AMEVCNTR1<n> and AMEVTYPER1<n> on page K1-7199.
- CONSTRAINED UNPREDICTABLE accesses to AMCNTENCLR1 and AMCNTENSET1 on page K1-7199.

CONSTRANDED UNPREDICTABLE accesses to AMEVCNTR0<n> and AMEVTYPER0<n>

If <n> is greater than the number of architected activity monitor event counters, reads and writes of AMEVCNTR0<n> and AMEVTYPER0<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP.

--- Note

AMCGCR.CG0NC identifies the number of architected activity monitor event counters.

CONSTRANDED UNPREDICTABLE accesses to AMEVCNTR1<n> and AMEVTYPE1<n>

If <n> is greater than the number of auxiliary activity monitor event counters, reads and writes of AMEVCNTR1<n> and AMEVTYPE1<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:
• Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP.

--- Note

AMCGCR.CG1NC identifies the number of auxiliary activity monitor event counters.

CONSTRANDED UNPREDICTABLE accesses to AMCNTENCLR1 and AMCNTENSET1

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENCLR1 and AMCNTENSET1 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:
• Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP.

--- Note

The number of auxiliary activity monitor event counters implemented is zero exactly when AMCFGR.NCG == 0b0000.

K1.1.18 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, this generates an exception:
• If this exception is taken to an Exception level that is using AArch64 then ESR_ELx is UNKNOWN.
• If this exception is taken to EL2 and EL2 is using AArch32, then the HSR is unknown.

--- Note

The value written to ESR or HSR must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but resulted from a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.1.19 Out of range VA

If the PE executes an instruction for which the instruction address, size, and alignment mean it contains the bytes 0xFFFF FFFF and 0x0000 0000, then the bytes that wrap around and appear to be from 0x0000 0000 onwards come from an UNKNOWN address.

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean it accesses bytes 0xFFFF FFFF and 0x0000 0000, then the bytes that wrap around and appear to be from 0x0000 0000 onwards come from an UNKNOWN address.
K1.1.20 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location when address translation is enabled.

If a branch causes the program counter to point to a location in memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

K1.1.21 Multi-access instructions that load the PC from Device memory

Multi-access instructions that load the PC from Device memory when address translation is enabled are UNPREDICTABLE in AArch32 state. In the ARMv8-A architecture in AArch32 state an implementation must perform one of the following behaviors:

- It loads the PC from the memory location as if the memory location had the Normal Non-cacheable attribute.
- It generates a permission fault.

K1.1.22 Programming CSSELR.Level for a cache level that is not implemented

If CSSELR.Level is programmed to a cache level that is not implemented, then a read of CSSELR returns an UNKNOWN value in CSSELR.Level.

If CSSELR.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR an implementation must perform one of the following behaviors:

- The CCSIDR read is treated as a NOP.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

When ARMv8.3-CCIDX is implemented, CCSIDR2 is implemented. If CSSELR.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR2 an implementation must perform one of the following behaviors:

- The CCSIDR2 read is treated as a NOP.
- The CCSIDR2 read is UNDEFINED.
- The CCSIDR2 read returns an UNKNOWN value.

K1.1.23 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an alignment fault caused by the memory type.

For the Non-secure PL1&0 translation regime:

— If the stage 1 translation causes the mismatch then the resulting exception is taken to PL1.
— If the stage 2 translation causes the mismatch then the resulting exception is taken to PL2.
Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors

K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

---

If both stages of translation cause the mismatch then the resulting exception can be taken to either PL1 or PL2.

- The instruction executes as a NOP.

**K1.1.24 Crossing a 4KB boundary with a Device access**

A memory access from a load or store instruction to Device memory that crosses a 4KB boundary results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses, except that there is no guarantee of ordering between memory accesses.
- The instruction generates an Alignment fault caused by the memory type.

For the Non-secure PL1&0 translation regime:

- If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to PL1.
- If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to PL2.
- If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either PL1 or PL2.

- The instruction executes as a NOP.

**Note**

The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.

---

**K1.1.25 UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs**

*Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-3611* defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. These cases were UNPREDICTABLE in ARMv7. In summary, these cases are:

- The target virtual address of a *StoreExcl* instruction is different from the virtual address of the preceding *LoadExcl* instruction in the same thread of execution.
- The transaction size of a *StoreExcl* instruction is different from the transaction size of the preceding *LoadExcl* instruction in the same thread of execution.
- The memory attributes for a *StoreExcl* instruction are different from the memory attributes for the preceding *LoadExcl* instruction in the same thread of execution, either:
  - Because the translation of the accessed address changes between the *LoadExcl* instruction and the *StoreExcl* instruction.
  - Because the *LoadExcl* instruction and the *StoreExcl* instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in *Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-3611* for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.
Note
Additional CONSTRAINED UNPREDICTABLE cases can apply to Load-Exclusive and Store-Exclusive instructions, see CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set on page K1-7203.

K1.1.26 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings

The A32 and T32 instruction sets include encodings that result in CONSTRAINED UNPREDICTABLE behavior when they are decoded.

CONSTRAINED UNPREDICTABLE behavior of CRC32 instruction encodings

In the A32 and T32 instruction sets, there are encodings of the CRC32 and CRC32C instructions that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in the following places in the A32 and T32 instruction sets:

- Cyclic Redundancy Check on page F4-3764 for the A32 instruction set, with sz = 11.
- Data-processing (two source registers) on page F3-3750 for the T32 instruction set, with op1 = 10x and op2 = 11.

The CONSTRAINED UNPREDICTABLE behavior for these encodings is described in CRC32 on page F5-3913 and CRC32C on page F5-3916.

CONSTRAINED UNPREDICTABLE behavior of other A32 instruction encodings

In the A32 instruction set, there are encodings that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in:

- Miscellaneous on page F4-3798.
- Memory hints and barriers on page F4-3808.
- Barriers on page F4-3809.

The CONSTRAINED UNPREDICTABLE behavior is that an implementation must treat the encodings in one of the following ways:

- The instruction encoding is UNDEFINED.
- The instruction encoding executes as NOP.

K1.1.27 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions DCCISW, DCCSW, and DCISW, if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Note
This CONSTRAINED UNPREDICTABLE behavior applies, also, to the A64 cache maintenance by set/way instructions DC CISW, DC CSW, and DC ISW.
K1.1.28 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 System instructions.

--- Note ---

If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

---

SRS (T32)

For a description of this instruction and the encoding, see SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-4301.

**CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - R13 of the current mode is used.
  - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

SRS (A32)

For a description of this instruction and the encoding, see SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-4301.

**CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - R13 of the current mode is used.
  - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

SUBS PC, LR and related instructions (T32)

For a description of this instruction and the encoding, see the exception return form of SUB, SUBS (immediate) on page F5-4403.

**CONSTRAINED UNPREDICTABLE behavior**

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
• If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return.

——— Note ————
An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

—————

For encoding T5:
• If hw2[3:0] are 0b1110, and the instruction is executed when not in Hyp mode, System mode, or User mode, then one of the following behaviors must occur:
  — The instruction is UNDEFINED.
  — The instruction is treated as a NOP.
  — The instruction is treated as if hw2[3:0] are 0b1110.
  — The program counter is set using the value in the register specified by hw2[3:0].

SUBS PC. LR and related instructions (A32)
For a description of this instruction and the encoding, see the exception return forms of MOV, MOVs (register) on page F5-4091 and SUB, SUBS (immediate) on page F5-4403.

CONSTRAINED UNPREDICTABLE behavior
For all encodings:
• If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.

• If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return.

——— Note ————
An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

—————
K1.1.29 CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 Advanced SIMD and floating-point instructions listed in Alphabetical list of Advanced SIMD and floating-point instructions on page F6-4528.

Note

• The pseudocode used in this section to describe cases that can result in CONSTRAINED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.

• If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

VCVT (between floating-point and fixed-point)

For a description of this instruction and the encoding, see VCVT (between floating-point and fixed-point, floating-point) on page F6-4685.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD1 (multiple single elements)

For a description of this instruction and the encoding, see VLD1 (multiple single elements) on page F6-4771.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD1 (single element to all lanes)

For a description of this instruction and the encoding, see VLD1 (single element to all lanes) on page F6-4768.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (multiple 2-element structures)

For a description of this instruction and the encoding, see VLD2 (multiple 2-element structures) on page F6-4788.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (single 2-element structure to one lane)

For a description of this instruction and the encoding, see VLD2 (single 2-element structure to one lane) on page F6-4779.
If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD2 (single 2-element structure to all lanes)**

For a description of this instruction and the encoding, see *VLD2 (single 2-element structure to all lanes)* on page F6-4785.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD3 (multiple 3-element structures)**

For a description of this instruction and the encoding, see *VLD3 (multiple 3-element structures)* on page F6-4802.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD3 (single 3-element structure to one lane)**

For a description of this instruction and the encoding, see *VLD3 (single 3-element structure to one lane)* on page F6-4793.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD3 (single 3-element structure to all lanes)**

For a description of this instruction and the encoding, see *VLD3 (single 3-element structure to all lanes)* on page F6-4799.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD4 (multiple 4-element structures)**

For a description of this instruction and the encoding, see *VLD4 (multiple 4-element structures)* on page F6-4814.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD4 (single 4-element structure to one lane)**

For a description of this instruction and the encoding, see *VLD4 (single 4-element structure to one lane)* on page F6-4805.
Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors

K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLD4 (single 4-element structure to all lanes)**

For a description of this instruction and the encoding, see [VLD4 (single 4-element structure to all lanes)](page F6-4811).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLDM**

For a description of this instruction and the encoding, see [VLDM, VLDMDB, VLDMIA](page F6-4817).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VMOV (between two general-purpose registers and two single-precision registers)**

For a description of this instruction and the encoding, see [VMOV (between two general-purpose registers and two single-precision registers)](page F6-4893).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VMOV (between two general-purpose registers and a doubleword floating-point register)**

For a description of this instruction and the encoding, see [VMOV (between two general-purpose registers and a doubleword floating-point register)](page F6-4872).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST1 (multiple single elements)**

For a description of this instruction and the encoding, see [VST1 (multiple single elements)](page F6-5134).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST2 (multiple 2-element structures)**

For a description of this instruction and the encoding, see [VST2 (multiple 2-element structures)](page F6-5148).
If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST2 (single 2-element structure from one lane)**

For a description of this instruction and the encoding, see *VST2 (single 2-element structure from one lane)* on page F6-5142.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST3 (multiple 3-element structures)**

For a description of this instruction and the encoding, see *VST3 (multiple 3-element structures)* on page F6-5159.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST3 (single 3-element structure from one lane)**

For a description of this instruction and the encoding, see *VST3 (single 3-element structure from one lane)* on page F6-5153.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST4 (multiple 4-element structures)**

For a description of this instruction and the encoding, see *VST4 (multiple 4-element structures)* on page F6-5168.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VST4 (single 4-element structure from one lane)**

For a description of this instruction and the encoding, see *VST4 (single 4-element structure from one lane)* on page F6-5162.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VSTM**

For a description of this instruction and the encoding, see *VSTM, VSTMDB, VSTMIA* on page F6-5171.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.
K1.1.30 CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR

The following subsections describe the CONSTRAINED UNPREDICTABLE behavior associated with programming the VTCR:

- Misprogramming VTCR.S.
- Misprogramming VTCR.{SL0, T0SZ}.

Misprogramming VTCR.S

VTCR.S must be programmed to the value of T0SZ[3], or the effect is CONSTRAINED UNPREDICTABLE. For the ARMv8-A architecture, if VTCR.S is not programmed correctly, then the VTCR.T0SZ value is treated as an UNKNOWN value.

--- Note ---
The CONSTRAINED UNPREDICTABLE behavior described in Misprogramming VTCR.{SL0, T0SZ} means the UNKNOWN VTCR.T0SZ value might generate a Translation fault.

Misprogramming VTCR.{SL0, T0SZ}

If the stage 2 input address size, as programmed in VTCR.T0SZ, is out of range with respect to the starting level, as programmed in the VTCR.SL0 field, or the VTCR.SL0 field is programmed to a reserved value, then at the time of a translation walk that uses the stage 2 translation, a stage 2 level 1 Translation Fault is generated.

K1.1.31 CONSTRAINED UNPREDICTABLE behavior of EL2 features

The following sections describe CONSTRAINED UNPREDICTABLE behavior that can occur in an implementation that includes EL2 where EL2 can use AArch32:

- ERET in User mode or System mode.
- Accessing Hyp mode from outside Hyp mode.
- Modifying PSTATE.M when in Hyp mode on page K1-7210
- Use of Hyp mode in Secure state on page K1-7210.
- Execution of Load/Store unprivileged instructions in Hyp mode on page K1-7210.
- Exception return to Hyp mode on page K1-7210.
- Accessing registers that cannot be accessed using MSR/MRS instructions on page K1-7210.
- Memory type handling on page K1-7211.
- Hyp mode TLB maintenance instructions on page K1-7211.
- Hyp mode VA to PA address translation instructions on page K1-7211.
- Stage 1 default memory type on page K1-7211.
- Trapping of general exceptions to Hyp mode on page K1-7211.
- Prevention of rootkits using Hyp mode or Secure state on page K1-7212.
- HVC on page K1-7212.
- MSR (banked register) and MRS (banked register) on page K1-7212.

ERET in User mode or System mode

If ERET is executed in User mode or System mode, it behaves as described in SUBS PC, LR and related instructions (T32) on page K1-7203.

Accessing Hyp mode from outside Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in SRS (T32) on page K1-7203 and SRS (A32) on page K1-7203.
Modifying PSTATE.M when in Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in SRS (T32) on page K1-7203 and SRS (A32) on page K1-7203.

Use of Hyp mode in Secure state

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in SRS (T32) on page K1-7203 and SRS (A32) on page K1-7203.

Execution of Load/Store unprivileged instructions in Hyp mode

If LDRT, LDRSHT, LDRHT, LDRSBT, LDRBT, STRT, STRHT or STRBT are executed in Hyp mode, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs the equivalent, corresponding LDR, LDRSH, LDRH, LDRSB, LDRB, STR, STRH or STRB instruction in Hyp mode.

Exception return to Hyp mode

Exception returns to Hyp mode when SCR.NS == 0 or from a Non-secure PL1 mode invokes the ARMv8 illegal exception return.

Accessing registers that cannot be accessed using MSR/MRS instructions

The following MSR and MRS instructions can lead to CONSTRAINED UNPREDICTABLE behavior:

  MSR <Rm>_<mode>, <Rn>
  MSR SPSR_<mode>, <Rn>
  MSR ELR_hyp, <Rn>
  MRS <Rn>, <Rm>_<mode>
  MRS <Rn>, SPSR_<mode>
  MRS <Rn>, ELR_hyp

If these instructions are executed in either Secure or Non-secure User mode, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.

If the MSR and MRS instructions attempt to access a register that cannot be legally accessed, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• For MRS instructions, the destination general-purpose register becomes UNKNOWN.
• For MSR instructions, if the register specified could be accessed from the current mode by other mechanisms, then this register is UNKNOWN. Otherwise the instruction executes as a NOP.
Memory type handling

If the attributes for a memory location after combining stage 1 and stage 2 of a translation regime is Normal Inner Non-cacheable, Outer Non-cacheable, then the shareability attributes after combining the two stages of translation is Outer Shareable.

Hyp mode TLB maintenance instructions

If a TLBIMVAH, TLBIMVALH, TLBIMVAHIS, TLBIMVALHIS, TLBIALLH, TLBIALLHIS, TLBIALLNSNH, TLBIALLNSNHIS, TLBIIPAS2, TLBIIPAS2L, TLBIIPAS2IS, or TLBIIPAS2LIS instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction is executes as if it had been executed in Monitor mode.

For more information about these instructions see The scope of TLB maintenance instructions on page G5-5546.

Hyp mode VA to PA address translation instructions

If an ATS1HR or ATS1HW instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction is executes as if it had been executed in Monitor mode.

For more information about these instructions see Address translation instruction naming and operation summary on page G5-5585.

Stage 1 default memory type

If HCR.DC == 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with:

• SCTLR.M == 0, regardless of the actual value of SCTLR.M, other than for the value returned by an explicit read of SCTLR.M.
• HCR.VM == 1, regardless of the actual value of HCR.VM, other than for an explicit read of this bit.

Trapping of general exceptions to Hyp mode

Attempting to perform an exception return to a Non-secure PL1 mode when HCR.TGE == 1 invokes an illegal exception return.

Attempting to change from Monitor mode to a Non-secure PL1 mode when HCR.TGE == 1 by executing a CPS or MSR instruction generates an Illegal Execution state exception, by not changing the mode, and setting PSTATE.IL to 1.

When EL3 is using AArch32, attempting to change from a Secure PL1 mode to a Non-secure PL1 mode when HCR.TGE is set, by changing SCR.NS from 0 to 1, results in no change of SCR.NS.

Because taking an exception into Non-secure PL1 modes leads to a CONSTRAINED UNPREDICTABLE situation, the following additional properties apply when HCR.TGE == 1:

• All exceptions that would be routed to EL1 are routed to EL2.
• Non-secure SCTLR.M is treated as being 0, regardless of its actual value, other than for an explicit read of this bit.
• HCR.FMO, HCR.IMO, and HCR.AMO are treated as being 1, regardless of their actual value, other than for an explicit read of these bits.
Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors
K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

• All virtual interrupts are disabled.
• Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.

Prevention of rootkits using Hyp mode or Secure state

If an HVC instruction is executed in Hyp mode when SCR.HCE == 0, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.

If an SMC instruction is executed in a Secure privileged mode when SCR.SCD == 1, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.

HVC

For a description of this instruction and the encoding, see HVC on page F5-3949.

For the A1 encoding, if cond field !=1110, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction executes unconditionally.
• The instruction executes conditionally.

MSR (banked register) and MRS (banked register)

Encoding and use of banked register transfer instructions on page F5-4523 identifies cases where attempted execution of an MRS (banked register) or MSR (banked register) was UNPREDICTABLE in ARMv7 and becomes CONSTRAINED UNPREDICTABLE in ARMv8. This includes cases where:
• The target register specified by the {R, SYS<n>} fields of the instruction encoding is not accessible from the PE mode in which the instruction was executed, see Usage restrictions on the banked register transfer instructions on page F5-4524.
• The instruction was executed specifying unallocated {R, SYS<n>} field values, see Encoding the register argument in the banked register transfer instructions on page F5-4525.

If one of these encodings for an MSR (banked register) or MRS (banked register) instruction is executed, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• An allocated MSR (banked register) or MRS (banked register) instruction is executed.

K1.1.32 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated, all unallocated or reserved values of fields with allocated values within the AArch32 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:
• The encoding maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
• The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.
• The encoding causes the field to have no functional effect.
Note

These constraints are identical to those for the equivalent AArch64 definitions, as given in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7227.

K1.1.33 CONSTRAINED UNPREDICTABLE behavior in Debug state

*Behavior in Debug state on page H2-6429* of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.
K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors

It contains the following sections:

• Overview of the constraints on AArch64 UNPREDICTABLE behaviors.
• SBZ or SBO fields in A64 instructions.
• CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values.
• CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization on page K1-7215.
• Translation table base address alignment on page K1-7216.
• The Performance Monitors Extension on page K1-7216.
• The Activity Monitors Extension on page K1-7217.
• Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED on page K1-7217.
• Out of range virtual address on page K1-7218.
• Instruction fetches from Device memory on page K1-7218.
• Programming the CSSELril.Level for a cache level that is not implemented on page K1-7218.
• Crossing a page boundary with different memory types or Shareability attributes on page K1-7219.
• Crossing a peripheral boundary with a Device access on page K1-7219.
• CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-7219.
• CONSTRAINED UNPREDICTABLE behavior for A64 instructions on page K1-7220.
• Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-7227.
• Reserved values in System and memory-mapped registers and translation table entries on page K1-7227.
• CONSTRAINED UNPREDICTABLE behavior in Debug state on page K1-7228.

K1.2.1 Overview of the constraints on AArch64 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch64 state, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Note
Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases being handled in any way other than those listed under the heading CONSTRAINED UNPREDICTABLE.

K1.2.2 SBZ or SBO fields in A64 instructions

Some A64 instructions have (0) or (1) in the instruction decode to indicate should-be-zero, SBZ, or should-be-one, SBO, as described in Fixed values in AArch64 instruction and System register descriptions on page C2-165. Except for specific cases identified in CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-7219, if the instruction bit pattern of an instruction is executed with these fields not having the should be values, one of the following must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction operates as if the bit had the should-be value.
• Any destination registers of the instruction become UNKNOWN.

K1.2.3 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.
Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes ARMv8.2-TTCNP, this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting TTBR.CnP to 1, as identified in the descriptions of the TTBR.CnP field. In this case, for a particular TTBR, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that TTBR on one of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.
- An amalgamation of the values of the translation table entries pointed to by that TTBR on two or more of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.

Note

If the Effective value of a control or data value that determines the behavior of the PE results from the amalgamation of two or more values then that Effective value must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.
- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a TTBR.CnP value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that TTBR and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits in a TLB might generate an exception, reporting the exception using the TLB conflict fault code, see TLB conflict aborts on page D5-2501.

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

K1.2.4 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The ARM architecture requires that changes to System registers must be synchronized before they take effect. This can lead to UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.
**K1.2.5 Translation table base address alignment**

In the translation table base registers TTBR0_EL1, TTBR1_EL1, TTBR0_EL2, VTTBR_EL2, and TTBR0_EL3, register bits[48:x] hold the translation table base address, where x depends on the translation table granule size and the size of the addressed translation table, as described in Memory translation granule size on page D5-2394. Register bits[(x-1):0], unless redefined for another purpose, correspond to bits[(x-1):0] of the translation table base address and therefore are RES0.

--- **Note** ---

- When ARMv8.2-LPA is implemented and the 64KB granule size is used, register bits[5:2] are redefined to hold bits[51:48] of the translation table base address.
- When ARMv8.2-TTCNP is implemented register bit[0] is redefined as the CnP bit.

For these registers, if one or more RES0 bits in register bits [(x-1):0] do not have a value of 0, this can result in a misaligned translation table base address. In this case, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all the bits had a value of 0:
  - The value read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using those registers might be corrupted in those bits that are nonzero.

For more information, see the appropriate TTBR.BADDR field description.

**K1.2.6 The Performance Monitors Extension**

The following cases can cause CONSTRAINED UNPREDICTABLE behavior:

- If PMSELR_EL0.SEL is not equal to 31, and PMSELR_EL0.SEL is greater than or equal to PMCR_EL0.N, and the PE is executing in an Exception level in Secure state or in EL2.
- If PMSELR_EL0.SEL is not 31, and PMSELR_EL0.SEL is greater than or equal to MDCR_EL2.HPMN, and the PE is executing in an Exception level in Non-secure state other than in EL2.

In these cases, one of the following behaviors must occur:

- Accesses to PMXEVTYPE_EL0 or PMXEVCNTR_EL0 from that state are UNDEFINED.
- Accesses to PMXEVTYPE_EL0 or PMXEVCNTR_EL0 from that state behave as RAZ/WI.
- Accesses to PMXEVTYPE_EL0 or PMXEVCNTR_EL0 from that state execute as NOPs.
- Accesses to PMXEVTYPE_EL0 or PMXEVCNTR_EL0 from that state behave as if PMSELR_EL0.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- Accesses to PMXEVTYPE_EL0 or PMXEVCNTR_EL0 from that state behave as if PMSELR_EL0.SEL is 31.
- In Non-secure state, for an access to PMXEVTYPE_EL0 or PMXEVCNTR_EL0 from EL0 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from EL0 are permitted when:
  - EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  - EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

If PMSELR_EL0.SEL is equal to 31, then one of the following behaviors must occur:

- Accesses to PMXEVCNTR_EL0 are UNDEFINED.
- Accesses to PMXEVCNTR_EL0 behave as RAZ/WI.
- Accesses to PMXEVCNTR_EL0 execute as NOPs.
• Accesses to PMXEVCNTR_EL0 behave as if PMSELR_EL0.SEL contains an unknown value that is less than the number of counters accessible at the current Exception level and Security state.

If MDCR_EL2.HPMN is set to 0, or to a value larger than PMCR_EL0.N, then the following CONSTRAINED UNPREDICTABLE behavior applies:

• The value returned by a direct read of MDCR_EL2.HPMN is UNKNOWN.

• Either:
  — An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if MDCR_EL2.HPMN is set to an UNKNOWN non-zero value less than PMCR_EL0.N.
  — All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

K1.2.7 The Activity Monitors Extension

If <n> is greater than the number of architected activity monitor event counters, reads and writes of AMEVCNTR0<n>_EL0 and AMEVTYPER0<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

• Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP.

Note AMCGCR_EL0.CG0NC identifies the number of architected activity monitor event counters.

If <n> is greater than the number of auxiliary activity monitor event counters, reads and writes of AMEVCNTR1<n>_EL0 and AMEVTYPER1<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

• Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP.

Note AMCGCR_EL0.CG1NC identifies the number of auxiliary activity monitor event counters.

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENCLR1_EL0 and AMCNTENSET0_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

• Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP.

Note The number of auxiliary activity monitor event counters implemented is zero exactly when AMCFGR_EL0.NCG == 0b0000.

K1.2.8 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, ESR_ELx is UNKNOWN.
--- Note ---
The value written to ESR_ELx must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but was the result of a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.2.9 Out of range virtual address

If the PE executes a load or store instruction with tagged addressing disabled in the current translation regime, and where the computed virtual address, total access size, and alignment mean that it accesses the bytes at 0xFFFF FFFF FFFF FFFF and 0x0000 0000 0000 0000, then the bytes that appear to be from 0x0000 0000 0000 0000 onwards are accessed at an UNKNOWN address.

If the PE executes a load or store instruction with tagged addressing enabled in the current translation regime, and where the computed address, total access size, and alignment mean that it accesses the bytes at 0xFFFF FFFF FFFF and 0x0000 0000 0000 0000, then the bytes that appear to be from 0x0000 0000 0000 0000 onwards are accessed at an unknown address and the tags associated with address also become unknown.

--- Note ---
Because of program counter alignment constraints, it is impossible for a PE to fetch an A64 instruction that includes both the byte at virtual address 0xFFFF FFFF FFFF FFFF and the byte at virtual address 0x0000 0000 0000 0000.

K1.2.10 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location at times when address translation is enabled.

If a branch causes the program counter to point to an area of memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

• It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
• It generates a Permission fault.

K1.2.11 Programming the CSSELR_EL1.Level for a cache level that is not implemented

If the CSSELR_EL1.Level is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 returns an UNKNOWN value in CSSELR_EL1.Level.

If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR_EL1 an implementation must perform one of the following behaviors:

• The CCSIDR_EL1 read is treated as a NOP.
• The CCSIDR_EL1 read is UNDEFINED.
• The CCSIDR_EL1 read returns an UNKNOWN value.

When ARMv8.3-CCIDX is implemented, CCSIDR2_EL1 is implemented. If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR2_EL1 an implementation must perform one of the following behaviors:

• The CCSIDR2_EL1 read is treated as a NOP.
• The CCSIDR2_EL1 read is UNDEFINED.
• The CCSIDR2_EL1 read returns an UNKNOWN value.
K1.2.12 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an Alignment fault caused by the memory type.

For the Non-secure EL1&0 translation regime:
- If the stage 1 translation generated the mismatch then the resulting exception is taken to EL1.
- If the stage 2 translation generated the mismatch then the resulting exception is taken to EL2.
- If both stages of translation generate the mismatch then the exception can be taken to either EL1 or EL2.

- The instruction executes as a NOP.

K1.2.13 Crossing a peripheral boundary with a Device access

Performing memory accesses from one load or store instruction to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between memory accesses.
- The instruction generates an alignment fault caused by the memory type.

For the Non-secure EL1&0 translation regime:
- If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to EL1.
- If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to EL2.
- If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either EL1 or EL2.

- The instruction executes as a NOP.

Note

The boundary referred to is between two Device memory regions that are both:

- Of the size of the smallest implemented translation granule.
- Aligned to the size of the smallest implemented translation granule.

K1.2.14 CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-141 defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. In summary, these cases are:

- The target virtual address of a StoreExc1 instruction is different from the virtual address of the preceding LoadExc1 instruction in the same thread of execution.
Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors

K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors

• The transaction size of a StoreExcl instruction is different from the transaction size of the preceding LoadExcl instruction in the same thread of execution.

• The StoreExcl instruction accesses a different number of registers than the preceding LoadExcl instruction in the same thread of execution.

• The memory attributes for a StoreExcl instruction are different from the memory attributes for the preceding LoadExcl instruction in the same thread of execution, either:
  — Because the translation of the accessed address changes between the LoadExcl instruction and the StoreExcl instruction.
  — Because the LoadExcl instruction and the StoreExcl instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-141 for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

K1.2.15 CONSTRAINED UNPREDICTABLE behavior for A64 instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A64 instructions listed in Chapter C6 A64 Base Instruction Descriptions and Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions.

LDAXP
For a description of this instruction and the encoding, see LDAXP on page C6-854.

CONSTRAINED UNPREDICTABLE behavior
If $t = t2$, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDNP
For a description of this instruction and the encoding, see LDNP on page C6-878.

CONSTRAINED UNPREDICTABLE behavior
If $t = t2$, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDNP (SIMD&FP)
For a description of this instruction and the encoding, see LDNP (SIMD&FP) on page C7-1662.

CONSTRAINED UNPREDICTABLE behavior
If $t = t2$, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDP

For a description of this instruction and the encoding, see LDP on page C6-880.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and (t == n || t2 == n) && n != 31, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If t == t2, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDP (SIMD&FP)

For a description of this instruction and the encoding, see LDP (SIMD&FP) on page C7-1664.

CONSTRAINED UNPREDICTABLE behavior

If t == t2, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDPSW

For a description of this instruction and the encoding, see LDPSW on page C6-883.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and (t == n || t2 == n) && n != 31, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If t == t2, then one of the following behaviors must occur:
• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.
**Note**
Pre-indexed addressing and post-indexed addressing imply writeback.

### LDR (immediate)

For a description of this instruction and the encoding, see *LDR (immediate)* on page C6-886.

**CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

**Note**
Pre-indexed addressing and post-indexed addressing imply writeback.

### LDRB (immediate)

For a description of this instruction and the encoding, see *LDRB (immediate)* on page C6-895.

**CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

**Note**
Pre-indexed addressing and post-indexed addressing imply writeback.

### LDRH (immediate)

For a description of this instruction and the encoding, see *LDRH (immediate)* on page C6-899.

**CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

**Note**
Pre-indexed addressing and post-indexed addressing imply writeback.
LDRSB (immediate)

For a description of this instruction and the encoding, see LDRSB (immediate) on page C6-903.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

--- Note ---

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSH (immediate)

For a description of this instruction and the encoding, see LDRSH (immediate) on page C6-908.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

--- Note ---

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSW (immediate)

For a description of this instruction and the encoding, see LDRSW (immediate) on page C6-913.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

--- Note ---

Pre-indexed addressing and post-indexed addressing imply writeback.

LDXP

For a description of this instruction and the encoding, see LDXP on page C6-974.
**CONSTRANGED UNPREDICTABLE behavior**

If \( t = t_2 \), then one of the following behaviors must occur:
- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs a load using the specified addressing mode, and the base register is set to an **UNKNOWN** value.

**STP**

For a description of this instruction and the encoding, see *STP on page C6-1131.*

**CONSTRANGED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( (t = n \ || \ t_2 = n) \ && \ n \neq 31 \), then one of the following behaviors must occur:
- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs a store using the specified addressing mode but the value stored is **UNKNOWN**.

--- **Note** ---

Pre-indexed addressing and post-indexed addressing imply writeback.

**STLXP**

For a description of this instruction and the encoding, see *STLP on page C6-1120.*

**CONSTRANGED UNPREDICTABLE behavior**

If \( s = t \ || \ (s = t_2) \), then one of the following behaviors must occur:
- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to the specified address, but the value stored is **UNKNOWN**.

If \( s = n \ && \ n \neq 31 \) then one of the following behaviors must occur:
- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to an **UNKNOWN** address.

**STLXR**

For a description of this instruction and the encoding, see *STLR on page C6-1123.*

**CONSTRANGED UNPREDICTABLE behavior**

If \( s = t \), then one of the following behaviors must occur:
- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to the specified address, but the value stored is **UNKNOWN**.

If \( s = n \ && \ n \neq 31 \) then one of the following behaviors must occur:
- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to an **UNKNOWN** address.
STLXRB

For a description of this instruction and the encoding, see STLXRB on page C6-1125.

**CONSTRAINED UNPREDICTABLE behavior**

If \( s = t \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to the specified address, but the value stored is **UNKNOWN**.

If \( s = n \land n \neq 31 \) then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to an **UNKNOWN** address.

STLXRH

For a description of this instruction and the encoding, see STLXRH on page C6-1127.

**CONSTRAINED UNPREDICTABLE behavior**

If \( s = t \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to the specified address, but the value stored is **UNKNOWN**.

If \( s = n \land n \neq 31 \) then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs the store to an **UNKNOWN** address.

STR (immediate)

For a description of this instruction and the encoding, see STR (immediate) on page C6-1134.

**CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- The instruction performs a store using the specified addressing mode but the value stored is **UNKNOWN**.

--- **Note** ---

Pre-indexed addressing and post-indexed addressing imply writeback.

---

STRB (immediate)

For a description of this instruction and the encoding, see STRB (immediate) on page C6-1139.

**CONSTRAINED UNPREDICTABLE behavior**

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
• The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

——— Note ————
Pre-indexed addressing and post-indexed addressing imply writeback.

STRH (immediate)
For a description of this instruction and the encoding, see STRH (immediate) on page C6-1143.

CONSTRAINED UNPREDICTABLE behavior
If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and \( n = t \land n \neq 31 \), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

——— Note ————
Pre-indexed addressing and post-indexed addressing imply writeback.

STXP
For a description of this instruction and the encoding, see STXP on page C6-1187.

CONSTRAINED UNPREDICTABLE behavior
If \( s = t \lor (s = t2) \), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If \( s = n \land n \neq 31 \) then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs the store to an UNKNOWN address.

STXR
For a description of this instruction and the encoding, see STXR on page C6-1190.

CONSTRAINED UNPREDICTABLE behavior
If \( s = t \), then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If \( s = n \land n \neq 31 \) then one of the following behaviors must occur:

• The instruction is UNDEFINED.
• The instruction executes as a NOP.
• The instruction performs the store to an UNKNOWN address.

STXRB
For a description of this instruction and the encoding, see STXRB on page C6-1192.
**Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors**

**K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors**

---

**CONSTRAINED UNPREDICTABLE behavior**

If \( s = t \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If \( s = n \) \&\& \( n \neq 31 \) then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

---

**STXRH**

For a description of this instruction and the encoding, see *STXRH* on page C6-1194.

**CONSTRAINED UNPREDICTABLE behavior**

If \( s = t \), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If \( s = n \) \&\& \( n \neq 31 \) then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

---

**K1.2.16 Out of range values of the Set/Way/Index fields in cache maintenance instructions**

In the cache maintenance by set/way instructions DC CISW, DC CSW, and DC ISW, if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

---

**Note**

This CONSTRAINED UNPREDICTABLE behavior applies, also, to the AArch32 cache maintenance by set/way instructions DCCISW, DCCSW, and DCISW.

---

**K1.2.17 Reserved values in System and memory-mapped registers and translation table entries**

Unless otherwise stated in this manual, all unallocated or reserved values of fields with allocated values within AArch64 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The unallocated value maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The unallocated value causes effects that could be achieved by a combination of more than one of the allocated values.
- The unallocated value causes the field to have no functional effect.
Note

These constraints are identical to those for the equivalent AArch32 definitions, as given in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7212.

K1.2.18 CONSTRAINED UNPREDICTABLE behavior in Debug state

*Behavior in Debug state* on page H2-6429 of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.
Appendix K2
Recommended External Debug Interface

This appendix describes the recommended external debug interface. It contains the following sections:

• About the recommended external debug interface on page K2-7230.
• PMUEVENT bus on page K2-7234.
• Recommended authentication interface on page K2-7235.
• Management registers and CoreSight compliance on page K2-7237.

Note

This recommended external debug interface specification is not part of the ARM architecture specification. Implementers and users of the ARMv8 architecture must not consider this appendix as a requirement of the architecture. It is included as an appendix to this manual only:

• As reference material for users of ARM products that implement this interface.
• As an example of how an external debug interface might be implemented.

The inclusion of this appendix is no indication of whether any ARM products might, or might not, implement this external debug interface. For details of the implemented external debug interface you must always see the appropriate product documentation.
# Appendix K2 Recommended External Debug Interface

## K2.1 About the recommended external debug interface

This specification provides a recommended external debug interface for ARMv8 to define a standard set of connections for validation environments. In general, the connection between components, such as between the PE and Trace extension, is not described here, although the table does include the signals for the CTI connection. Table K2-1 shows the signals in the recommended interface.

See the Note on the first page of this appendix for information about the architectural status of this recommended debug interface.

Figure K2-1 shows the recommended debug interface.
K2.1.1  **EDBGRQ and DBGACK**

**EDBGRQ** is an **IMPLEMENTATION DEFINED** means of generating the External Debug Request debug event described in *External Debug Request debug event on page H3-6475*. The PE asserts **DBGACK** when the PE is in Debug state. The PE might also include variants of this signal:

**DBGTRIGGER**

Asserted by the PE when it commits to entering Debug state.

**DBGCPUDONE**

Asserted by the PE when it has completed all Non-debug state memory accesses and Debug state entry is complete. **DBGCPUDONE** indicates that memory accesses issued by the PE result from operations originating from debugger commands.

In previous architecture versions, these signals provide an interface between the PE and cross-trigger logic. In ARMv8, the architectural Cross-Trigger Interface provides this functionality for external debuggers.

K2.1.2  **Secure and Non-secure views of the debug registers**

If ARMv8.4-Debug is implemented, the external debug interface has views of Secure and Non-secure debug registers. The DAP must ensure that accesses are made only when permitted. The ARM debug interface describes a standard APB-AP programmers model for APB4 which signals Secure and Non-secure accesses on the **PPROT[1]** signal, and is recommended for new designs.

If ARMv8.4-Debug is implemented, and an APB-AP implements an APB3 master port, which does not support Secure and Non-secure views, ARM recommends that the following is implemented:

- If **SPIDEN** is HIGH and **DBGEN** is HIGH, all external debug accesses are treated as Secure.
- If either **SPIDEN** is LOW or **DBGEN** is LOW, all external debug accesses are treated as Non-secure.

If the PE APB slave port is APB4, this might be implemented by, for example, fixing **PPROT[1]** to the inverse of (**SPIDEN & DBGEN**) when bridging from APB3 to APB4.
K2.2 PMUEVENT bus

The PMUEVENT bus exports Performance Monitor events from the PE to an on-chip agent. ARM recommends that it has the following characteristics:

- The bus is synchronous.
- The width of the bus is IMPLEMENTATION DEFINED.
- It is IMPLEMENTATION DEFINED which events are exported on the bus.
- Each exported event occupies a contiguous sub-field of the bus. ARM recommends that the sub-fields of the bus are occupied in the same order as the event numbers.
- If the event can only occur once per cycle, it occupies a single bit. If the event can occur more than once per cycle, it is IMPLEMENTATION DEFINED how the event is encoded. The encoding depends on constraints such as the designated use of the event bus and the number of pins available. For example, the event can be encoded:
  - As a count, using a plain binary number. This is the most useful encoding when exporting to an external counter. It is not a useful encoding for exporting to a Trace extension external input.
  - As a count, using thermometer encoding. This is the most useful encoding when exporting to a Trace extension.
  - Using a single bit encoding to indicate whether the event count is zero or nonzero. This is useful for exporting to an activity monitor where the number of pins is constrained.

If a Trace extension is implemented, the PMUEVENT bus is normally connected to the Trace extension using the external inputs. TRCEXTINSEL multiplexes a wide PMUEVENT bus to a narrow set of inputs. An external PMUEVENT bus might also be provided. For more information, contact ARM.
K2.3 Recommended authentication interface

An implementation of the ARMv8 architecture must support debug authentication described in Required debug authentication on page H1-6416.

The details of the debug authentication interface are IMPLEMENTATION DEFINED, but ARM recommends the use of the CoreSight interface, which includes the following signals for external debug authentication:

- **DBGEN**.
- **SPIDEN**.

If ARMv8.4-Debug is not implemented, ARM also recommends using the following signals:

- **NIDEN**.
- **SPNIDEN**.

ARM recommends an interface in which DBGEN and SPIDEN are also used for self-hosted Secure debug authentication if either:

- EL3 is using AArch32 and SDCR.SPD == 0b00.
- Secure EL1 is using AArch32 and MDCR_EL3.SPD32 == 0b00.

If EL3 is not implemented and the PE is in Non-secure state, SPIDEN and SPNIDEN are not implemented, and the PE behaves as if these signals were tied LOW.

If EL3 is not implemented and the PE is in Secure state, SPIDEN is usually connected to DBGEN and SPNIDEN is connected to NIDEN, but this is not required. The recommended interface is defined as if all four signals are implemented.

How the authentication signals are driven is IMPLEMENTATION DEFINED. For example, the signals might be hard-wired, connected to fuses, or to an authentication module. The architecture permits PEs within a cluster to have independent authentication interfaces, but this is not required. ARM recommends that any Trace extension has the same authentication interface as the PE it is connected to.

If ARMv8.4-Debug and CoreSight ETR are both implemented, the ETR has an independent DBGEN signal that must be tied HIGH to enable self-hosted use of trace.

Table K2-2 shows the debug authentication pseudocode functions and the recommended implementations.

<table>
<thead>
<tr>
<th>Pseudocode function</th>
<th>Description</th>
<th>Implementation</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()</td>
<td>Secure invasive self-hosted debug enabled in AArch32 state (legacy)</td>
<td>(DBGEN AND SPIDEN)</td>
</tr>
<tr>
<td>ExternalSecureNoninvasiveDebugEnabled()</td>
<td>Secure non-invasive debug enabled</td>
<td>(DBGEN OR NIDEN)&lt;sup&gt;b&lt;/sup&gt; AND (SPIDEN OR SPNIDEN)&lt;sup&gt;c&lt;/sup&gt;</td>
</tr>
<tr>
<td>ExternalSecureInvasiveDebugEnabled()</td>
<td>Secure invasive debug enabled</td>
<td>(DBGEN AND SPIDEN)</td>
</tr>
<tr>
<td>ExternalNoninvasiveDebugEnabled()</td>
<td>Non-secure non-invasive debug enabled</td>
<td>(DBGEN OR NIDEN)&lt;sup&gt;b&lt;/sup&gt;</td>
</tr>
<tr>
<td>ExternalInvasiveDebugEnabled()</td>
<td>Non-secure invasive debug enabled</td>
<td>DBGEN</td>
</tr>
</tbody>
</table>

---

a. If ARMv8.4-Debug is implemented, ExternalSecureNoninvasiveDebugEnabled() == ExternalSecureInvasiveDebugEnabled().
b. If ARMv8.4-Debug is implemented, the NIDEN signal is not implemented.
c. If ARMv8.4-Debug is implemented, the SPNIDEN signal is not implemented.
d. If ARMv8.4-Debug is implemented, ExternalNoninvasiveDebugEnabled() == TRUE.
The `Debug_authentication()` pseudocode function on `shared/debug` on page J1-7082 defines the authentication signals DBGEN, SPIDEN, NIDEN and SPNIDEN.
K2.4 Management registers and CoreSight compliance

The CoreSight architecture requires the implementation of a set of management registers that occupy the memory map from 0xF00 upwards in each of the debug components.

CoreSight compliance and complete implementation of the management registers is OPTIONAL, but ARM recommends that the registers are implemented.

The CoreSight architecture specification recommends that any integration test registers are implemented starting from 0xEFC downwards. Each of the debug components has an IMPLEMENTATION DEFINED region from 0xE80 to 0xEFC for this purpose.

K2.4.1 CoreSight interface register map

Table K2-3 shows the external management register maps for the following registers:

</table>
K2.4.2 Management register access permissions

Access to the OPTIONAL Integration Control register (ITCTRL) is IMPLEMENTATION DEFINED.

If the Debug power domain is off, all register accesses return an error.

Otherwise, Table K2-4 on page K2-7239, Table K2-5 on page K2-7240, and Table K2-6 on page K2-7241 show the response to accesses by the external debug interface to the CoreSight management registers. For definitions of the terms used in the tables, see External debug interface register access permissions summary on page H8-6549.

--- Note ---
Access to the CoreSight management registers is not affected by the values of EDAD and EPMAD.

Table K2-4 on page K2-7239, Table K2-5 on page K2-7240, and Table K2-6 on page K2-7241 include reserved management registers, because the CoreSight architecture requires that these registers are always RES0. The descriptions in Reserved and unallocated registers on page H8-6549 does not apply to reserved management registers if the implementation is CoreSight compliant.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses. See Register access permissions for memory-mapped accesses on page H8-6544.

When HaveSecureExtDebugView() == TRUE, each debug component has a Secure and Non-secure view. The Secure view of a debug component is mapped into Secure physical memory and the Non-secure view of a debug component is mapped into Non-secure memory. Apart from access conditions, the Non-secure and Secure views of the debug components are identical.

The terms in Table K2-4 on page K2-7239, Table K2-5 on page K2-7240, and Table K2-6 on page K2-7241 are defined as follows:

**Domain**
This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

**Conditions**
This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.

The conditions are:

- **Off**  EDPRSR.PU == 0. The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed.
Note

If debug power is off, then all external debug interface accesses return an error.

DLK
If the OS Double Lock is implemented and `doubleLockStatus()` == TRUE. The OS Double Lock is locked.

OSLK  OSLR.OSLK == 1. The OS Lock is locked.

Default
This provides the default access permissions, if there are no conditions that prevent access to the register.

SLK
This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See Register access permissions for memory-mapped accesses on page H8-6544. For all other accesses, this column is ignored.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.

RO
This means that the register or field is read-only.

RW
This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.

RC
This means that the bit clears to 0 after a read.

(SE)
This means that accesses to this register have indirect write side effects. A side effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.

WO
This means that the register or field is write-only.

WI
This means that the register or field ignores writes.

IMP DEF
This means that the access permissions are IMPLEMENTATION DEFINED.

K2.4.3 Management register resets

Table K2-7 shows the management register resets. This table does not include:

- Read-only identification registers that have a fixed value from reset. These registers include those with the DEVAFFn, DEVARCH, DEVID[n], DEVTYPE, PIDRn, and CIDRn mnemonics.
- Registers that have the AUTHSTATUS mnemonic. This is a read-only status register that reflects the status outside of the reset domain of the register.
- Registers that have the LAR mnemonic. These are write-only registers that only have an effect on writes.

All other fields in the management registers are reset to an IMPLEMENTATION DEFINED value which can be UNKNOWN. The registers are in the reset domain specified in the table.

Table K2-7 shows a summary of the management register resets.

K2.4.4 About the Peripheral identification scheme

The Peripheral Identification scheme provides the standard information required by all components that conform to the ARM® Debug Interface Architecture Specification, ADIv5.0 to ADIv5.2, that implements the CoreSight identification scheme. They identify a peripheral in a particular namespace. For more information, see the ARM® CoreSight™ Architecture Specification.

Table K2-8 lists the Peripheral ID Registers that make up the Peripheral Identification scheme for each component.

Figure K2-2 shows the register field allocation scheme for the Peripheral ID Registers.

![Figure K2-2 Peripheral ID register format](image)

Software can consider the eight Peripheral ID Registers as defining a single 64-bit Peripheral ID, as shown in Figure K2-3.

![Figure K2-3 Mapping between Peripheral ID Registers and a 64-bit Peripheral ID Value](image)

Figure K2-3 shows the fields in the 64-bit Peripheral ID value, and includes the field values for fields that:
- Have fixed values, including the bits that are reserved.
- Have fixed values in an implementation that is designed by ARM.

For more information about the fields and their values see Table K2-9 on page K2-7244.
Figure K2-4 Peripheral ID fields, with values for a implementation designed by ARM

Table K2-9 shows the fields in the Peripheral ID.

</tr>
</tbody>
</table>

A component is identified uniquely by the combination of the following fields:

- JEP106 continuation code.
- JEP106 identity code.
- Part number.
- Revision.
- Customer Modified.
For components with a Component class of 0x9, Debug component, indicated by the Component Identification Registers, multiple components can have the same Part number, provided each component has a different CoreSight Device type. However, ARM strongly recommends that each device has a unique Part number. For more information:

- About the Component Identification Registers, see About the Component Identification scheme.
- About the CoreSight Device type, see EDDEVTYPE, CTIDEVTYPE, or PMDEVTYPE.
- About CoreSight components and their identification, see the ARM® Debug Interface Architecture Specification.

### Allocating revisions and part numbers

Within the Peripheral Identification registers, the allocation of major and minor revisions, part numbers, and customer-modified fields is IMPLEMENTATION DEFINED, with the following set of restrictions so that:

- The REVISION field must increase monotonically with revisions.

  __Note__

  ARM recommends that the REVISION field is updated for each update to the RTL, regardless of whether this is a major or minor update.

- The REVAND field should increase monotonically with revisions.

  __Note__

  ARM recommends that the REVAND field is used only for post-release changes. For example, those due to engineering change order (ECO) fixes related to the debug component of the processor.

- The PART field must have a degree of uniqueness:

  - Two component designs can have the same part number so long as they are sub-components of the same part and the programmers’ model for the part has the means to disambiguate sub-components.
  - Otherwise, two component designs must have unique part numbers.

The DEVARCH (if implemented) or DEVTYPE (otherwise) register provides the means to disambiguate sub-components of the Debug Architecture.

A ROM table has no DEVTYPE or DEVARCH register. However, if it is the only CLASS 0x1 component in a processor cluster, it can still be disambiguated.

Multiple instances of the same component design have the same part number.

### K2.4.5 About the Component Identification scheme

The Component Identification Registers identify the processor as an ARM Debug Interface v5 component. For more information, see the ARM® Debug Interface Architecture Specification and the ARM® CoreSight™ Architecture Specification.
The Component Identification Registers occupy the last four words of the 4KB block of debug registers.

Figure K2-5 shows the register field allocation scheme for the Component ID Registers.

![Figure K2-5 Component ID Register format](image)

Software can consider the eight Component ID Registers as defining a single 32-bit Component ID, as shown in Figure K2-6.

![Figure K2-6 Mapping between Component ID Registers and a 32-bit Component ID Value](image)
Appendix K3
Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events

This appendix describes the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. It contains the following sections:

• ARM recommendations for IMPLEMENTATION DEFINED event numbers on page K3-7248.
• Summary of events for exceptions taken to an Exception level using AArch64 on page K3-7263.
K3.1 ARM recommendations for IMPLEMENTATION DEFINED event numbers

These are the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. ARM does not define these events as rigorously as those in the architectural and microarchitectural event lists, and an implementation might:

- Modify the definition of an event to better correspond to the implementation.
- Not use some, or many, of these event numbers.

Table K3-1 lists the PMU IMPLEMENTATION DEFINED event numbers in event number order.

---

**Notes:**

- For more information, see *Relationship between REFILL events and associated access events on page K3-7261.*
- The Glossary defines the term *Taken locally.* See also *Exception levels on page D1-2134* for more information.

---

0x0040, L1D_CACHE_RD, Attributable Level 1 data cache access, read
This event is similar to Level 1 data cache access, L1D_CACHE, but the counter counts only memory-read operations that access at least the Level 1 data or unified cache.

0x0041, L1D_CACHE_WR, Attributable Level 1 data cache access, write
This event is similar to Level 1 data cache access, L1D_CACHE, but the counter counts only memory-write operations that access at least the Level 1 data or unified cache.
The counter counts DC ZVA as a store instruction.

0x0042, L1D_CACHE_REFILL_RD, Attributable Level 1 data cache refill, read
This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-read operations that cause a refill of at least the Level 1 data or unified cache.
See also Relationship between REFILL events and associated access events. on page K3-7261.

0x0043, L1D_CACHE_REFILL_WR, Attributable Level 1 data cache refill, write
This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-write operations that cause a refill of at least the Level 1 data or unified cache.
The counter counts DC ZVA as a store instruction.
See also Relationship between REFILL events and associated access events. on page K3-7261.

0x0044, L1D_CACHE_REFILL_INNER, Attributable Level 1 data cache refill, inner
This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-read and memory-write operations that generate refills satisfied by transfer from another cache inside of the immediate cluster.

Note
The boundary between inner and outer is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

0x0045, L1D_CACHE_REFILL_OUTER, Attributable Level 1 data cache refill, outer
This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-read and memory-write operations that generate refills satisfied from outside of the immediate cluster.

0x0046, L1D_CACHE_WB_VICTIM, Attributable Level 1 data cache Write-Back, victim
This event is similar to Level 1 data cache Write-Back, L1D_CACHE_WB, but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.
If ARMv8.4-PMU is not implemented, Write-Backs caused by the execution of a cache maintenance instruction are not counted. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether Write-Backs caused by the execution of a cache maintenance instruction are counted.
It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x0047, L1D_CACHE_WB_CLEAN, Level 1 data cache Write-Back, cleaning and coherency
This event is similar to Attributable Level 1 data cache Write-Back, L1D_CACHE_WB, but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.
If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.
Note

The transfer of a dirty cache line from the Level 1 data cache of this PE to the Level 1 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 2 cache or memory.

0x0048, L1D_CACHE_INVALID, Attributable Level 1 data cache invalidate

The counter counts each invalidation of a cache line in the Level 1 data or unified cache. The counter does not count events if a cache refill invalidates a line.

If ARMv8.4-PMU is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x004C, L1D_TLB_REFILL_RD, Attributable Level 1 data TLB refill, read

This event is similar to Level 1 data TLB refill, L1D_TLB_REFILL, but the counter counts only memory-read operations that cause a data TLB refill of at least the Level 1 data or unified TLB.

See also Relationship between REFILL events and associated access events on page K3-7261.

0x004D, L1D_TLB_REFILL_WR, Attributable Level 1 data TLB refill, write

This event is similar to Level 1 data TLB refill, L1D_TLB_REFILL, but the counter counts only memory-write operations that cause a data TLB refill of at least the Level 1 data or unified TLB.

The counter counts DC ZVA as a store instruction.

See also Relationship between REFILL events and associated access events on page K3-7261.

0x004E, L1D_TLB_RD, Attributable Level 1 data or unified TLB access, read

This event is similar to Level 1 data or unified TLB access, L1D_TLB, but the counter counts only memory-read operations that cause a TLB access to at least the Level 1 data or unified TLB.

0x004F, L1D_TLB_WR, Attributable Level 1 data or unified TLB access, write

This event is similar to Level 1 data or unified TLB access, L1D_TLB, but the counter counts only memory-write operations that cause a TLB access to at least the Level 1 data or unified TLB.

The counter counts DC ZVA as a store instruction.

0x0050, L2D_CACHE_RD, Attributable Level 2 data cache access, read

This event is similar to Attributable Level 2 data cache access, L2D_CACHE, but the counter counts only memory-read operations that access at least the Level 2 data or unified cache.

0x0051, L2D_CACHE_WR, Attributable Level 2 data cache access, write

This event is similar to Attributable Level 2 data cache access, L2D_CACHE, but the counter counts only memory-write operations that access at least the Level 2 data or unified cache.

The counter counts DC ZVA as a store instruction.

0x0052, L2D_CACHE_REFILL_RD, Attributable Level 2 data cache refill, read

This event is similar to Attributable Level 2 data cache refill, L2D_CACHE_REFILL, but the counter counts only memory-read operations that cause a refill of at least the Level 2 data or unified cache.

See also Relationship between REFILL events and associated access events on page K3-7261.

0x0053, L2D_CACHE_REFILL_WR, Attributable Level 2 data cache refill, write

This event is similar to Attributable Level 2 data cache refill, L2D_CACHE_REFILL, but the counter counts only memory-write operations that cause a refill of at least the Level 2 data or unified cache.

The counter counts DC ZVA as a store instruction.
Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events

K3.1 ARM recommendations for IMPLEMENTATION DEFINED event numbers

See also *Relationship between REFILL events and associated access events.* on page K3-7261.

0x0056, **L2D_CACHE_WB_VICTIM**, Attributable Level 2 data cache Write-Back, victim

This event is similar to Attributable Level 2 data cache Write-Back, **L2D_CACHE_WB**, but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

If ARMv8.4-PMU is not implemented, Write-Backs caused by the execution of a cache maintenance instruction are not counted. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether Write-Backs caused by the execution of a cache maintenance instruction are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x0057, **L2D_CACHE_WB_CLEAN**, Level 2 data cache Write-Back, cleaning and coherency

This event is similar to Attributable Level 2 data cache Write-Back, **L2D_CACHE_WB**, but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

--- Note ---

The transfer of a dirty cache line from the Level 2 data cache of this PE to the Level 2 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

---

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x0058, **L2D_CACHE_INVVAL**, Attributable Level 2 data cache invalidate

The counter counts each invalidation of a cache line in the Level 2 data or unified cache.

The counter does not count events if a cache refill invalidates a line.

If ARMv8.4-PMU is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

--- Note ---

Software that uses this event must know whether the Level 2 data cache is shared with other PEs. This event does not follow the general rule of Level 2 data cache events of only counting events that directly affect this PE.

---

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x005C, **L2D_TLB_REFILL_RD**, Attributable Level 2 data or unified TLB refill, read

This event is similar to Attributable Level 2 data or unified TLB refill, **L2D_TLB_REFILL**, but the counter counts only Attributable memory read operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also *Relationship between REFILL events and associated access events.* on page K3-7261.

0x005D, **L2D_TLB_REFILL_WR**, Attributable Level 2 data or unified TLB refill, write

This event is similar to Attributable Level 2 data or unified TLB refill, **L2D_TLB_REFILL**, but the counter counts only Attributable memory write operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also *Relationship between REFILL events and associated access events.* on page K3-7261.
0x005E, L2D_TLB_RD, Attributable Level 2 data or unified TLB access, read

This event is similar to Attributable Level 2 data or unified TLB access, L2D_TLB, but the counter counts only Attributable memory read operations that cause a TLB access to at least the Level 2 data or unified TLB.

0x005F, L2D_TLB_WR, Attributable Level 2 data or unified TLB access, write

This event is similar to Attributable Level 2 data or unified TLB access, L2D_TLB, but the counter counts only Attributable memory write operations that cause a TLB access to at least the Level 2 data or unified TLB.

0x0060, BUS_ACCESS_RD, Bus access, read

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read operations that access outside the boundary of the PE and its closely-coupled caches.

0x0061, BUS_ACCESS_WR, Bus access, write

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-write operations that access outside the boundary of the PE and its closely-coupled caches.

0x0062, BUS_ACCESS_SHARED, Bus access, Normal, Cacheable, Shareable

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make Normal, Cacheable, Shareable accesses outside the boundary of the PE and its closely-coupled caches.

--- Note ---

It is IMPLEMENTATION DEFINED how the PE translates the attributes from the translation table entry for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

---

0x0063, BUS_ACCESS_NOT_SHARED, Bus access, not Normal, Cacheable, Shareable

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make accesses outside the boundary of the PE and its closely-coupled caches that are not Normal, Cacheable, Shareable. For example, the counter counts accesses marked as:

- Normal, Cacheable, Non-shareable.
- Normal, Non-cacheable.
- Device.

--- Note ---

It is IMPLEMENTATION DEFINED, how the PE translates the attributes from the translation table entries for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.
Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events
K3.1 ARM recommendations for IMPLEMENTATION DEFINED event numbers

0x0064, BUS_ACCESS_NORMAL, Bus access, normal
This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make Normal accesses outside the boundary of the PE and its closely-coupled caches. For example, the counter counts Normal, Cacheable and Normal, Non-cacheable accesses but does not count Device accesses.

0x0065, BUS_ACCESS_PERIPH, Bus access, peripheral
This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make Device accesses outside the boundary of the PE and its closely-coupled caches.

0x0066, MEM_ACCESS_RD, Data memory access, read
This event is similar to Data memory access, MEM_ACCESS, but the counter counts only memory-read operations that the PE made.

0x0067, MEM_ACCESS_WR, Data memory access, write
This event is similar to Data memory access, MEM_ACCESS, but the counter counts only memory-write operations made by the PE.

0x0068, UNALIGNED_LD_SPEC, Unaligned access, read
This event is similar to Data memory access, MEM_ACCESS, but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x0069, UNALIGNED_ST_SPEC, Unaligned access, write
This event is similar to Data memory access, MEM_ACCESS, but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x006A, UNALIGNED_LDST_SPEC, Unaligned access
This event is similar to Data memory access, MEM_ACCESS, but the counter counts only unaligned memory-read operations and unaligned memory-write operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x006C, LDREX_SPEC, Exclusive operation speculatively executed, Load-Exclusive
The counter counts Load-Exclusive instructions speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x006D, STREX_PASS_SPEC, Exclusive operation speculatively executed, Store-Exclusive pass
The counter counts Store-Exclusive instructions speculatively executed that completed a write. The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the LDREX_SPEC event.

0x006E, STREX_FAIL_SPEC, Exclusive operation speculatively executed, Store-Exclusive fail
The counter counts Store-Exclusive instructions speculatively executed that fail to complete a write. It is within the IMPLEMENTATION DEFINED definition of speculatively executed whether this includes conditional instructions that fail the condition code check. The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the LDREX_SPEC event.

0x006F, STREX_SPEC, Exclusive operation speculatively executed, Store-Exclusive
The counter counts Store-Exclusive instructions speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED but it must be the same as for the LDREX_SPEC event.
ARM recommends that this event is implemented if it is not possible to implement the exclusive operation speculatively executed, Store-Exclusive pass, and exclusive operation speculatively executed, Store-Exclusive fail, events with the same degree of speculation as the LDREX_SPEC event.

0x0070, **LD_SPEC, Operation speculatively executed, load**

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only memory-reading instructions, as defined by the LD_RETIRED event.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

0x0071, **ST_SPEC, Operation speculatively executed, store**

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only memory-writing instructions, as defined by the ST_RETIRED event.

The counter counts DC ZVA as a store operation.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

0x0072, **LDST_SPEC, Operation speculatively executed, load or store**

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only memory-reading instructions and memory-writing instructions, as defined by the LD_RETIRED and ST_RETIRED events.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

0x0073, **DP_SPEC, Operation speculatively executed, integer data processing**

This event is similar to Operation speculatively executed, INST_SPEC, but counts only integer data-processing instructions. It counts the following operations that operate on the general-purpose registers:

- In AArch64 state, Data processing - immediate on page C3-193 and Data processing - register on page C3-198.
- In AArch32 state, Data-processing instructions on page F1-3622.

This includes MOV and MVN operations.

This event also counts the following miscellaneous instructions:

- In AArch64 state, System register instructions on page C3-172, System instructions on page C3-172, and Hint instructions on page C3-173.
- In AArch32 state, PSTATE and banked register access instructions on page F1-3630, Banked register access instructions on page F1-3630, Miscellaneous instructions on page F1-3635, other than ISB and preload, and System register access instructions on page F1-3639, other than LDC and STC instructions.

If the preload instructions PRFM, PLD, PLDW, and PLI, do not count as memory-reading instructions then they must count as integer data-processing instructions.

If ISBś do not count as software change of the PC then they must count as integer data-processing instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the INST_SPEC event.

It is IMPLEMENTATION DEFINED whether the following instructions are counted as integer data-processing operations, SIMD operations, or floating-point operations, but ARM recommends that the instructions are all counted as integer data-processing operations:

- For AArch64 state, from the A64 floating-point convert to integer class, operations that move a value between a general-purpose register and a SIMD and floating-point register without type conversion:
  - FMOV (general).
• For AArch64 state, from the SIMD Move group, operations that move a value between a general-purpose register and an element or elements in a SIMD and floating-point register:
  — DUP (general).
  — SMOV.
  — UMOV.
  — INS (general).
• For AArch32 state:
  — VDUP (general-purpose register) and all VMOV instructions that transfer data between a general-purpose register and a SIMD and floating-point register.
  — VMRS.
  — VMSR.

0x0074, ASE_SPEC, Operation speculatively executed, Advanced SIMD
This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only Advanced SIMD data-processing instructions, see:
• For AArch64 state, the SIMD operations listed in Data processing - SIMD and floating-point on page C3-206.
• For AArch32 state, Advanced SIMD data-processing instructions on page F1-3643.
This includes all operations that operate on the SIMD and floating-point registers, except those that are counted as:
• Integer data-processing operations.
• Floating-point data-processing operations.
• Memory-reading operations.
• Memory-writing operations.
• Cryptographic operations other than PMULL, in AArch64 state.
• VMULL, in AArch32 state.
Advanced SIMD scalar operations are counted as Advanced SIMD operations, including those which operate on floating-point values. In AArch64 state, PMULL, and in AArch32 state, VMULL are counted as Advanced SIMD operations.
The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the INST_SPEC event.

0x0075, VFP_SPEC, Operation speculatively executed, floating-point
This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only floating-point data-processing instructions, see:
• In AArch64 state, only the scalar floating-point operations listed in Data processing - SIMD and floating-point on page C3-206.

________ Note
This event does not count the SIMD floating-point operations listed in Data processing - SIMD and floating-point on page C3-206.

• In AArch32 state, Floating-point data-processing instructions on page F1-3653.
This includes all operations that operate on the SIMD and floating-point registers as floating-point values, except for SIMD scalar operations and those that are counted as one of:
• Integer data processing.
• Memory-reading operations.
• Memory-writing operations.
The following instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point), are counted as floating-point data-processing operations:

- In AArch64 state, FCVT{<mode>}, UCVT, and SCVT.
- In AArch32 state, VCVT{mode}(floating-point), VCVT, VCVTT, and VCVTB.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the INST_SPEC event.

0x0076, PC_WRITE_SPEC, Operation speculatively executed, software change of the PC

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only software changes of the PC. Defined by the instruction architecturally executed, condition code check pass, software change of the PC event, see Common event numbers on page D6-2546.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

See also PC_WRITE_RETIRED.

0x0077, CRYPTO_SPEC, Operation speculatively executed, Cryptographic instruction

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only Cryptographic instructions, except PMULL and VMULL, see The Cryptographic Extension on page C3-226.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

See also PC_WRITE_RETIRED.

0x0078, BR_IMMED_SPEC, Branch speculatively executed, immediate branch

The counter counts immediate branch instructions speculatively executed. Defined by the instruction architecturally executed, immediate branch event, see Common event numbers on page D6-2546.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also BR_IMMED_RETIRED.

0x0079, BR_RETURN_SPEC, Branch speculatively executed, procedure return

The counter counts procedure return instructions speculatively executed. Defined by the BR_RETURN_RETIRED event.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also BR_RETURN_RETIRED.

0x007A, BR_INDIRECT_SPEC, Branch speculatively executed, indirect branch

The counter counts indirect branch instructions speculatively executed. This includes software change of the PC other than exception-generating instructions and immediate branch instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x007C, ISB_SPEC, Barrier speculatively executed, ISB

The counter counts Instruction Synchronization Barrier instructions speculatively executed, including CP15ISB.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x007D, DSB_SPEC, Barrier speculatively executed, DSB

The counter counts data synchronization barrier instructions speculatively executed, including CP15DSB.

The definition of speculatively executed is IMPLEMENTATION DEFINED.
0x007E, **DMB_SPEC, Barrier speculatively executed, DMB**

The counter counts data memory barrier instructions speculatively executed, including CP15DSB. It does not include the implied barrier operations of load/store operations with release consistency semantics.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x0081, **EXC_UNDEF, Exception taken, other synchronous**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only those exceptions *Taken locally* that are not counted as:

- Exception taken, Supervisor Call (EXC_SVC).
- Exception taken, Secure Monitor Call (EXC_SMC).
- Exception taken, Hypervisor Call (EXC_HVC).
- Exception taken, Instruction Abort (EXC_PABORT).
- Exception taken, Data Abort or SError (EXC_DABORT).
- Exception taken, IRQ (EXC_IRQ).
- Exception taken, FIQ (EXC_FIQ).

0x0082, **EXC_SVC, Exception taken, Supervisor Call**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Supervisor Call exceptions that are *Taken locally*.

0x0083, **EXC_PABORT, Exception taken, Instruction Abort**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Instruction Abort exceptions that are *Taken locally*.

0x0084, **EXC_DABORT, Exception taken, Data Abort or SError**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Data Abort or SError interrupt exceptions. The counter counts only exceptions *Taken locally*.

0x0086, **EXC_IRQ, Exception taken, IRQ**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only IRQ exceptions that are *Taken locally*, including Virtual IRQ exceptions.

0x0087, **EXC_FIQ, Exception taken, FIQ**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only FIQ exceptions that are *Taken locally*, including Virtual FIQ exceptions.

0x0088, **EXC_SMC, Exception taken, Secure Monitor Call**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Secure Monitor Call exceptions. The counter does not increment on SMC instructions trapped as a Hyp Trap exception.

0x008A, **EXC_HVC, Exception taken, Hypervisor Call**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Hypervisor Call exceptions. The counter counts for both Hypervisor Call exceptions *Taken locally* in the hypervisor and those taken as an exception from Non-secure EL1.

0x0088, **EXC_TRAP_PABORT, Exception taken, Instruction Abort not Taken locally**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Instruction Abort exceptions not *Taken locally*.

0x008C, **EXC_TRAP_DABORT, Exception taken, Data Abort or SError not Taken locally**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Data Abort or SError interrupt exceptions not *Taken locally*. 
0x008D, EXC_TRAP_OTHER, Exception taken, other traps not Taken locally
   This event is similar to Exception taken, EXC_TAKEN, but the counter counts only those traps that
   are not counted as:
   • Exception taken, Secure Monitor Call (EXC_SMC).
   • Exception taken, Hypervisor Call (EXC_HVC).
   • Exception taken, Instruction Abort not Taken locally (EXC_TRAP_PABORT).
   • Exception taken, Data Abort or SError not Taken locally (EXC_TRAP_DABORT).
   • Exception taken, IRQ not Taken locally (EXC_TRAP_IRQ).
   • Exception taken, FIQ not Taken locally (EXC_TRAP_FIQ).

0x008E, EXC_TRAP_IRQ, Exception taken, IRQ not Taken locally
   This event is similar to Exception taken, EXC_TAKEN, but the counter counts only IRQ exceptions
   not Taken locally.

0x008F, EXC_TRAP_FIQ, Exception taken, FIQ not Taken locally
   This event is similar to Exception taken, EXC_TAKEN, but the counter counts only FIQ exceptions
   not Taken locally.

0x0090, RC_LD_SPEC, Release consistency operation speculatively executed, Load-Acquire
   The counter counts memory-read operations with acquire or acquirepc semantics that are
   speculatively executed.

0x0091, RC_ST_SPEC, Release consistency operation speculatively executed, Store-Release
   The counter counts memory-write operations with release semantics that are speculatively executed.

0x00A0, L3D_CACHE_RD, Attributable Level 3 data or unified cache access, read
   This event is similar to Attributable Level 3 data or unified cache access, L3D_CACHE, but the
   counter counts only attributable memory read operations that cause a cache access to at least the
   Level 3 data or unified cache.

0x00A1, L3D_CACHE_WR, Attributable Level 3 data or unified cache access, write
   This event is similar to Attributable Level 3 data or unified cache access, L3D_CACHE, but the
   counter counts only attributable memory write operations that cause a cache access to at least the
   Level 3 data or unified cache.

0x00A2, L3D_CACHE_REFILL_RD, Attributable Level 3 data or unified cache refill, read
   This event is similar to Attributable Level 3 data or unified cache refill, L3D_CACHE_REFILL,
   but the counter counts only attributable memory read operations that cause a refill of at least the
   Level 3 data or unified cache from outside the Level 3 cache. See also Relationship between REFILL
   events and associated access events on page K3-7261

0x00A3, L3D_CACHE_REFILL_WR, Attributable Level 3 data or unified cache refill, write
   This event is similar to Attributable Level 3 data or unified cache refill, L3D_CACHE_REFILL,
   but the counter counts only attributable memory write operations that cause a refill of at least the
   Level 3 data or unified cache from outside the Level 3 cache. See also Relationship between REFILL
   events and associated access events on page K3-7261

0x00A6, L3D_CACHE_WB_VICTIM, Attributable Level 3 data or unified cache Write-Back, victim
   This event is similar to Attributable Level 3 data cache Write-Back, L3D_CACHE_WB, but the
   counter counts only Write-Backs that are a result of the line being allocated for an access made by
   the PE.
   If ARMv8.4-PMU is not implemented, Write-Backs caused by the execution of a cache
   maintenance instruction are not counted. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION
   DEFINED whether Write-Backs caused by the execution of a cache maintenance instruction are
   counted.
It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x00A7, L3D_CACHE_WB_CLEAN, Level 3 data or unified cache Write-Back, cache clean

This event is similar to Attributable Level 3 data cache Write-Back, L3D_CACHE_WB, but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

--- Note ---
The transfer of a dirty cache line from the Level 3 data cache of this PE to the Level 3 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x00A8, L3D_CACHE_INV, Attributable Level 3 data or unified cache access, invalidate

The counter counts each invalidation of a cache line in the Level 3 data or unified cache. The counter does not count events if a cache refill invalidates a line. If ARMv8.4-PMU is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

--- Note ---
Software that uses this event must know whether the Level 3 data cache is shared with other PEs. This event does not follow the general rule of Level 3 data cache events of only counting Attributable events.

### K3.1.1 Relationship between REFILL events and associated access events.

CACHE_REFILL and TLB_REFILL events count the refills for accesses that are counted by the corresponding CACHE or TLB event. Table K3-2 shows this correspondence.

<table>
<thead>
<tr>
<th>REFILL event</th>

**Note**

The Glossary defines the term *Taken locally*, that is used in event definitions in this chapter. See also Exception levels on page D1-2134 for more information.
Appendix K4
Recommendations for reporting memory attributes on an interconnect

This appendix describes the ARM recommendations for reporting the memory attributes that are assigned by the PE. It contains the following section:

• ARM recommendations for reporting memory attributes on an interconnect on page K4-7266.
K4.1 ARM recommendations for reporting memory attributes on an interconnect

The ARM architecture defines the architectural interface between software and the PE hardware. This means the mechanisms by which different memory type and Cacheability attributes are presented on an interface to an interconnect fabric such as AMBA® AXI are, strictly, outside the scope of the architecture. This appendix describes an approach for the interface between a PE implementation and an interconnect fabric that ARM strongly recommends, but these recommendations do not form part of the ARMv8 architecture.

K4.1.1 Effect of microarchitectural choices on memory attributes

Implementations of the ARM architecture permit considerable variability in the presentation of memory attributes on the interconnect fabric, particularly in cases where the PE implementation does not provide optimized support for a memory type. For example, an implementation might treat Write-Through locations as Non-cacheable at some level of cache, because functionally this is consistent with the definition of Write-Through, but for the particular implementation the performance trade-off does not merit the hardware directly providing Write-Through capability. However, in such implementations, the assigned memory attributes are not changed by the microarchitectural choices. The microarchitecture simply implements different ways of handling some memory attributes.

Therefore, ARM strongly recommended that where any or all of the following memory attributes are presented on the interface between a PE and an interconnect fabric, the attributes that are presented are completely consistent with the attributes defined by the translation system:

- The memory type, Normal or Device.
- The Early write acknowledgement attribute.
- The ordering requirements.
- The Shareability.
- The Cacheability, including where practicable, the allocation hints.

Effect when memory accesses are forced to be Non-cacheable

ARM also strongly recommends that the effects of forcing accesses to Normal memory to be Non-cacheable, as described in Enabling and disabling the caching of memory accesses on page D4-2345 for AArch64 and in Enabling and disabling the caching of memory accesses in AArch32 state on page G4-5437 for AArch32, are reflected on the interconnect by the memory type and attributes used for memory transactions generated while the cache is disabled.
Appendix K5
Additional Information for Implementations of the Generic Timer

This appendix gives additional information about implementations of the Generic Timer. It contains the following sections:

• Providing a complete set of features in a system level implementation on page K5-7268.
• Gray-count scheme for timer distribution scheme on page K5-7270.
K5.1 Providing a complete set of features in a system level implementation

As an example system design, using memory-mapped Generic Timer components as described in Chapter 12 System Level Implementation of the Generic Timer, the feature set of a System registers counter and timer, in an implementation that includes EL2 and EL3, can be implemented using the following set of timer frames:

- A CNTCTLB frame.
- The following CNTBaseN timer frames:

  Frame 0 Accessible by Non-secure accesses, with second view and virtual capability. This provides the Non-secure EL1&0 timers.

  Frame 1 Accessible by Non-secure accesses, with no second view and no virtual capability. This provides the Non-secure EL2 timers.

  Frame 2 Accessible only by Secure accesses, with a second view but no virtual capability. This provides the Secure PL1&0 timers, meaning:
  - Compared to a PE where EL3 is using AArch32, it provides the only Secure state timer.
  - Compared to a PE where EL3 is using AArch64, it provides the Secure EL1&0 timer.

  Frame 3 Accessible only by Secure accesses, with no second view and no virtual capability. This provides the Secure EL3 timers.

Note

This frame is not required for a memory-mapped timer that provides only the feature set of a PE for which EL3 is using AArch32.

In this implementation, the full set of implemented frames, and accessibility as memory pages in the different translation regimes, is as follows:

CNTCTLB

The control frame. This frame is accessible in both the Secure and Non-secure memory maps, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

CNTBase0

The first view of the Non-secure EL1&0 timers. This frame is accessible only in the Non-secure memory map, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible only at EL1.

CNTEL0Base0

The second view of CNTBase0, meaning it is the EL0 view of the Non-secure EL1&0 timers. This frame is accessible only in the Non-secure memory map, and:

- In the Secure EL1&0 translation regime, the architecture permits this frame to be accessible at EL1, or at EL1 and EL0, but does not require either of these options.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible only at EL1.

CNTBase1

The first and only view of the Non-secure EL2 timers. This frame is accessible only in Non-secure memory map, and:

- When EL3 is using AArch64:
  — In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
  — In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.
CNTBase2

The first view of the Secure EL1&0, or PL1&0 timers.

Note

In AArch64 state, these timers are always called the Secure EL1&0 timers. In AArch32 state they are usually called the Secure PL1&0 timers because, in AArch32 Secure state, whether some of the PE modes map to EL1 or to EL3 depends on whether EL3 is using AArch64 or is using AArch32, see Security state, Exception levels, and AArch32 execution privilege on page G1-5226.

This frame is accessible only in the Secure memory map, and:

• When EL3 is using AArch64:
  — In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
  — In the Secure EL3 translation regime, this frame is accessible.

• When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).

• Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTEL0Base2

The second view of CNTBase2, meaning it is the EL0 view of the Secure EL1&0, or PL1&0, timers.

Note

See the Note in the description of the CNTBase2 frame for more information about the naming of these timers.

This frame is accessible only in the Secure memory map, and:

• When EL3 is using AArch64:
  — In the Secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.
  — In the Secure EL3 translation regime, this frame is accessible.

• When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible at PL1 (EL3) and EL0.

• Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTBase3

The first and only view of the EL3 timers. This frame is accessible only in the Secure memory map, and:

• When EL3 is using AArch64:
  — In the Secure EL1&0 translation regime, this frame is not accessible.
  — In the Secure EL3 translation regime, this frame is accessible.

• When EL3 is using AArch32, this frame is not accessible.

• Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

Note

About the Virtual Memory System Architecture (VMSA) on page D5-2372 describes the VMSAv8-64 translation regimes, and About VMSAv8-32 on page G5-5464 describes the VMSAv8-32 translation regimes.
**K5.2 Gray-count scheme for timer distribution scheme**

The distribution of the Counter value using a Gray-code provides a relatively simple mechanism to avoid any danger of the count being sampled with an intermediate value even if the clocking is asynchronous. It has a further advantage that the distribution is relatively low power, since only one bit changes on the main distribution wires for each clock tick.

A suitable Gray-coding scheme can be achieved with the following logic:

\[
\begin{align*}
\text{Gray}[N] &= \text{Count}[N] \\
\text{Gray}[i] &= \text{XOR} (\text{Gray}[N:i+1])) \text{ XOR } \text{Count}[i] \quad \text{for } N-1 \geq i \geq 0 \\
\text{Count}[i] &= \text{XOR} (\text{Gray}[N:i]) \quad \text{for } N \geq i \geq 0
\end{align*}
\]

This is for an \(N+1\) bit counter, where Count is a conventional binary count value, and Gray is the corresponding Gray count value.

--- **Note** ---

This scheme has the advantage of being relatively simple to switch, in either direction, between operating with low-frequency and low-precision, and operating with high-frequency and high-precision. To achieve this, the ratio of the frequencies must be \(2^n\), where \(n\) is an integer. A switch-over can occur only on the \(2n+1\) boundary to avoid losing the Gray-coding property on a switch-over.
Appendix K6
Legacy Instruction Syntax for AArch32 Instruction Sets

This appendix describes the legacy instruction syntax in the ARM instruction sets, and their Unified Assembler Language (UAL) equivalents. It contains the following section:

• Legacy Instruction Syntax on page K6-7272.
K6.1 Legacy Instruction Syntax

Early versions of the ARM Architecture defined an assembly language for A32 (ARM) instructions, and a separate assembly language for T32 (Thumb) instructions. UAL is based on the A32 assembly language, with some changes to the instruction syntax. The appendix describes those changes. The pre-UAL mnemonics are compatible with UAL, and might be supported by an assembler.

The original T32 assembly language is not compatible with UAL, and is not described in the manual.

K6.1.1 Pre-UAL instruction syntax for the A32 base instructions

Table K6-1 lists the syntax for the A32 base instructions that have changed after UAL was introduced.

**K6.1.3 FCONST**

The syntax of FCONST is

FCNST<dest>{<c>} <Fd>, #<imm8>
where:

<dest> Specifies the destination data type. It must be one of:

S Single-precision floating-point.
D Double-precision floating-point.

<c> This is an optional field. It specifies the condition under which the instruction is executed. See Conditional execution on page F2-3661 for the range of available conditions and their encoding. If <c> is omitted, it defaults to always (AL).

<Fd> Specifies the destination register. It must be one of:

<Dd> 64-bit name of the SIMD&FP destination register.
<Sd> 32-bit name of the SMID&FP destination register.

<imm8> Specifies the immediate value used to generate the floating-point constant.

FCONST{<c>} <Dd>, #<imm8> maps to VMOV.F64 <Dd>, #<fpimm>
FCONST{<c>} <Sd>, #<imm8> maps to VMOV.F32 <Sd>, #<fpimm>
Appendix K7
Address translation examples

This appendix gives examples of address translations using the translation regimes described in Chapter D5 The AArch64 Virtual Memory System Architecture and Chapter G5 The AArch32 Virtual Memory System Architecture. It contains the following sections:

• AArch64 Address translation examples on page K7-7280.
• AArch32 Address translation examples on page K7-7292.

Note

This chapter gives examples of translation table lookups for the ARMv8 address translation stages. It does not define any part of the address translation mechanism. If any information in this appendix appears to contradict the information in Chapter D5 The AArch64 Virtual Memory System Architecture or Chapter G5 The AArch32 Virtual Memory System Architecture then the information in Chapter D5 or Chapter G5 must be taken as the definition of the required behavior.
Appendix K7 Address translation examples

K7.1 AArch64 Address translation examples

Figure D5-1 on page D5-2381 shows the VMSAv8 address translation stages that are controlled by an Exception level that is using AArch64. The VMSAv8-64 address translation system on page D5-2380 describes the VMSAv8-64 address translation scheme. This section gives examples of the use of that scheme, for common translation requirements.

System registers relevant to MMU operation on page D5-2387 specifies the relevant registers, including the TCR_ELx and TTBR_ELx, or TTBR_ELxs, for each stage of address translation.

For any stage of translation, a TCR_ELx.TnSZ field indicates the supported input address size. For a stage of address translation controlled from an Exception level using AArch64, the supported input address size is 2^{(64-TnSZ)}.

This section describes:

- Performing the initial lookup, for an address for which the initial lookup is either:
  - At the highest lookup level used for the appropriate translation granule size.
  - Because of the concatenation of translation tables at the initial lookup level, one level down from the highest level used for the translation granule size.

These descriptions take account of the following cases:

- The IA size is smaller than the largest size for the translation level, see Reduced IA width on page D5-2398.
- For a stage 2 translation, translation tables are concatenated, to move the initial lookup level down by one level, see Concatenated translation tables on page D5-2399.

For examples of performing the initial lookup, see Examples of performing the initial lookup.

- The full translation flow for resolving a page of memory. These examples describe resolving the largest IA size supported by the initial lookup level. For these examples, see Full translation flows for VMSAv8-64 address translation on page K7-7286.

K7.1.1 Examples of performing the initial lookup

The address ranges used for the initial translation table lookup depend on the translation granule, as described in:

- Performing the initial lookup using the 4KB translation granule.
- Performing the initial lookup using the 16KB granule on page K7-7282.
- Performing the initial lookup using the 64KB translation granule on page K7-7284.

Performing the initial lookup using the 4KB translation granule

This subsection describes examples of the initial lookup when using the 4KB translation granule that Table D5-12 on page D5-2405 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in The VMSAv8-64 address translation system on page D5-2380.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D5-12 on page D5-2405 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- Initial lookup at level 0, 4KB translation granule on page K7-7281.
- Initial lookup at level 1, 4KB translation granule on page K7-7281.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see Overview of stage 2 translations, 4KB granule on page D5-2405.
Appendix K7 Address translation examples
K7.1 AArch64 Address translation examples

Initial lookup at level 0, 4KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\). As Table D5-12 on page D5-2405 shows, a stage 1 or stage 2 initial lookup at level 0 is required when \(39 \leq n \leq 47\). For these lookups:

- TTBR_ELx[47:(n-35)] specify the translation table base address.
- Bits\([n:39]\) of the input address are bits\([n-36:3]\) of the descriptor offset in the translation table.

--- Note ---

This means that, when the input address width is less than 48 bits

- The size of the translation table is reduced.
- More low-order bits of the TTBR_ELx are required to specify the translation table base address.
- Fewer input address bit are used to specify the descriptor offset in the translation table.

For example, if the input address width is 46 bits:

- The translation table size is 1KB,
- TTBR_ELx bits\([47:10]\) specify the translation table base address.
- Input address bits\([45:39]\) specify bits\([9:3]\) of the descriptor offset.

Figure K7-1 shows this lookup.

---

Initial lookup at level 1, 4KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\).

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D5-12 on page D5-2405 shows, this applies to \(IA[n:0]\), where \(30 \leq n \leq 38\). For these lookups:

- There is a single translation table at this level.
- TTBR_ELx[47:(n-26)] specify the translation table base address.
- Bits\([n:30]\) of the input address are bits\([n-27:3]\) of the descriptor offset in the translation table.

Figure K7-2 on page K7-7282 shows this lookup.
Appendix K7 Address translation examples
K7.1 AArch64 Address translation examples

Figure K7-2 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, without concatenation

For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D5-12 on page D5-2405 shows, this applies to IA\[n:0\], where 39 ≤ n ≤ 42. For these lookups:

- There are 2\((n-38)\) concatenated translation tables at this level.
- These concatenated translation tables must be aligned to 2\((n-38)\)×4KB. This means TTBR\_EL\[x\] must be zero.
- TTBR\_EL\[47:(n-26)\] specify the base address of the block of concatenated translation tables.
- Bits\[n:30\] of the input address are bits\[(n-27):3\] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K7-3 shows this lookup.

Figure K7-3 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 16KB granule

This subsection describes examples of the initial lookup when using the 16KB translation granule that Table D5-14 on page D5-2408 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in The VMSAv8-64 address translation system on page D5-2380.
Note

For stage 2 translations, the same principles apply to an initial lookup that Table D5-14 on page D5-2408 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- Initial lookup at level 0, 16KB translation granule.
- Initial lookup at level 1, 16KB translation granule.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see Overview of stage 2 translations, 16KB granule on page D5-2408.

Initial lookup at level 0, 16KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(\text{IA}[n:0]\). As Table D5-13 on page D5-2407 shows, the only case where an address translation using the 16KB granule starts at level 0 is a stage 1 translation of a 48-bit input address, \(\text{IA}[47:0]\). For this lookup:

- The required translation table has only two entries, meaning its size is 16 bytes, and it must be aligned to 16 bytes.
- \(\text{TTBR}_{\text{EL}x}[47:4]\) specify the translation table base address.
- \(\text{Bit}[47]\) of the input address is \(\text{bits}[3]\) of the descriptor offset in the translation table.

Figure K7-4 shows this lookup.

Figure K7-4 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 0

Initial lookup at level 1, 16KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(\text{IA}[n:0]\).

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D5-14 on page D5-2408 shows, this applies to \(\text{IA}[n:0]\), where \(36 \leq n \leq 46\). For these lookups:

- There is a single translation table at this level.
- \(\text{TTBR}_{\text{EL}x}[47:(n-32)]\) specify the translation table base address.
- \(\text{Bits}[n:36]\) of the input address are \(\text{bits}[(n-33):3]\) of the descriptor offset in the translation table.

Figure K7-5 on page K7-7284 shows this lookup.
For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D5-14 on page D5-2408 shows, the only case where an address translation using the 16KB granule starts at level 1 because of concatenation of translation tables is a stage 2 translation of a 48-bit input address, IA[47:0]. For this lookup:

- There are two concatenated translation tables at this level.
- These concatenated translation tables must be aligned to 2 × 16KB. This means TTBR_ELx[14] must be zero.
- TTBR_ELx[47:15] specify the base address of the block of two concatenated translation tables.
- Bits[47:36] of the input address are bits[14:3] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K7-6 shows this lookup.

Supported input address range is IA[y:0], 4 ≤ x ≤ 14, y = x + 32.
† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.
* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-6 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 64KB translation granule

This subsection describes examples of the initial lookup when using the 64KB translation granule that Table D5-16 on page D5-2412 shows as starting at level 1 or at level 2. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 2. This means that it gives specific examples of the mechanisms described in The VMSAv8-64 address translation system on page D5-2380.
Note

For stage 2 translations, the same principles apply to an initial lookup that Table D5-16 on page D5-2412 shows as starting at level 2. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 3.

The following subsections describe these examples of the initial lookup:

- Initial lookup at level 1, 64KB translation granule.
- Initial lookup at level 2, 64KB translation granule.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see Overview of stage 2 translations, 64KB granule on page D5-2412.

Initial lookup at level 1, 64KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\). As Table D5-16 on page D5-2412 shows, a stage 1 or stage 2 initial lookup at level 1 is required when \(42 \leq n \leq 47\). For these lookups:

- The size of the translation table is \(2^{(n-39)}\) bytes. This means the size of the translation table, at this level, is always less than the granule size. The address of this translation table must align to the size of the table.
- Bits\([n:42]\) of the input address are bits\([n-39):3]\) of the descriptor offset in the translation table.
- Bits\([47:(n-38)]\) of the TTBR_ELx specify the translation table base address.

Figure K7-7 shows this lookup.

Initial lookup at level 2, 64KB translation granule

This subsection describes initial lookups with an input address width of \((n+1)\) bits, meaning the input address is \(IA[n:0]\). For a stage 1 or stage 2 initial lookup at level 2, without the use of concatenated translation tables

As Table D5-16 on page D5-2412 shows, this applies to \(IA[n:0]\), where \(29 \leq n \leq 41\). For these lookups:

- There is a single translation table at this level.
- TTBR_ELx[47:(n-25)] of the specify the translation table base address.
- Bits\([n:29]\) of the input address are bits\([n-26):3]\) of the descriptor offset in the translation table.

Figure K7-8 on page K7-7286 shows this lookup.
Figure K7-8 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, without concatenation

For a stage 2 initial lookup at level 2, with concatenated translation tables

As Table D5-16 on page D5-2412 shows, this applies to I[n:0], where 42 ≤ n ≤ 45. For these lookups:

- There are 2m-41 concatenated translation tables at this level.
- These concatenated translation tables must be aligned to 2m-41 × 64KB. This means TTBR_ELx[(n-26):16] must be zero.
- TTBR_ELx[47:(n-25)] specify the base address of the block of translation tables.
- Bits[n:42] of the input address are bits[(n-26):16] of the descriptor offset from the base address of the block of translation tables.

Figure K7-9 shows this lookup.

Supported input address range is IA[y:0], 4 ≤ x ≤ 16, y = x + 25.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-9 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, with concatenation

K7.1.2 Full translation flows for VMSAv8-64 address translation

In a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR_ELx. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

This section describes example full translation flows, from the initial lookup to the address of a memory page. The example flows:

- Resolve the maximum-sized IA range supported by the initial lookup level.
• Do not have any concatenation of translation tables.
• Cover only the 4KB and the 64KB translation granules.

*Examples of performing the initial lookup on page K7-7280 described how either reducing the IA range or concatenating translation tables affects the initial lookup.*

**Note**
Reducing the IA range or concatenating translation tables affects only the initial lookup.

The following sections describe full VMSA v8-64 translation flows, down to an entry for a memory page:
• The address and properties fields shown in the translation flows.
• Full translation flow using the 4KB granule and starting at level 0.
• Full translation flow using the 4KB granule and starting at level 1 on page K7-7289.
• Full translation flow using the 64KB granule and starting at level 1 on page K7-7290.
• Full translation flow using the 64KB granule and starting at level 2 on page K7-7291.

**The address and properties fields shown in the translation flows**
For the Non-secure EL1&0 stage 1 translation:
• Any descriptor address is the IPA of the required descriptor.
• The final output address is the IPA of the block or page.

In these cases, an EL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

*Properties* indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see *Memory attribute fields in the VMSA v8-64 translation table format descriptors* on page D5-2437.

**Full translation flow using the 4KB granule and starting at level 0**
Figure K7-10 on page K7-7288 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows.*
Figure K7-10 Complete stage 1 translation of a 48-bit address using the 4KB translation granule

If the level 1 lookup or level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-10 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.
Full translation flow using the 4KB granule and starting at level 1

Figure K7-11 shows the complete translation flow for a stage 1 translation table walk for a 39-bit input address. This lookup must start with a level 1 lookup. For more information about the fields shown in the figure see The address and properties fields shown in the translation flows on page K7-7287.

Figure K7-11 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K7-10 on page K7-7288, shows how the translation for the 42-bit address start the same lookup process one stage later.

**Figure K7-11 Complete stage 1 translation of a 39-bit address using the 4KB translation granule**

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-11 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K7-10 on page K7-7288, shows how the translation for the 42-bit address start the same lookup process one stage later.

For details of Properties fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.
Full translation flow using the 64KB granule and starting at level 1

Figure K7-10 on page K7-7288 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows on page K7-7287.*

Figure K7-12 Complete stage 1 translation of a 48-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-12 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

The level 1 lookup resolves only 6 bits of the input address. As described in *Performing the initial lookup using the 64KB translation granule on page K7-7284,* this means:
- The translation table size for this level is only 512 bytes.
- The required translation table alignment for this level is 512 bytes.
- The Base address field in the TTBR_ELx is extended, at the low-order end, to be bits[47:9].
Full translation flow using the 64KB granule and starting at level 2

Figure K7-11 on page K7-7289 shows the complete translation flow for a stage 1 translation table walk for a 42-bit input address. This lookup must start with a level 2 lookup. For more information about the fields shown in the figure see The address and properties fields shown in the translation flows on page K7-7287.

Figure K7-13 Complete stage 1 translation of a 42-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-13 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K7-12 on page K7-7290, shows:

- The translation for the 42-bit address starts the same lookup process one stage later.
- Because the initial lookup resolves 13 bits of address:
  - The translation table size for this level is 64KB.
  - The required translation table alignment for this level is 64KB.
  - The Base address field in the TTBR_ELx is bits[47:16].
K7.2  AArch32 Address translation examples

The following sections give address translation examples for the VMSAv8-32 address translation formats:

- Address translation examples using the VMSAv8-32 Short descriptor translation table format.
- Address translation examples using the VMSAv8-32 Long descriptor translation table format on page K7-7297.

K7.2.1  Address translation examples using the VMSAv8-32 Short descriptor translation table format

VMSAv8-32 Short-descriptor translation table format descriptors on page G5-5482 describes the memory section and page option for a single VMSAv8-32 address translation. The following sections show the full translation flow for each of these options:

- Translation flow for a Supersection.
- Translation flow for a Section on page K7-7293.
- Translation flow for a Large page on page K7-7294.
- Translation flow for a Small page on page K7-7295.

The address and Properties fields shown in the translation flows on page K7-7296 summarizes the information returned by the lookup.

Translation flow for a Supersection

Figure K7-14 on page K7-7293 shows the complete translation flow for a Supersection. For more information about the fields shown in this figure see The address and Properties fields shown in the translation flows on page K7-7296.
Figure K7-14 shows how, when the input address, the VA, addresses a Supersection, the top four bits of the Supersection index bits of the address overlap the bottom four bits of the Table index bits. For more information, see Additional requirements for Short-descriptor format translation tables on page G5-5485.

Translation flow for a Section

Figure K7-15 on page K7-7294 shows the complete translation flow for a Section. For more information about the fields shown in this figure see The address and Properties fields shown in the translation flows on page K7-7296.
Translation flow for a Large page

Figure K7-16 on page K7-7295 shows the complete translation flow for a Large page. For more information about the fields shown in this figure see The address and Properties fields shown in the translation flows on page K7-7296.
Appendix K7 Address translation examples

K7.2 AArch32 Address translation examples

Note
Figure K7-16 shows how, when the input address, the VA, addresses a Large page, the top four bits of the page index bits of the address overlap the bottom four bits of the level 1 table index bits. For more information, see Additional requirements for Short-descriptor format translation tables on page G5-5485.

Translation flow for a Small page
Figure K7-17 shows the complete translation flow for a Small page. For more information about the fields shown in this figure see The address and Properties fields shown in the translation flows.
The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation tables:
• Any descriptor address is the IPA of the required descriptor.
• The final output address is the IPA of the Section, Supersection, Large page, or Small page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

Otherwise, the address is the PA of the descriptor, Section, Supersection, Large page, or Small page.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see Information returned by a translation table lookup on page G5-5477, and the description of the register or translation table descriptor.
For translations using the Short-descriptor translation table format, *VMSAv8-32 Short-descriptor translation table format descriptors* on page G5-5482 describes the descriptors formats.

**K7.2.2 Address translation examples using the VMSAv8-32 Long descriptor translation table format**

As described in *Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format* on page G5-5505, in a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

The following sections give examples of full VMSAv8-32 Long-descriptor format address translation flows, down to an entry for a 4KB page:

- **Full translation flow, starting at level 1 lookup.**
- **Full translation flow, starting at level 2 lookup** on page K7-7299.

*The address and Properties fields shown in the translation flows* on page K7-7296 summarizes the information returned by the lookup.

**Full translation flow, starting at level 1 lookup**

*Figure K7-18 on page K7-7298* shows the complete translation flow for a VMSAv8-32 Long-descriptor stage 1 translation table walk that starts with a level 1 lookup. For more information about the fields shown in the figure see *The address and Properties fields shown in the translation flows* on page K7-7296.
Figure K7-18 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 1

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

If bits[47:40] of the TTBR or the descriptor are not zero then the lookup will generate an Address size fault, see Address size fault on page G5-5556.

A stage 2 translation that starts at a level 1 lookup differs from the translation shown in Figure K7-18 only as follows:
- The possible values of \( n \) are 4-13, to support an input address of between 31 and 40 bits.
- A descriptor and output addresses are always PAs.
Full translation flow, starting at level 2 lookup

Figure K7-19 shows the complete translation flow for a stage 1 VMSAv8-32 Long-descriptor translation table walk that starts at a level 2 lookup. For more information about the fields shown in the figure see The address and Properties fields shown in the translation flows on page K7-7296.

For details of Properties fields, see the register or descriptor description.
‡ See the lookup description for more information about bits[40:47] of the TTBR and descriptors

The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation:
• Any descriptor address is the IPA of the required descriptor.
• The final output address is the IPA of the block or page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.
For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

*Properties* indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see *Information returned by a translation table lookup on page G5-5477*, and the description of the register or translation table descriptor.

For translations using the Long-descriptor translation table format, *VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5491* describes the descriptors formats.
Appendix K8
Example OS Save and Restore Sequences

This appendix provides possible OS Save and Restore sequences for a v8 Debug implementation. It contains the following sections:

• Save Debug registers on page K8-7302.
• Restore Debug registers on page K8-7304.
K8.1 Save Debug registers

This section shows how to save the registers that are used by an external debugger.

; On entry, X0 points to a block to save the debug registers in.
; Returns the pointer beyond the block and corrupts X1-X3

SaveDebugRegisters

; (1) Set OS lock.
    MOV     X2,#1                       ; Set the OS lock. In AArch64 state, the OS lock
    MSR     OSLAR_EL1,X2                ; is writable via OSLAR.
    ISB                                 ; Context synchronization event

; (2) Walk through the registers, saving them
    MRS     X1,OSDTRRX_EL1              ; Read DTRRX
    MRS     X2,OSDTRTX_EL1              ; Read DTRTX
    STP     W1,W2,[X0],#8               ; Save { DTRRX, DTRTX }
    MRS     X1,OSECCR_EL1               ; Read ECCR
    MRS     X2,MDSCR_EL1                ; Read DSCR
    STP     W1,W2,[X0],#8               ; Save { ECCR, DSCR }
[ AARCH32_SUPPORTED
    MRS     X1(DBGVCR32_EL2)            ; Read DBGVCR
    MRS     X2(DBGCLAIMCLR_EL1)         ; Read CLAIM - note, have to read via CLAIMCLR
    STP     W1,W2,[X0],#8               ; Save { VCR, CLAIM }
]

;; Macros for saving off a "register pair"
;; $WB   is W for watchpoint, B for breakpoint
;; $num  is the pair's number

K8.2 Restore Debug registers
Appendix K9
Recommended Upload and Download Processes for External Debug

This appendix contains the following section:
• Using memory access mode in AArch64 state on page K9-7308.

Note
This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might find this information useful.
K9.1 Using memory access mode in AArch64 state

Figure K9-1 and Figure K9-2 on page K9-7309 show the processes for using memory access mode to implement a download (external host to target) and an upload (target to external host).

To transfer $n$ words of data:
- The download sequence needs $n+6$ accesses by the external debug interface.
- The upload sequence needs $n+8$ accesses by the external debug interface.

In both cases, in the innermost loop the debugger can make an external access to a DTR without polling EDSCR after each write as underrun and overrun detection prevent failure. Normally external accesses from the debugger are outpaced by the memory accesses of the PE, making underruns and overruns unlikely. If this is not the case, the EDSCR.ERR flag is set to 1. This is checked once at the end of the sequence, although a debugger can check it more often, for example once for each page. If the EDSCR.ERR flag is set to 1 because of overrun or underrun, the debugger can restart. The address to restart from is frozen in X0. EDSCR.ERR might also be set because of a Data abort.

If underruns and overruns are common, the debugger can pace itself accordingly.

--- Note ---
- The base address must be a multiple of 4.
- The order of the writes that set up the address does not matter in Debug state.

---

Figure K9-1 Fast code download in AArch64 state (external host to target)
In Figure K9-1 on page K9-7308, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
   a. Write address [31:0] to DBGDTRRX_EL0.
   b. Write address [63:32] to DBGDTRTX_EL0.
   c. Write MRS X0, DBGDTR_EL0 to EDITR. The PE executes this instruction.
   d. Set EDSCR.MA to 1.

2. Loop $n$ times. From the external debug interface:
   a. Write to DBGDTRRX_EL0. The PE reads the word from DTRRX and stores it to memory. It increments X0 by 4.

3. Epilogue. From the external debug interface:
   a. Clear EDSCR.MA to 0.
   b. Read EDSCR to check for overruns or Data Aborts during download.

In Figure K9-2, the sequence for the fast data upload is as follows:

1. Setup. From the external debug interface:
   a. Write address [31:0] to DBGDTRRX_EL0.
b. Write address [63:32] to DBGDTRTX_EL0.

c. Write MRS X0, DBGDTR_EL0 to EDITR.

d. Write MSR DBGDTR_EL0, X0 to EDITR. This dummy operation ensures EDSCR.TXfull == 1.

e. Set EDSCR.MA to 1.

f. Read DBGDTRTX_EL0 and discard the value. The PE returns the previous DTR value, loads the first word, and writes it to DTR. It increments X0 by 4.

2. Loop \( n-1 \) times. From the external debug interface:
   a. Read DBGDTRTX_EL0. The PE returns the previous DTRTX value, loads a new word, and writes it to DTRTX. It increments X0 by 4.

3. Epilogue. From the external debug interface:
   a. Clear EDSCR.MA to 0.
   b. Read DBGDTRTX_EL0 for the \( n \)th value.
   c. Read EDSCR to check for underruns, overruns or Data Aborts during upload.
Appendix K10
Software Usage Examples

This appendix gives software usage examples, for cases where these are likely to contribute significantly to an understanding of the Arm architecture.

It contains the following sections:

• Use of the Advanced SIMD complex number instructions on page K10-7312.
• Use of the ARMv8.2 extensions to the Cryptographic Extension on page K10-7314.
K10.1 Use of the Advanced SIMD complex number instructions

ARMv8.3-CompNum provides instructions to aid floating-point computations of complex numbers. This section illustrates the use of these instructions for complex arithmetic. It is not part of the ARM architecture definition.

This section uses the AArch64 instructions FCADD and FCMLA - usage of the AArch32 instructions VCADD and VOIL is similar.

When using the instructions implemented by ARMv8.3-CompNum, a complex numbers is represented in a SIMD&FP register as a pair of adjacent elements, each holding a floating-point number, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number.

K10.1.1 Complex addition

Simple complex addition on a vector of complex numbers is already provided by the vector form of the FADD instruction.

The functionality that FCADD adds is to rotate each complex number in the second vector by 90 degrees or 270 degrees counterclockwise (considering the complex numbers on an Argand diagram) before performing the addition. Mathematically, this is equivalent to multiplying the second complex number by i or -i before addition.

This means, given a complex number z stored in a pair of elements in one vector, and a complex number w stored in the corresponding element pair in another vector:

- FADD calculates \( z + w \).
- FCADD calculates \( z \pm iw \).

K10.1.2 Complex multiplication

The FCMLA instruction does not provide functionality for complex multiplication directly. However, a pair of FCMLA instructions can provide this function.

The FCMLA instruction operates on corresponding pairs of complex numbers stored in SIMD&FP vector registers, and adds the result to the corresponding complex number in the destination SIMD&FP vector register. This computation is as follows:

1. The second complex number is rotated by 0, 90, 180 or 270 degrees counterclockwise.
2. That complex number is multiplied by either the real or imaginary part of the first complex number:
   - When the rotation is 0 or 180 degrees, the real part is used.
   - When the rotation is 90 or 270 degrees, the imaginary part is used.
3. The resulting complex number is added to the corresponding complex number in the destination register.

Mathematically, considering the complex numbers on an Argand diagram:

- Rotation by 180 degrees is equivalent to negation.
- Rotation by 90 degrees is equivalent to multiplying by i.
- Rotation by 270 degrees is equivalent to multiplying by -i.

This means that, for a first complex number \( z \), where \( z = a + bi \), and a second complex number \( w \), if initially the corresponding complex number in the destination register is zero:

- When the rotation is 0 degrees the result of the multiply-add is \( aw \).
- When the rotation is 180 degrees, the result is \(-aw\).
- When the rotation is 90 degrees, the result is \( biw \).
- When the rotation is 270 degrees, the result is \(-biw \).
This means that, if the destination register is zeroed and an FOMLA instruction is executed with a rotation parameter of 0, and then the same instruction is executed with a rotation parameter of 90:

- The first execution returns $aw$ in the destination register.
- The second execution accumulates $biw$ to this, meaning the result is $aw + biw$.
- This result is the product of $(a+bi)w$, which is the product $zw$.

So, this pair of instructions can be used to implement complex multiplication.

After zeroing V0, the syntax of a pair of instructions to perform this complex number multiplication might be:

```
FOMLA V0.4S, V1.4S, V2.4S, #0
FOMLA V0.4S, V1.4S, V2.4S, #90
```

Other simple pairs of FOMLA instructions perform useful computations. For example, considering a first complex number $z$ and second complex number $w$, defined as before, and a destination register that has been zeroed before the first FOMLA instruction is executed:

1. The following pair of instructions calculates the complex conjugate of $z$ multiplied by $w$.
   ```
   FOMLA V0.4S, V1.4S, V2.4S, #0
   FOMLA V0.4S, V1.4S, V2.4S, #270
   ```

2. The following pair of instructions calculates the negation of $z$ multiplied by $w$.
   ```
   FOMLA V0.4S, V1.4S, V2.4S, #180
   FOMLA V0.4S, V1.4S, V2.4S, #270
   ```

3. The following pair of instructions calculates the negation of the complex conjugate of $z$ multiplied by $w$.
   ```
   FOMLA V0.4S, V1.4S, V2.4S, #180
   FOMLA V0.4S, V1.4S, V2.4S, #90
   ```

**Note**

For these examples, the following caveats must be considered:

- FOMLA performs a fused multiply-add, meaning there is no intermediate rounding. This lack of intermediate rounding can give unexpected results in some cases. ARM expects that these instructions are only used in situations where the effect of the rounding of these results is not material to the calculation.
- When using the FOMLA instructions, the behavior of $(\infty + \infty i)$ multiplied by $(0 + i)$ is $(\text{NaN} + \text{NaN}i)$, rather than the result expected by ISO C, which is complex $\infty$. 

K10.2 Use of the ARMv8.2 extensions to the Cryptographic Extension

K10.2.1 Use of the SHA512 instructions

These instructions are implemented when ARMv8.2-SHA is implemented.

The following code sequence shows the use of the SHA512 instructions to calculate a SHA512 hash iteration of 80 rounds. This code is not fully optimized.

```assembly
// X0 contains the pointer to the bottom of the (padded) 16*64 bytes of message to be
// hashed, with space above that message to hold a further 64 * 64 bytes of working
// data
// X1 contains the pointer to the 0th element of 80 64-bit constants (in ascending addresses) defined in
// the SHA2 specification
// X2 contains a loop variable
// V4, V5, V6, V7 hold VS0 to VS3 respectively
// V8 holds running hash V1
// V9 holds running hash V0

Appendix K11
Barrier Litmus Tests

This appendix gives examples of the use of the barrier instructions provided by the ARMv8 architecture. It contains the following sections:

- Introduction on page K11-7322.
- Load-Acquire, Store-Release and barriers on page K11-7325.
- Load-Acquire Exclusive, Store-Release Exclusive and barriers on page K11-7329.
- Using a mailbox to send an interrupt on page K11-7334.
- Cache and TLB maintenance instructions and barriers on page K11-7335.
- ARMv7 compatible approaches for ordering, using DMB and DSB barriers on page K11-7347.

Note

This information is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.
K11.1 Introduction

The exact rules for the insertion of barriers into code sequences is a very complicated subject, and this appendix describes many of the corner cases and behaviors that are possible in an implementation of the ARMv8 architecture. This appendix is to help programmers, hardware design engineers, and validation engineers understand the need for the different kinds of barriers.

K11.1.1 Overview of memory consistency

Early generations of microprocessors were relatively simple processing engines that executed each instruction in program order. In such processors, the effective behavior was that each instruction was executed in its entirety before a subsequent instruction started to be executed. This behavior is sometimes referred to as the Sequential Execution Model (SEM), and in this Manual it is described as Simple sequential execution of the program.

In later processor generations, the needs to increase processor performance, both in terms of the frequency of operation and the number of instructions executed each cycle, mean that such a simple form of execution is abandoned. Many techniques, such as pipelining, write buffering, caching, speculation, and out-of-order execution, are introduced to provide improved performance.

For general purpose PEs, such as ARM, these microarchitectural innovations are largely hidden from the programmer by a number of microarchitectural techniques. These techniques ensure that, within an individual PE, the behavior of the PE largely remains the same as the SEM. There are some exceptions to this where explicit synchronization is required. In the ARM architecture, these are limited to cases such as:

- Synchronization of changes to the instruction stream.
- Synchronization of changes to System registers.

In both these cases, the ISB instruction provides the necessary synchronization.

While the effect of ordering is largely hidden from the programmer within a single PE, the microarchitectural innovations have a profound impact on the ordering of memory accesses. Write buffering, speculation, and cache coherency protocols, in particular, can all mean that the order in which memory accesses occur, as seen by an external observer, differs significantly from the order of accesses that would appear in the SEM. This is usually invisible in a uniprocessor environment, but the effect becomes much more significant when multiple PEs are trying to communicate with memory. In reality, these effects are often only significant at particular synchronization boundaries between the different threads of execution.

The problems that arise from memory ordering considerations are sometimes described as the problem of memory consistency. Processor architectures have adopted one or more memory consistency models, or memory models, that describe the permitted limits of the memory re-ordering that can be performed by an implementation of the architecture. The comparison and categorization of these has generated significant research and comment in academic circles, and ARM recommends the Memory Consistency Models for Shared Memory-Multiprocessors paper as an excellent detailed treatment of this subject.

This appendix does not reproduce such a work, but instead concentrates on some cases that demonstrate the features of the weakly-ordered memory model of the ARM architecture from ARMv6. In particular, the examples show how the use of the DMB and DSB memory barrier instructions can provide the necessary safeguards to limit memory ordering effects at the required synchronization points.

K11.1.2 Barrier operation definitions

The following reference, or provide, definitions of terms used in this appendix:

**DMB**
See Data Memory Barrier (DMB) on page B2-104.

**DSB**
See Data Synchronization Barrier (DSB) on page B2-106.

**ISB**
See Instruction Synchronization Barrier (ISB) on page B2-104.

**Observer, Completion**
See Definition of the ARMv8 memory model on page B2-97.
See Completion and endpoint ordering on page B2-102.
Program order

The order of instructions as they appear in an assembly language program. This appendix does not attempt to describe or define the legal transformations from a program written in a higher level programming language, such as C or C++, into the machine language that can then be disassembled to give an equivalent assembly language program. Such transformations are a function of the semantics of the higher level language and the capabilities and options on the compiler.

K11.1.3 Conventions

Many of the examples are written in a stylized extension to ARM assembler, to avoid confusing the examples with unnecessary code sequences.

AArch32

The construct \texttt{WAIT(Rx==1)} describes the following sequence:

\begin{verbatim}
loop
 LDR R12, [Rx]
 CMP R12, #1
 BNE loop
\end{verbatim}

Also, the construct \texttt{WAIT_ACQ(Rx==1)} describes the following sequence:

\begin{verbatim}
loop
 LDA R12, [Rx]       ; load acquire ensures it is ordered before subsequent loads/stores
 CMP R12, #1
 BNE loop
\end{verbatim}

R12 is chosen as an arbitrary temporary register that is not in use. It is named to permit the generation of a false dependency to ensure ordering.

AArch64

The construct \texttt{WAIT(Xx==1)} describes the following sequence:

\begin{verbatim}
loop
 LDR W12, [Xx]
 CMP W12, #1
 B.NE loop
\end{verbatim}

Also, the construct \texttt{WAIT_ACQ(Xx==1)} describes the following sequence:

\begin{verbatim}
loop
 LDAR W12, [Xx]       ; load acquire ensures it is ordered before subsequent loads/stores
 CMP W12, #1
 B.NE loop
\end{verbatim}

For each example, a code sequence is preceded by an identifier of the observer running it:

- P0, P1…Px refer to caching coherent PEs that implement the ARMv8 architecture, and are in the same shareability domain.
- E0, E1…Ex refer to non-caching observers, that do not participate in the coherency protocol, but execute ARMv8 instructions and have a weakly-ordered memory model. This does not preclude these observers being different objects, such as DMA engines or other system masters.

These observers are unsynchronized other than as required by the documented code sequence.

--- Note ---

Throughout this appendix, \textit{ARMv8 instruction} and \textit{instruction} refer to instructions from the A64, A32, or T32 instruction set, provided by ARMv8 implementations.
Results are expressed in terms of `<agent>:<register>`, such as `P0:R5`. The results can be described as:

**Permissible**
This does not imply that the results expressed are required or are the only possible results. In most cases they are results that would not be possible under a sequentially consistent running of the code sequences on the agents involved. In general terms, this means that these results might be unexpected to anyone unfamiliar with memory consistency issues.

**Not permissible**
Results that the architecture expressly forbids.

**Required**
Results that the architecture expressly requires.

The examples omit the required shareability domain arguments of `DMB` and `DSB` instructions. The arguments are assumed to be selected appropriately for the shareability domains of the observers.

In AArch32 state, where the barrier function in the litmus test can be achieved by a `DMB ST`, that is a barrier to stores only, this is shown by the use of `DMB [ST]`. This indicates that the ST qualifier can be omitted without affecting the result of the test. In some implementations `DMB ST` is faster than `DMB`.

For AArch64 code, the shareability domain of the `DMB` or `DSB` must be included. This is shown in this manual using the notation `DMB <domain>` and `DSB <domain>` respectively.

Except where otherwise stated, other conventions are:

- All memory initializes to 0.
- R0 and W0 contain the value 1.
- R1 - R4 and W1 - W4 contain arbitrary independent addresses that initialize to the same value on all PEs. The addresses held in these registers are shareable and:
  - The addresses held in R1 and R2 are in Write-Back Cacheable Normal memory.
  - The address held in R3 is in Write-Through Cacheable Normal memory.
  - The address held in R4 is in Non-cacheable Normal memory.
- R5 - R8 and W5 - W8 contain:
  - When used with an `STR` instruction, `0x55`, `0x66`, `0x77`, and `0x88` respectively.
  - When used with an `LDR` instruction, the value 0.
- R11 and W11 contain a new instruction or new translation table entry, as appropriate, and R10 contains the virtual address and the ASID, for use in this change of translation table entry.
- Memory locations are Normal memory locations unless otherwise stated.

The examples use mnemonics for the cache maintenance and TLB maintenance instructions. The following tables describe the mnemonics:

- *Cache maintenance system instructions* on page K13-7437.
- *TLB maintenance system instructions* on page K13-7438.
K11.2 Load-Acquire, Store-Release and barriers

The following sections show that most of the examples in sections Simple ordering and barrier cases on page K11-7347 and Load-Exclusive, Store-Exclusive and barriers on page K11-7351 can be achieved using the Load-Acquire and Store-Release instructions without the need for additional barriers.

K11.2.1 Message passing

The following sections describe:

- Resolving weakly-ordered message passing by using Acquire and Release.
- Resolving message passing by the use of Store-Release and address dependency on page K11-7326.

Resolving weakly-ordered message passing by using Acquire and Release

The message passing problem described in Weakly-ordered message passing problem on page K11-7347 can be solved by the use of Load-Acquire and Store-Release instructions when accessing the communications flag:

**AArch32**

P1

```asm
STR R5, [R1]          ; sets new data
STL R0, [R2]          ; sends flag indicating data ready, which is ordered after the STR
```

P2

```asm
WAIT_ACQ([R2]==1)     ; waits on flag
LDR R5, [R1]
```

**AArch64**

P1

```asm
STR W5, [X1]          ; sets new data
STLR W0, [X2]         ; sends flag indicating data ready, which is ordered after the STR
```

P2

```asm
WAIT_ACQ([X2]==1)     ; waits on flag
LDR W5, [X1]
```

This ensures the observed order of both the reads and the writes allows transfer of data such that the result P2:R5==0x55 is guaranteed.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

**AArch32**

P3

```asm
WAIT_ACQ([R2]==1)     ; waits on flag
LDR RS, [R1]
```

**AArch64**

P3

```asm
WAIT_ACQ([X2]==1)     ; waits on flag
LDR WS, [X1]
```
Resolving message passing by the use of Store-Release and address dependency

The lack of ordering of stores discussed in *Message passing with multiple observers* on page K11-7348 can be resolved by the use of Store-Release for the store of the valid flag by P1, even when the observers are using an address dependency:

**AArch32**

P1

\begin{verbatim}
STR R5, [R1]          ; sets new data
STL R0, [R2]          ; sends flag indicating data ready using a Store-Release
\end{verbatim}

P2

\begin{verbatim}
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12]     ; the load has an address dependency on R12
: and so is ordered after the flag has been seen
\end{verbatim}

**AArch64**

P1

\begin{verbatim}
STR W5, [X1]          ; sets new data
STLR W0, [X2]         ; sends flag indicating data ready using a Store-Release
\end{verbatim}

P2

\begin{verbatim}
WAIT([X2]==1)
AND W12, W12, WZR     ; W12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12]     ; the load has an address dependency on W12
: and so is ordered after the flag has been seen
\end{verbatim}

This ensures the observed order of the writes allows transfer of data such that P2:R5 and P3:R5 contain the same value of 0x55.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

**AArch32**

P3

\begin{verbatim}
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12]     ; the load has an address dependency on R12
: and so is ordered after the flag has been seen
\end{verbatim}

**AArch64**

P3

\begin{verbatim}
WAIT([X2]==1)
AND W12, W12, WZR     ; W12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12]     ; the load has an address dependency on W12
: and so is ordered after the flag has been seen
\end{verbatim}
K11.2.2 Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object. A Store-Release can be used to ensure the order of the update of the base address:

**AArch32**

P1

```
STR R5, [R1, #offset] ; sets new data in a field
STL R1, [R2] ; updates base address
```

P2

```
LDR R1, [R2] ; reads base address
CMP R1, #0 ; checks if it is valid
BEQ null_trap
LDR R5, [R1, #offset] ; uses base address to read field
```

**AArch64**

P1

```
STR W5, [X1, #offset] ; sets new data in a field
STLR X1, [X2] ; updates base address
```

P2

```
LDR X1, [X2] ; reads base address
CMP X1, #0 ; check if it is valid
B.EQ null_trap
LDR W5, [X1, #offset] ; uses base address to read field
```

It is required that P2:R5==0x55 if the null_trap is not taken. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not need a barrier to ensure this behavior.

The read of the base address in P2 could be a Load-Acquire, but it is not necessary in this case.
K11.2.3 WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. An explicit DSB barrier instruction is required if it is necessary to ensure memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in Posting a store before polling for acknowledgement on page K11-7350, or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

**AArch32**

P1

    STR R0, [R2]
    DSB
Loop
    WFI
    B Loop

**AArch64**

P1

    STR W0, [X2]
    DSB <domain>
Loop
    WFI
    B Loop

This requirement is unchanged in ARMv8 by the presence of Load-Acquire or Store-Release.
K11.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

The ARMv8 architecture adds the acquire and release semantics to Load-Exclusive and Store-Exclusive instructions, which allows them to gain ordering acquire and/or release semantics.

The Load-Exclusive instruction can be specified to have acquire semantics, and the Store-Exclusive instruction can be specified to have release semantics. These can be arbitrarily combined to allow the atomic update created by a successful Load-Exclusive and Store-Exclusive pair to have any of:

- No Ordering semantics (using `LDREX` and `STREX`).
- Acquire only semantics (using `LDAEX` and `STREX`).
- Release only semantics (using `LDREX` and `STLEX`).
- Sequentially consistent semantics (using `LDAEX` and `STLEX`).

In addition, the ARMv8 specification requires that the clearing of a global monitor will generate an event for the PE associated with the global monitor, which can simplify the use of `WFE`, by removing the need for a `DSB` barrier and `SEV` instruction.

K11.3.1 Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

Note

The inclusion of AArch32 PLDw instructions or AArch64 PFRM PST* instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

For a critical region, the requirement on taking a lock is usually for acquire semantics, while the clearing of a lock requires release semantics:

AArch32

```
Px

PLDw[R1]              ; preload into cache in unique state
Loop
LDAEX R5, [R1]        ; read lock with acquire
CMP R5, #0            ; check if 0
STREXEQ R5, R0, [R1]  ; attempt to store new value
CMPEQ R5, #0          ; test if store succeeded
BNE Loop              ; retry if not

; loads and stores in the critical region can now be performed
```

AArch64

```
Px

PRFM PSTLKEEP, [X1]   ; preload into cache in unique state
Loop
LDAXR W5, [X1]       ; read lock with acquire
CBNZ W5, Loop        ; check if 0
STXR W5, W0, [X1]    ; attempt to store new value
CBNZ W5, Loop        ; test if store succeeded and retry if not

; loads and stores in the critical region can now be performed
```

The acquire associated with the load is sufficient to ensure the required ordering in a lock situation. The Store-Exclusive will fail (and so be retried) if there is a store to the location being monitored between the Load-Exclusive and the Store-Exclusive.
K11.3.2 Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, the lock release needs release semantics:

**AArch32**

```assembly
; loads and stores in the critical region
MOV R0, #0
STL R0, [R1] ; clear the lock with release semantics
```

**AArch64**

```assembly
; loads and stores in the critical region
STLR WZR, [X1] ; clear the lock with release semantics
```

K11.3.3 Ticket locks

When a lock is free, in order to avoid a rush to get the lock by many PEs, the use of ticket locks is common in more advanced systems. When the use is requested, the ticket locks determine the order of the users of the critical sections, in order to avoid starvation that can occur with a simple contention based spin lock.

A ticket lock allocates each thread a ticket number when it first requests the lock, and then compares that number with the current number for the lock. If they are the same, then the critical section can be entered. Otherwise the thread waits until the current number is equal to the ticket number for that thread.

The reading of the current number of the lock needs acquire semantics for the lock to be acquired.

--- Note ---

- The code in this section is little-endian code, as it views the combined current and next values as a single combined quantity. The addresses of the current and next ticket values need to be adjusted for a big-endian system.

- The inclusion of AArch32 **PLDW** instructions or AArch64 **PFRM PSTX** instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

---

This is shown in the implementation below:

**AArch32**

```assembly
; R1 holds two 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

PLDW[R1] ; preload into cache in unique state
Loop1
LDAEX R5, [R1] ; read current and next
ADD R5, R5, #0x10000 ; increment the next number
STREX R6, R5, [R1] ; and update the value
CMP R6, #0 ; did the exclusive pass
BNE Loop1 ; retry if not
CMP R5, R5, ROR #16 ; is the current ticket ours
BEQ block_start
Loop2
LDAH R6, [R1] ; read current value
```
Appendix K11 Barrier Litmus Tests

K11.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

```asm
CMP R6, R5, LSR #16 ; compare it with our allocated ticket
BNE Loop2 ; retry (spin) if it is not the same

block_start

AArch64

Px

; X1 holds 2 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

PRFM PSTL1KEEP, [X1] ; preload into cache in unique state

Loop1
  LDAXR W5, [X1] ; read current and next
  ADD W5, W5, #0x10000 ; increment the next number
  STXR W6, W5, [X1] ; and update the value
  CBNZ W6, Loop1 ; did the exclusive pass - retry if not

  AND W6, W5, #0xFFFF
  CMP W6, W5, LSR #16 ; is the current ticket ours
  B.EQ block_start

Loop2
  LDARH W6, [X1] ; read current value
  CMP W6, W5, LSR #16 ; compare it with the our allocated ticket
  B.NE Loop2 ; retry (spin) if it isn't the same

block_start

Releasing the ticket lock simply involves incrementing the current ticket number, that is still assumed to be in R3, and doing a Store-Release:

AArch32

ADD R6, R6, #1
STLH R6, [R1]

AArch64

ADD W6, W6, #1
STLRH W6, [X1]
```

K11.3.4 Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture can use the Wait For Event mechanism to minimise the energy cost of polling variables by putting the PE into a low power state, suspending execution, until an asynchronous exception or an explicit event is seen by that PE. In ARMv8, the event can be generated as a result of clearing the global monitor, so removing the need for a DSB barrier or an explicit send event message.

This can be used with simple locks or with ticket locks.

--- Note ---

The inclusion of AArch32 PLDW instructions or AArch64 PRFM PST* instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

---

Simple lock

The following is an example of lock acquire code using WFE:

AArch32

Loop2
WFE
LDAXRH W6, [X1] ; read current value
CMP W6, W5, LSR #16 ; compare it with our allocated ticket
B.NE Loop2 ; retry (spin) if it is not the same
```

block_start
K11.4 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

**AArch32**

P1

```
STR R5, [R1]          ; message stored to shared memory location
DSB ST
STR R0, [R4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

**AArch64**

P1

```
STR W5, [X1]          ; message stored to shared memory location
DSB ST
STR W0, [X4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR W5, [X1]
```
K11.5 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- Data cache maintenance instructions.
- Instruction cache maintenance instructions on page K11-7339.
- TLB maintenance instructions and barriers on page K11-7342.

K11.5.1 Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- Message passing to non-caching observers.
- Multiprocessing message passing to non-caching observers.
- Invalidating DMA buffers, non-functional example on page K11-7336.
- Invalidating DMA buffers, functional example with single PE on page K11-7337.
- Invalidating DMA buffers, functional example with multiple coherent PEs on page K11-7338.

Message passing to non-caching observers

The ARMv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. The Load-Acquire and Store-Release instructions have no effect on cache maintenance instruction. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

AArch32

P1

```
STR R5, [R1]          ; updates data (assumed to be in P1 cache)
DCCMVAC R1            ; cleans cache to point of coherency
DMB                   ; ensures effects of the clean will be observed before the
                      ; flag is set
STR R0, [R4]          ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([R4] == 1)  ; waits for the flag (with order)
LDR R5, [R1]          ; reads the data
```

AArch64

P1

```
STR W5, [X1]          ; updates data (assumed to be in P1 cache)
DC CVAC, X1           ; cleans cache to point of coherency
DMB ISH               ; ensures effects of the clean will be observed before the
                      ; flag is set
STR W0, [X4]          ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([X4] == 1)  ; waits for the flag (with order)
LDR W5, [X1]          ; reads the data
```

In this example, it is required that E1:R5==0x55.

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions combined with properties of barriers, means that the message passing principle for non-caching observers is:

AArch32

P1
Appendix K11 Barrier Litmus Tests
K11.5 Cache and TLB maintenance instructions and barriers

STR R5, [R1] ; updates data (assumed to be in P1 cache)
STL R0, [R2] ; sends a flag for P2 (ordered by the store release)

P2

WAIT ([R2] == 1) ; waits for P1 flag
DMB ; ensures cache clean is observed after P1 flag is observed
DCCMVAC R1 ; cleans cache to point of coherency – will clean P1 cache
DMB ; ensures effects of the clean will be observed before the
 ; flag to E1 is set
STR R0, [R4] ; sends flag to E1

E1

WAIT_ACQ ([R4] == 1) ; waits for P2 flag (ordered)
LDR R5, [R1] ; reads data

AArch64

P1

STR WS, [X1] ; updates data (assumed to be in P1 cache)
STLR W0, [X2] ; sends a flag for P2 (ordered)

P2

WAIT ([X2] == 1) ; waits sfor P1 flag
DMB SY ; ensure cache clean is observed after P1 flag is observed
DC CVAC, X1 ; cleans cache to point of coherency, will clean P1 cache
DMB SY ; ensures effects of the clean will be observed before the
 ; flag to E1 is set
STR W0, [X4] ; sends flag to E1

E1

WAIT_ACQ ([X4] == 1) ; waits for P2 flag
LDR WS, [X1] ; reads data

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the
P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

Note
The cache maintenance instructions are not ordered by the Load-Acquire and Store-Release instructions.

Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable
memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute
can be allocated into a cache at any time, for example as a result of speculation. The following example shows this
possibility:

AArch32

P1

DCIMVAC R1 ; ensures cache is not dirty. A clean operation could be used
 ; but as the DMA will subsequently overwrite this region an
DMB ; invalidate operation is sufficient and usually more efficient
 ; invalidation is observed before the next store
STR R0, [R3] ; sends flag to external agent
WAIT_ACQ ([R4]==1) ; waits for a different flag from an external agent
LDR R5, [R1]
Appendix K11 Barrier Litmus Tests

K11.5 Cache and TLB maintenance instructions and barriers

E1

WAIT ([R3] == 1) ; waits for flag
STR R5, [R1] ; stores new data
STL R0, [R4] ; sends a flag

AArch64

P1

DC IVAC, X1 ; ensure cache is not dirty. A clean operation could be used but as the DMA will subsequently overwrite this region an invalidate operation is sufficient and usually more efficient
DMB SY ; ensures cache invalidation is observed before the next store is observed
STR W0, [X3] ; sends flag to external agent
WAIT_ACQ ([X4]==1) ; waits for a different flag from an external agent
LDR W5, [X3]

E1

WAIT ([X3] == 1) ; waits for flag
STR W5, [X1] ; stores new data
STLR W0, [X4] ; sends a flag

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Invalidating DMA buffers, functional example with single PE

AArch32

P1

DCIMVAC R1 ; ensures cache is not dirty. A clean operation could be used but as the DMA will subsequently overwrite this region an invalidate operation is sufficient and usually more efficient
DMB ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3] ; sends flag to external agent
WAIT ([R4]==1) ; waits for a different flag from an external agent
DMB ; from external agent is observed
DCIMVAC R1 ; ensures cache discards stale copies before use
LDR R5, [R1]

E1

WAIT ([R3] == 1) ; waits for flag
STR R5, [R1] ; stores new data
STL R0, [R4] ; sends a flag

AArch64

P1

DC IVAC, X1 ; ensures cache is not dirty. A clean operation could be used but as the DMA will subsequently overwrite this region an invalidate operation is sufficient and usually more efficient
DMB SY ; ensures cache invalidation is observed before the next store is observed
STR W0, [X3] ; sends flag to external agent
WAIT ([X4]==1) ; waits for a different flag from an external agent
DMB SY ; from external agent is observed
DC IVAC, X1 ; ensures cache discards stale copies before use
LDR W5, [X3]

E1
WAIT ([X3] == 1) ; waits for flag
STR W5, [X3] ; stores new data
STLR W0, [X4] ; sends a flag

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

**Invalidating DMA buffers, functional example with multiple coherent PEs**

The broadcasting of cache maintenance instructions, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

**AArch32**

P0

(Use data from [R1], potentially using [R1] as scratch space)

STL R0, [R2] ; signals release of [R1]
WAIT_ACQ ([R2] == 0) ; waits for new value from DMA
LDR R5, [R1]

P1

WAIT ([R2] == 1) ; waits for release of [R1] by P0
DCIMVAC R1 ; ensures caches are not dirty, an invalidate is sufficient
DMB
STR R0, [R3] ; requests new data for [R1]
WAIT ([R4] == 1) ; waits for new data
DMB
DCIMVAC R1 ; ensures caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2] ; signals availability of new [R1]

E1

WAIT ([R3] == 1) ; waits for new data request
STR R5, [R1] ; sends new [R1]
DMB [ST]
STR R0, [R4] ; indicates that new data is available to P1

**AArch64**

P0

(Use data from [X1], potentially using [X1] as scratch space)

STLR W0, [X2] ; signals release of [X1]
WAIT ACQ ([X2] == 0) ; waits for new value from DMA
LDR W5, [X1]

P1

WAIT ([X2] == 1) ; waits for release of [R1] by P0
DCIMVAC X1 ; ensures caches are not dirty, an invalidate is sufficient
DMB SY
STR W0, [X3] ; requests new data for [R1]
WAIT ([X4] == 1) ; waits for new data
DMB SY
DCIMVAC X1 ; ensures caches discard stale copies before use
DMB SY
STR WZR, [X2] ; signals availability of new [R1]

E1

WAIT ([X3] == 1) ; waits for new data request
STR W5, [X1] ; sends new [R1]
STR W0, [X4] ; indicates new data is available to P1
In this example, the result \( P0:R5 = 0x55 \) is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to \([R1]\). The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in \([R2]\).

### K11.5.2 Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- **Ensuring the visibility of updates to instructions for a uniprocessor.**
- **Ensuring the visibility of updates to instructions for a multiprocessor.**

#### Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

**AArch32**

P1

```
STR R11, [R1]         ; R11 contains a new instruction to be stored in program memory
DCMVAVU R1           ; clean to PoU makes the new instruction visible to the instruction cache
DSB                  ; ensures instruction cache/branch predictor discards stale data
ICIMVAVU R1          ; ensures completion of the invalidation
BPIMVA R1            ; ensures instruction fetch path sees new instruction cache state
DSB                  ; ensures completion of the invalidation
ISB                  ; ensures instruction fetch path sees new instruction cache state
BX R1
```

In AArch64 state, the branch predictor maintenance is not required.

**AArch64**

P1

```
STR W11, [X1]         ; W11 contains a new instruction to be stored in program memory
DC CVAU, X1           ; clean to PoU makes the new instruction visible to instruction cache
DSB ISH               ; ensures instruction cache/branch predictor discards stale data
IC IVAU, X1           ; ensures completion of the invalidation
DSB ISH               ; ensures instruction fetch path sees new instruction cache state
ISB                   ; ensures instruction fetch path sees new instruction cache state
BR X1
```

---

**Note**

Where the changes to the instructions span multiple cache lines, then the data cache and instruction cache maintenance instructions can be duplicated to cover each of the lines to be cleaned and to be invalidated.

---

#### Ensuring the visibility of updates to instructions for a multiprocessor

The ARMv8 architecture requires a PE that executes an instruction cache maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:
AArch32

P1

STR R11, [R1] ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1 ; clean to PoU makes the new instruction visible to the instruction cache
DSB ; ensures completion of the clean on all PEs
ICIMVAU R1 ; ensures instruction cache discards stale data
BPIMVA R ; ensures branch predictor discards stale data
DSB ; ensures completion of the instruction cache and branch predictor invalidation on all PEs
STR R0, [R2] ; sets flag to signal completion
ISB ; synchronizes context on this PE
BX R1 ; branches to new code

P2-Px

WAIT ([R2] == 1) ; waits for flag signalling completion
ISB ; synchronizes context on this PE
BX R1 ; branches to new code

AArch64

P1

STR X11, [X1] ; X11 contains a new instruction to be stored in program memory
DC CVAU, X1 ; clean to PoU makes the new instruction visible to the instruction cache
DSB ISH ; ensures completion of the clean on all PEs
IC IVAU, X1 ; ensures instruction cache/branch predictor discards stale data
DSB ISH ; ensures completion of the instruction cache/branch predictor invalidation on all PEs
STR W0, [X2] ; sets flag to signal completion
ISB ; synchronizes context on this PE
BR R1 ; branches to new code

P2-Px

WAIT ([X2] == 1) ; waits for flag signalling completion
ISB ; synchronizes context on this PE
BR X1 ; branches to new code

Nonfunctional approach

The following sequence does not have the same effect, because a DSB is not required to complete the instruction cache maintenance instructions that other PEs issue:

AArch32

P1

STR R11, [R1] ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1 ; clean to PoU makes the new instruction visible to the instruction cache
DSB ; ensures completion of the clean on all PEs
ICIMVAU R1 ; ensures instruction cache discards stale data
BPIMVA R ; ensures branch predictor discards stale data
DMB ; ensures ordering of the store after the invalidation ; DOES NOT guarantee completion of instruction cache/branch predictor on other PEs
STR R0, [R2] ; sets flag to signal completion
DSB ; ensures completion of the invalidation on all PEs
ISB ; synchronizes context on this PE
BX R1 ; branches to new code

P2-Px

WAIT ([R2] == 1) ; waits for flag signalling completion
DSB ; this DSB does not guarantee completion of P1
ICIMVAU/BPIMVA
ISB
BX R1
AArch64

**P1**

- `STR W11, [X1]` ; W11 contains a new instruction to be stored in program memory
- `DC CVAU, X1` ; clean to PoU makes the new instruction visible to instruction cache
- `DSB ISH` ; ensures completion of the clean on all PEs
- `IC IVAU, X1` ; ensures instruction cache/branch predictor discards stale data
- `DMB ISH` ; ensures ordering of the store after the invalidation
  - DOES NOT guarantee completion of instruction cache/branch predictor on other PEs
- `STR W0, [X2]` ; sets flag to signal completion
- `DSB ISH` ; ensures completion of the invalidation on all PEs
- `ISB` ; synchronizes context on this PE
- `BR X1` ; branches to new code

**P2-Px**

- `WAIT ([X2] == 1)` ; waits for flag signalling completion
- `DSB ISH` ; this DSB does not guarantee completion of P1
  - ICIMVAU/BPIMVA
- `ISB`
- `BR X1`

In this example, P2…Px might not see the updated region of code at R1.
K11.5.3 TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- Ensuring the visibility of updates to translation tables for a uniprocessor.
- Ensuring the visibility of updates to translation tables for a multiprocessor.
- Paging memory in and out on page K11-7343.
- Using break-before-make when updating translation table entries on page K11-7344.

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

The ARMv8 architecture requires that translation table walks look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

AArch32

P1

STR R11, [R1] ; updates the translation table entry
DSB ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB ; ensures completion of the BP and TLB invalidation
ISB ; synchronises context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed

AArch64

P1

STR X11, [X1] ; updates the translation table entry
DSB ISH ; ensures visibility of the update to translation table walks
TLB I VAE1, X10 ; assumes we are in the EL1
DSB ISH ; ensures completion of the TLB invalidation
ISB ; synchronises context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. The ARMv8 architecture requires a PE that executes a TLB maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.
Appendix K11 Barrier Litmus Tests

K11.5 Cache and TLB maintenance instructions and barriers

AArch32

P1

STR R11, [R1] ; updates the translation table entry
DSB ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB ; ensures completion of the BP and TLB invalidation
ISB ; Note ISB is not broadcast and must be executed locally
; on other PEs
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed

AArch64

P1

STR X11, [X1] ; updates the translation table entry
DSB ISH ; ensures visibility of the update to translation table walks
TLBI VAEIS, X10
DSB ISH ; ensures completion of the TLB invalidation
ISB ; Note ISB is not broadcast and must be executed locally
; on other PEs
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed

The completion of the TLB maintenance instruction is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance instruction. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

AArch32

P1

STR R11, [R1] ; updates the translation table for the region being paged out
DSB ; ensures visibility of the update to translation table walks
TLBIMVAIS R10 ; invalidates the old entry
DSB ; ensures completion of the invalidation on all PEs
ISB ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB ; ensures completion of the memory transfer (this could be part of
; LoadMemoryFromBackingStore)
ICIALLUIS ; also invalidates the branch predictor
STR R9, [R1] ; creates a new translation table entry with a new mapping
DSB ; ensures completion of the instruction cache
; and branch predictor invalidation
; AND ensures visibility of the new translation table mapping
This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of SaveMemoryPageToBackingStore and LoadMemoryFromBackingStore. LoadMemoryFromBackingStore is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of ICIAULLUIS in AArch32 state and IC IALLUIS in AArch64 state to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU in AArch32 state and IC IVAU operations in AArch64 state. This invalidation must be done when the mapping used for the ICIMVAU and IC IVAU operations is valid but not executable.

Using break-before-make when updating translation table entries

The ARM Architecture requires that reads to the same location are observed in order, and since application level software relies on this behavior, the operating system needs to maintain this illusion when it is changing a virtual to physical address mapping for a location, as is the case with copy on write or other memory management techniques. This illusion can be maintained provided that the software uses a break-before-make sequence when updating translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation entries involves any of:

- Changing the memory type.
- Changing the cacheability attributes
- Changing the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable.

The architecture requires use of a break-before make sequence in these situations, see Using break-before-make when updating translation table entries on page D5-2504 for more information. However, if software did not use a break-before-make approach, an implementation might give a result that would occur if the two reads to the same virtual address did not occur in program order. An example of such an occurrence would be an implementation of copy-on-write, where one PE is performing two reads to the same virtual address at the same time as a second PE, running code associated with the operating system, is copying the data from one physical location that is mapped to by that virtual address, where the page was mapped as read-only, to a different physical location which will be mapped as read-write.

If the operating system changed the address mapping without going through an invalid entry, then it would be possible for a third PE to perform a write to the location that would be seen by the first load by the first PE, and not seen by the second load by the same PE.

The required break-before-make code sequence in this case is:

AArch32
K11.5 Cache and TLB maintenance instructions and barriers

P1

; R1, R2 contain an invalid translation table entry (that is, one with bit[0] == 0)
; R3 contains the address of the translation table entry
; R4 contains the Virtual Address and ASID of the VA being remapped
; R5, R6 contain the new valid translation table entry
STRD R1, R2, [R3]          ; stores invalid entry
DSB ISH                    ; ensures visibility of the update to translation table walks
TLBIMVAIS R4               ; invalidates the old entry
DSB ISH                    ; ensures completion of the invalidation on all PEs
ICIALLUIS                  ; also invalidates the branch predictor
STRD R5, R6, [R3]          ; store new mapping
DSB ISH                    ; ensures visibility of the update to translation table walks
ISB                         ; ensures synchronisation of this instruction stream

Note

This example shows an update to an entry in a translation table that is using the long-descriptor format.

AArch64

P1

; X1 contains an invalid translation table entry (that is, one with bit[0] == 0)
; X2 contains the address of the translation table entry
; X3 contains the Virtual Address and ASID of the VA being remapped
; X4 contains the new valid translation table entry
STR X1, [X2]              ; stores invalid entry
DSB ISH                   ; ensures visibility of the update to translation table walks
TLBI VAEIS, X3           ; invalidates the old entry
DSB ISH                   ; ensures completion of the invalidation on all PEs
ICI IALLUIS                ; also invalidates the branch predictor
STR X4, [X2]              ; store new mapping
DSB ISH                   ; ensures visibility of the update to translation table walks
ISB                       ; ensures synchronisation of this instruction stream

If this sequence is correctly followed, then the architecture guarantees that the loads to a virtual address being remapped will be seen in the correct order.

The instruction cache maintenance is only required if the mapping from input address to output address has been changed as part of the change of the translation table entries, and the memory being moved is executable. In this example, the use of ICIALLUIS in AArch32 state and IC IALLUIS in AArch64 state to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU in AArch32 state, and IC IVAU in AArch64 state. This invalidation must be done when the mapping used for the ICIMVAU and IC IVAU operations is valid but not executable.

K11.5.4 Ordering of Memory-mapped device control with payloads

With a Memory-mapped peripheral, such as a DMA, which can also access memory for its own use, it is common to have control or status registers which are Memory-mapped. These registers need to be accessed in an ordered manner with respect to the data that the Memory-mapped peripheral is handling.

Two simple examples of this are:

• When a processing element is writing a buffer of data, and then writing to a control register in the DMA peripheral to start that peripheral to access the buffer of data.
• When a DMA peripheral has written to a buffer of data in memory, and the processing element is reading a status register to determine that the DMA transfer has completed, and then is reading the data.

For the case of the processing element writing a buffer of data, before starting the DMA peripheral, the ordering requirements between the stores to the data buffer and the stores to the Memory-mapped a to the DMA peripheral can be met by the insertion of a DSB <domain> instruction between these sets of accesses as this ensures the global observation of the stores before the DMA is started. this is shown by the following code:

AArch32
Appendix K11 Barrier Litmus Tests
K11.5 Cache and TLB maintenance instructions and barriers

P1

STR R5, [R2]          ; data written to the data buffer
DSB
STR R0, [R4]          ; R4 contains the address of the DMA control register

AArch64

P1

STR W5, [X2]          ; data written to the data buffer
DSB <domain>
STR W0, [X4]          ; X4 contains the address of the DMA control register

For the case of DMA peripheral writing the data buffer and then setting a status register when those stores are complete (and so globally observed) and then having this status register polled by the processing element before the processing element reads the data buffer, the processing element must insert a DSB <domain> between the load that reads the status register, and the read of the buffer. A DMB, or load-acquire, is not sufficient as this problem is not solely concerned with observation order, since the polling read is actually a read of a status register at a slave, not the polling a data value that has been written by an observer.

For this case, the code is therefore:

AArch32

P1

WAIT ([R4] == 1)      ; R4 contains the address of the status register, and the value '1' indicates completion of the DMA transfer
DSB
LDR R5, [R2]          ; reads data from the data buffer

AArch64

P1

WAIT ([X4] == 1)      ; X4 contains the address of the status register, and the value '1' indicates completion of the DMA transfer
DSB <domain>
LDR W5, [X2]          ; reads data from the data buffer
K11.6 ARMv7 compatible approaches for ordering, using DMB and DSB barriers

The following sections describe the ARMv7 compatible approaches for ordering, using DMB and DSB barriers:

- Simple ordering and barrier cases.
- Load-Exclusive, Store-Exclusive and barriers on page K11-7351.
- Using a mailbox to send an interrupt on page K11-7353.
- Cache and TLB maintenance instructions and barriers on page K11-7353.

K11.6.1 Simple ordering and barrier cases

ARM implements a weakly consistent memory model for Normal memory. In general terms, this means that the order of memory accesses observed by other observers might not be the order that appears in the program, for either loads or stores.

This section includes examples of this.

Simple weakly consistent ordering example

P1

```asm
STR R5, [R1]  
LDR R6, [R2]  
```

P2

```asm
STR R6, [R2]  
LDR R5, [R1]  
```

In the absence of barriers, the result of P1: R6=0, P2: R5=0 is permissible.

Message passing

The following sections describe:

- Weakly-ordered message passing problem.
- Message passing with multiple observers on page K11-7348.

Weakly-ordered message passing problem

P1

```asm
STR R5, [R1] ; sets new data  
STR R0, [R2] ; sends flag indicating data ready  
```

P2

```asm
WAIT([R2]==1) ; waits on flag  
LDR R5, [R1] ; reads new data  
```

In the absence of barriers, an end result of P2: R5=0 is permissible.

Resolving by the addition of barriers

The addition of barriers, to ensure the observed order of the reads and the writes, ensures that data is transferred so that the result P2:R5==0x55 is guaranteed, as follows:

P1

```asm
STR R5, [R1] ; sets new data  
DMB [ST] ; ensures all observers observe data before the flag  
STR R0, [R2] ; sends flag indicating data ready  
```

P2

```asm
WAIT([R2]==1) ; waits on flag  
```
Appendix K11 Barrier Litmus Tests

K11.6 ARMv7 compatible approaches for ordering, using DMB and DSB barriers

```
DMB                      ; ensures that the load of data is after the flag has been observed
LDR R5, [R1]
```

**Resolving by the use of barriers and address dependency**

There is a rule within the ARM architecture that:

- Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, then these two memory accesses are observed in program order.

Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, this is called an *address dependency*. An address dependency exists even if the value returned by the first read has no effect on the virtual address. This might occur if the value returned is masked off before it is used, or if it confirms a predicted address value that it might have changed.

This restriction applies only when the data value returned by a read is used as a data value to calculate the address of a subsequent read or write. It does not apply if the data value returned by a read determines the condition flags values, and the values of the flags are used for condition code evaluation to determine the address of a subsequent read, either through conditional execution or the evaluation of a branch. This is called a *control dependency*.

Where both a control and address dependency exist, the ordering behavior is consistent with the address dependency.

Table K11-1 shows examples of address dependencies, control dependencies, and an address and control dependency.

<table>
<thead>
<tr>
<th>Address dependency</th>
<th>Control dependency</th>
<th>Address and control dependency</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a) LDR r1, [r0]</td>
<td>(c) LDR r1, [r0]</td>
<td>(e) LDR r1, [r0]</td>
</tr>
<tr>
<td>LDR r2, [r1]</td>
<td>CMP r1, #0</td>
<td>CMP r1, #0</td>
</tr>
<tr>
<td></td>
<td>MOVNE r4, #22</td>
<td>LDRNE r2, [r1]</td>
</tr>
<tr>
<td></td>
<td>LDR r2, [r3, r1]</td>
<td>LDR r2, [r3, r4]</td>
</tr>
</tbody>
</table>

a. The address dependency takes priority.

This means that the data transfer example of *Weakly-ordered message passing problem* on page K11-7347 can also be satisfied as shown in the following example:

P1

```
STR R5, [R1]          ; sets new data
DMB [ST]              ; ensures all observers observe data before the flag
STR R0, [R2]          ; sends flag indicating data ready
```

P2

```
WAIT([R2==1])
AND R12, R12, #0      ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12]     ; the load has an address dependency on R12
```

The load of R5 by P2 is ordered with respect to the load from [R2] because there is an address dependency using R12. P1 uses a DMB to ensure that P2 does not observe the write of [R2] before the write of [R1].

**Message passing with multiple observers**

Where the ordering of Normal memory accesses is not resolved by the use of barriers or dependencies, then different observers might observe the accesses in a different order, as shown in the following example:
K11.6 ARMv7 compatible approaches for ordering, using DMB and DSB barriers

P1

```
STR R5, [R1] ; sets new data
STR R0, [R2] ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
; and so is ordered after the flag has been seen
```

P3

```
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load is address dependent on R12
; and so is ordered after the flag has been seen
```

In this case, it is permissible for P2:R5 and P3:R5 to contain different values, because there is no order guaranteed between the two stores performed by P1.

**Resolving by the addition of barriers**

The addition of a barrier by P1, as shown in the following example, ensures the observed order of the writes, transferring data so that P2:R5 and P3:R5 both contain the value 0x55:

P1

```
STR R5, [R1] ; sets new data
DMB [ST] ; ensures all observers observe data before the flag
STR R0, [R2] ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
; and so is ordered after the flag has been seen
```

P3

```
WAIT([R2]==1)
AND R12, R12, #0 ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12] ; the load has an address dependency on R12
; and so is ordered after the flag has been seen
```

**Address dependency with object construction**

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object:

P1

```
STR R5, [R1, #offset] ; sets new data in a field
DMB [ST] ; ensures all observers observe data before base address is updated
STR R1, [R2] ; updates base address
```

P2

```
LDR R1, [R2] ; reads for base address
CMP R1, #0 ; checks if it is valid
BEQ null_trap
LDR R5, [R1, #offset] ; uses base address to read field
```

If the null_trap is not taken, it is required that P2:R5==0x55. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not require a barrier to ensure this behavior.
P1 requires a barrier to ensure the observed order of the writes by P1. In general, the impact of requiring a barrier during the construction phase is much less than the impact of requiring a barrier for every read access.

**Posting a store before polling for acknowledgement**

In the case where an observer stores to a location, and then polls for an acknowledge from a different observer, the weak ordering of the memory model can lead to a deadlock, as the following example shows:

**P1**
```
STR R0, [R2]
WAIT ([R3]==1)
```

**P2**
```
WAIT ([R2]==1)
STR R0, [R3]
```

In ARMv7 implementations that do not include the Multiprocessing Extensions, then this can deadlock because P2 might not observe the store by P1 in finite time. For ARMv7 implementations with the Multiprocessing Extensions and for ARMv8, this is not an issue as all stores must be observed by all observers within their shareability domain in finite time.

The addition of a `DMB` instruction prevents this deadlock in ARMv7 implementations that do not include the Multiprocessing Extensions:

**P1**
```
STR R0, [R2]
DMB
WAIT ([R3]==1)
```

**P2**
```
WAIT ([R2]==1)
STR R0, [R3]
```

The `DMB` executed by P1 ensures that P2 observes the store by P1 before it observes the load by P1. This ensures a timely completion.

The following example is a variant of the previous example, where the two observers poll the same memory location:

**P1**
```
STR R0, [R2]
WAIT ([R2]==2)
```

**P2**
```
WAIT ([R2]==1)
LDR R0, [R2]
ADD R0, R0, #1
STR R0, [R2]
```

In this example, the same deadlock can occur in ARMv7 implementations that do not include the Multiprocessing Extensions, because the architecture permits P1 to read the result of its own store to [R2] early, and continue doing so for an indefinite amount of time. The addition of a `DMB` instruction prevents this deadlock:

**P1**
```
STR R0, [R2]
DMB
WAIT ([R2]==2)
```

**P2**
```
WAIT ([R2]==1)
LDR R0, [R2]
```
ADD R0, R0, #1
STR R0, [R2]

**WFE and WFI and barriers**

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. A DSB barrier instruction is required if it is necessary to ensure that memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in *Posting a store before polling for acknowledgement on page K11-7350*, or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

P1

STR R0, [R2]
DSB
Loop
WFI
B Loop

However, if the example in *Posting a store before polling for acknowledgement on page K11-7350* is extended to include a WFE, there is no risk of a deadlock. The extended example is:

P1

STR R0, [R2]
DMB
Loop
LDR R12, [R3]
CMP R12, #1
WFENE
BNE Loop

P2

WAIT ([R2]==1)
STR R0, [R3]
DSB
SEV

In this example:

- The DMB by P1 ensures that P2 observes the store by P1 before it observes the load by P1.
- The dependency of the WFE on the result of the load by P1 means that this load must complete before P1 executes the WFE.

For more information about SEV, see *Use of Wait For Event (WFE) and Send Event (SEV) with locks on page K11-7352*.

**K11.6.2 Load-Exclusive, Store-Exclusive and barriers**

The Load-Exclusive and Store-Exclusive instructions, described in *Synchronization and semaphores on page B2-135*, are predictable only with Normal memory. These instructions do not have any implicit barrier functionality. Therefore, any use of these instructions to implement locks of any type requires the addition of explicit barriers.

**Acquiring a lock**

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.
The lack of implicit barriers in the Load-Exclusive and Store-Exclusive instructions means that the mechanism requires a DMB instruction between acquiring a lock and making the first access to the critical region, to ensure that all observers observe the successful claim of the lock before they observe any subsequent loads or stores to the region. This example shows Px acquiring a lock:

Px
Loop
  LDREX R5, [R1] ; reads lock
  CMP R5, #0 ; checks if 0
  STREXEQ R5, R0, [R1] ; attempts to store new value
  CMPEQ R5, #0 ; tests if store succeeded
  BNE Loop ; retries if not
  DMB ; ensures that all subsequent accesses are observed after the
  ; gaining of the lock is observed
  ; loads and stores in the critical region can now be performed

Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, a DMB usually precedes the lock release, as the following example shows.

Px
  ; loads and stores in the critical region
  MOV R0, #0
  DMB ; ensures all previous accesses are observed before the lock is cleared
  STR R0, [R1] ; clears the lock

Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture includes Wait For Event and Send Event instructions, that can be executed to reduce the required number of iterations of a lock-acquire loop, or spinlock, to reduce power. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction that suspends execution on that observer until an asynchronous exception or an explicit event, sent by some other observer using the SEV instruction, is seen by the suspended observer. An observer that holds the lock executes an SEV instruction to send an event after it has released the lock.

The Event signal is a non-memory communication, and therefore the memory update that releases the lock must be observable by all observers before the SEV instruction is executed and the event is sent. This requires the use of DSB instruction, rather than DMB.

Therefore, the following is an example of lock acquire code using WFE:

Px
  Loop
  LDREX R5, [R1] ; reads lock
  CMP R5, #0 ; checks if 0
  WFENE ; sleeps if the lock is held
  STREXEQ R5, R0, [R1] ; attempts to store new value
  CMPEQ R5, #0 ; tests if store succeeded
  BNE Loop ; retries if not
  DMB ; ensures that all subsequent accesses are observed after the
  ; gaining of the lock is observed
  ; loads and stores in the critical region can now be performed

And the following is an example of lock release code using SEV:

Px
  ; loads and stores in the critical region
  MOV R0, #0
  DMB ; ensures all previous accesses are observed before the lock is cleared
K11.6 ARMv7 compatible approaches for ordering, using DMB and DSB barriers

K11.6.3 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

P1

```
STR R5, [R1]  ; message stored to shared memory location
DSB [ST]     ; R4 contains the address of a mailbox
STR R1, [R4]  ; message stored to shared memory location
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

--- Note ---

The DSB executed by P1 ensures global observation of the store to [R1]. The interrupt timing ensures that the code executed by P2 is executed after the global observation of the update to [R1], and therefore must see this update. In some implementations, this might be implemented by requiring that interrupts flush non-coherent buffers that hold speculatively loaded data.

K11.6.4 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- Data cache maintenance instructions.
- Instruction cache maintenance instructions on page K11-7356.
- TLB maintenance instructions and barriers on page K11-7357.

Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- Message passing to non-caching observers.
- Multiprocessing message passing to non-caching observers on page K11-7354.
- Invalidating DMA buffers, non-functional example on page K11-7354.
- Invalidating DMA buffers, functional example with single PE on page K11-7355.
- Invalidating DMA buffers, functional example with multiple coherent PEs on page K11-7355.

Message passing to non-caching observers

The ARMv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

P1

```
STR R5, [R1]  ; updates data (assumed to be in P1's cache)
DCCMVAC R1    ; cleans cache to point of coherency
DMB           ; ensures effects of the clean will be observed before the flag is set
STR R0, [R4]  ; sends flag to external agent (Non-cacheable location)
```
E1

WAIT ([R4] == 1) ; waits for the flag
DMB ; ensures that flag has been seen before reading data
LDR R5, [R1] ; reads the data

In this example, it is required that E1:R5==0x55.

**Multiprocessing message passing to non-caching observers**

The broadcast nature of the cache maintenance instructions in ARMv8, and in ARMv7 implementations that include the Multiprocessing Extensions, combined with properties of barriers, means that the message passing principle for non-caching observers is:

P1

STR R5, [R1] ; updates data (assumed to be in P1’s cache)
DMB [ST] ; ensures new data is observed before the flag to P2 is set
STR R0, [R2] ; sends flag to P2

P2

WAIT ([R2] == 1) ; waits for flag from P1
DMB ; ensures cache clean is observed after P1 flag is observed
DCCMVAC R1 ; cleans cache to point of coherency - this cleans the cache of P1
DMB ; ensures effects of the clean are observed before the flag to E1 is set
STR R0, [R4] ; sends flag to E1

E1

WAIT ([R4] == 1) ; waits for flag from P2
DMB ; ensures that flag has been observed before reading the data
LDR R5, [R1] ; reads the data

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

**Invalidating DMA buffers, non-functional example**

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

P1

DCIMVAC R1 ; ensures caches are not dirty. A clean operation could be
; used but the DMA overwrites this region so an invalidate operation
; is sufficient and usually more efficient
DMB ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3] ; sends flag to external agent
WAIT ([R4] == 1) ; waits for a different flag from an external agent
DMB ; observes flag from external agent before reading new data. However [R1]
; could have been brought into cache earlier
LDR R5, [R1]

E1

WAIT ([R3] == 1) ; waits for flag
STR R5, [R1] ; stores new data
DMB
STR R0, [R4] ; sends a flag

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.
Invalidating DMA buffers, functional example with single PE

P1

DCIMVAC R1 ; ensures cache is not dirty. A clean operation could be
; used but the DMA overwrites this region so an invalidate operation
; is sufficient and usually more efficient
DMB ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3] ; sends flag to external agent
WAIT ([R4]==1) ; waits for a different flag from an external agent
DMB ; ensures that cache invalidate is observed after the flag
; from external agent is observed
DCIMVAC R1 ; ensures cache discards stale copies before use
LDR R5, [R1]

E1

WAIT ([R3] == 1) ; waits for flag
STR R5, [R1] ; stores new data
DMB [ST]
STR R0, [R4] ; sends a flag

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

P0

(Use data from [R1], potentially using [R1] as scratch space)
DMB
STR R0, [R2] ; signals release of [R1]
WAIT ([R2] == 0) ; waits for new value from DMA
DMB
LDR R5, [R1]

P1

WAIT ([R2] == 1) ; waits for release of [R1] by P0
DCIMVAC R1 ; ensures caches are not dirty, invalidate is sufficient
DMB
STR R0, [R3] ; requests new data for [R1]
WAIT ([R4] == 1) ; waits for new data
DMB
DCIMVAC R1 ; ensures caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2] ; signals availability of new [R1]

E1

WAIT ([R3] == 1) ; waits for new data request
STR R5, [R1] ; sends new [R1]
DMB [ST]
STR R0, [R4] ; indicates new data available to P1

In this example, the result P0:R5 == 0x55 is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].
Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- **Ensuring the visibility of updates to instructions for a uniprocessor.**
- **Ensuring the visibility of updates to instructions for a multiprocessor.**

### Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a `DSB` instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a `DSB`, and an `ISB` is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

```
P1
  STR R11, [R1] ; R11 contains a new instruction to store in program memory
  DCCMVAU R1 ; clean to PoU makes new instructions visible to instruction cache
  DSB
  ICIMVAU R1 ; ensures instruction cache and branch predictor discard stale data
  BPIMVA R1
  DSB ; ensures completion of the invalidation
  ISB ; ensures instruction fetch path observes new instruction cache state
  BX R1
```

### Ensuring the visibility of updates to instructions for a multiprocessor

ARMv8, and an ARMv7 implementation that includes the Multiprocessing Extensions, requires a PE that executes an instruction cache maintenance instruction to execute a `DSB` instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An `ISB` is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own `ISB` synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

```
P1
  STR R11, [R1] ; R11 contains a new instruction to store in program memory
  DCCMVAU R1 ; clean to PoU makes new instructions visible to instruction cache
  DSB
  ICIMVAU R1 ; ensures completion of the clean on all processors
  BPIMVA R1
  DSB ; ensures completion of the instruction cache and branch predictor
  ICIMVAU R1 ; invalidation on all PEs
  STR R0, [R2] ; sets flag to signal completion
  ISB ; synchronizes context on this PE
  BX R1 ; branches to new code

P2-Px
  WAIT ([R2] == 1) ; waits for flag signaling completion
  ISB ; synchronizes context on this processor
  BX R1 ; branches to new code
```

### Nonfunctional approach

The following sequence does not have the same effect, because a `DSB` is not required to complete the instruction cache maintenance instructions that other PEs issue:

```
P1
  STR R11, [R1] ; R11 contains a new instruction to store in program memory
  DCCMVAU R1 ; clean to PoU makes new instructions visible to instruction cache
```

Appendix K11 Barrier Litmus Tests

K11.6 ARMv7 compatible approaches for ordering, using DMB and DSB barriers

DSB
; ensure completion of the clean on all PEs
ICIMVAU R1
; ensure instruction cache/branch predictor discards stale data
BPIMVA R1
DMB
; ensure ordering of the store after the invalidation
; DOES NOT guarantee completion of instruction cache/branch
; predictor on other PEs
STR R0, [R2]
; sets flag to signal completion
DSB
; ensures completion of the invalidation on all PEs
ISB
; synchronizes context on this PE
BX R1
; branches to new code

P2-Px

WAIT ([R2] == 1)
; waits for flag signaling completion
DSB
; this DSB does not guarantee completion of P1's ICIMVAU/BPIMVA
ISB
BX R1

In this example, P2…Px might not see the updated region of code at R1.

TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

• Ensuring the visibility of updates to translation tables for a uniprocessor.
• Ensuring the visibility of updates to translation tables for a multiprocessor on page K11-7358.
• Paging memory in and out on page K11-7358.

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, translation table walks must look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

P1

STR R11, [R1]
; updates the translation table entry
DSB
; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIMVA
DSB
; ensures completion of the BP and TLB invalidation
ISB
; synchronizes context on this PE
BX R1
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using the old mapping have been completed

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.
Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, a PE that executes a TLB maintenance instruction must execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

```
P1
  STR R11, [R1]            ; updates the translation table entry
  DSB                      ; ensures visibility of the update to translation table walks
  TLBIMVAIS R10           ; invalidates the old entry
  BPIALLIS                 ; ensures completion of the BP and TLB invalidation
  DSB                      ; ensures completion of the BP and TLB invalidation
  ISB                      ; Note ISB is not broadcast and must be executed locally on other PEs
; new translation table entry can be relied upon at this point and all accesses generated by any
; observers affected by the broadcast TLBIMVAIS operation using the old mapping have completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance instruction. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

```
P1
  STR R11, [R1]            ; updates the translation table entry
  DSB                      ; ensures visibility of the update to translation table walks
  TLBIMVAIS R10
  BPIALLIS
  DSB                      ; ensures completion of the BP and TLB invalidation
  ISB                      ; Note ISB is not broadcast and must be executed locally on other PEs
  BL SaveMemoryPageToBackingStore
  BL LoadMemoryFromBackingStore
  DSB                      ; ensures completion of the memory transfer (this could be part of
                             ; LoadMemoryFromBackingStore
  ICALLU5S                 ; also invalidates the branch predictor
  STR R9, [R1]             ; creates a new translation table entry with a new mapping
  DSB                      ; ensures completion of instruction cache and branch predictor invalidation
  ISB                      ; and ensures visibility of the new translation table mapping
                             ; and ensures synchronization of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of `SaveMemoryPageToBackingStore` and `LoadMemoryFromBackingStore`. `LoadMemoryFromBackingStore` is required to ensure that the memory updates that it makes are visible to instruction fetches.
In this example, the use of ICIALLUIS to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU operations. This invalidation must be done when the mapping used for the ICIMVAU operations is valid but not executable.

Appendix K12
ARM Pseudocode Definition

This appendix provides a definition of the pseudocode that is used in this manual, and defines some helper procedures and functions that are used by pseudocode. It contains the following sections:

- *About the ARM pseudocode* on page K12-7362.
- *Pseudocode for instruction descriptions* on page K12-7363.
- *Data types* on page K12-7365.
- *Operators* on page K12-7370.
- *Statements and control structures* on page K12-7376.
- *Built-in functions* on page K12-7381.
- *Miscellaneous helper procedures and functions* on page K12-7384.
- *ARM pseudocode definition index* on page K12-7386.

--- Note ---
This appendix is not a formal language definition for the pseudocode. It is a guide to help understand the use of ARM pseudocode. This appendix is not complete. Changes are planned for future releases.
### K12.1 About the ARM pseudocode

The ARM pseudocode provides precise descriptions of some areas of the ARM architecture. This includes description of the decoding and operation of all valid instructions. *Pseudocode for instruction descriptions on page K12-7363* gives general information about this instruction pseudocode, including its limitations.

The following sections describe the ARM pseudocode in detail:

- Data types on page K12-7365.
- Operators on page K12-7370.
- Statements and control structures on page K12-7376.

*Built-in functions on page K12-7381* and *Miscellaneous helper procedures and functions on page K12-7384* describe some built-in functions and pseudocode helper functions that are used by the pseudocode functions that are described elsewhere in this manual. *ARM pseudocode definition index on page K12-7386* contains the indexes to the pseudocode.

### K12.1.1 General limitations of ARM pseudocode

The pseudocode statements IMPLEMENTATION_DEFINED, SEE, UNDEFINED, and UNPREDICTABLE indicate behavior that differs from that indicated by the pseudocode being executed. If one of them is encountered:

- Earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed.
- No subsequent behavior indicated by the pseudocode occurs.

For more information, see *Special statements on page K12-7380*.

K12.2 Pseudocode for instruction descriptions

Each instruction description includes pseudocode that provides a precise description of what the instruction does, subject to the limitations described in General limitations of ARM pseudocode on page K12-7362 and Limitations of the instruction pseudocode on page K12-7364.

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction. Instruction encoding diagrams and instruction pseudocode gives more information about the pseudocode provided for each instruction.

K12.2.1 Instruction encoding diagrams and instruction pseudocode

Instruction descriptions in this manual contain:

- An Encoding section, containing one or more encoding diagrams, each followed by some encoding-specific pseudocode that translates the fields of the encoding into inputs for the common pseudocode of the instruction, and picks out any encoding-specific special cases.

- An Operation section, containing common pseudocode that applies to all of the encodings being described. The Operation section pseudocode contains a call to the EncodingSpecificOperations() function, either at its start or only after a condition code check performed by if ConditionPassed() then.

An encoding diagram specifies each bit of the instruction as one of the following:

- An obligatory 0 or 1, represented in the diagram as 0 or 1. If this bit does not have this value, the encoding corresponds to a different instruction.

- A should be 0 or 1, represented in the diagram as (0) or (1). If this bit does not have this value, the instruction is CONSTRAINED UNPREDICTABLE. For more information, see SBZ or SBO fields T32 and A32 in instructions on page K1-7194.

- A named single bit or a bit in a named multi-bit field. The cond field in bits[31:28] of many A32/T32 instructions has some special rules associated with it.

An encoding diagram matches an instruction if all obligatory bits are identical in the encoding diagram and the instruction, and one of the following is true:

- The encoding diagram is not for an A32/T32 instruction.

- The encoding diagram is for an A32/T32 instruction that does not have a cond field in bits[31:28].

- The encoding diagram is for an A32/T32 instruction that has a cond field in bits[31:28], and bits[31:28] of the instruction are not 0b1111.

In the context of the instruction pseudocode, the execution model for an instruction is:

1. Find all encoding diagrams that match the instruction. It is possible that no encoding diagram matches. In that case, abandon this execution model and consult the relevant instruction set chapter instead to find out how the instruction is to be treated. The bit pattern of such an instruction is usually reserved and UNDEFINED, though there are some other possibilities. For example, unallocated hint instructions are documented as being reserved and executed as NOPs.

2. If the operation pseudocode for the matching encoding diagrams starts with a condition code check, perform that check. If the condition code check fails, abandon this execution model and treat the instruction as a NOP. If there are multiple matching encoding diagrams, either all or none of their corresponding pieces of common pseudocode start with a condition code check.

3. Perform the encoding-specific pseudocode for each of the matching encoding diagrams independently and in parallel. Each such piece of encoding-specific pseudocode starts with a bitstring variable for each named bit or multi-bit field in its corresponding encoding diagram, named the same as the bit or multi-bit field and initialized with the values of the corresponding bit or bits from the bit pattern of the instruction.
In a few cases, the encoding diagram contains more than one bit or field with same name. In these cases, the values of the different instances of those bits or fields must be identical. The encoding-specific pseudocode contains a special case using the Consistent() function to specify what happens if they are not identical. Consistent() returns TRUE if all instruction bits or fields with the same name as its argument have the same value, and FALSE otherwise.

If there are multiple matching encoding diagrams, all but one of the corresponding pieces of pseudocode must contain a special case that indicates that it does not apply. Discard the results of all such pieces of pseudocode and their corresponding encoding diagrams.

There is now one remaining piece of pseudocode and its corresponding encoding diagram left to consider. This pseudocode might also contain a special case, most commonly one indicating that it is CONSTRAINED UNPREDICTABLE. If so, abandon this execution model and treat the instruction according to the special case.

4. Check the should be bits of the encoding diagram against the corresponding bits of the bit pattern of the instruction. If any of them do not match, abandon this execution model and treat the instruction as CONSTRAINED UNPREDICTABLE, see SBZ or SBO fields T32 and A32 in instructions on page K1-7194.

5. Perform the rest of the operation pseudocode for the instruction description that contains the encoding diagram. That pseudocode starts with all variables set to the values they were left with by the encoding-specific pseudocode.

The ConditionPassed() call in the common pseudocode, if present, performs step 2, and the EncodingSpecificOperations() call performs steps 3 and 4.

K12.2.2 Limitations of the instruction pseudocode

The pseudocode descriptions of instruction functionality have a number of limitations. These are mainly due to the fact that, for clarity and brevity, the pseudocode is a sequential and mostly deterministic language.

These limitations include:

- Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses. For a description of the ordering requirements on memory accesses see Ordering constraints on page E2-3572.

- Pseudocode does not describe the exact rules when an UNDEFINED instruction fails its condition code check. In such cases, the UNDEFINED pseudocode statement lies inside the if ConditionPassed() then ... structure, either directly or in the EncodingSpecificOperations() function call, and so the pseudocode indicates that the instruction executes as a NOP. Conditional execution of undefined instructions on page G1-5284 describes the exact rules.

- Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped. Combinations of floating-point exceptions on page E1-3552 describes the exact rules.

---

**Note**

There is no limitation in the case where all the floating-point exceptions are untrapped, because the pseudocode specifies the same behavior as the cross-referenced section.

---

- An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function such as Abort(), or implicitly, for example if an interrupt is taken during execution of an LDM instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs. To determine that, see the descriptions of the exceptions in Handling exceptions that are taken to an Exception level using AArch32 on page G1-5247.
K12.3 Data types

This section describes:

- General data type rules.
- Bitstrings.
- Integers on page K12-7366.
- Reals on page K12-7366.
- Booleans on page K12-7366.
- Enumerations on page K12-7367.
- Structures on page K12-7367.
- Tuples on page K12-7368.
- Arrays on page K12-7369.

K12.3.1 General data type rules

ARM architecture pseudocode is a strongly typed language. Every literal and variable is of one of the following types:

- Bitstring.
- Integer.
- Boolean.
- Real.
- Enumeration.
- Tuple.
- Struct.
- Array.

The type of a literal is determined by its syntax. A variable can be assigned to without an explicit declaration. The variable implicitly has the type of the assigned value. For example, the following assignments implicitly declare the variables x, y and z to have types integer, bitstring of length 1, and Boolean, respectively.

```
x = 1;
y = '1';
z = TRUE;
```

Variables can also have their types declared explicitly by preceding the variable name with the name of the type. The following example declares explicitly that a variable named count is an integer.

```
integer count;
```

This is most often done in function definitions for the arguments and the result of the function.

The remaining subsections describe each data type in more detail.

K12.3.2 Bitstrings

This section describes the bitstring data type.

Syntax

```
b(C)     The type name of a bitstring of length C.
b       A synonym of bits(1).
```

Description

A bitstring is a finite-length string of 0s and 1s. Each length of bitstring is a different type. The minimum permitted length of a bitstring is 0.
Bitstring constants literals are written as a single quotation mark, followed by the string of 0s and 1s, followed by another single quotation mark. For example, the two constants literals of type bit are '0' and '1'. Spaces can be included in bitstrings for clarity.

The bits in a bitstring are numbered from left to right $N$-1 to 0. This numbering is used when accessing the bitstring using bitslices. In conversions to and from integers, bit $N$-1 is the MSByte and bit 0 is the LSByte. This order matches the order in which bitstrings derived from encoding diagrams are printed.

Every bitstring value has a left-to-right order, with the bits being numbered in standard little-endian order. That is, the leftmost bit of a bitstring of length $N$ is bit $(N-1)$ and its rightmost bit is bit 0. This order is used as the most-significant-to-least-significant bit order in conversions to and from integers. For bitstring constants and bitstrings that are derived from encoding diagrams, this order matches the way that they are printed.

Bitstrings are the only concrete data type in pseudocode, corresponding directly to the contents values that are manipulated in registers, memory locations, and instructions. All other data types are abstract.

### K12.3.3 Integers

This section describes the data type for integer numbers.

#### Syntax

```plaintext
integer
```

The type name for the integer data type.

#### Description

Pseudocode integers are unbounded in size and can be either positive or negative. That is, they are mathematical integers rather than what computer languages and architectures commonly call integers. Computer integers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as integers.

Integer literals are normally written in decimal form, such as 0, 15, -1234. They can also be written in C-style hexadecimal form, such as 0x55 or 0x80000000. Hexadecimal integer literals are treated as positive unless they have a preceding minus sign. For example, 0x80000000 is the integer $+2^{31}$. If $-2^{31}$ needs to be written in hexadecimal, it must be written as -0x80000000.

### K12.3.4 Reals

This section describes the data type for real numbers.

#### Syntax

```plaintext
real
```

The type name for the real data type.

#### Description

Pseudocode reals are unbounded in size and precision. That is, they are mathematical real numbers, not computer floating-point numbers. Computer floating-point numbers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as reals.

Real constant literals are written in decimal form with a decimal point. This means 0 is an integer constant literal, but 0.0 is a real constant literal.

### K12.3.5 Booleans

This section describes the Boolean data type.

#### Syntax

```plaintext
boolean
```

The type name for the Boolean data type.
The two values a Boolean variable can take.

**Description**

A Boolean is a logical TRUE or FALSE value.

--- Note ---

This is not the same type as bit, which is a bitstring of length 1. A Boolean can only take on one of two values: TRUE or FALSE.

### K12.3.6 Enumerations

This section describes the enumeration data type.

**Syntax and examples**

```
enumeration
    
    enumeration Example {Example_One, Example_Two, Example_Three};
```

A definition of a new enumeration called Example, which can take on the values Example_One, Example_Two, Example_Three.

**Description**

An enumeration is a defined set of named values.

An enumeration must contain at least one named value. A named value must not be shared between enumerations.

Enumerations must be defined explicitly, although a variable of an enumeration type can be declared implicitly by assigning one of the named values to it. By convention, each named value starts with the name of the enumeration followed by an underscore. The name of the enumeration is its type name, or type, and the named values are its possible values.

### K12.3.7 Structures

This section describes the structure data type.

**Syntax and examples**

```
type
    
    type ShiftSpec is (bits(2) shift, integer amount)
```

An example definition for a new structure called ShiftSpec that contains an bitstring member called shift and a integer member named amount. Structure definitions must not be terminated with a semicolon.

```
ShiftSpec abc;
```

A declaration of a variable named abc of type ShiftSpec.

```
abc.shift
```

Syntax to refer to the individual members within the structure variable.

**Description**

A structure is a compound data type composed of one or more data items. The data items can be of different data types. This can include compound data types. The data items of a structure are called its members and are named.
In the syntax section, the example defines a structure called `ShiftSpec` with two members. The first is a bitstring of length 2 named `shift` and the second is an integer named `amount`. After declaring a variable of that type named `abc`, the members of this structure are referred to as `abc.shift` and `abc.amount`.

Every definition of a structure creates a different type, even if the number and type of their members are identical. For example:

```plaintext
type ShiftSpec1 is (bits(2) shift, integer amount)
type ShiftSpec2 is (bits(2) shift, integer amount)
```

`ShiftSpec1` and `ShiftSpec2` are two different types despite having identical definitions. This means that the value in a variable of type `ShiftSpec1` cannot be assigned to variable of type `ShiftSpec2`.

### K12.3.8 Tuples

This section describes the tuple data type.

#### Examples

```plaintext
(bits(32) shifter_result, bit shifter_carry_out)
```

An example of the tuple syntax.

```plaintext
(shift_t, shift_n) = ('00', 0);
```

An example of assigning values to a tuple.

#### Description

A tuple is an ordered set of data items, separated by commas and enclosed in parentheses. The items can be of different types and a tuple must contain at least one data item.

Tuples are often used as the return type for functions that return multiple results. For example, in the syntax section, the example tuple is the return type of the function `Shift_C()`, which performs a standard A32/T32 shift or rotation. Its return type is a tuple containing two data items, with the first of type `bits(32)` and the second of type `bit`.

Each tuple is a separate compound data type. The compound data type is represented as a comma-separated list of ordered data types between parentheses. This means that the example tuple at the start of this section is of type `(bits(32), bit)`. The general principle that types can be implied by an assignment extends to implying the type of the elements in the tuple. For example, in the syntax section, the example assignment implicitly declares:

- `shift_t` to be of type `bits(2)`.
- `shift_n` to be of type `integer`.
- `(shift_t, shift_n)` to be a tuple of type `(bits(2), integer)`.
K12.3.9 Arrays

This section describes the array data type.

Syntax

array array data_type array_name[A..B];

Declaration of an array of type data_type, which might be compound data type. It is named array_name and is indexed with an integer range from \( A \) to \( B \).

Description

An array is an ordered set of fixed size containing items of a single data type. This can include compound data types. Pseudocode arrays are indexed by either enumerations or integer ranges. An integer range is represented by the lower inclusive end of the range, then \( \ldots \), then the upper inclusive end of the range.

For example:

The following example declares an array of 31 bitstrings of length 64, indexed from 0 to 30.

array bits(64) _R[0..30];

Arrays are always explicitly declared, and there is no notation for a constant literal array. Arrays always contain at least one element data item, because:

- Enumerations always contain at least one symbolic constant named value.
- Integer ranges always contain at least one integer.

An array declared with an enumeration type as the index must be accessed using enumeration values of that enumeration type. An array declared with an integer range type as the index must be accessed using integer values from that inclusive range. Accessing such an array with an integer value outside of the range is a coding error.

Arrays do not usually appear directly in pseudocode. The items that syntactically look like arrays in pseudocode are usually array-like functions such as \( R[i], \text{MemU}[\text{address, size}] \) or \( \text{Elem}[\text{vector, i, size}] \). These functions package up and abstract additional operations normally performed on accesses to the underlying arrays, such as register banking, memory protection, endian-dependent byte ordering, exclusive-access housekeeping and Advanced SIMD element processing. See Function and procedure calls on page K12-7376.
K12.4 Operators

This section describes:

- Relational operators.
- Boolean operators.
- Bitstring operators on page K12-7371.
- Arithmetic operators on page K12-7371.
- The assignment operator on page K12-7372.
- Precedence rules on page K12-7374.
- Conditional expressions on page K12-7374.
- Operator polymorphism on page K12-7374.

K12.4.1 Relational operators

The following operations yield results of type boolean.

Equality and non-equality

If two variables \( x \) and \( y \) are of the same type, their values can be tested for equality by using the expression \( x == y \) and for non-equality by using the expression \( x != y \). In both cases, the result is of type boolean.

Both \( x \) and \( y \) must be of type bits(N), real, enumeration, boolean, or integer. Named values from an enumeration can only be compared if they are both from the same enumeration. An exception is that a bitstring can be tested for equality with an integer to allow a \( d==15 \) test.

A special form of comparison is defined with a bitstring literal that can contain bit values '0', '1', and 'x'. Any bit with value 'x' is ignored in determining the result of the comparison. For example, if \( \text{opcode} \) is a 4-bit bitstring, the expression \( \text{opcode} == '1x0x' \) matches the values '1000', '1100', '1001', and '1101'. This is known as a bitmask.

--- Note ---

This special form is permitted in the implied equality comparisons in the when parts of case ... of ... structures.

Comparisons

If \( x \) and \( y \) are integers or reals, then \( x < y \), \( x <= y \), \( x > y \), and \( x >= y \) are less than, less than or equal, greater than, and greater than or equal comparisons between them, producing Boolean results.

Set membership with IN

\(<\text{expression}>\ IN\ \{<\text{set}>\} \) produces TRUE if \(<\text{expression}>\) is a member of \(<\text{set}>\). Otherwise, it is FALSE. \(<\text{set}>\) must be a list of expressions separated by commas.

K12.4.2 Boolean operators

If \( x \) is a Boolean expression, then \( !x \) is its logical inverse.

If \( x \) and \( y \) are Boolean expressions, then \( x \&\& y \) is the result of ANDing them together. As in the C language, if \( x \) is FALSE, the result is determined to be FALSE without evaluating \( y \).

--- Note ---

This is known as short circuit evaluation.

If \( x \) and \( y \) are booleans, then \( x \mid\mid y \) is the result of ORing them together. As in the C language, if \( x \) is TRUE, the result is determined to be TRUE without evaluating \( y \).
--- Note ---

If x and y are booleans or Boolean expressions, then the result of x != y is the same as the result of exclusive-ORing x and y together. The operator EOR only accepts bitstring arguments.

---

K12.4.3 Bitstring operators

The following operations can be applied only to bitstrings.

**Logical operations on bitstrings**

If x is a bitstring, NOT(x) is the bitstring of the same length obtained by logically inverting every bit of x.

If x and y are bitstrings of the same length, x AND y, x OR y, and x EOR y are the bitstrings of that same length obtained by logically ANDing, logically ORing, and exclusive-ORing corresponding bits of x and y together.

**Bitstring concatenation and slicing**

If x and y are bitstrings of lengths N and M respectively, then x:y is the bitstring of length N+M constructed by concatenating x and y in left-to-right order.

The bitstring slicing operator addresses specific bits in a bitstring. This can be used to create a new bitstring from extracted bits or to set the value of specific bits. Its syntax is x<integer_list>, where x is the integer or bitstring being sliced, and <integer_list> is a comma-separated list of integers enclosed in angle brackets. The length of the resulting bitstring is equal to the number of integers in <integer_list>. In x<integer_list>, each of the integers in <integer_list> must be:

- >= 0.
- < Len(x) if x is a bitstring.

The definition of x<integer_list> depends on whether integer_list contains more than one integer:

- If integer_list contains more than one integer, x<i, j, k, ..., n> is defined to be the concatenation:
  x<i> : x<j> : x<k> : ... : x<n>.

- If integer_list consists of just one integer i, x<i> is defined to be:
  — If x is a bitstring, '0' if bit i of x is a zero and '1' if bit i of x is a one.
  — If x is an integer, and y is the unique integer in the range 0 to 2^((i+1)-1) that is congruent to x modulo 2^((i+1)). Then x<i> is '0' if y < 2^i and '1' if y >= 2^i.

Loosely, this definition treats an integer as equivalent to a sufficiently long two’s complement representation of it as a bitstring.

The notation for a range expression is i:j with i >= j is shorthand for the integers in order from i down to j, with both end values included. For example, instr<31:28> represents instr<31, 30, 29, 28>.

x<integer_list> is assignable provided x is an assignable bitstring and no integer appears more than once in <integer_list>. In particular, x<i> is assignable if x is an assignable bitstring and 0 <= i < Len(x).

Encoding diagrams for registers frequently show named bits or multi-bit fields. For example, the encoding diagram for the APSR shows its bit<31> as N. In such cases, the syntax APSR.N is used as a more readable synonym for APSR<31> as named bits can be referred to with the same syntax as referring to members of a struct. A comma-separated list of named bits enclosed in angle brackets following the register name allows multiple bits to be addressed simultaneously. For example, APSR.<N, C, Q> is synonymous with APSR <31, 29, 27>.

K12.4.4 Arithmetic operators

Most pseudocode arithmetic is performed on integer or real values, with operands obtained by conversions from bitstrings and results converted back to bitstrings. As these data types are the unbounded mathematical types, no issues arise about overflow or similar errors.
Unary plus and minus
If \(x\) is an integer or real, then \(+x\) is \(x\) unchanged, \(-x\) is \(x\) with its sign reversed. Both are of the same type as \(x\).

Addition and subtraction
If \(x\) and \(y\) are integers or reals, \(x+y\) and \(x-y\) are their sum and difference. Both are of type integer if \(x\) and \(y\) are both of type integer, and real otherwise.

There are two cases where the types of \(x\) and \(y\) can be different. A bitstring and an integer can be added together to allow the operation \(PC + 4\). An integer can be subtracted from a bitstring to allow the operation \(PC - 2\).

If \(x\) and \(y\) are bitstrings of the same length \(N\), so that \(N = \text{Len}(x) = \text{Len}(y)\), then \(x+y\) and \(x-y\) are the least significant \(N\) bits of the results of converting \(x\) and \(y\) to integers and adding or subtracting them. Signed and unsigned conversions produce the same result:

\[
x+y = (\text{SInt}(x) + \text{SInt}(y))_{N-1:0}
\]
\[
= (\text{UInt}(x) + \text{UInt}(y))_{N-1:0}
\]
\[
x-y = (\text{SInt}(x) - \text{SInt}(y))_{N-1:0}
\]
\[
= (\text{UInt}(x) - \text{UInt}(y))_{N-1:0}
\]

If \(x\) is a bitstring of length \(N\) and \(y\) is an integer, \(x+y\) and \(x-y\) are the bitstrings of length \(N\) defined by \(x+y = x + y_{N-1:0}\) and \(x-y = x - y_{N-1:0}\). Similarly, if \(x\) is an integer and \(y\) is a bitstring of length \(M\), \(x+y\) and \(x-y\) are the bitstrings of length \(M\) defined by \(x+y = x_{M-1:0} + y\) and \(x-y = x_{M-1:0} - y\).

Multiplication
If \(x\) and \(y\) are integers or reals, then \(x \times y\) is the product of \(x\) and \(y\). It is of type integer if \(x\) and \(y\) are both of type integer, and real otherwise.

Division and modulo
If \(x\) and \(y\) are reals, then \(x/y\) is the result of dividing \(x\) by \(y\), and is always of type real.

If \(x\) and \(y\) are integers, then \(x \div y\) and \(x \mod y\) are defined by:

\[
x \div y = \text{RoundDown}(x/y)
\]
\[
x \mod y = x - y \times (x \div y)
\]

It is a pseudocode error to use any of \(x/y\), \(x \mod y\), or \(x \div y\) in any context where \(y\) can be zero.

Scaling
If \(x\) and \(n\) are of type integer, then:
- \(x << n = \text{RoundDown}(x \times 2^n)\).
- \(x >> n = \text{RoundDown}(x \times 2^{-(n)})\).

Raising to a power
If \(x\) is an integer or a real and \(n\) is an integer then \(x^n\) is the result of raising \(x\) to the power of \(n\), and:
- If \(x\) is of type integer then \(x^n\) is of type integer.
- If \(x\) is of type real then \(x^n\) is of type real.

K12.4.5 The assignment operator
The assignment operator is the \(=\) character, which assigns the value of the right-hand side to the left-hand side. An assignment statement takes the form:

\[
\text{<assignable_expression>} = \text{<expression>};
\]

This following subsection defines valid expression syntax.
General expression syntax

An expression is one of the following:
• A literal.
• A variable, optionally preceded by a data type name to declare its type.
• The word `UNKNOWN` preceded by a data type name to declare its type.
• The result of applying a language-defined operator to other expressions.
• The result of applying a function to other expressions.

Variable names normally consist of alphanumeric and underscore characters, starting with an alphabetic or underscore character.

Each register defined in an ARM architecture specification defines a correspondingly named pseudocode bitstring variable, and that variable has the stated behavior of the register. For example, if a bit of a register is defined as RAZ/WI, then the corresponding bit of its variable reads as '0' and ignore writes.

An expression like `bits(32) UNKNOWN` indicates that the result of the expression is a value of the given type, but the architecture does not specify what value it is and software must not rely on such values. The value produced must not:
• Return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE and do not return UNKNOWN values,
• Be promoted as providing any useful information to software.

Note

UNKNOWN values are similar to the definition of UNPREDICTABLE, but do not indicate that the entire architectural state becomes unspecified.

Only the following expressions are assignable. This means that these are the only expressions that can be placed on the left-hand side of an assignment.
• Variables.
• The results of applying some operators to other expressions.
  The description of each language-defined operator that can generate an assignable expression specifies the circumstances under which it does so. For example, those circumstances might require that one or more of the expressions the operator operates on is an assignable expression.
• The results of applying array-like functions to other expressions. The description of an array-like function specifies the circumstances under which it can generate an assignable expression.

Note

If the right-hand side in an assignment is a function returning a tuple, an item in the assignment destination can be written as - to indicate that the corresponding item of the assigned tuple value is discarded. For example:

```
(shifted, -) = LSL_C(operand, amount);
```

The expression on the right-hand side itself can be a tuple. For example:

```
(x, y) = (function_1(), function_2());
```

Every expression has a data type.
• For a literal, this data type is determined by the syntax of the literal.
• For a variable, there are the following possible sources for the data type
  — An optional preceding data type name.
  — A data type the variable was given earlier in the pseudocode by recursive application of this rule.
— A data type the variable is being given by assignment, either by direct assignment to the variable, or by assignment to a list of which the variable is a member.

It is a pseudocode error if none of these data type sources exists for a variable, or if more than one of them exists and they do not agree about the type.

• For a language-defined operator, the definition of the operator determines the data type.

• For a function, the definition of the function determines the data type.

K12.4.6 Precedence rules

The precedence rules for expressions are:

1. Literals, variables and function invocations are evaluated with higher priority than any operators using their results, but see Boolean operators on page K12-7370.

2. Operators on integers follow the normal operator precedence rules of exponentiation before multiply/divide before add/subtract, with sequences of multiply/divides or add/subtracts evaluated left-to-right.

3. Other expressions must be parenthesized to indicate operator precedence if ambiguity is possible, but need not be if all permitted precedence orders under the type rules necessarily lead to the same result. For example, if i, j and k are integer variables, i > 0 && j > 0 && k > 0 is acceptable, but i > 0 && j > 0 || k > 0 is not.

K12.4.7 Conditional expressions

If x and y are two values of the same type and t is a value of type boolean, then if t then x else y is an expression of the same type as x and y that produces x if t is TRUE and y if t is FALSE.

K12.4.8 Operator polymorphism

Operators in pseudocode can be polymorphic, with different functionality when applied to different data types. Each resulting form of an operator has a different prototype definition. For example, the operator + has forms that act on various combinations of integers, reals and bitstrings.

Table K12-1 summarizes the operand types valid for each unary operator and the result type. Table K12-2 on page K12-7375 summarizes the operand types valid for each binary operator and the result type.

K12.5 Statements and control structures

This section describes the statements and program structures available in the pseudocode:

- Statements and Indentation.
- Function and procedure calls.
- Conditional control structures on page K12-7378.
- Loop control structures on page K12-7379.
- Special statements on page K12-7380.
- Comments on page K12-7380.

K12.5.1 Statements and Indentation

A simple statement is either an assignment, a function call, or a procedure call. Each statement must be terminated with a semicolon.

Indentation normally indicates the structure in compound statements. The statements contained in structures such as if ... then ... else ... or procedure and function definitions are indented more deeply than the statement structure itself. The end of a compound statement structure and their end is indicated by returning to the original indentation level or less.

Indentation is normally done by four spaces for each level. Standard indentation uses four spaces for each level of indent.

K12.5.2 Function and procedure calls

This section describes how functions and procedures are defined and called in the pseudocode.
Procedure and function definitions

A procedure definition has the form:

\[
<\text{procedure name}>(<\text{argument prototypes}>)
\]

\[
<\text{statement 1}>;
\]

\[
<\text{statement 2}>;
\]

\[
\cdots
\]

\[
<\text{statement n}>;
\]

where \(<\text{argument prototypes}>\) consists of zero or more argument definitions, separated by commas. Each argument definition consists of a type name followed by the name of the argument.

\[\text{Note}\]

This first definition line is not terminated by a semicolon. This distinguishes it from a procedure call.

A function definition is similar, but also declares the return type of the function:

\[
<\text{return type}> <\text{function name}>(<\text{argument prototypes}>)
\]

\[
<\text{statement 1}>;
\]

\[
<\text{statement 2}>;
\]

\[
\cdots
\]

\[
<\text{statement n}>;
\]

\[\text{Note}\]

A function or procedure name can include a ".". This is a convention used for functions that have similar but different behaviors in AArch32 and AArch64 states.

Array-like functions are similar, but are written with square brackets and have two forms. These two forms exist because reading from and writing to an array element require different functions. They are frequently used in memory operations. An array-like function definition with a return type is equivalent to reading from an array. For example:

\[
<\text{return type}> <\text{function name}>[<\text{argument prototypes}>]
\]

\[
<\text{statement 1}>;
\]

\[
<\text{statement 2}>;
\]

\[
\cdots
\]

\[
<\text{statement n}>;
\]

Its related function definition with no return type is equivalent to writing to an array. For example:

\[
<\text{function name}>[<\text{argument prototypes}>] = <\text{value prototype}>
\]

\[
<\text{statement 1}>;
\]

\[
<\text{statement 2}>;
\]

\[
\cdots
\]

\[
<\text{statement n}>;
\]

The value prototype determines what data type can be written to the array. The two related functions must share the same name, but the value prototype and return type can be different.

Procedure calls

A procedure call has the form:

\[
<\text{procedure name}>(<\text{arguments}>)
\]

Return statements

A procedure return has the form:

\[
\text{return};
\]

A function return has the form:

return <expression>;

where <expression> is of the type declared in the function prototype line.

K12.5.3 Conditional control structures

This section describes how conditional control structures are used in the pseudocode.

if ... then ... else ...

In addition to being a ternary operator, a multi-line if ... then ... else ... structure can act as a control structure and has the form:

if <boolean_expression> then
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;
elsif <boolean_expression> then
    <statement a>;
    <statement b>;
    ...
    <statement z>;
else
    <statement A>;
    <statement B>;
    ...
    <statement Z>;

The block of lines consisting of elsif and its indented statements is optional, and multiple elsif blocks can be used. The block of lines consisting of else and its indented statements is optional.

Abbreviated one-line forms can be used when the then part, and in the else part if it is present, contain only simple statements such as:

if <boolean_expression> then <statement 1>;
if <boolean_expression> then <statement 1>; else <statement A>;
if <boolean_expression> then <statement 1>; <statement 2>; else <statement A>;

--- Note ---

In these forms, <statement 1>, <statement 2> and <statement A> must be terminated by semicolons. This and the fact that the else part is optional distinguish its use as a control structure from its use as a ternary operator.

case ... of ...

A case .. of .. structure has the form:

case <expression> of
    when <literal values1>
        <statement 1>;
        <statement 2>;
        ...
        <statement n>;
    when <literal values2>
        <statement 1>;
        <statement 2>;
        ...
        <statement n>;
    ... more "when" groups if required ...

return <expression>;

where <expression> is of the type declared in the function prototype line.
otherwise
  <statement A>;
  <statement B>;
  ...
  <statement Z>;

In this structure, `<literal values1>` and `<literal values2>` consist of literal values of the same type as `<expression>`, separated by commas. There can be additional `when` groups in the structure. Abbreviated one line forms of `when` and `otherwise` parts can be used when they contain only simple statements.

If `<expression>` has a bitstring type, the literal values can also include bitstring literals containing 'x' bits, known as bitmasks. For details see "Equality and non-equality on page K12-7370."

**K12.5.4 Loop control structures**

This section describes the three loop control structures used in the pseudocode.

**repeat ... until ...**

A repeat .. until .. structure has the form:

```
repeat
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
until <boolean_expression>;
```

It executes the statement block at least once, and the loop repeats until `<boolean expression>` evaluates to TRUE. Variables explicitly declared inside the loop body have scope local to that loop and might not be accessed outside the loop body.

**while ... do**

A while .. do structure has the form:

```
while <boolean_expression> do
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
```

It begins executing the statement block only if the Boolean expression is true. The loop then runs until the expression is false.

**for ...**

A for .. structure has the form:

```
for <assignable_expression> = <integer_expr1> to <integer_expr2>
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
```

The `<assignable_expression>` is initialized to `<integer_expr1>` and compared to `<integer_expr2>`. If `<integer_expr1>` is less than `<integer_expr2>`, the loop body is executed and the `<assignable_expression>` incremented by one. This repeats until `<assignable expression>` is more than or equal to `<integer_expr2>`. There is an alternate form:

```
for <assignable_expression> = <integer_expr1> downto <integer_expr2>
```

where `<integer_expr1>` is decremented after the loop body executes and continues until `<assignable expression>` is less than or equal than `<integer_expr2>`. 
K12.5.5 Special statements

This section describes statements with particular architecturally-defined behaviors.

**UNDEFINED**

This subsection describes the statement:

UNDEFINED;

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that the Undefined Instruction exception is taken.

**UNPREDICTABLE**

This subsection describes the statement:

UNPREDICTABLE;

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is UNPREDICTABLE.

**SEE...**

This subsection describes the statement:

SEE <reference>;

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that nothing occurs as a result of the current pseudocode because some other piece of pseudocode defines the required behavior. The <reference> indicates where that other pseudocode can be found.

It usually refers to another instruction, but can also refer to another encoding or note of the same instruction.

**IMPLEMENTATION_DEFINED**

This subsection describes the statement:

IMPLEMENTATION_DEFINED "<text>";

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is IMPLEMENTATION_DEFINED. An optional <text> field can give more information.

K12.5.6 Comments

The pseudocode supports two styles of comments:

- // starts a comment that is terminated by the end of the line.
- /* starts a comment that is terminated by */.

/**/ statements might not be nested, and the first */ ends the comment.

--- **Note** ---

Comment lines do not require a terminating semicolon.
K12.6 Built-in functions

This section describes:

- Bitstring manipulation functions.
- Arithmetic functions on page K12-7382.

K12.6.1 Bitstring manipulation functions

The following bitstring manipulation functions are defined:

**Bitstring length and most significant bit**

If \( x \) is a bitstring:

- The bitstring length function \( \text{Len}(x) \) returns the length of \( x \) as an integer.

**Bitstring concatenation and replication**

If \( x \) is a bitstring and \( n \) is an integer with \( n \geq 0 \):

- \( \text{Replicate}(x, n) \) is the bitstring of length \( n \times \text{Len}(x) \) consisting of \( n \) copies of \( x \) concatenated together.
- \( \text{Zeros}(n) = \text{Replicate}'0', n) \).
- \( \text{Ones}(n) = \text{Replicate}'1', n) \).

**Bitstring count**

If \( x \) is a bitstring, \( \text{BitCount}(x) \) is an integer result equal to the number of bits of \( x \) that are ones.
Testing a bitstring for being all zero or all ones

If x is a bitstring:

- IsZero(x) produces TRUE if all of the bits of x are zeros and FALSE if any of them are ones
- IsZeroBit(x) produces '1' if all of the bits of x are zeros and '0' if any of them are ones.

IsOnes(x) and IsOnesBit(x) work in the corresponding ways. This means:

\[
\text{IsZero}(x) = (\text{BitCount}(x) == 0) \\
\text{IsOnes}(x) = (\text{BitCount}(x) == \text{Len}(x)) \\
\text{IsZeroBit}(x) = \text{if IsZero}(x) \text{ then '1' else '0'} \\
\text{IsOnesBit}(x) = \text{if IsOnes}(x) \text{ then '1' else '0'}
\]

Lowest and highest set bits of a bitstring

If x is a bitstring, and N = Len(x):

- LowestSetBit(x) is the minimum bit number of any of the bits of x that are ones. If all of its bits are zeros, LowestSetBit(x) = N.
- HighestSetBit(x) is the maximum bit number of any of the bits of x that are ones. If all of its bits are zeros, HighestSetBit(x) = -1.
- CountLeadingZeroBits(x) is the number of zero bits at the left end of x, in the range 0 to N. This means:
  \[\text{CountLeadingZeroBits}(x) = N - 1 - \text{HighestSetBit}(x)\]
- CountLeadingSignBits(x) is the number of copies of the sign bit of x at the left end of x, excluding the sign bit itself, and is in the range 0 to N-1. This means:
  \[\text{CountLeadingSignBits}(x) = \text{CountLeadingZeroBits}(x^{<N-1:1>} \text{ EOR } x^{<N-2:0>})\]

Zero-extension and sign-extension of bitstrings

If x is a bitstring and i is an integer, then ZeroExtend(x, i) is x extended to a length of i bits, by adding sufficient zero bits to its left. That is, if i == Len(x), then ZeroExtend(x, i) = x, and if i > Len(x), then:

ZeroExtend(x, i) = Replicate('0', i-Len(x)) : x

If x is a bitstring and i is an integer, then SignExtend(x, i) is x extended to a length of i bits, by adding sufficient copies of its leftmost bit to its left. That is, if i == Len(x), then SignExtend(x, i) = x, and if i > Len(x), then:

SignExtend(x, i) = Replicate(TopBit(x), i-Len(x)) : x

It is a pseudocode error to use either ZeroExtend(x, i) or SignExtend(x, i) in a context where it is possible that i < Len(x).

Converting bitstrings to integers

If x is a bitstring, SInt() is the integer whose two’s complement representation is x.

UInt() is the integer whose unsigned representation is x.

Int(x, unsigned) returns either SInt(x) or UInt(x) depending on the value of its second argument.

K12.6.2 Arithmetic functions

This section defines built-in arithmetic functions.

Absolute value

If x is either of type real or integer, Abs(x) returns the absolute value of x. The result is the same type as x.
Rounding and aligning

If \( x \) is a real:

- \( \text{RoundDown}(x) \) produces the largest integer \( n \) such that \( n \leq x \).
- \( \text{RoundUp}(x) \) produces the smallest integer \( n \) such that \( n \geq x \).
- \( \text{RoundTowardsZero}(x) \) produces:
  - \( \text{RoundDown}(x) \) if \( x > 0.0 \).
  - 0 if \( x = 0.0 \).
  - \( \text{RoundUp}(x) \) if \( x < 0.0 \).

If \( x \) and \( y \) are both of type integer, \( \text{Align}(x, y) = y \times (x \div y) \), and is of type integer.

If \( x \) is of type bitstring and \( y \) is of type integer, \( \text{Align}(x, y) = (\text{Align}(\text{UInt}(x), y))\ll (\text{Len}(x)-1:0) \), and is a bitstring of the same length as \( x \).

It is a pseudocode error to use either form of \( \text{Align}(x, y) \) in any context where \( y \) can be 0. In practice, \( \text{Align}(x, y) \) is only used with \( y \) a constant power of two, and the bitstring form used with \( y = 2^n \) has the effect of producing its argument with its \( n \) low-order bits forced to zero.

Maximum and minimum

If \( x \) and \( y \) are integers or reals, then \( \text{Max}(x, y) \) and \( \text{Min}(x, y) \) are their maximum and minimum respectively. \( x \) and \( y \) must both be of type integer or of type real. The function returns a value of the same type as its operands.
K12.7 Miscellaneous helper procedures and functions

This section lists the prototypes of miscellaneous helper procedures and functions used by the pseudocode, together with a brief description of the effect of the procedure or function. The pseudocode does not define the operation of these helper procedures and functions.

--- Note ---

Chapter J1 ARMv8 Pseudocode also has an entry for each of these functions, but currently these entries do not say anything about the effect of the function. When this information is added in Chapter J1 this section will be removed from the manual.

K12.7.1 EndOfInstruction()

This procedure terminates processing of the current instruction.

EndOfInstruction();

K12.7.2 Hint_Debug()

This procedure supplies a hint to the debug system.

Hint_Debug(bits(4) option);

K12.7.3 Hint_PreloadData()

This procedure performs a preload data hint.

Hint_PreloadData(bits(32) address);

K12.7.4 Hint_PreloadDataForWrite()

This procedure performs a preload data hint with a probability that the use will be for a write.

Hint_PreloadDataForWrite(bits(32) address);

K12.7.5 Hint_PreloadInstr()

This procedure performs a preload instructions hint.

Hint_PreloadInstr(bits(32) address);

K12.7.6 Hint_Yield()

This procedure performs a Yield hint.

Hint_Yield();

K12.7.7 IsExternalAbort()

This function returns TRUE if the abort currently being processed is an External abort and FALSE otherwise. It is used only in exception entry pseudocode.

boolean IsExternalAbort(Fault type)
assert type != Fault_None;
boolean IsExternalAbort(FaultRecord fault);
K12.7.8  IsAsyncAbort()

This function returns TRUE if the abort currently being processed is an asynchronous abort, and FALSE otherwise. It
is used only in exception entry pseudocode.

boolean IsAsyncAbort(Fault type)
  assert type != Fault_None;

boolean IsAsyncAbort(FaultRecord fault);

K12.7.9  LSInstructionSyndrome()

This function returns the extended syndrome information for a fault reported in the HSR.

bits(11) LSInstructionSyndrome();

K12.7.10  ProcessorID()

This function returns an integer that uniquely identifies the executing PE in the system.

integer ProcessorID();

K12.7.11  RemapRegsHaveResetValues()

This function returns TRUE if the remap registers PRRR and NMRR have their IMPLEMENTATION DEFINED reset
values, and FALSE otherwise.

boolean RemapRegsHaveResetValues();

K12.7.12  ResetControlRegisters()

This function resets the System registers and memory-mapped control registers that have architecturally-defined
reset values to those values. For more information about the affected registers see:

•  PE state on reset to AArch64 state on page D1-2155.
•  PE state on reset into AArch32 state on page G1-5305.

AArch64.ResetControlRegisters(boolean ResetIsCold)
AArch32.ResetControlRegisters(boolean ResetIsCold)

K12.7.13  ThisInstr()

This function returns the bitstring encoding of the currently-executing instruction.

bits(32) ThisInstr();

Note
Currently, this function is used only on 32-bit instruction encodings.

K12.7.14  ThisInstrLength()

This function returns the length, in bits, of the current instruction. This means it returns 32 or 16:

integer ThisInstrLength();
K12.8 ARM pseudocode definition index

This section contains the following tables:

- Table K12-3 which contains the pseudocode data types.
- Table K12-4 which contains the pseudocode operators.
- Table K12-5 on page K12-7387 which contains the pseudocode keywords and control structures.
- Table K12-6 on page K12-7388 which contains the statements with special behaviors.

### Table K12-3 Index of pseudocode data types

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>array</td>
<td>Type name for the array type</td>
</tr>
<tr>
<td>bit</td>
<td>Keyword equivalent to bits(1)</td>
</tr>
<tr>
<td>bits(N)</td>
<td>Type name for the bitstring of length N data type</td>
</tr>
<tr>
<td>boolean</td>
<td>Type name for the Boolean data type</td>
</tr>
<tr>
<td>enumeration</td>
<td>Keyword to define a new enumeration type</td>
</tr>
<tr>
<td>integer</td>
<td>Type name for the integer data type</td>
</tr>
<tr>
<td>real</td>
<td>Type name for the real data type</td>
</tr>
<tr>
<td>type</td>
<td>Keyword to define a new structure</td>
</tr>
</tbody>
</table>

### Table K12-4 Index of pseudocode operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>Unary minus on integers or reals</td>
</tr>
<tr>
<td></td>
<td>Subtraction of integers, reals and bitstrings</td>
</tr>
<tr>
<td></td>
<td>Used in the left-hand side of an assignment or a tuple to discard the result</td>
</tr>
<tr>
<td>+</td>
<td>Unary plus on integers or reals</td>
</tr>
<tr>
<td></td>
<td>Addition of integers, reals and bitstrings</td>
</tr>
<tr>
<td>.</td>
<td>Extract named member from a list</td>
</tr>
<tr>
<td></td>
<td>Extract named bit or field from a register</td>
</tr>
<tr>
<td>:</td>
<td>Bitstring concatenation</td>
</tr>
<tr>
<td>!</td>
<td>Boolean NOT</td>
</tr>
<tr>
<td>!=</td>
<td>Comparison for inequality</td>

</tr>
</tbody>
</table>
Appendix K13
Registers Index

This appendix provides indexes to the register descriptions in this manual. It contains the following sections:

• Introduction and register disambiguation on page K13-7390.
• Alphabetical index of AArch64 registers and System instructions on page K13-7395.
• Functional index of AArch64 registers and System instructions on page K13-7408.
• Alphabetical index of AArch32 registers and System instructions on page K13-7422.
• Functional index of AArch32 registers and System instructions on page K13-7432.
• Alphabetical index of memory-mapped registers on page K13-7443.
• Functional index of memory-mapped registers on page K13-7451.
K13.1 **Introduction and register disambiguation**

In some sections of this manual, registers are referred to by a general name, where the description applies to more than one context. Generally, this is one of the following:

- The description applies to both AArch32 state and AArch64 state, and therefore the register names could apply to either AArch32 System registers or AArch64 System registers.
- The description applies to multiple Exception levels, and therefore at a particular Exception level the register names need to take the appropriate Exception level suffix, _EL0, _EL1, _EL2, or _EL3.

The following sections disambiguate the general register names:

- Register name disambiguation by Execution state.
- Register name disambiguation by Exception level on page K13-7394.

K13.1.1 **Register name disambiguation by Execution state**

Table K13-1 disambiguates the general names of the registers by Execution state.

<table>
<thead>
<tr>
<th>General name</th>
<th>Short description</th>
<th>AArch64 register</th>
<th>AArch32 register</th>
</tr>
</thead>

K13.3 Functional index of AArch64 registers and System instructions

This section is an index of the AArch64 registers and System instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- Special-purpose registers.
- VMSA-specific registers on page K13-7409.
- ID registers on page K13-7410.
- Performance monitors registers on page K13-7411.
- Debug registers on page K13-7412.
- Generic timer registers on page K13-7413.
- Cache maintenance system instructions on page K13-7413.
- Address translation system instructions on page K13-7414.
- TLB maintenance system instructions on page K13-7415.
- Base system registers on page K13-7417.

K13.3.1 Special-purpose registers

This section is an index to the registers in the Special-purpose registers functional group.

K13.5 Functional index of AArch32 registers and System instructions

This section is an index of the AArch32 registers and System instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- Special-purpose registers.
- VMSA-specific registers.
- ID registers on page K13-7433.
- Performance monitors registers on page K13-7434.
- Debug registers on page K13-7435.
- Generic timer registers on page K13-7436.
- Cache maintenance system instructions on page K13-7437.
- Address translation system instructions on page K13-7437.
- TLB maintenance system instructions on page K13-7438.
- Legacy feature registers and system instructions on page K13-7439.
- Base system registers on page K13-7439.

K13.5.1 Special-purpose registers

This section is an index to the registers in the Processor state registers functional group.

K13.7 Functional index of memory-mapped registers

This section is an index of the memory-mapped registers, divided by functional group. Each of the following sections lists the registers for a functional group:

• **ID registers**.
• **Performance monitors registers**.
• **Debug registers on page K13-7452**.
• **Cross-trigger interface registers on page K13-7454**.

K13.7.1 ID registers

This section is an index to the registers in the Identification registers functional group.

Glossary

**A32 instruction**  A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in A32 state. A32 instructions must be word-aligned.

A32 instructions were previously called ARM instructions.

*See also* A32 state, A64 instruction, T32 instruction.

**A32 state**  The AArch32 Instruction set state in which the PE executes A32 instructions.

A32 state was previously called ARM state.

*See also* T32 instruction, T32 state.

**A64 instruction**  A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch64. A64 instructions must be word-aligned.

*See also* A32 instruction, T32 instruction.

**AArch32**  The 32-bit Execution state. In AArch32 state, addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets.

*See also* AArch64, A32 instruction, T32 instruction.

**AArch64**  The 64-bit Execution state. In AArch64 state, addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

*See also* AArch32, A64 instruction.

**Abort**  An exception caused by an illegal memory access. Aborts can be caused by the external memory system or the MMU.

**Addressing mode**  Means a method for generating the memory address used by a load/store instruction.

**Advanced SIMD**  A feature of the ARM architecture that provides SIMD operations on a register file of SIMD and floating-point registers. Where an implementation supports both Advanced SIMD and floating-point instructions, these instructions operate on the same register file.
**Aligned**
A data item stored at an address that is exactly divisible by the highest power of 2 that divides exactly into its size in bytes. Aligned halfwords, words and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.

An aligned access is one where the address of the access is aligned to the size of each element of the access.

**Architecturally executed**
An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired it has been *architecturally executed*. Any instruction that, in a simple sequential execution of a program, is treated as a *nop* because it fails its condition code check, is an architecturally executed instruction.

In a PE that performs speculative execution, an instruction is not architecturally executed if the PE discards the results of a speculative execution.

*See also* Condition code check, Simple sequential execution.

**Architecturally mapped**
Where this manual describes a register as being *architecturally mapped* to another register, this indicates that, in an implementation that supports both of the registers, the two registers access the same state.

**Architecturally UNKNOWN**
An architecturally UNKNOWN value is a value that is not defined by the architecture but must meet the requirements of the definition of UNKNOWN. Implementations can define the value of the field, but are not required to do so.

*See also* IMPLEMENTATION DEFINED.

**ARM core registers**
Some older documentation uses *ARM core registers* to refer to the following set of registers for execution in AArch32 state:

- The 13 general-purpose registers, R0-R12, that software can use for processing.
- SP, the *stack pointer*, that can also be referred to as R13.
- LR, the *link register*, that can also be referred to as R14.
- PC, the *program counter*, that can also be referred to as R15.

*See also* General-purpose registers.

**ARM instruction**
See A32 instruction.

**Associativity**
See Cache associativity.

**Atomicity**
Describes either single-copy atomicity or multi-copy atomicity. *Atomicity in the Arm architecture* on page B2-92 defines these forms of atomicity for the ARM architecture.

*See also* Multi-copy atomicity, Single-copy atomicity.

**Banked register**
A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.

**Base register**
A register specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the virtual address that is sent to memory.

**Base register writeback**
Describes writing back a modified value to the base register used in an address calculation.

**Behaves as if**
Where this manual indicates that a PE *behaves as if* a certain condition applies, all descriptions of the operation of the PE must be re-evaluated taking account of that condition, together with any other conditions that affect operation.

**Big-endian memory**
Means that, for example:

- A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.
• A byte at a halfword-aligned address is the most significant byte in the halfword at that address.

See also Endianness, Little-endian memory.

Blocking

Describes an operation that does not permit following instructions to be executed before the operation completes. A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.

Branch prediction

Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target.

See also Prefetching.

Breakpoint

A debug event triggered by the execution of a particular instruction, specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.

Byte

An 8-bit data item.

Cache associativity

The number of locations in a cache set to which an address can be assigned. Each location is identified by its way value.

Cache level

The position of a cache in the cache hierarchy. In the ARM architecture, the lower numbered levels are those closest to the PE. For more information, see Terms used in describing the cache maintenance instructions on page D4-2348.

Cache line

The basic unit of storage in a cache. Its size in words is always a power of two, usually 4 or 8 words. A cache line must be aligned to a suitable memory boundary. A memory cache line is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.

Cache lockdown

Enables critical software and data to be loaded into the cache so that the cache lines containing them are not subsequently reallocated. It alleviates the delays caused by accessing a cache in a worst-case situation. This ensures that all subsequent accesses to the software and data concerned are cache hits and so complete quickly.

Cache miss

A memory access that cannot be processed at high speed because the data it addresses is not in the cache.

Cache sets

Areas of a cache, divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two.

Cache way

A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to (Associativity-1). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way n consists of the cache line with index n from each cache set.

Coherence order

See Coherent.

Coherent

Data accesses from a set of observers to a byte in memory are coherent if accesses to that byte in memory by the members of that set of observers are consistent with there being a single total order of all writes to that byte in memory by all members of the set of observers. This single total order of all to writes to that memory location is the coherence order for that byte in memory.

Condition code check

The process of determining whether a conditional instruction executes normally or is treated as a NOP. For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally. For a T32 instruction in an IT block, the value of PSTATE.IT determines whether the instruction is executed normally.

See also Condition code field, Condition flags, Conditional execution.

Condition code field

A 4-bit field in an instruction that specifies the condition under which the instruction executes.

See also Condition code check.
**Condition flags**

The N, Z, C, and V bits of PSTATE, an SPSR, or FPSCR. See the register descriptions for more information.

*See also* *Condition code check, PSTATE.*

**Conditional execution**

When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a *NOP.*

*See also* *Condition code check.*

**CONSTRAINED UNPREDICTABLE**

Where an instruction can result in *UNPREDICTABLE* behavior, the ARMv8 architecture specifies a narrow range of permitted behaviors. This range is the range of *CONSTRAINED UNPREDICTABLE* behavior. All implementations that are compliant with the architecture must follow the *CONSTRAINED UNPREDICTABLE* behavior.

Execution at Non-secure EL1 or EL0 of an instruction that is *CONSTRAINED UNPREDICTABLE* can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not *UNPREDICTABLE* and is not *CONSTRAINED UNPREDICTABLE* causes a trap exception that is taken to EL2.

In body text, the term *CONSTRAINED UNPREDICTABLE* is shown in SMALL CAPITALS.

*See also* *UNPREDICTABLE.*

**Context switch**

The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.

**Context synchronization event**

One of:

- Performing an ISB operation. An ISB operation is performed when an ISB instruction is executed and does not fail its condition code check.

- Taking an exception.

- Returning from an exception.

- Exit from Debug state.

- Executing a DCPS instruction.

- Executing a DRPS instruction.

The effects of a Context synchronization event are:

- All unmasked interrupts that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.

- If halting is allowed, all Halting debug events that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.

- No instructions appearing in program order after an instruction that causes a Context synchronization event will have performed any part of their functionality until the Context synchronization event has occurred.

- All direct and indirect writes to System registers that are made before the Context synchronization event affect any instruction, including a direct read, that appears in program order after the instruction causing the Context synchronization event.

- All completed changes to the translation tables for entries that, before the change, were not permitted to be cached in a TLB, affect all instruction fetches that appear in program order after the instruction causing the Context synchronization event.

- All invalidations of TLBs, instruction caches, and, in AArch32 state, branch predictors, that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.

- In AArch32 state, all Non-cacheable writes that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.
• Changes to the Debug external authentication interfaces that are made before the Context synchronization event affect any instruction that appears in program order after the instruction causing the Context synchronization event.

―― Note ―――
• The architecture requires that instructions that generate Context synchronization events do not appear to be executed speculatively, except that the performance monitor counters are permitted to reveal such speculation.
• Context synchronization events were previously described as context synchronization operations.

Data independent timing (DIT)
The time that it takes to execute a piece of code where the time is not a function of the data being operated on. For more information, see About PSTATE.DIT on page B1-87 and About the DIT bit on page E1-3546.

Debugger
In most of this manual, debugger refers to any agent that is performing debug. However, some chapters or parts of this manual require a more rigorous definition, and define debugger locally. See:
• Definition of a debugger in the context of self-hosted debug on page D2-2270.
• Definition of a debugger in the context of self-hosted debug on page G2-5358.
• Definition and constraints of a debugger in the context of external debug on page H1-6414.

Deprecated
Something that is present in the ARM architecture for backwards compatibility. Whenever possible software must avoid using deprecated features. Features that are deprecated but are not optional are present in current implementations of the ARM architecture, but might not be present, or might be deprecated and OPTIONAL, in future versions of the ARM architecture.

See also OPTIONAL.

Digital signal processing (DSP)
Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.

Direct Memory Access (DMA)
An operation that accesses main memory directly, without the PE performing any accesses to the data concerned.

Direct read
A direct read of a System register is a read performed by a System register access instruction.

For more information, see Direct read on page D12-2665.

See also Direct write, Indirect read, Indirect write.

Direct write
A direct write of a System register is a write performed by a System register access instruction.

For more information, see Direct write on page D12-2665.

See also Direct read, Indirect read, Indirect write.

DMA
See Direct Memory Access (DMA).

DNM
See Do-Not-Modify (DNM).

Domain
In the ARM architecture, domain is used in the following contexts.

Shareability domain Defines a set of observers for which the shareability attributes make the data or unified caches transparent for data accesses.

Power domain Defines a block of logic with a single, common, power supply.

Memory regions domain
When using the Short-descriptor translation table format, defines a collection of Sections, Large pages and Small pages of memory, that can have their access permissions switched rapidly by writing to the Domain Access Control Register (DACR). ARM deprecates any use of memory regions domains.
Do-Not-Modify (DNM)
 means the value must not be altered by software. DNM fields read as UNKOWN values, and must only be written with the value read from the same field on the same PE.

Double-precision value
consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the IEEE Standard for Floating-point Arithmetic.

Doubleword
A 64-bit data item. Doublewords are normally at least word-aligned in ARM systems.

Doubleword-aligned
means that the address is divisible by 8.

DSP
See Digital signal processing (DSP).

Effective value
A register control field, meaning a field in a register that controls some aspect of the behavior, can be described as having an Effective value:

- In some cases, the description of a control a specifies that when control a is active it causes a register control field b to be treated as having a fixed value for all purposes other than direct reads, or direct reads and direct writes, of the register containing control field b. When control a is active that fixed value is described as the Effective value of register control field b. For example, when the value of HCR.DC is 1, the Effective value of HCR.VM is 1, regardless of its actual value.

- In other cases, in some contexts a register control field b is not implemented or is not accessible, but behavior of the PE is as if control field b was implemented and accessible, and had a particular value. In this case, that value is the Effective value of register control field b.

Note
Where a register control field is introduced in a particular version of the architecture, and is not implemented in an earlier version of the architecture, typically it will have an Effective value in that earlier version of the architecture.

- Otherwise, the Effective value of a register control field is the value of that field.

Endianness
An aspect of the system memory mapping.

See also Big-endian memory and Little-endian memory.

Exception
Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.

Exception vector
A fixed address that contains the address of the first instruction of the corresponding exception handler.

Execution stream
The stream of instructions that would have been executed by sequential execution of the program.

Explicit access
A read from memory, or a write to memory, generated by a load or store instruction executed by the PE. Reads and writes generated by hardware translation table accesses are not explicit accesses.

External abort
An abort that is generated by the external memory system.

Fast Context Switch Extension (FCSE)
Modifies the behavior of an ARM memory system to enable multiple programs running on the ARM PE to use identical address ranges, while ensuring that the addresses they present to the rest of the memory system differ. From ARMv6, ARM deprecates any use of the FCSE. The FCSE is:

- Optional in an ARMv7 implementation that does not include the Multiprocessing Extensions.
- Obsolete from the introduction of the Multiprocessing Extensions.

FCSE
See Fast Context Switch Extension (FCSE).

Flat address mapping
Is where the physical address for every access is equal to its virtual address.
Flush-to-zero mode
A processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and intermediate results with zeros, without significantly affecting the accuracy of their final results.

General-purpose registers
The registers that the base instructions use for processing:

• In AArch32 state the general-purpose registers are R0-R14, that can also be described as R0-R12, SP, LR.

  ___ Note ___ 
Older documentation defines the AArch32 general-purpose registers as R0-R12, and the ARM core registers as R0-R12, SP, LR, and PC.

• In AArch64 state the general-purpose registers are:
  — W0-W30 when accessed as 32-bit registers.
  — X0-X30 when accessed as 64-bit registers.

See also High registers, Low registers.

Generated by
The memory model is written in terms of reads from memory and writes to memory. These reads and writes:

• Are generated by instructions such as loads, stores, and atomic memory accesses.

• Correspond to the memory accesses, other than translation table walks, that are defined in the instruction pseudocode.

Some instructions generate more than one read or write.

Halfword
A 16-bit data item. Halfwords are normally halfword-aligned in ARM systems.

Halfword-aligned
Means that the address is divisible by 2.

High registers
In AArch32 state, the general-purpose registers R8-R14. Most 16-bit T32 instructions cannot access the high registers.

  ___ Note ___ 
In some contexts, high registers refers to R8-R15, meaning R8-R14 and the PC.

See also General-purpose registers, Low registers.

High vectors
An alternative location for the exception vectors. The high vector address range is near the top of the address space, rather than at the bottom.

IGNORED
Indicates that the architecture guarantees that the bit or field is not interpreted or modified by hardware.

In body text, the term IGNORED is shown in SMALL CAPITALS.

Immediate and offset fields
Are unsigned unless otherwise stated.

Immediate value
A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many A64, A32, and T32 instructions can be used with an immediate argument.

IMP
An abbreviation used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.

IMPLEMENTATION DEFINED
Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations.

In body text, the term IMPLEMENTATION DEFINED is shown in SMALL CAPITALS.
Index register  A register specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the virtual address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.

Indirect read  When an instruction uses a System register value to establish operating conditions, that use of the System register is an indirect read of the System register.

For more information, including additional examples of indirect reads, see Indirect read on page D12-2666.

See also  Direct read, Direct write, Indirect write.

Indirect write  An indirect write of a System register occurs when the contents of a register are updated by some mechanism other than a Direct write to that register. For example, an indirect write to a register might occur as a side-effect of executing an instruction that does not perform a direct write to the register, or because of some operation performed by an external agent.

For more information, see Indirect write on page D12-2666.

See also  Direct read, Direct write, Indirect read.

Inline literals  These are constant addresses and other data items held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.

Intermediate physical address (IPA)  An implementation of virtualization, the address to which a Guest OS maps a VA. A hypervisor might then map the IPA to a PA. Typically, the Guest OS is unaware of the translation from IPA to PA.

See also  Physical address (PA), Virtual address (VA).

Interworking  A method of working that permits branches between software using the A32 and T32 instruction sets.

IPA  See Intermediate physical address (IPA).

Level  See Cache level.

Level of Coherence (LoC)  The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency.

For more information, see Terms used in describing the cache maintenance instructions on page D4-2348.

See also  Cache level, Point of coherency (PoC).

Level of Unification, Inner Shareable (LoUIS)  The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain. For more information, see Terms used in describing the cache maintenance instructions on page D4-2348.

See also  Cache level, Point of unification (PoU).

Level of Unification, uniprocessor (LoUU)  For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE. For more information, see Terms used in describing the cache maintenance instructions on page D4-2348.

See also  Cache level, Point of unification (PoU).

Line  See  Cache line.

Little-endian memory  Means that, for example:

- A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the least significant byte in the halfword at that address.

See also  Big-endian memory, Endianness.
Load/Store architecture
An architecture where data-processing operations only operate on register contents, not directly on memory contents.

LoC
See Level of Coherence (LoC).

LoUIS
See Level of Unification, Inner Shareable (LoUIS).

LoUU
See Level of Unification, uniprocessor (LoUU).

Lockdown
See Cache lockdown.

Low registers
In AArch32 state, general-purpose registers R0-R7. Unlike the high registers, all T32 instructions can access the Low registers.

See also General-purpose registers, High registers.

Memory barrier
See Memory barriers on page B2-103.

Memory coherency
The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.

Memory Management Unit (MMU)
Provides detailed control of the part of a memory system that provides a single stage of address translation. Most of the control is provided using translation tables that are held in memory, and define the attributes of different regions of the physical memory map.

Memory Protection Unit (MPU)
A hardware unit whose registers provide simple control of a limited number of protection regions in memory.

Miss
See Cache miss.

MMU
See Memory Management Unit (MMU).

MPU
See Memory Protection Unit (MPU).

Multi-copy atomicity
The form of atomicity described in Requirements for multi-copy atomicity on page B2-94.

See also Atomicity, Single-copy atomicity.

NaN
Not a Number. A floating-point value that can be used when neither a numeric value nor an infinity is appropriate. A NaN can be a quiet NaN, that propagate through most floating-point operations, or a signaling NaN, that causes an Invalid Operation floating-point exception when used. For more information, see the IEEE Standard for Floating-point Arithmetic.

See also Quiet NaN, Signaling NaN.

Natural eviction
A natural eviction is an eviction that occurs in the course of the normal operation of the memory system, rather than because of an operation that explicitly causes an eviction from the cache, such as the execution of a cache maintenance instruction. Typically, a natural eviction occurs when the caching algorithm requires data to be cached but the cache does not have room for that data.

Observer
A PE or mechanism in the system, such as a peripheral device, that can generate reads from or writes to memory.

Obsolete
Obsolete indicates something that is no longer supported by ARM. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.

Offset addressing
Means that the memory address is formed by adding or subtracting an offset to or from the base register value.
OPTIONAL

When applied to a feature of the architecture, OPTIONAL indicates a feature that is not required in an implementation of the ARM architecture:

• If a feature is OPTIONAL and deprecated, this indicates that the feature is being phased out of the architecture. ARM expects such a feature to be included in a new implementation only if there is a known backwards-compatibility reason for the inclusion of the feature.
  
  A feature that is OPTIONAL and deprecated might not be present in future versions of the architecture.

• A feature that is OPTIONAL but not deprecated is, typically, a feature added to a version of the ARM architecture after the initial release of that version of the architecture. ARM recommends that such features are included in all new implementations of the architecture.

In body text, these meanings of the term OPTIONAL are shown in SMALL CAPITALS.

——— Note ————

Do not confuse these ARM-specific uses of OPTIONAL with other uses of optional, where it has its usual meaning. These include:

• Optional arguments in the syntax of many instructions.

• Behavior determined by an implementation choice, for example the optional byte order reversal in an ARMv7-R implementation, where the SCTLR.IE bit indicates the implemented option.

See also Deprecated.

PA

See Physical address (PA).

PE

See Processing element (PE).

Physical address (PA)

An address that identifies a location in the physical memory map.

See also Intermediate physical address (IPA), Virtual address (VA).

PoC

See Point of coherency (PoC).

PoU

See Point of unification (PoU).

Point of coherency (PoC)

For a particular VA, the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. For more information, see Terms used in describing the cache maintenance instructions on page D4-2348.

Point of unification (PoU)

For a particular PE, the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. For more information, see Terms used in describing the cache maintenance instructions on page D4-2348.

Post-indexed addressing

Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

Prefetching

Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.

In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.
Note

The Prefetch Abort exception can be generated on any instruction fetch, and is not limited to speculative instruction fetches.

See also Simple sequential execution.

Pre-indexed addressing

Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

Processing element (PE)

The abstract machine defined in the ARM architecture, as documented in an ARM Architecture Reference Manual. A PE implementation compliant with the ARM architecture must conform with the behaviors described in the corresponding ARM Architecture Reference Manual.

Protection region

A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

Protection Unit

See Memory Protection Unit (MPU).

Pseudo-instruction

UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, MOV <Rd>, <Rm>, LSL #<n> is a pseudo-instruction that is expected to disassemble as LSL <Rd>, <Rm>, #<n>.

PSTATE

An abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

See also Condition flags.

Quadword

A 128-bit data item. Quadwords are normally at least word-aligned in ARM systems.

Quadword-aligned

Means that the address is divisible by 16.

Quiet NaN

A NaN that propagates unchanged through most floating-point operations.

See also NaN, Signaling NaN.

RAO

See Read-As-One (RAO).

RAZ

See Read-As-Zero (RAZ).

RAO/SBOP

In versions of the ARM architecture before ARMv8, Read-As-One, Should-Be-One-or-Preserved on writes.

In ARMv8, RES1 replaces this description.

See also UNK/SBOP, Read-As-One (RAO), RES1, Should-Be-One-or-Preserved (SBOP).

RAO/WI

Read-As-One, Writes Ignored.

Hardware must implement the field as Read-as-One, and must ignore writes to the field.

Software can rely on the field reading as all 1s, and on writes being ignored.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also Read-As-One (RAO).

RAZ/SBZP

In versions of the ARM architecture before ARMv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes.

In ARMv8, RES0 replaces this description.

See also UNK/SBZP, Read-As-Zero (RAZ), RES0, Should-Be-Zero-or-Preserved (SBZP).

RAZ/WI

Read-As-Zero, Writes Ignored.

Hardware must implement the field as Read-as-Zero, and must ignore writes to the field.
Software can rely on the field reading as all 0s, and on writes being ignored.
This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also Read-As-Zero (RAZ).

Read-allocate cache
A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.

Read-As-One (RAO)
Hardware must implement the field as reading as all 1s.

Software:
• Can rely on the field reading as all 1s.
• Must use a SBOP policy to write to the field.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also RAO/SBOP, RAO/WI, RES1.

Read-As-Zero (RAZ)
Hardware must implement the field as reading as all 0s.

Software:
• Can rely on the field reading as all 0s
• Must use a SBZP policy to write to the field.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also RAZ/SBZP, RAZ/WI, RES0.

Read, modify, write
In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields updated in that register, and the new value written back.

RES0
A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:
• Is RES0 in some defined architectural context.
• Has different defined behavior in a different architectural context.

——— Note ———
• RES0 is not used in descriptions of instruction encodings.
• Where an AArch32 System register is Architecturally mapped to an AArch64 System register, and a bit or field in that register is RES0 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

This means the definition of RES0 for fields in read/write registers is:

If a bit is RES0 in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 0. In this case:
   • Reads of the bit always return 0.
   • Writes to the bit are ignored.

2. The bit can be written. In this case:
   • An indirect write to the register sets the bit to 0.
   • A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.
If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES0 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

**If a bit is RES0 only in some contexts**

For a bit in a read/write register, when the bit is described as RES0:

- An indirect write to the register sets the bit to 0.
- A read of the bit must return the value last successfully written to the bit, by either a direct or an indirect write, regardless of the use of the register when the bit was written.
  
  If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES0 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES0 indicates that the bit reads as 0, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES0 indicates that software must treat the bit as SBZ.

A bit that is RES0 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 0.
- Must use an SBZP policy to write to the bit.

This RES0 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES0.

In body text, the term RES0 is shown in SMALL CAPITALS.

*See also* Read-As-Zero (RAZ), RES1, Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.

**RES1**

A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:

- Is RES1 in some defined architectural context.
- Has different defined behavior in a different architectural context.

**Note**

- RES1 is not used in descriptions of instruction encodings.
- Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES1 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.
This means the definition of RES1 for fields in read/write registers is:

**If a bit is RES1 in all contexts**

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 1. In this case:
   - Reads of the bit always return 1.
   - Writes to the bit are ignored.
2. The bit can be written. In this case:
   - An indirect write to the register sets the bit to 1.
   - A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.
     If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
   - A direct write to the bit must update a storage location associated with the bit.
   - The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES1 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

**If a bit is RES1 only in some contexts**

For a bit in a read/write register, when the bit is described as RES1:

- An indirect write to the register sets the bit to 1.
- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

--- **Note** ---

As indicated in this list, this value might be written by an indirect write to the register.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES1 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES1 indicates that the bit reads as 1, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES1 indicates that software must treat the bit as SBO.

A bit that is RES1 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 1.
- Must use an SBOP policy to write to the bit.

This RES1 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES1.

In body text, the term RES1 is shown in SMALL CAPITALS.

*See also Read-As-One (RAO), RES0, Should-Be-One-or-Preserved (SBOP), UNKNOWN.*
Reserved

Unless otherwise stated:

- Instructions that are reserved or that access reserved registers have UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
- Bit positions described as reserved are:
  - In an RW or WO register, RES0.
  - In an RO register, UNK.

See also CONSTRAINED UNPREDICTABLE, RES0, RES1, UNDEFINED, UNK, UNPREDICTABLE.

RISC

Reduced Instruction Set Computer.

Rounding error

The value of the rounded result of an arithmetic operation minus the exact result of the operation.

Rounding mode

Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format. The rounding modes are defined by the IEEE Standard for Floating-point Arithmetic, see Floating-point standards, and terminology on page A1-51.

Saturated arithmetic

Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in ARM processors, in which overflowing results wrap around from \(+2^{31}−1\) to \(−2^{31}\) or vice versa.

SBO

See Should-Be-One (SBO).

SBOP

See Should-Be-One-or-Preserved (SBOP).

SBZ

See Should-Be-Zero (SBZ).

SBZP

See Should-Be-Zero-or-Preserved (SBZP).

Security hole

A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. The ARM architecture forbids security holes.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Self-modifying code

Code that writes one or more instructions to memory and then executes them. When using self-modifying code, you must use cache maintenance and barrier instructions to ensure synchronization. For more information, see Caches and memory hierarchy on page B2-111.

Set

See Cache sets.

Should-Be-One (SBO)

Hardware must ignore writes to the field.

ARM strongly recommends that software writes the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Should-Be-One-or-Preserved (SBOP)

From the introduction of the ARMv8 architecture, the description Should-Be-One-or-Preserved (SBOP) is superseded by RES1.

Note

The ARMv7 Large Physical Address Extension modified the definition of SBOP for register bits that are SBOP in some but not all contexts. The behavior of these bits is covered by the RES1 definition, but not by the generic definition of SBOP given here.
Hardware must ignore writes to the field.

When writing this field, software must either write all 1s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is unpredictable.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Should-Be-Zero (SBZ)**

Hardware must ignore writes to the field.

ARM strongly recommends that software writes the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Should-Be-Zero-or-Preserved (SBZP)**

From the introduction of the ARMv8 architecture, the description *Should-Be-Zero-or-Preserved (SBZP)* is superseded by *RES0*.

Note

The ARMv7 Large Physical Address Extension modified the definition of SBZP for register bits that are SBZP in some but not all contexts. The behavior of these bits is covered by the *RES0* definition, but not by the generic definition of SBZP given here.

Hardware must ignore writes to the field.

When writing this field, software must either write all 0s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is unpredictable.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Signaling NaN**

An Invalid Operation floating-point exception occurs whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

See also NaN, Quiet NaN.

**Signed immediate and offset fields**

Are encoded in two’s complement notation unless otherwise stated.

**SIMD**

Single-Instruction, Multiple-Data.

The SIMD instructions in AArch32 state are:

- The instructions summarized in *Parallel addition and subtraction instructions on page F1-3628*.

- The Advanced SIMD instructions summarized in *Advanced SIMD and floating-point instructions on page E1-3548*, when operating on vectors.

Note

In ARMv7, some VFP instructions can operate on vectors. However, ARM deprecates those instruction uses, and strongly recommends that Advanced SIMD instructions are always used for vector operations.
**Simple sequential execution**
The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and ARM does not expect this model to correspond to a realistic implementation of the architecture.

**Single-copy atomicity**
The form of atomicity described in *Properties of single-copy atomic accesses on page B2-93.*

See also Atomicity, Multi-copy atomicity.

**Single-precision value**
A 32-bit word that is interpreted as a basic single-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic.*

**Spatial locality**
The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

**Speculative**
Speculative operations are:

- Operations that are generated by instructions that appear in the Execution stream after a branch that is not architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after an instruction where a synchronous exception condition has not been architecturally resolved.
- Operations that are generated by conditional instructions for which the conditions for the instruction have not been architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after the point at which a precise asynchronous exception will be taken.
- Reads or writes generated by load or store instructions for which the data being written or the address being accessed comes from a register that has not been architecturally resolved.
- Operations generated by the hardware that are not directly generated by any instructions appearing in the Execution stream.

See also Execution stream.

**Special-purpose register**
One of a specified set of registers for which all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization:

- [Special-purpose registers](#) on page C5-354 specifies the AArch64 Special-purpose registers.
- [AArch32 Special-purpose registers](#) on page G1-5236 lists the AArch32 Special-purpose registers.

**T32 instruction**
One or two halfwords that specify an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in T32 state. T32 instructions must be halfword-aligned.

T32 instructions were previously called Thumb instructions.

See also A32 instruction, A64 instruction, T32 state.

**T32 state**
The AArch32 Instruction set state in which the PE executes T32 instructions.

T32 state was previously called Thumb state.

See also A32 state, T32 instruction.

**Taken locally**
*Taken locally* is a qualifier that determines which instances of an exception are counted by particular PMU events. See, in particular, *ARM recommendations for IMPLEMENTATION DEFINED event numbers on page K3-7248.*

In this context, an exception that is *Taken locally* means an exception that is one of:

- Taken to the current Exception level.
Note
This is not possible when the current Exception level is EL0.

• Taken from EL0 to EL1.
• Taken from EL0 to EL2 because the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

Note
An exception taken from EL0 to EL2 because the Effective value of HCR_EL2.{E2H, TGE} is {0, 1} is not Taken locally. This includes exceptions taken to EL2 using AArch32 when HCR.TGE is 1.

Temporal locality
The observed effect that after a program has accesses a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.

Thumb instruction
See T32 instruction.

TLB
See Translation Lookaside Buffer (TLB).

TLB lockown
A way to prevent specific translation table walk results being accessed. This ensures that accesses to the associated memory areas never cause a translation table walk.

Translation Lookaside Buffer (TLB)
A memory structure containing the results of translation table walks. They help to reduce the average cost of a memory access. Usually, there is a TLB for each memory interface of the ARM implementation.

Translation table
A table held in memory that defines the properties of memory areas of various sizes from 1KB to 1MB.

Translation table walk
The process of doing a full translation table lookup. It is performed automatically by hardware.

Trap enable bits
In VFPv2, VFPv3U, and VFPv4U, determine whether trapped or untrapped exception handling is selected. If trapped exception handling is selected, the way it is carried out is IMPLEMENTATION DEFINED.

Unaligned
An unaligned access is an access where the address of the access is not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

Unallocated
Except where otherwise stated in this manual, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE, or as an unallocated hint instruction.

A bit in a register is unallocated if the architecture does not assign a function to that bit.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE.

UNDEFINED
Indicates cases where an attempt to execute a particular encoding bit pattern generates an exception, that is taken to the current Exception level, or to the default Exception level for taking exceptions if the UNDEFINED encoding was executed at EL0. This applies to:

• Any encoding that is not allocated to any instruction.
• Any encoding that is defined as never accessible at the current Exception level.
• Some cases where an enable, disable, or trap control means an encoding is not accessible at the current Exception level.

If the generated exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception.
Note

On reset, the default Exception level for taking exceptions from EL0 is EL1. However, an implementation might include controls that can change this, effectively making EL1 inactive. See the description of the Exception model for more information.

In body text, the term UNDEFINED is shown in SMALL CAPITALS.

See also Undefined Instruction exception on page G1-5282.

Unified cache
Is a cache used for both processing instruction fetches and processing data loads and stores.

Unindexed addressing
Means addressing in which the base register value is used directly as the virtual address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0.

In ARMv7 and earlier versions of the ARM architecture, and in the M-profile, the LDC, LDC2, STC, and STC2 instructions have an explicit unindexed addressing mode that permits the offset field in the instruction to specify additional coprocessor options.

UNK
An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a multi-bit field. Software must not rely on the field reading as zero.

See also UNKNOWN.

UNK/SBOP
Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also Read-As-One (RAO), Should-Be-One-or-Preserved (SBOP), UNKNOWN.

UNK/SBZP
Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also Read-As-Zero (RAZ), Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.

UNKNOWN
An UNKNOWN value does not contain valid data, and can vary from moment to moment, instruction to instruction, and implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE, are not CONSTRAINED UNPREDICTABLE, and do not return UNKNOWN values.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.

In body text, the term UNKNOWN is shown in SMALL CAPITALS.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNK, UNPREDICTABLE.

UNPREDICTABLE
Means the behavior cannot be relied upon. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.
Execution at Non-secure EL1 or EL0 of an instruction that is UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term UNPREDICTABLE is shown in SMALL CAPITALS.

*See also* CONSTRAINED UNPREDICTABLE, UNDEFINED.

**VA**  
See Virtual address (VA).

**VFP**  
In ARMv7, an extension to the ARM architecture, that provides single-precision and double-precision floating-point arithmetic.

**Virtual address (VA)**  
An address generated by an ARM PE. This means it is an address that might be held in the program counter of the PE. For a PMSA implementation, the virtual address is identical to the physical address.  

*See also* Intermediate physical address (IPA), Physical address (PA).

**Watchpoint**  
A debug event triggered by an access to memory, specified in terms of the address of the location in memory being accessed.

**Way**  
*See Cache way.*

**WI**  
Writes Ignored. In a register that software can write to, a WI attribute applied to a bit or field indicates that the bit or field ignores the value written by software and retains the value it had before that write.

*See also* RAO/WI, RAZ/WI, RES0, RES1.

**Word**  
A 32-bit data item. Words are normally word-aligned in ARM systems.

**Word-aligned**  
Means that the address is divisible by 4.

**Write-allocate cache**  
A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.

**Write-back cache**  
A cache in which when a cache hit occurs on a store access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to main memory when the cache line is cleaned or reallocated. Another common term for a write-back cache is a *copy-back cache*.

**Write-through cache**  
A cache in which when a cache hit occurs on a store access, the data is written both to the cache and to main memory. This is normally done via a write buffer, to avoid slowing down the PE.

**Write buffer**  
A block of high-speed memory that optimizes stores to main memory.
