- The instruction is executed at EL2 when the Effective value on page Glossary-7462 of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes on page C1-157.

Unscaled offset variant

STTRH <Wt>, [<Xn|SP>{, #<simm>}

Decode for this encoding

bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

<Wt>    Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>  Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !(EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '1');
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '1';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 | unpriv_at_el2) then
  acctype = AccType_UNPRIV;
else
  acctype = AccType_NORMAL;

Operation

bits(64) address;
bits(16) data;

if n == 31 then
  CheckSPAilignment();
  address = SP[];
else
address = X[n];

address = address + offset;

data = X[t];
Mem[address, 2, acctype] = data;

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.275  STUMAXB, STUMAXLB

Atomic unsigned maximum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- STUMAXB has no memory ordering semantics.
- STUMAXLB stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-108.

For information about memory accesses see Load/Store addressing modes on page C1-157.

This instruction is an alias of the LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB.
- The description of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB gives the operational pseudocode for this instruction.

### ARMv8.1

No memory ordering variant

Applies when R == 0.

STUMAXB <\#s>, [\<Xn|SP\>]

is equivalent to

LDUMAXB <\#s>, WZR, [\<Xn|SP\>]

and is always the preferred disassembly.

Release variant

Applies when R == 1.

STUMAXLB <\#s>, [\<Xn|SP\>]

is equivalent to

LDUMAXLB <\#s>, WZR, [\<Xn|SP\>]

and is always the preferred disassembly.

### Assembler symbols

<\#s>       Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<\<Xn|SP\>>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.276 STUMAXH, STUMAXLH

Atomic unsigned maximum on halfword in memory, without return, atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- STUMAXH has no memory ordering semantics.
- STUMAXLH stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-108.

For information about memory accesses see Load/Store addressing modes on page C1-157.

This instruction is an alias of the LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH.
- The description of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when R == 0.

STUMAXH <Ws>, [<Xn|SP>]
is equivalent to

LDUMAXH <Ws>, WZR, [<Xn|SP>]
and is always the preferred disassembly.

Release variant

Applies when R == 1.

STUMAXLH <Ws>, [<Xn|SP>]
is equivalent to

LDUMAXLH <Ws>, WZR, [<Xn|SP>]
and is always the preferred disassembly.

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.277       STUMAX, STUMAXL

Atomic unsigned maximum on word or doubleword in memory, without return, atomically loads a 32-bit word or
64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back
to memory, treating the values as unsigned numbers.

• STUMAX has no memory ordering semantics.
• STUMAXL stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and

For information about memory accesses see Load/Store addressing modes on page C1-157.

This instruction is an alias of the LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL instruction. This means
that:

• The encodings in this description are named to match the encodings of LDUMAX, LDUMAXA,
  LDUMAXAL, LDUMAXL.
• The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational pseudocode
  for this instruction.

32-bit LDUMAX alias variant

Applies when size == 10 && R == 0.

STUMAX <Ws>, [<Xn|SP>]
is equivalent to

LDUMAX <Ws>, RZR, [<Xn|SP>]

and is always the preferred disassembly.

32-bit LDUMAXL alias variant

Applies when size == 10 && R == 1.

STUMAXL <Ws>, [<Xn|SP>]
is equivalent to

LDUMAXL <Ws>, RZR, [<Xn|SP>]

and is always the preferred disassembly.

64-bit LDUMAX alias variant

Applies when size == 11 && R == 0.

STUMAX <Xs>, [<Xn|SP>]
is equivalent to

LDUMAX <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.
64-bit LDUMAXL alias variant

Applies when size == 11 && R == 1.

STUMAXL <Xs>, [<Xn|SP>]

is equivalent to

LDUMAXL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.278   STUMINB, STUMINLB

Atomic unsigned minimum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers.

• STUMINB has no memory ordering semantics.

• STUMINLB stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-108.

For information about memory accesses see Load/Store addressing modes on page C1-157.

This instruction is an alias of the LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB instruction. This means that:

• The encodings in this description are named to match the encodings of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB.

• The description of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when R == 0.

STUMINB <Ws>, [<Xn|SP>]

is equivalent to

LDUMINB <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Release variant

Applies when R == 1.

STUMINLB <Ws>, [<Xn|SP>]

is equivalent to

LDUMINLB <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler symbols

<Ws>          Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP>     Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation
The description of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB gives the operational pseudocode for this instruction.

Operational information
If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.279 STUMINH, STUMINLH

Atomic unsigned minimum on halfword in memory, without return, atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers.

- STUMINH has no memory ordering semantics.
- STUMINLH stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-108.

For information about memory accesses see Load/Store addressing modes on page C1-157.

This instruction is an alias of the LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH.
- The description of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH gives the operational pseudocode for this instruction.

ARMv8.1

No memory ordering variant

Applies when \( R == 0 \).

STUMINH \(<Rs\>, \ [<Xn|SP>]\)

is equivalent to

LDUMINH \(<Rs\>, WZR, \ [<Xn|SP>]\)

and is always the preferred disassembly.

Release variant

Applies when \( R == 1 \).

STUMINLH \(<Rs\>, \ [<Xn|SP>]\)

is equivalent to

LDUMINLH \(<Rs\>, WZR, \ [<Xn|SP>]\)

and is always the preferred disassembly.

Assembler symbols

\(<Rs>\) Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

\(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

The description of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.280   STUMIN, STUMINL

Atomic unsigned minimum on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers.

- STUMIN has no memory ordering semantics.
- STUMINL stores to memory with release semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-108.

For information about memory accesses see Load/Store addressing modes on page C1-157.

This instruction is an alias of the LDUMIN, LDUMINA, LDUMINAL, LDUMINL instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMIN, LDUMINA, LDUMINAL, LDUMINL.
- The description of LDUMIN, LDUMINA, LDUMINAL, LDUMINL gives the operational pseudocode for this instruction.

ARMv8.1

32-bit LDUMIN alias variant

Applies when \( size == 10 && R == 0 \).

STUMIN <Ws>, [<Xn|SP>]

is equivalent to

LDUMIN <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

32-bit LDUMINL alias variant

Applies when \( size == 10 && R == 1 \).

STUMINL <Ws>, [<Xn|SP>]

is equivalent to

LDUMINL <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

64-bit LDUMIN alias variant

Applies when \( size == 11 && R == 0 \).

STUMIN <Xs>, [<Xn|SP>]

is equivalent to

LDUMIN <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.
64-bit LDUMINL alias variant

Applies when size == 11 && R == 1.

STUMINL <Xs>, [<Xn|SP>]

is equivalent to

LDUMINL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDUMIN, LDUMINA, LDUMINAL, LDUMINL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.281 STUR

Store Register (unscaled) calculates an address from a base register value and an immediate offset, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about memory accesses, see Load/Store addressing modes on page C1-157.

32-bit variant
Applies when \( size == 10 \).

\[
\text{STUR } <Wt>, [<Xn|SP>{, #<simm>}]
\]

64-bit variant
Applies when \( size == 11 \).

\[
\text{STUR } <Xt>, [<Xn|SP>{, #<simm>}]
\]

**Decode for all variants of this encoding**

integer \( \text{scale} = \text{UInt}(size) \);

bits(64) \( \text{offset} = \text{SignExtend}(\text{imm9}, 64) \);

**Assembler symbols**

- \(<Wt>\): Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- \(<Xt>\): Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- \(<Xn|SP>\): Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- \(<\text{simm}>\): Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

**Shared decode for all encodings**

integer \( n = \text{UInt}(Rn) \);

integer \( t = \text{UInt}(Rt) \);

integer \( \text{datasize} = 8 \ll \text{scale} \);

**Operation**

bits(64) \( \text{address} \);

bits(\( \text{datasize} \)) \( \text{data} \);

\[
\text{if } n == 31 \text{ then}
\]

\[
\text{CheckSPA}lignment();
\]

\[
\text{address} = \text{SP}[];
\]

\[
\text{else}
\]

\[
\text{address} = X[n];
\]

\[
\text{address} = \text{address} + \text{offset};
\]

\[
\text{data} = X[t];
\]

\[
\text{Mem}[\text{address}, \text{datasize} \div 8, \text{AccType}_{\text{NORMAL}}] = \text{data};
\]
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.282 STURB

Store Register Byte (unscaled) calculates an address from a base register value and an immediate offset, and stores a byte to the calculated address, from a 32-bit register. For information about memory accesses, see Load/Store addressing modes on page C1-157.

<table>

else
    address = X[n];

address = address + offset;
data = X[t];
Mem[address, 2, AccType_NORMAL] = data;

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.284   STXP

Store Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords from two registers to a memory location if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-135. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and, if the Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. For information about memory accesses see Load/Store addressing modes on page C1-157.

32-bit variant

Applies when sz == 0.
STXP <Ws>, <Wt1>, <Wt2>, [<Xn|SP>{,#0}]

64-bit variant

Applies when sz == 1.
STXP <Ws>, <Xt1>, <Xt2>, [<Xn|SP>{,#0}]

Decode for all variants of this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);  // ignored by load/store single register
integer s = UInt(Rs);  // ignored by all loads and store-release

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly STXP on page K1-7226.

Assembler symbols

<Ws>  Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
0 If the operation updates memory.
1 If the operation fails to update memory.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- \(\langle\text{ds}\rangle\) is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation**

```plaintext
bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

if s == t || (s == t2) then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE; // store UNKNOWN value
        when Constraint_NONE rt_unknown = FALSE; // store original value
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();

if s == n && n != 31 then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rn_unknown = TRUE; // address is UNKNOWN
        when Constraint_NONE rn_unknown = FALSE; // address is original base
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();

if n == 31 then
    CheckSPAlignment();
    address = SP();
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];

if rt_unknown then
    data = bits(datasize) UNKNOWN;
else
    bits(datasize DIV 2) el1 = X[t];
    bits(datasize DIV 2) el2 = X[t2];
    data = if BigEndian() then el1:el2 else el2:el1;
    bit status = '1';
    // Check whether the Exclusives monitors are set to include the
    // physical memory locations corresponding to virtual address
    // range [address, address+dbytes-1].
    if AArch64.ExclusiveMonitorsPass(address, dbytes) then
        // This atomic write will be rejected if it does not refer
        // to the same physical locations after address translation.
        Mem[address, dbytes, AccType_ATOMIC] = data;
        status = ExclusiveMonitorsStatus();
        X[s] = ZeroExtend(status, 32);
```

```
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.285   STXR

Store Exclusive Register stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-135. For information about memory accesses see Load/Store addressing modes on page C1-157.

Applies when size == 11.
STXR <Ws>, <Xt>, [<Xn|SP>{,#0}]

Decode for all variants of this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);    // ignored by all loads and store-release

integer elsize = 8 << UInt(size);

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly STXR on page K1-7226.

Assembler symbols

<Ws>     Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
          0     If the operation updates memory.
          1     If the operation fails to update memory.

<Xt>     Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Wt>     Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP>   Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

• Memory is not updated.
• <Ws> is not updated.
Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64.ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64.ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation**

```plaintext
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

if s == t then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_NONE rt_unknown = FALSE;    // store original value
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();
fi

if s == n && n != 31 then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_NONE rn_unknown = FALSE;    // address is original base
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();
fi

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];

if rt_unknown then
    data = bits(elsize) UNKNOWN;
else
    data = X[t];

bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, dbytes) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, dbytes, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
    X[s] = ZeroExtend(status, 32);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.286   STXRB

Store Exclusive Register Byte stores a byte from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-135. The memory access is atomic.

For information about memory accesses see Load/Store addressing modes on page C1-157.

No offset variant

STXRB <Ws>, <Wt>, [<Xn|SP>{,#0}]

Decode for this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);    // ignored by all loads and store-release

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly STXRB on page K1-7226.

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0     If the operation updates memory.
1     If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

• Memory is not updated.
• <Ws> is not updated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

bits(64) address;
bits(8) data;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

if s == t then
  Constraint c = ConstrainUnpredictable();
  assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};

  // This atomic write will be rejected if it does not refer
  // to the same physical locations after address translation.
  Mem[address, 1, AccType_ATOMIC] = data;
  status = ExclusiveMonitorsStatus();
  X[s] = ZeroExtend(status, 32);

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STXRH

Store Exclusive Register Halfword stores a halfword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores on page B2-135. The memory access is atomic.

For information about memory accesses see Load/Store addressing modes on page C1-157.

STXRH <Ws>, <Wt>, [<Xn|SP>{,#0}]

Decode for this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);    // ignored by all loads and store-release

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
0 If the operation updates memory.
1 If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

• Memory is not updated.

• <Ws> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

• If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.

• Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

</tr>
</thead>
<tbody>
<tr>
<td>NEG (shifted register)</td>
<td>( Rn == '11111' )</td>
</tr>
</tbody>
</table>

#### Assembler symbols

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
- LSL when shift = 00
- LSR when shift = 01
- ASR when shift = 10

The encoding shift = 11 is reserved.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.291   SUBS (extended register)

Subtract (extended register), setting flags, subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMP (extended register). See Alias conditions for details of when each alias is preferred.

32-bit variant

Applies when sf == 0.

SUBS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

64-bit variant

Applies when sf == 1.

SUBS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then UNDEFINED;

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMP (extended register)</td>
<td>Rd == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

<Wd>          Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn|WSP>        Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<Wm>          Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>          Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>        Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<R>  Is a width specifier, encoded in the "option" field. It can have the following values:
  W  when option = 00x
  W  when option = 010
  X  when option = x11
  W  when option = 10x
  W  when option = 110

<m>  Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in
  the "Rm" field.

<extend>  For the 32-bit variant: is the extension to be applied to the second source operand, encoded in
  the "option" field. It can have the following values:
    UXTB  when option = 000
    UXTH  when option = 001
    LSL|UXTW  when option = 010
    UXTX  when option = 011
    SXTB  when option = 100
    SXTH  when option = 101
    SXTW  when option = 110
    SXTX  when option = 111

    If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when
    "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

    For the 64-bit variant: is the extension to be applied to the second source operand, encoded in
    the "option" field. It can have the following values:
    UXTB  when option = 000
    UXTH  when option = 001
    UXTW  when option = 010
    LSL|UXTX  when option = 011
    SXTB  when option = 100
    SXTH  when option = 101
    SXTW  when option = 110
    SXTX  when option = 111

    If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3"
    is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount>  Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in
  the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL,
  and is optional when <extend> is present but not LSL.

Operation

bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;

operand2 = NOT(operand2);
(result, nzcv) = AddWithCarry(operand1, operand2, '1');
PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.292   SUBS (immediate)

Subtract (immediate), setting flags, subtracts an optionally-shifted immediate value from a register value, and writes
the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMP (immediate). See *Alias conditions* for details of when each alias is
preferred.

& \text{when } '1' \text{ imm} = \text{ZeroExtend}(\text{imm12}:\text{Zeros}(12), \text{datasize});
\end{align*}
\]

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMP (immediate)</td>
<td>Rd == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

\(<Wd>\)   Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Wn|WSP>\) Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

\(<Xd>\)   Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xn|SP>\) Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

\(<imm>\)   Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

\(<\text{shift}>\) Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:

\[
\begin{align*}
& \text{LSL } #0 \quad \text{when } sh = 0 \\
& \text{LSL } #12 \quad \text{when } sh = 1
\end{align*}
\]
**Operation**

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2;
bits(4) nzcv;

operand2 = NOT(imm);
(result, nzcv) = AddWithCarry(operand1, operand2, '1');

PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```  

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.293 SUBS (shifted register)

Subtract (shifted register), setting flags, subtracts an optionally-shifted register value from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the aliases CMP (shifted register) and NEGS. See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when $sf == 0$.

```
SUBS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant
Applies when $sf == 1$.

```
SUBS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if $sf == '1'$ then 64 else 32;
if shift == '11' then UNDEFINED;
if $sf == '0'$ && imm6<5> == '1' then UNDEFINED;
ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMP (shifted register)</td>
<td>Rd == '11111'</td>
</tr>
<tr>
<td>NEGS</td>
<td>Rn == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

- $<Wd>$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Wn>$ Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<Wm>$ Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- $<Xd>$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Xn>$ Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<Xm>$ Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
- LSL when shift = 00
- LSR when shift = 01
- ASR when shift = 10

The encoding shift = 11 is reserved.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(4) nzcv;

operand2 = NOT(operand2);
(result, nzcv) = AddWithCarry(operand1, operand2, '1');

PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.294 SVC

Supervisor Call causes an exception to be taken to EL1.

On executing an SVC instruction, the PE records the exception as a Supervisor Call exception in ESR_ELx, using the EC value 0x15, and the value of the immediate argument.

\[
\begin{array}{cccccccccccc}
| & | & | & 5 & 4 & 3 & 2 & 1 & 0 & \hline
1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & \end{array}
\]

System variant

SVC #<imm>

Decode for this encoding

// Empty.

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

AArch64.CallSupervisor(imm16);
C6.2.295   SWPB, SWPAB, SWPALB, SWPLB

Swap byte in memory atomically loads an 8-bit byte from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, SWPAB and SWPALB load from memory with acquire semantics.
- SWPLB and SWPALB store to memory with release semantics.
- SWPB has no memory ordering requirements.

For more information about memory ordering semantics see Load-Acquire, Load-AcquirePC, and Store-Release on page B2-108.

For information about memory accesses see Load/Store addressing modes on page C1-157.

X[t] = ZeroExtend(data, regsize);
```
C6.2.298   SXTB

Signed Extend Byte extracts an 8-bit value from a register, sign-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf == 0 \&\& N == 0$.

SXTB <Wd>, <Wn>
is equivalent to

SBFM <Wd>, <Wn>, #0, #7

and is always the preferred disassembly.

64-bit variant

Applies when $sf == 1 \&\& N == 1$.

SXTB <Xd>, <Wn>
is equivalent to

SBFM <Xd>, <Xn>, #0, #7

and is always the preferred disassembly.

Assembler symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.299   SXTH

Sign Extend Halfword extracts a 16-bit value, sign-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

32-bit variant
Applies when \( sf = 0 \land N = 0 \).

\[ SXTH <Wd>, <Wn> \]

is equivalent to

\[ SBFM <Wd>, <Wn>, #0, #15 \]

and is always the preferred disassembly.

64-bit variant
Applies when \( sf = 1 \land N = 1 \).

\[ SXTH <Xd>, <Wn> \]

is equivalent to

\[ SBFM <Xd>, <Xn>, #0, #15 \]

and is always the preferred disassembly.

Assembler symbols

- \(<Wd>\)  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xd>\)  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\)  Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{im}m>\)  Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
The response of this instruction to asynchronous exceptions does not vary based on:

- The values of the data supplied in any of its registers.
- The values of the NZCV flags.
SXTW

Sign Extend Word sign-extends a word to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

**64-bit variant**

SXTW `<Xd>`, `<Xn>`

is equivalent to

SBFM `<Xd>`, `<Xn>`, #0, #31

and is always the preferred disassembly.

**Assembler symbols**

- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Wn>` is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

**Operation**

The description of SBFM gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### C6.2.301  SYS

System instruction. For more information, see *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions on page C5-346* for the encodings of System instructions.

This instruction is used by the aliases AT, DC, IC, and TLBI. See *Alias conditions* for details of when each alias is preferred.

#### System variant

SYS #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}

#### Decode for this encoding

```c
AArch64.CheckSystemAccess('01', op1, CRn, CRm, op2, Rt, L);

integer t = UInt(Rt);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);
```

#### Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>AT</td>
<td>CRn == '0111' &amp;&amp; CRm == '100x' &amp;&amp; SysOp(op1,'0111',CRm,op2) == Sys_AT</td>
</tr>
<tr>
<td>DC</td>
<td>CRn == '0111' &amp;&amp; SysOp(op1,'0111',CRm,op2) == Sys_DC</td>
</tr>
<tr>
<td>IC</td>
<td>CRn == '0111' &amp;&amp; SysOp(op1,'0111',CRm,op2) == Sys_IC</td>
</tr>
<tr>
<td>TLBI</td>
<td>CRn == '1000' &amp;&amp; SysOp(op1,'1000',CRm,op2) == Sys_TLB</td>
</tr>
</tbody>
</table>

#### Assembler symbols

- **<op1>**  Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- **<Cn>**  Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
- **<Cm>**  Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
- **<op2>**  Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
- **<Xt>**  Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

#### Operation

```c
AArch64.SysInstr(1, sys_op1, sys_crn, sys_crm, sys_op2, X[t]);
```
C6.2.302   SYSL

System instruction with result. For more information, see \( op0 = 0b01 \), cache maintenance, TLB maintenance, and address translation instructions on page C5-346 for the encodings of System instructions.

\[
\begin{array}{ccccccccccccccccccccccc}
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 16 | 15 | 12 | 11 | 8 | 7 | 5 | 4 | 0 |  \\
1 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & \text{CRn} & \text{CRm} & \text{op2} & \text{Rt} & \end{array}
\]

**System variant**

\text{SYSL} <Xt>, #<op1>, <Cn>, <Cm>, #<op2>

**Decode for this encoding**

\text{AArch64.CheckSystemAccess('01', op1, CRn, CRm, op2, Rt, L)};

\text{integer t = UInt(Rt);};

\text{integer sys\_op1 = UInt(op1);};

\text{integer sys\_op2 = UInt(op2);};

\text{integer sys\_crn = UInt(CRn);};

\text{integer sys\_crm = UInt(CRm);};

**Assembler symbols**

\text{<Xt>}  Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.

\text{<op1>}  Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

\text{<Cn>}  Is a name 'Cn', with ‘n' in the range 0 to 15, encoded in the "CRn" field.

\text{<Cm>}  Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

\text{<op2>}  Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

**Operation**

\text{X[t] = AArch64.SysInstrWithResult(1, sys\_op1, sys\_crn, sys\_crm, sys\_op2);}
C6.2.303  TBNZ

Test bit and Branch if Nonzero compares the value of a bit in a general-purpose register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

```
|31 30 29 28|27 26 25 24|23 |19 18 | | 5 4 | 0 |
b5 0 1 0 1 1 1   b40   imm14   |   Rt |
```

**14-bit signed PC-relative branch offset variant**

TBNZ <R><t>, #<imm>, <label>

**Decode for this encoding**

```
integer t = UInt(Rt);
integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
b înt14) offset = SignExtend(imm14:'00', 64);
```

**Assembler symbols**

- `<R>` Is a width specifier, encoded in the "b5" field. It can have the following values:
  - W when b5 = 0
  - X when b5 = 1

  In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

- `<t>` Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

- `<imm>` Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

- `<label>` Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

**Operation**

```
b înt14) operand = X[t];
if operand<bit_pos> == op then
    BranchTo(PC[] + offset, BranchType_DIR);
```
C6.2.304   TBZ

Test bit and Branch if Zero compares the value of a test bit with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

![Instruction Format]

14-bit signed PC-relative branch offset variant

TBZ <R><t>, #<imm>, <label>

Decode for this encoding

```plaintext```
integer t = UInt(Rt);
integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bits(64) offset = SignExtend(imm14:'00', 64);
```

Assembler symbols

- `<R>` is a width specifier, encoded in the "b5" field. It can have the following values:
  - W when b5 = 0
  - X when b5 = 1
  In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.
- `<t>` is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.
- `<imm>` is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".
- `<label>` is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

Operation

```plaintext```
bits(datasize) operand = X[t];
if operand<bit_pos> == op then
  BranchTo(PC()[+ offset, BranchType_DIR);
```

```
C6.2.305 TLBI

TLB Invalidate operation. For more information, see op0==0b01, cache maintenance, TLB maintenance, and address translation instructions on page C5-346.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

System variant

TLBI <tlbi_op>{, <Xt>}

is equivalent to

SYS #<op1>, C8, <Cm>, #<op2>{, <Xt>}

and is the preferred disassembly when SysOp(op1,'1000',CRm,op2) == Sys_TLBI.

Assembler symbols

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<tlbi_op> Is a TLBI instruction name, as listed for the TLBI system instruction group, encoded in the "op1:CRm:op2" field. It can have the following values:

<table>
<thead>
<tr>
<th>tlb</th>
<th>CRn</th>
<th>op1</th>
<th>CRm</th>
<th>op2</th>
<th>Rt</th>
</tr>
</thead>
<tbody>
<tr>
<td>11010101000</td>

RVALE3 when \( op1 = 110, \text{CM} = 0110, \text{op2} = 101 \)

\(<Xt>\) Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

**Operation**

The description of **SYS** gives the operational pseudocode for this instruction.
C6.2.306  TSB CSYNC

Trace Synchronization Barrier. This instruction is a barrier that synchronizes the trace operations of instructions. If the Self-Hosted Trace Extension is not implemented, this instruction executes as a NOP.

ARMv8.4

|31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11|8|7|5|4|3|2|1|0|
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
|1 |1 |0 |1 |0 |1 |0 |0 |0 |0 |1 |1 |0 |0 |1 |0 |0 |

CRm  op2

System variant
TSB CSYNC

Decode for this encoding
if !HaveSelfHostedTrace() then EndOfInstruction();

Operation
TraceSynchronizationBarrier();
C6.2.307   TST (immediate)

Test bits (immediate), setting the condition flags and discarding the result: \( Rn \ AND \ imm \)

This instruction is an alias of the ANDS (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ANDS (immediate).
- The description of ANDS (immediate) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf == 0 \ AND \ N == 0 \).

TST \(<Wn>, \#<imm>\)

is equivalent to

ANDS WZR, \(<Wn>, \#<imm>\)

and is always the preferred disassembly.

64-bit variant

Applies when \( sf == 1 \).

TST \(<Xn>, \#<imm>\)

is equivalent to

ANDS XZR, \(<Xn>, \#<imm>\)

and is always the preferred disassembly.

Assembler symbols

- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<imm>\) For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".
  For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

Operation

The description of ANDS (immediate) gives the operational pseudocode for this instruction.
C6.2.308   TST (shifted register)

Test (shifted register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ANDS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ANDS (shifted register).
- The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

32-bit variant

Applies when sf == 0.

TST <Wn>, <Wm>{, <shift> #<amount>}

is equivalent to

ANDS WZR, <Wn>, <Wm>{, <shift> #<amount>}

and is always the preferred disassembly.

64-bit variant

Applies when sf == 1.

TST <Xn>, <Xm>{, <shift> #<amount>}

is equivalent to

ANDS XZR, <Xn>, <Xm>{, <shift> #<amount>}

and is always the preferred disassembly.

Assembler symbols

- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when shift = 00
  - LSR when shift = 01
  - ASR when shift = 10
  - ROR when shift = 11
- <amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
Operation

The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.309  UBFIZ

Unsigned Bitfield Insert in Zeros copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, setting the destination bits above and below the bitfield to zero.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

32-bit variant
Applies when \( sf = 0 \) && \( N = 0 \).

UBFIZ \(<Wd>, <Wn>, #<lsb>, #<width>\)

is equivalent to

UBFM \(<Wd>, <Wn>, #(-<lsb> \text{ MOD } 32), #(<width>-1)\)

and is the preferred disassembly when \( \text{UInt}(\text{imms}) < \text{UInt}(\text{immr}) \).

64-bit variant
Applies when \( sf = 1 \) && \( N = 1 \).

UBFIZ \(<Xd>, <Xn>, #<lsb>, #<width>\)

is equivalent to

UBFM \(<Xd>, <Xn>, #(-<lsb> \text{ MOD } 64), #(<width>-1)\)

and is the preferred disassembly when \( \text{UInt}(\text{imms}) < \text{UInt}(\text{immr}) \).

Assembler symbols
\(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
\(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
\(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
\(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
\(<lsb>\) For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
\(<width>\) For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation
The description of UBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.310 UBFM

Unsigned Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly.

If \( \text{imms} \) is greater than or equal to \( \text{immr} \), this copies a bitfield of \((\text{imms}-\text{immr}+1)\) bits starting from bit position \( \text{immr} \) in the source register to the least significant bits of the destination register.

If \( \text{imms} \) is less than \( \text{immr} \), this copies a bitfield of \((\text{imms}+1)\) bits from the least significant bits of the source register to bit position \((\text{regsize}-\text{immr})\) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases the destination bits below and above the bitfield are set to zero.

This instruction is used by the aliases LSL (immediate), LSR (immediate), UBFIZ, UBFX, UXTB, and UXTH. See Alias conditions on page C6-1236 for details of when each alias is preferred.

32-bit variant

Applies when \( sf == 0 \) && \( N == 0 \).

UBFM \(<Wd>, <Wn>, \#<immr>, \#<imms>\)

64-bit variant

Applies when \( sf == 1 \) && \( N == 1 \).

UBFM \(<Xd>, <Xn>, \#<immr>, \#<imms>\)

Decode for all variants of this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

integer R;
bits(datasize) wmask;
bits(datasize) tmask;

if sf == '1' && N != '1' then UNDEFINED;
if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then UNDEFINED;
R = UInt(immr);
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE);
```

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<immr> For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field.
For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.

<imms> For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field.
For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

Operation

bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = ROR(src, R) AND wmask;

// combine extension bits and result bits
X[d] = bot AND tmask;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.311 UBFX

Unsigned Bitfield Extract copies a bitfield of \(<\text{width}\>\) bits starting from bit position \(<\text{lsb}\>\) in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to zero.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

32-bit variant

Applies when \(sf == 0 \&\& N == 0\).

\[ \text{UBFX} \quad <\text{Wd}>, \quad <\text{Wn}>, \quad #<\text{lsb}>, \quad #<\text{width}> \]

is equivalent to

\[ \text{UBFM} \quad <\text{Wd}>, \quad <\text{Wn}>, \quad #<\text{lsb}>, \quad #(<\text{lsb}>+<\text{width}>-1) \]

and is the preferred disassembly when \(\text{BFXPreferred}(sf, \quad \text{opc}<1>, \quad \text{imms}, \quad \text{immr})\).

64-bit variant

Applies when \(sf == 1 \&\& N == 1\).

\[ \text{UBFX} \quad <\text{Xd}>, \quad <\text{Xn}>, \quad #<\text{lsb}>, \quad #<\text{width}> \]

is equivalent to

\[ \text{UBFM} \quad <\text{Xd}>, \quad <\text{Xn}>, \quad #<\text{lsb}>, \quad #(<\text{lsb}>+<\text{width}>-1) \]

and is the preferred disassembly when \(\text{BFXPreferred}(sf, \quad \text{opc}<1>, \quad \text{imms}, \quad \text{immr})\).

Assembler symbols

\(<\text{Wd}\>) \quad \text{Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.}
\(<\text{Wn}\>) \quad \text{Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.}
\(<\text{Xd}\>) \quad \text{Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.}
\(<\text{Xn}\>) \quad \text{Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.}
\(<\text{lsb}\>) \quad \text{For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.}
\quad \text{For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.}
\(<\text{width}\>) \quad \text{For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<\text{lsb}>.}
\quad \text{For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<\text{lsb}>.}

Operation

The description of UBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.312 UDF

Permanently Undefined generates an Undefined Instruction exception (ESR_ELx.EC = 0b000000). The encodings for UDF used in this section are defined as permanently UNDEFINED in the Armv8-A architecture.

**Integer variant**

UDF #<imm>

**Decode for this encoding**

// The imm16 field is ignored by hardware.
UNDEFINED;

**Assembler symbols**

<imm> is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field. The PE ignores the value of this constant.

**Operation**

// No operation.
C6.2.313   UDIV

Unsigned Divide divides an unsigned integer register value by another unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

32-bit variant

Applies when \( sf == 0 \).

UDIV <Wd>, <Wn>, <Wm>

64-bit variant

Applies when \( sf == 1 \).

UDIV <Xd>, <Xn>, <Xm>

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(\text{Rd}); \\
\text{integer } n &= \text{UInt}(\text{Rn}); \\
\text{integer } m &= \text{UInt}(\text{Rm}); \\
\text{integer } \text{datasize} &= \text{if } \text{sf} == '1' \text{ then } 64 \text{ else } 32;
\end{align*}
\]

Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

\[
\begin{align*}
\text{bits}(\text{datasize}) \text{ operand1} &= X[n]; \\
\text{bits}(\text{datasize}) \text{ operand2} &= X[m]; \\
\text{integer } \text{result}; \\
\text{if } \text{IsZero}(\text{operand2}) \text{ then} \\
& \quad \text{result} = 0; \\
\text{else} \\
& \quad \text{result} = \text{RoundTowardsZero}(\text{Real}((\text{Int}(\text{operand1}, \text{TRUE})) / \text{Real}((\text{Int}(\text{operand2}, \text{TRUE}))))); \\
X[d] &= \text{result}<\text{datasize}-1:0>;
\end{align*}
\]
C6.2.314   UMADDL

Unsigned Multiply-Add Long multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMULL. See Alias conditions for details of when each alias is preferred.

<table>
<thead>
<tr>

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa> Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation

bits(32) operand1 = X[n];
bits(32) operand2 = X[m];
bits(64) operand3 = X[a];

integer result;

result = Int(operand3, TRUE) + (Int(operand1, TRUE) * Int(operand2, TRUE));

X[d] = result<63:0>;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.315   UMNEGL

Unsigned Multiply-Negate Long multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This instruction is an alias of the UMSUBL instruction. This means that:

• The encodings in this description are named to match the encodings of UMSUBL.
• The description of UMSUBL gives the operational pseudocode for this instruction.

64-bit variant

UMNEGL <Xd>, <Wn>, <Wm>

is equivalent to

UMSUBL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of UMSUBL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.316  UMSUBL

Unsigned Multiply-Subtract Long multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMNegl. See Alias conditions for details of when each alias is preferred.

64-bit variant

UMSUBL <Xd>, <Wn>, <Wm>, <Xa>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);

Alias conditions

<table>

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation

bits(32) operand1 = X[n];
bits(32) operand2 = X[m];
bits(64) operand3 = X[a];

integer result;

result = Int(operand3, TRUE) - (Int(operand1, TRUE) \* Int(operand2, TRUE));
X[d] = result<63:0>;
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.317 UMULH

Unsigned Multiply High multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.

64-bit variant

UMULH <Xd>, <Xn>, <Xm>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

bits(64) operand1 = X[n];
bits(64) operand2 = X[m];
integer result;
result = Int(operand1, TRUE) * Int(operand2, TRUE);
X[d] = result<127:64>;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.318 UMULL

Unsigned Multiply Long multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This instruction is an alias of the UMADDL instruction. This means that:

- The encodings in this description are named to match the encodings of UMADDL.
- The description of UMADDL gives the operational pseudocode for this instruction.

64-bit variant

UMULL <Xd>, <Wn>, <Wm>

is equivalent to

UMADDL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of UMADDL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.319  UXTB

Unsigned Extend Byte extracts an 8-bit value from a register, zero-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

### 32-bit variant

UXTB <Wd>, <Wn>

is equivalent to

UBFM <Wd>, <Wn>, #0, #7

and is always the preferred disassembly.

### Assembler symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

### Operation

The description of UBFM gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.320   UXTH

Unsigned Extend Halfword extracts a 16-bit value from a register, zero-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

32-bit variant

UXTH <Wd>, <Wn>

is equivalent to

UBFM <Wd>, <Wn>, #0, #15

and is always the preferred disassembly.

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.321   WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any PE in the multiprocessor system. For more information, see *Wait for Event mechanism and Send event* on page D1-2243.

As described in *Wait for Event mechanism and Send event* on page D1-2243, the execution of a WFE instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-2199.
- Traps to EL2 of EL0 and EL1 execution of WFE and WFI instructions on page D1-2217.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-2232.

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12| 11 8 7 5 4 3 2 1 0 |

Operation

if IsEventRegisterSet() then
    ClearEventRegister();
else
    if PSTATE.EL == EL0 then
        // Check for traps described by the OS which may be EL1 or EL2.
        AArch64.CheckForWFxTrap(EL1, TRUE);
    if PSTATE.EL IN {EL0, EL1} && EL2Enabled() && !IsInHost() then
        // Check for traps described by the Hypervisor.
        AArch64.CheckForWFxTrap(EL2, TRUE);
    if HaveEL(EL3) && PSTATE.EL != EL3 then
        // Check for traps described by the Secure Monitor.
        AArch64.CheckForWFxTrap(EL3, TRUE);
    WaitForEvent();
```
C6.2.322 WFI

Wait For Interrupt is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. For more information, see Wait For Interrupt on page D1-2246.

As described in Wait For Interrupt on page D1-2246, the execution of a WFI instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-2199.
- Traps to EL2 of EL0 and EL1 execution of WFE and WFI instructions on page D1-2217.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-2232.

System variant

WFI

Decode for this encoding

// Empty.

Operation

if !InterruptPending() then
    if PSTATE.EL == EL0 then
        // Check for traps described by the OS which may be EL1 or EL2.
        AArch64.CheckForWFxTrap(EL1, FALSE);
        if PSTATE.EL IN {EL0, EL1} && EL2Enabled() && !IsInHost() then
            // Check for traps described by the Hypervisor.
            AArch64.CheckForWFxTrap(EL2, FALSE);
        if HaveEL(EL3) && PSTATE.EL != EL3 then
            // Check for traps described by the Secure Monitor.
            AArch64.CheckForWFxTrap(EL3, FALSE);
        WaitForInterrupt();
C6.2.323   XPACD, XPACI, XPAACLRI

Strip Pointer Authentication Code. This instruction removes the pointer authentication code from an address. The address is in the specified general-purpose register for XPACI and XPACD, and is in LR for XPAACLRI.

The XPACD instruction is used for data addresses, and XPACI and XPAACLRI are used for instruction addresses.

`Hint_Yield();`
This chapter describes the A64 Advanced SIMD and floating-point instructions.
It contains the following sections:

- About the A64 SIMD and floating-point instructions on page C7-1256.
- Alphabetical list of A64 Advanced SIMD and floating-point instructions on page C7-1258.
C7.1 About the A64 SIMD and floating-point instructions

Alphabetical list of A64 Advanced SIMD and floating-point instructions on page C7-1258 gives full descriptions of
the A64 instructions that are in the following instruction groups:
• Loads and store instructions associated with the SIMD and floating-point registers.
• Data processing instructions with SIMD and floating-point registers.

A64 instruction set encoding on page C4-232 in the A64 Instruction Encodings chapter provides an overview of the
instruction encodings as part of an instruction class within a functional group.

The rest of this section is a general description of the SIMD and floating-point instructions. It contains the following
subsections:
• Register size.
• Data types.
• Condition flags and related instructions on page C7-1257.
• General capabilities on page C7-1257.

C7.1.1 Register size

A64 provides a comprehensive set of packed Single Instruction Multiple Data (SIMD) and scalar operations using
data held in the 32 entry 128-bit wide SIMD and floating-point register file.

Each SIMD and floating-point register can be used to hold:
• A single scalar value of the floating-point or integer type.
• A 64-bit wide vector containing one or more elements.
• A 128-bit wide vector containing two or more elements.

Where the entire 128-bit wide register is not fully utilized, the vector or scalar quantity is held in the least significant
bits of the register, with the most significant bits being cleared to zero on a write, see Vector formats on page A1-40.

The following instructions can insert data into individual elements within a SIMD and floating-pointer register
without clearing the remaining bits to zero:
• Insert vector element from another vector element or general-purpose register, INS.
• Load structure into a single lane, for example LD3.
• All second-part narrowing operations, for example SHRN2.

C7.1.2 Data types

The A64 instruction set provides support for arithmetic, conversion, and bitwise operations on:
• Half-precision, single-precision, and double-precision floating-points.
• Signed and unsigned integers.
• Polynomials over \{0, 1\}.
• When ARMv8.3-CompNum is implemented, complex numbers.

For all AArch64 floating-point operations, including SIMD operations, the rounding mode and exception trap
handling are controlled by the FPCR.

--- Note ---
• AArch32 Advanced SIMD operations always use ARM standard floating-point arithmetic, regardless of the
  rounding mode specified by the AArch64 FPCR or the AArch32 FPSCR.
• In AArch64 state, floating-point multiply-add operations are always performed as fused operations, but
  AArch32 state provides both fused and chained multiply-add instructions.
In addition to operations that consume and produce values of the same width and type, the A64 instruction set supports SIMD and scalar operations that produce a wider or narrower vector result:

- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the A64 instruction set provides a second-part operation, for example SHR2, that can pack the result of a second operation into the upper part of the same destination register.

- Where a SIMD operation widens a 64-bit vector to a 128-bit vector, the A64 instruction set provides a second-part operation, for example SMLA2, that can extract the source from the upper 64 bits of the source registers.

All SIMD operations that could produce side-effects that are not limited to the destination SIMD and floating-point register, for example a potential update of FPSR.Q or FPSR.IDC, have a dedicated scalar variant to support the use of SIMD with loops requiring specialised head or tail handling, or both.

### C7.1.3 Condition flags and related instructions

The A64 instruction set provides support for flag setting and conditional operations on the SIMD and floating-point register file:

- Floating-point FCSEL and FCMPI instructions are equivalent to the integer CSEL and COP instructions.

- Floating-point FOP, FOP, FCOP, and FCMPI instructions set the PSTATE.{N, Z, C, V} flags based on the result of the floating-point comparison.

- Floating-point FJVTZS instruction sets the PSTATE.Z flag if the result of the conversion, when converted back to a double-precision floating-point number, gives precisely the same value as the original. Other PSTATE flags are cleared by this instruction.

- Floating-point and integer instructions provide a means of producing either a scalar or a vector mask based on a comparison in a SIMD and floating-point register, for example FCMEQ.

#### Note

FCMP and FCMPE differ from the A32/T32 VCMP and VCMPE instructions, which use the dedicated FPSCR.NZCV field for the result. A64 instructions store the result of an FCMP or FCMPE operation in the PSTATE.{N, Z, C, V} field.

### C7.1.4 General capabilities

A64 SIMD and floating-point instructions provide the following capabilities:

- General arithmetic on vector and scalar floating-point and integer values.

- Dedicated polynomial multiply over \{0, 1\}.

- Vector and scalar fused multiply-addition of single-precision and double-precision floating-points, and for half-precision floating-points when ARMv8.2-FP16 is implemented.

- Load and store of single and pairs of SIMD and floating-point registers.

- Load and store of structures and individual lanes of between one and four SIMD and floating-point registers.

- Direct conversion between 64-bit integers and floating-point values, with explicit rounding.

- When ARMv8.3-JSC is implemented, conversion from double precision floating-point values to 32-bit integers, with rounding to zero.

- Double-rounding free conversion between double-precision and half-precision floating-point values.

- Comprehensive SIMD with widening and narrowing support.

- Vector to scalar reduction returning the minimum or maximum value, or the sum.

- Floating-point to nearest integer in floating-point format.

- When ARMv8.3-CompNum is implemented, complex number arithmetic.
C7.2 Alphabetical list of A64 Advanced SIMD and floating-point instructions

This section lists every section in the Advanced SIMD and floating-point categories of the A64 instruction set. For details of the format used, see Structure of the A64 assembler language on page C1-151.
C7.2.1 ABS

Absolute value (vector). This instruction calculates the absolute value of each vector element in the source SIMD&FP register, puts the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

<table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Scalar variant

ABS <V><d>, <V><n>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean neg = (U == '1');

Vector

<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>

<td>Rd</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Vector variant

ABS <Vd>.<T>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = if Q == '1' then 128 else 64;
integer datasize = datasize DIV esize;
boolean neg = (U == '1');

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

D when size = 11

The following encodings are reserved:

• size = 0x.
• size = 10.
<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

---

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.2 ADD (vector)

Add (vector). This instruction adds corresponding elements in the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

```
0 1 0 1 1 1 0 | size 1 | Rm 1 0 0 0 0 1 | Rd
```

Scalar variant

ADD <V><d>, <V><n>, <V><m>

Decoding for this encoding

- integer d = UInt(Rd);
- integer n = UInt(Rn);
- integer m = UInt(Rm);
- if size != '11' then UNDEFINED;
- integer esize = 8 << UInt(size);
- integer datasize = esize;
- integer elements = 1;
- boolean sub_op = (U == '1');

Vector

```
0 0 0 1 1 1 0 | size 1 | Rm 1 0 0 0 0 1 | Rd
```

Vector variant

ADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decoding for this encoding

- integer d = UInt(Rd);
- integer n = UInt(Rn);
- integer m = UInt(Rm);
- if size:Q == '110' then UNDEFINED;
- integer esize = 8 << UInt(size);
- integer datasize = esize;
- integer elements = 1;
- boolean sub_op = (U == '1');

Assembler symbols

- <V> is a width specifier, encoded in the "size" field. It can have the following values:
  - D when size = 11
  - The following encodings are reserved:
    - size = 0x.
    - size = 10.
<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<v>d> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<n> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
baby(datasize) operand1 = V[n];
baby(datasize) operand2 = V[m];
baby(esize) element1;
baby(esize) element2;
for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if sub_op then
        Elem[result, e, esize] = element1 - element2;
    else
        Elem[result, e, esize] = element1 + element2;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.3 ADDHN, ADDHN2

Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are truncated. For rounded results, see RADDHN, RADDHN2.

The ADDHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the ADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

ADDHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');

Assembler symbols

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 8H when size = 00
- 4S when size = 01
- 2D when size = 10

The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;

for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;
Vpart[d, part] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.4   ADDP (scalar)

Add Pair of elements (scalar). This instruction adds two vector elements in the source SIMD&FP register and writes the scalar result into the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
[31 30 29 28] [27 26 25 24] [23 22 21 20] [19 18 17 16] [15 14 13 12] [11 10 9] | 5 4 | 0 |
0 1 0 1 1 1 1 0  size  1 1 0 0 1 1 0 1 1 0  Rd |
```

Advanced SIMD variant

ADDP <V><d>, <Vn>.<T>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '11' then UNDEFINED;

integer esize = 8 << UInt(size);
integer datasize = esize * 2;

**Assembler symbols**

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:

- when size = 11

The following encodings are reserved:

- size = 0x.
- size = 10.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is the source arrangement specifier, encoded in the "size" field. It can have the following values:

- when size = 11

The following encodings are reserved:

- size = 0x.
- size = 10.

**Operation**

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_ADD, operand, esize);
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.5 ADDP (vector)

Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register.

 Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

![Instruction Format](image)

Three registers of the same type variant

ADDP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- **8B** when size = 00, Q = 0
- **16B** when size = 00, Q = 1
- **4H** when size = 01, Q = 0
- **8H** when size = 01, Q = 1
- **2S** when size = 10, Q = 0
- **4S** when size = 10, Q = 1
- **2D** when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
bits(esize) element1;
bits(esize) element2;
for e = 0 to elements-1
    element1 = Elem[concat, 2*e, esize];
    element2 = Elem[concat, (2*e)+1, esize];
    Elem[result, e, esize] = element1 + element2;

V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.6  ADDV

Add across Vector. This instruction adds every vector element in the source SIMD&FP register together, and writes
the scalar result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

ADDV <V><d>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if size:Q == '100' then UNDEFINED;
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
B when size = 00
H when size = 01
S when size = 10
The encoding size = 11 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
4S when size = 10, Q = 1
The following encodings are reserved:
• size = 10, Q = 0.
• size = 11, Q = x.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_ADD, operand, esize);
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.7 AESD

AES single round decryption.

Advanced SIMD variant

AESD <Vd>.16B, <Vn>.16B

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if !HaveAESExt() then UNDEFINED;

Assembler symbols

<Vd> Is the name of the SIMD&FP source and destination register, encoded in the "Rd" field.
<Vn> Is the name of the second SIMD&FP source register, encoded in the "Rn" field.

Operation

AArch64.CheckFPAdvSIMDEnabled();

bits(128) operand1 = V[d];
bits(128) operand2 = V[n];
bits(128) result;
result = operand1 EOR operand2;
result = AESInvSubBytes(AESInvShiftRows(result));
V[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.8 AESE

AES single round encryption.

Advanced SIMD variant

AESE <V_d>.16B, <V_n>.16B

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if !HaveAESExt() then UNDEFINED;

Assembler symbols

<V_d> Is the name of the SIMD&FP source and destination register, encoded in the "Rd" field.
<V_n> Is the name of the second SIMD&FP source register, encoded in the "Rn" field.

Operation

AArch64.CheckFPAdvSIMDEnabled();

bits(128) operand1 = V[d];
bits(128) operand2 = V[n];
bits(128) result;
result = operand1 EOR operand2;
result = AESSubBytes(AESShiftRows(result));
V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.9 AESIMC

AES inverse mix columns.

### Advanced SIMD variant

AESIMC <Vd>.16B, <Vn>.16B

### Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HaveAESExt() then UNDEFINED;
```

### Assembler symbols

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

### Operation

```plaintext
AArch64.CheckFPAdvSIMDEnabled();

bits(128) operand = V[n];
bits(128) result;
result = AESInvMixColumns(operand);
V[d] = result;
```

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.10 AESMC

AES mix columns.

\[
\begin{array}{cccccccccccccccccc}
0 & 1 & 0 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & \mid & Rn & Rd & D
\end{array}
\]

**Advanced SIMD variant**

AESMC \(\langle V_d \rangle.16B, \langle V_n \rangle.16B\)

**Decode for this encoding**

\[
\text{integer } d = \text{UInt}(Rd);
\text{integer } n = \text{UInt}(Rn);
\text{if } !\text{HaveAESExt}() \text{ then UNDEFINED;}
\]

**Assembler symbols**

\(\langle V_d \rangle\) Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\(\langle V_n \rangle\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

\[
\text{AArch64.CheckFPAdvSIMDEnabled();}
\text{bits(128) operand} = V[n];
\text{bits(128) result;}
\text{result} = \text{AESMixColumns}(\text{operand});
\text{V[}d\text{]} = \text{result;}
\]

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.11   AND (vector)

Bitwise AND (vector). This instruction performs a bitwise AND between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
0 | Q | 0 | 1 | 1 | 0 | 0 | 0 | 1 | Rm | 0 | 0 | 0 | 1 | 1 | Rn | Rd | size
```

**Three registers of the same type variant**

AND <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;

**Assembler symbols**

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
result = operand1 AND operand2;
V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.12  BCAX

Bit Clear and Exclusive OR performs a bitwise AND of the 128-bit vector in a source SIMD&FP register and the complement of the vector in another source SIMD&FP register, then performs a bitwise exclusive OR of the resulting vector and the vector in a third source SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when ARMv8.2-SHA is implemented.

ARMv8.2

Advanced SIMD variant

BCAX <Vd>.16B, <Vn>.16B, <Vm>.16B, <Va>.16B

Decode for this encoding

if !HaveSHA3Ext() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<Va> Is the name of the third SIMD&FP source register, encoded in the "Ra" field.

Operation

AArch64.CheckFPAdvSIMDEnabled();

bits(128) Vm = V[m];
bits(128) Vn = V[n];
bits(128) Va = V[a];
V[d] = Vn ^ (Vm & ~Va);

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.13  BIC (vector, immediate)

Bitwise bit Clear (vector, immediate). This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise AND between each result and the complement of an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

16-bit variant

Applies when cmode == 10x1.

BIC <Vd>.<T>, #<imm8>{, LSL #<amount>}

32-bit variant

Applies when cmode == 0xx1.

BIC <Vd>.<T>, #<imm8>{, LSL #<amount>}

Decode for all variants of this encoding

integer rd = UInt(Rd);
integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
  when '0xx01' operation = ImmediateOp_MVNI;
  when '0xx11' operation = ImmediateOp_BIC;
  when '10x01' operation = ImmediateOp_MVNI;
  when '10x11' operation = ImmediateOp_BIC;
  when '110x1' operation = ImmediateOp_MVNI;
  when '1110x' operation = ImmediateOp_MOVI;
  when '11111' // FMOV Dn,#imm is in main FP instruction set
    if Q == '0' then UNDEFINED;
    operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);

Assembler symbols

<Vd> Is the name of the SIMD&FP register, encoded in the "Rd" field.
<T> For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0
8H when Q = 1
For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
2S when Q = 0
4S when Q = 1

<imm8> Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

<amount> For the 16-bit variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:
0 when cmode<1> = 0
8 when cmode<1> = 1
defaulting to 0 if LSL is omitted.

For the 32-bit variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:
0 when cmode<2:1> = 00
8 when cmode<2:1> = 01
16 when cmode<2:1> = 10
24 when cmode<2:1> = 11
defaulting to 0 if LSL is omitted.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
  when ImmediateOp_MOVI
    result = imm;
  when ImmediateOp_MVNI
    result = NOT(imm);
  when ImmediateOp_ORR
    operand = V[rd];
    result = operand OR imm;
  when ImmediateOp_BIC
    operand = V[rd];
    result = operand AND NOT(imm);

V[rd] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.14 **BIC (vector, register)**

Bitwise bit Clear (vector, register). This instruction performs a bitwise AND between the first source SIMD&FP register and the complement of the second source SIMD&FP register, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

BIC <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

#### Decode for this encoding

```plaintext
ingterator d = UInt(Rd);
ingterator n = UInt(Rn);
ingterator m = UInt(Rm);
ingterator datasize = if Q == '1' then 128 else 64;
```

#### Assembler symbols

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - `8B` when Q = 0
  - `16B` when Q = 1
- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

#### Operation

```plaintext
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
operand2 = NOT(operand2);
result = operand1 AND operand2;
V[d] = result;
```

#### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
BIF

Bitwise Insert if False. This instruction inserts each bit from the first source SIMD&FP register into the destination SIMD&FP register if the corresponding bit of the second source SIMD&FP register is 0, otherwise leaves the bit in the destination register unchanged.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

BIF <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand3;
bits(datasize) operand4 = V[n];
operand1 = V[d];
operand3 = NOT(V[m]);
V[d] = operand1 EOR ((operand1 EOR operand4) AND operand3);

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.16 BIT

Bitwise Insert if True. This instruction inserts each bit from the first source SIMD&FP register into the SIMD&FP destination register if the corresponding bit of the second source SIMD&FP register is 1, otherwise leaves the bit in the destination register unchanged.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.
C7.2.17   BSL

Bitwise Select. This instruction sets each bit in the destination SIMD&FP register to the corresponding bit from the first source SIMD&FP register when the original destination bit was 1, otherwise from the second source SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

BSL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  8B when Q = 0
  16B when Q = 1
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand3;
bits(datasize) operand4 = V[n];
operand1 = V[m];
operand3 = V[d];
V[d] = operand1 EOR ((operand1 EOR operand4) AND operand3);

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
The values of the NZCV flags.
C7.2.18 CLS (vector)

Count Leading Sign bits (vector). This instruction counts the number of consecutive bits following the most significant bit that are the same as the most significant bit in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The count does not include the most significant bit itself.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Vector variant

CLS \(<Vd>.<T>, <Vn>.<T>\)

#### Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

CountOp countop = if U == '1' then CountOp_CLZ else CountOp_CLS;
```

#### Assembler symbols

- \(<Vd>\): Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- \(<T>\): Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 2S when size = 10, Q = 0
  - 4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

- \(<Vn>\): Is the name of the SIMD&FP source register, encoded in the "Rn" field.

#### Operation

```plaintext
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

integer count;
for e = 0 to elements-1
  if countop == CountOp_CLS
    count = CountLeadingSignBits(Elem[operand, e, esize]);
  else
```
count = CountLeadingZeroBits(Elem[operand, e, esize]);
Elem[result, e, esize] = count<esize-1:0>;
V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.19  CLZ (vector)

Count Leading Zero bits (vector). This instruction counts the number of consecutive zeros, starting from the most significant bit, in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

CLZ <Vd>.<T>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
CountOp countop = if U == '1' then CountOp_CLZ else CountOp_CLS;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
   8B when size = 00, Q = 0
   16B when size = 00, Q = 1
   4H when size = 01, Q = 0
   8H when size = 01, Q = 1
   2S when size = 10, Q = 0
   4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
bites(datasize) operand = V[n];
bites(datasize) result;

integer count;
for e = 0 to elements-1
  if countop == CountOp_CLS then
    count = CountLeadingSignBits(Elem[operand, e, esize]);
  else
count = CountLeadingZeroBits(Elem[operand, e, esize]);
Elem[result, e, esize] = count<esize-1:0>;
V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.20 CMEQ (register)

Compare bitwise Equal (vector). This instruction compares each vector element from the first source SIMD&FP register with the corresponding vector element from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.22 CMGE (register)

Compare signed Greater than or Equal (vector). This instruction compares each vector element in the first source SIMD&FP register with the corresponding vector element in the second source SIMD&FP register and if the first signed integer value is greater than or equal to the second signed integer value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

\(<V>\)  Is a width specifier, encoded in the "size" field. It can have the following values:

D when size = 11
The following encodings are reserved:

- size = 0x.
- size = 10.

<d>
Is the number of the SIMD&FP destination register, in the "Rd" field.

<n>
Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m>
Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd>
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T>
Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn>
Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm>
Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
boolean test_passed;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    test_passed = if cmp_eq then element1 >= element2 else element1 > element2;
    Elem[result, e, esize] = if test_passed then Ones() else Zeros();
V[d] = result;
```

**Operational information**

Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean cmp_eq = (eq == '1');
```

Assembler symbols

```
<V> Is a width specifier, encoded in the "size" field. It can have the following values:
D when size = 11
```

C7-1308
The following encodings are reserved:

- size = 0x.
- size = 10.

- Is the number of the SIMD&FP destination register, in the "Rd" field.
- Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
- Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 2S when size = 10, Q = 0
  - 4S when size = 10, Q = 1
  - 2D when size = 11, Q = 1
  The encoding size = 11, Q = 0 is reserved.

- Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
b bits(datasize) operand1 = V[n];
b bits(datasize) operand2 = V[m];
b bits(datasize) result;
integer element1;
integer element2;
boolean test_passed;
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    test_passed = if cmp_eq then element1 >= element2 else element1 > element2;
    Elem[result, e, esize] = if test_passed then Ones() else Zeros();
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.28 CMLE (zero)

Compare signed Less than or Equal to zero (vector). This instruction reads each vector element in the source SIMD&FP register and if the signed integer value is less than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Operational information

If \text{PSTATE.DIT} is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.30 CMTST

Compare bitwise Test bits nonzero (vector). This instruction reads each vector element in the first source SIMD&FP register, performs an AND with the corresponding vector element in the second source SIMD&FP register, and if the result is not zero, sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

CMTST <V><d>, <V><n>, <V><m>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size != '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean and_test = (U == '0');

Vector

Vector variant

CMTST <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean and_test = (U == '0');

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

D when size = 11

The following encodings are reserved:

• size = 0x.
• **size = 10.**

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
boolean test_passed;
for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if and_test then
        test_passed = !IsZero(element1 AND element2);  
    else
        test_passed = (element1 == element2);
    Elem[result, e, esize] = if test_passed then Ones() else Zeros();
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.31 CNT

Population Count per byte. This instruction counts the number of bits that have a value of one in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

CNT <Vd>.<T>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if size != '00' then UNDEFINED;
integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

integer count;
for e = 0 to elements-1
    count = BitCount(Elem[operand, e, esize]);
    Elem[result, e, esize] = count<esize-1:0>;
V[d] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.32   DUP (element)

Duplicate vector element to vector or scalar. This instruction duplicates the vector element at the specified element index in the source SIMD&FP register into a scalar or each element in a vector, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (scalar). The alias is always the preferred disassembly.

Scalar

DUP <V><d>, <Vn>.<T>[<index>]

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;

integer index = UInt(imm5<4:size+1>);
integer idxdsize = if imm5<4> == '1' then 128 else 64;

integer esize = 8 << size;
integer datasize = esize;
integer elements = 1;

Vector

DUP <Vd>.<T>, <Vn>.<Ts>[<index>]

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;

integer index = UInt(imm5<4:size+1>);
integer idxdsize = if imm5<4> == '1' then 128 else 64;

if size == 3 && Q == '0' then UNDEFINED;
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
Assembler symbols

\(<T>\) For the scalar variant: is the element width specifier, encoded in the "imm5" field. It can have the following values:

- \(B\) when \(imm5 = xxxx1\)
- \(H\) when \(imm5 = xxx10\)
- \(S\) when \(imm5 = xx100\)
- \(D\) when \(imm5 = x1000\)

The encoding \(imm5 = x0000\) is reserved.

For the vector variant: is an arrangement specifier, encoded in the "imm5:Q" field. It can have the following values:

- \(8B\) when \(imm5 = xxxx1, Q = 0\)
- \(16B\) when \(imm5 = xxxx1, Q = 1\)
- \(4H\) when \(imm5 = xxx10, Q = 0\)
- \(8H\) when \(imm5 = xxx10, Q = 1\)
- \(2S\) when \(imm5 = xx100, Q = 0\)
- \(4S\) when \(imm5 = xx100, Q = 1\)
- \(2D\) when \(imm5 = x1000, Q = 1\)

The following encodings are reserved:

- \(imm5 = x0000, Q = x\)
- \(imm5 = x1000, Q = 0\).

\(<Ts>\) Is an element size specifier, encoded in the "imm5" field. It can have the following values:

- \(B\) when \(imm5 = xxxx1\)
- \(H\) when \(imm5 = xxx10\)
- \(S\) when \(imm5 = xx100\)
- \(D\) when \(imm5 = x1000\)

The encoding \(imm5 = x0000\) is reserved.

\(<V>\) Is the destination width specifier, encoded in the "imm5" field. It can have the following values:

- \(B\) when \(imm5 = xxxx1\)
- \(H\) when \(imm5 = xxx10\)
- \(S\) when \(imm5 = xx100\)
- \(D\) when \(imm5 = x1000\)

The encoding \(imm5 = x0000\) is reserved.

\(<Vn>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

\(<index>\) Is the element index encoded in the "imm5" field. It can have the following values:

- \(imm5<4:1>\) when \(imm5 = xxxx1\)
- \(imm5<4:2>\) when \(imm5 = xxx10\)
- \(imm5<4:3>\) when \(imm5 = xx100\)
- \(imm5<4>\) when \(imm5 = x1000\)

The encoding \(imm5 = x0000\) is reserved.

\(<d>\) Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

\(<Vd>\) Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n];
bits(datasize) result;
bits(esize) element;

element = Elem[operand, index, esize];
for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.33   DUP (general)

Duplicate general-purpose register to vector. This instruction duplicates the contents of the source general-purpose register into a scalar or each element in a vector, and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15 14 13 12|11 10 9 |  5 4 |  0 |
|0  Q  0  1  1  1  0  0  0 | imm5 | 0  0  0  1  1 | Rn |  Rd |
```

**Advanced SIMD variant**

DUP <Vd>.<T>, <R><n>

**Decode for this encoding**

```plaintext
integer d = Uint(Rd);
integer n = Uint(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;
// imm5<4:size+1> is IGNORED
if size == 3 && Q == '0' then UNDEFINED;
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

**Assembler symbols**

- `<Vd>` is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` is an arrangement specifier, encoded in the "imm5:Q" field. It can have the following values:
  - 8B when imm5 = xxxx1, Q = 0
  - 16B when imm5 = xxxx1, Q = 1
  - 4H when imm5 = xxx10, Q = 0
  - 8H when imm5 = xxx10, Q = 1
  - 2S when imm5 = xx100, Q = 0
  - 4S when imm5 = xx100, Q = 1
  - 2D when imm5 = x1000, Q = 1

The following encodings are reserved:
- imm5 = x0000, Q = x.
- imm5 = x1000, Q = 0.

- `<R>` is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:
  - W when imm5 = xxxx1
  - W when imm5 = xxxx10
  - W when imm5 = xx100
  - X when imm5 = x1000
The encoding \( \text{imm5} = x0000 \) is reserved. Unspecified bits in "imm5" are ignored but should be set to zero by an assembler.

\(<n> \) Is the number \([0-30]\) of the general-purpose source register or ZR (31), encoded in the "Rn" field.

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n];
bits(datasize) result;
for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.34 EOR (vector)

Bitwise Exclusive OR (vector). This instruction performs a bitwise Exclusive OR operation between the two source SIMD&FP registers, and places the result in the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15 14 13 12|11 10 9 | 5 4 | 0 |
|---|---|---|---|---|---|---|---|---|
| 0 | Q | 1 | 0 | 1 | 1 | 0 | 0 | 1 |
| Rm | 0 | 0 | 0 | 1 | 1 | Rn | Rd |

Three registers of the same type variant
EOR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;

Assemble symbols
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
   8B when Q = 0
   16B when Q = 1
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;

V[d] = operand1 EOR ((operand2 EOR operand4) AND operand3);

Operational information
If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
The values of the NZCV flags.
C7.2.35 EOR3

Three-way Exclusive OR performs a three-way exclusive OR of the values in the three source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when ARMv8.2-SHA is implemented.

ARMv8.2

| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15 14 | 10 9 | 5 4 | 0 |

EOR3 <Vd>.16B, <Vn>.16B, <Vm>.16B, <Va>.16B

**Decode for this encoding**

if !HaveSHA3Ext() then UNDEFINED;
integer d = UInt(Rd);
intrinsic n = UInt(Rn);
intrinsic m = UInt(Rm);
intrinsic a = UInt(Ra);

**Assembler symbols**

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<Va> Is the name of the third SIMD&FP source register, encoded in the "Ra" field.

**Operation**

AArch64.CheckFPAdvSIMDEnabled();

bits(128) Vm = V[m];
bits(128) Vn = V[n];
bits(128) Va = V[a];
V[d] = Vn EOR Vm EOR Va;

**Operational information**

If PSTATE.DBT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.36   EXT

Extract vector from pair of vectors. This instruction extracts the lowest vector elements from the second source SIMD&FP register and the highest vector elements from the first source SIMD&FP register, concatenates the results into a vector, and writes the vector to the destination SIMD&FP register vector. The index value specifies the lowest vector element to extract from the first source register, and consecutive elements are extracted from the first, then second, source registers until the destination vector is filled.

The following figure shows the operation of EXT doubleword operation for Q = 0 and imm4<2:0> = 3.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

EXT <Vd>.<T>, <Vn>.<T>, <Vm>.<T>, #<index>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if Q == '0' && imm4<3> == '1' then UNDEFINED;
integer datasize = if Q == '1' then 128 else 64;
integer position = UInt(imm4) << 3;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
   8B when Q = 0
   16B when Q = 1
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<index> Is the lowest numbered byte element to be extracted, encoded in the "Q:imm4" field. It can have the following values:
   imm4<2:0> when Q = 0, imm4<3> = 0
   imm4 when Q = 1, imm4<3> = x
The encoding Q = 0, imm4<3> = 1 is reserved.
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) hi = V[m];
bits(datasize) lo = V[n];
bits(datasize*2) concat = hi:lo;

V[d] = concat<position+datasize-1:position>;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.37 FABD

Floating-point Absolute Difference (vector). This instruction subtracts the floating-point values in the elements of the second source SIMD&FP register, from the corresponding floating-point values in the elements of the first source SIMD&FP register, places the absolute value of each result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Floating-point Absolute Compare Greater than (vector). This instruction compares the absolute value of each vector element in the first source SIMD&FP register with the absolute value of the corresponding vector element in the second source SIMD&FP register and if the first value is greater than the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_FADD, operand, esize);
```
C7.2.45  FADDP (vector)

Floating-point Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    element2 = Elem[operand2, e, esize];
  Elem[result, e, esize] = FPAdd(element1, element2, FPCR);
V[d] = result;
C7.2.46  FCADD

Floating-point Complex Add.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
2D when size = 11, Q = 1

The following encodings are reserved:

- size = 00, Q = x.
- size = 11, Q = 0.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<rotate> Is the rotation, encoded in the "rot" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>90</td>
<td>when rot = 0</td>
</tr>
<tr>
<td>270</td>
<td>when rot = 1</td>
</tr>
</tbody>
</table>

**Operation**

```plaintext
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;
bits(esize) element1;
bits(esize) element3;

for e = 0 to (elements DIV 2)-1
  case rot of
    when '0'
      element1 = FPNeg(Elem[operand2, e*2+1, esize]);
      element3 = Elem[operand2, e*2, esize];
    when '1'
      element1 = Elem[operand2, e*2+1, esize];
      element3 = FPNeg(Elem[operand2, e*2, esize]);
  Elem[result, e*2, esize] = FPAdd(Elem[operand1, e*2, esize], element1, FPCR);
  Elem[result, e*2+1, esize] = FPAdd(Elem[operand1, e*2+1, esize], element3, FPCR);
V[d] = result;
```
C7.2.47  FCCMP

Floating-point Conditional quiet Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE. {N, Z, C, V} flags. If the condition does not pass then the PSTATE. {N, Z, C, V} flags are set to the flag bit specifier.

It raises an Invalid Operation exception only if either operand is a signaling NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision variant
Applies when ftype == 11.

FCCMP <Hn>, <Hm>, #<nzcv>, <cond>

Single-precision variant
Applies when ftype == 00.

FCCMP <Sn>, <Sm>, #<nzcv>, <cond>

Double-precision variant
Applies when ftype == 01.

FCCMP <Dn>, <Dm>, #<nzcv>, <cond>

Decode for all variants of this encoding

bits(4) flags = nzcv;

Assembler symbols

<Dn>  Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<Dm>  Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<Hn>  Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit
NZCV condition flags, encoded in the "nzcv" field.

<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either
or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 ==
Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1,
and V=1.

Operation

CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = V[m];
if ConditionHolds(cond) then
    flags = FPCompare(operand1, operand2, FALSE, FPCR);
PSTATE.<N,Z,C,V> = flags;
C7.2.48  FCCMPE

Floating-point Conditional signaling Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE.{N, Z, C, V} flags. If the condition does not pass then the PSTATE.{N, Z, C, V} flags are set to the flag bit specifier.

If either operand is any type of NaN, or if either operand is a signaling NaN, the instruction raises an Invalid Operation exception.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

                UNDEFINED;
    endcase

bits(4) flags = nzcv;
```

Assembler symbols

- `<Dn>` Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Dm>` Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<hn> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

**NaNs**

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1, and V=1.

FCOMPE raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

**Operation**

```
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = V[m];
if ConditionHolds(cond) then
    flags = FPCompare(operand1, operand2, TRUE, FPCR);
PSTATE.<N,Z,C,V> = flags;
```
C7.2.49   FCMEQ (register)

Floating-point Compare Equal (vector). This instruction compares each floating-point value from the first source SIMD&FP register, with the corresponding floating-point value from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

V[d] = result;
C7.2.51  FCMGE (register)

Floating-point Compare Greater than or Equal (vector). This instruction reads each floating-point value in the first source SIMD&FP register and if the value is greater than or equal to the corresponding floating-point value in the second source SIMD&FP register sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.52 FCMGE (zero)

Floating-point Compare Greater than or Equal to zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is greater than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.55 FCMLA (by element)

Floating-point Complex Multiply Accumulate (by element).

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on complex numbers from the first source register and the destination register with the specified complex number from the second source register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

V[d] = result;
C7.2.59   FCMP

Floating-point quiet Compare (scalar). This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the PSTATE. \{N, Z, C, V\} flags.

It raises an Invalid Operation exception only if either operand is a signaling NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Decode for all variants of this encoding**

```plaintext
integer n = UInt(Rn);
integer m = UInt(Rm); // ignored when opc<0> == '1'

integer datasize;
case ftype of
  when '00' datasize = 32;
  when '01' datasize = 64;
```

Integer arithmetic operations can be executed when opc<1> == '0', and floating-point operations can be executed when opc<1> == '1'.
when '10' UNDEFINED;
when '11' if HaveFP16Ext() then
datasize = 16;
else
    UNDEFINED;

boolean signal_all_nans = (opc<1> == '1');
boolean cmp_with_zero = (opc<0> == '1');

Assembler symbols

<Dn>
For the double-precision variant: is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
For the double-precision, zero variant: is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Hn>
For the half-precision variant: is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
For the half-precision, zero variant: is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Hm>
Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Sn>
For the single-precision variant: is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Sm>
Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

NaNs
The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1, and V=1.

Operation

CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;

operand2 = if cmp_with_zero then FPZero('0') else V[m];

PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR);
C7.2.60  FCMPE

Floating-point signaling Compare (scalar). This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the PSTATE.\{N, Z, C, V\} flags.

If either operand is any type of NaN, or if either operand is a signaling NaN, the instruction raises an Invalid Operation exception.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
| 31 30 29 28|27 26 25 24|23 22 21 20| 16|15 14 13 12|11 10 9 | 5 4 3 2 1 0 |
| 0 0 0 |1 1 1 0 |type 1 | Rm | 0 0 |1 0 0 0 | Rn |1 x 0 0 0 |

Half-precision variant

Applies when ftype == 11 && opc == 10.
FCMPE <Hn>, <Hm>

Half-precision, zero variant

Applies when ftype == 11 && Rm == (00000) && opc == 11.
FCMPE <Hn>, #0.0

Single-precision variant

Applies when ftype == 00 && opc == 10.
FCMPE <Sn>, <Sm>

Single-precision, zero variant

Applies when ftype == 00 && Rm == (00000) && opc == 11.
FCMPE <Sn>, #0.0

Double-precision variant

Applies when ftype == 01 && opc == 10.
FCMPE <Dn>, <Dm>

Double-precision, zero variant

Applies when ftype == 01 && Rm == (00000) && opc == 11.
FCMPE <Dn>, #0.0

Decode for all variants of this encoding

Assembler symbols

<Dn> For the double-precision variant: is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
For the double-precision, zero variant: is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Hn> For the half-precision variant: is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
For the half-precision, zero variant: is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Sn> For the single-precision variant: is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1, and V=1.

FCMPE raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

Operation

CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = if cmp_with_zero then FPZero('0') else V[m];
PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR);
C7.2.61   FCSEL

Floating-point Conditional Select (scalar). This instruction allows the SIMD&FP destination register to take
the value from either one or the other of two SIMD&FP source registers. If the condition passes, the first SIMD&FP
source register value is taken, otherwise the second SIMD&FP source register value is taken.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
result = if ConditionHolds(cond) then V[n] else V[m];
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.62   FCVT

Floating-point Convert precision (scalar). This instruction converts the floating-point value in the SIMD&FP source register to the precision for the destination register data type using the rounding mode that is determined by the FPCR and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<V> Is a width specifier, encoded in the "sz" field. It can have the following values:
- S when sz = 0
- D when sz = 1

<db> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 4H  when Q = 0
- 8H  when Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- 2S  when sz = 0, Q = 0
- 4S  when sz = 0, Q = 1
- 2D  when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, 0, unsigned, FPCR, rounding);

V[d] = result;
```
C7.2.64  **FCVTAS (scalar)**

Floating-point Convert to Signed integer, rounding to nearest with ties to Away (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round to Nearest with Ties to Away rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<V> Is a width specifier, encoded in the "sz" field. It can have the following values:
  S when sz = 0
  D when sz = 1
<bd> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
4H  when Q = 0
8H  when Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
2S  when sz = 0, Q = 0
4S  when sz = 0, Q = 1
2D  when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

    CheckFPAdvSIMDEnabled64();
    bits(datasize) operand = V[n];
    bits(datasize) result;
    bits(esize) element;

    for e = 0 to elements-1
        element = Elem[operand, e, esize];
        Elem[result, e, esize] = FPToFixed(element, 0, unsigned, FPCR, rounding);

    V[d] = result;
C7.2.66 FCVTAU (scalar)

Floating-point Convert to Unsigned integer, rounding to nearest with ties to Away (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit unsigned integer using the Round to Nearest with Ties to Away rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    fltsize = 16;
  else
    UNDEFINED;

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Dn> Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
b bits(fltsize) fltval;
b bits(intsize) intval;
fltval = V[n];
intval = FPToFixed(fltval, 0, TRUE, FPCR, FPRounding_TIEAWAY);
X[d] = intval;
C7.2.67   FCVTL, FCVTL2

Floating-point Convert to higher precision Long (vector). This instruction reads each element in a vector in the
SIMD&FP source register, converts each value to double the precision of the source element using the rounding
mode that is determined by the FPCR, and writes each result to the equivalent element of the vector in the
SIMD&FP destination register.

Where the operation lengthens a 64-bit vector to a 128-bit vector, the FCVTL2 variant operates on the elements in the
top 64 bits of the source register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception
results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

Decode for this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } esize &= 16 \ll \text{UInt}(sz); \\
\text{integer } datasize &= 64; \\
\text{integer } part &= \text{UInt}(Q); \\
\text{integer } elements &= \text{datasize} \div esize;
\end{align*}
\]

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper
64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have
the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "sz" field. It can have the following values:
4S when sz = 0
2D when sz = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
4H when sz = 0, Q = 0
8H when sz = 0, Q = 1
2S when sz = 1, Q = 0
4S when sz = 1, Q = 1
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(2*datasize) result;

for e = 0 to elements-1
    Elem[result, e, 2*esize] = FPConvert(Elem[operand, e, esize], FPCR);

V[d] = result;
C7.2.68 FCVTMS (vector)

Floating-point Convert to Signed integer, rounding toward Minus infinity (vector). This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round towards Minus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

```
C7.2.71 FCVTMU (scalar)

Floating-point Convert to Unsigned integer, rounding toward Minus infinity (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit unsigned integer using the Round towards Minus Infinity rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Half-precision to 32-bit variant**
Applies when \( sf == 0 \) \&\& \( ftype == 11 \).

FCVTMU \(<Wd>, <Hn>\)

**Half-precision to 64-bit variant**
Applies when \( sf == 1 \) \&\& \( ftype == 11 \).

FCVTMU \(<Xd>, <Hn>\)

**Single-precision to 32-bit variant**
Applies when \( sf == 0 \) \&\& \( ftype == 00 \).

FCVTMU \(<Wd>, <Sn>\)

**Single-precision to 64-bit variant**
Applies when \( sf == 1 \) \&\& \( ftype == 00 \).

FCVTMU \(<Xd>, <Sn>\)

**Double-precision to 32-bit variant**
Applies when \( sf == 0 \) \&\& \( ftype == 01 \).

FCVTMU \(<Wd>, <Dn>\)

**Double-precision to 64-bit variant**
Applies when \( sf == 1 \) \&\& \( ftype == 01 \).

FCVTMU \(<Xd>, <Dn>\)

**Decode for all variants of this encoding**

\[
\begin{align*}
\text{integer } d & = \text{UInt(Rd)}; \\
\text{integer } n & = \text{UInt(Rn)}; \\
\text{integer } \text{intsize} & = \text{if } sf == '1' \text{ then 64 else } 32; \\
\text{integer } \text{fltsize} & = \text{FPRounding } \text{rounding};
\end{align*}
\]
case ftype of

            fltsize = 16;
        else
            UNDEFINED;
    rounding = FPDecodeRounding(rmode);

Assemble symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Dn> Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();

bits(fltsize) fltval;
bits(intsize) intval;
fltval = V[n];
intval = FPToFixed(fltval, 0, TRUE, FPCR, rounding);
X[d] = intval;
C7.2.72 FCVTN, FCVTN2

Floating-point Convert to lower precision Narrow (vector). This instruction reads each vector element in the SIMD&FP source register, converts each result to half the precision of the source element, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The rounding mode is determined by the FPCR.

The FCVTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the FCVTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Vector single-precision and double-precision variant

FCVTN{2} <Vd>.<Tb>, <Vn>.<Ta>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16 << UInt(sz);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

4H when sz = 0, Q = 0
8H when sz = 0, Q = 1
2S when sz = 1, Q = 0
4S when sz = 1, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "sz" field. It can have the following values:

4S when sz = 0
2D when sz = 1

**Operation**

```c
CheckFPAdvSIMDEnabled64();

bits(2*datasize) operand = V[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = FPConvert(Elem[operand, e, 2*esize], FPCR);

Vpart[d, part] = result;
```

C7.2.73 FCVTNS (vector)

Floating-point Convert to Signed integer, rounding to nearest with ties to even (vector). This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round to Nearest rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

fltval = V[n];
intval = FPtoFixed(fltval, 0, TRUE, FPCR, rounding);
X[d] = intval;
C7.2.81  **FCVTXN, FCVTXN2**

Floating-point Convert to lower precision Narrow, rounding to odd (vector). This instruction reads each vector element in the source SIMD&FP register, narrows each value to half the precision of the source element using the Round to Odd rounding mode, writes the result to a vector, and writes the vector to the destination SIMD&FP register.

--- Note ---

This instruction uses the Round to Odd rounding mode which is not defined by the IEEE 754-2008 standard. This rounding mode ensures that if the result of the conversion is inexact the least significant bit of the mantissa is forced to 1. This rounding mode enables a floating-point value to be converted to a lower precision format via an intermediate precision format while avoiding double rounding errors. For example, a 64-bit floating-point value can be converted to a correctly rounded 16-bit floating-point value by first using this instruction to produce a 32-bit value and then using another instruction with the wanted rounding mode to convert the 32-bit value to the final 16-bit floating-point value.

The FCVTXN instruction writes the vector to the lower half of the destination register and clears the upper half, while the FCVTXN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps on page D1-2184*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

if sz == '0' then UNDEFINED;
integer esize = 32;
integer datasize = 64;
integer elements = 2;
integer part = UInt(Q);

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
   [absent] when Q = 0
   [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
   2S when sz = 1, Q = 0
   4S when sz = 1, Q = 1

The encoding sz = 0, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "sz" field. It can have the following values:
   2D when sz = 1

The encoding sz = 0 is reserved.

<Vb> Is the destination width specifier, encoded in the "sz" field. It can have the following values:
   S when sz = 1

The encoding sz = 0 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Va> Is the source width specifier, encoded in the "sz" field. It can have the following values:
   D when sz = 1

The encoding sz = 0 is reserved.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;

for e = 0 to elements-1
   Elem[result, e, esize] = FPConvert(Elem[operand, e, 2*esize], FPCR, FPRounding_ODD);

Vpart[d, part] = result;
C7.2.82 FCVTZS (vector, fixed-point)

Floating-point Convert to Signed fixed-point, rounding toward Zero (vector). This instruction converts a scalar or each element in a vector from floating-point to fixed-point signed integer using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

<sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

result = FPDiv(operand1, operand2, FPCR);

V[d] = result;
```
C7.2.92   FJCVTZS

Floating-point Javascript Convert to Signed fixed-point, rounding toward Zero. This instruction converts the
double-precision floating-point value in the SIMD&FP source register to a 32-bit signed integer using the Round
towards Zero rounding mode, and writes the result to the general-purpose destination register. If the result is too
large to be accommodated as a signed 32-bit integer, then the result is the integer modulo 2^{32}, as held in a 32-bit
signed integer.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results
in either a flag being set in FPSR or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

ARMv8.3

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 16|14 13 12|11 10 9 | 5 4 | 0 ]

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Dn> Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.
```

Operation

```
CheckFPAdvSIMDEnabled64();
bits(64) fltval;
bits(32) intval;
fltval = V[n];
intval = FPToFixedJS(fltval, FPCR, TRUE);
X[d] = ZeroExtend(intval<31:0>, 64);
```
**C7.2.93  FMADD**

Floating-point fused Multiply-Add (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, adds the product to the value of the third SIMD&FP source register, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see "Floating-point exceptions and exception traps" on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.95   FMAX (scalar)

Floating-point Maximum (scalar). This instruction compares the two source SIMD&FP registers, and writes the larger of the two floating-point values to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision variant
Applies when ftype == 11.
FMAX <Hd>, <Hn>, <Hm>

Single-precision variant
Applies when ftype == 00.
FMAX <Sd>, <Sn>, <Sm>

Double-precision variant
Applies when ftype == 01.
FMAX <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```plaintext
d = UInt(Rd);
n = UInt(Rn);
m = UInt(Rm);

datasize =
case ftype of
    when '00' : datasize = 32;
    when '01' : datasize = 64;
    when '10' : UNDEFINED;
    when '11' : if HaveFP16Ext() then datasize = 16; else UNDEFINED;
end
```

Assembler symbols

- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
- <Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Hn> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

result = FPMax(operand1, operand2, FPCR);
V[d] = result;
```
C7.2.96  **FMAXNM (vector)**

Floating-point Maximum Number (vector). This instruction compares corresponding vector elements in the two source SIMD&FP registers, writes the larger of the two floating-point values into a vector, and writes the vector to the destination SIMD&FP register.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result placed in the vector is the numerical value, otherwise the result is identical to FMAX (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

\[
\langle V \rangle
\]

For the half-precision variant: is the destination width specifier, encoded in the "sz" field. It can have the following values:

\[
\text{H} \quad \text{when} \ \text{sz} = 0
\]

The encoding sz = 1 is reserved.
For the single-precision and double-precision variant: is the destination width specifier, encoded in the "sz" field. It can have the following values:
S when sz = 0
D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
</d>

</Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
</Vn>

</T> For the half-precision variant: is the source arrangement specifier, encoded in the "sz" field. It can have the following values:
2H when sz = 0
The encoding sz = 1 is reserved.

For the single-precision and double-precision variant: is the source arrangement specifier, encoded in the "sz" field. It can have the following values:
2S when sz = 0
2D when sz = 1

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_FMAXNUM, operand, esize);
C7.2.99 FMAXNMP (vector)

Floating-point Maximum Number Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result is the numerical value, otherwise the result is identical to FMAX (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  if minimum then
    Elem[result, e, esize] = FPMin(element1, element2, FPCR);
  else
    Elem[result, e, esize] = FPMax(element1, element2, FPCR);
V[d] = result;
C7.2.103  **FMAXV**

Floating-point Maximum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### Single-precision and double-precision variant

FMAXV <V><d>, <Vn>.<T>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q != '01' then UNDEFINED;

integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;

### Assembler symbols

<V>  
For the half-precision variant: is the destination width specifier, H.
For the single-precision and double-precision variant: is the destination width specifier, encoded in the "sz" field. It can have the following values:
5 when sz = 0
The encoding sz = 1 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
4H when Q = 0
8H when Q = 1

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "Q:sz" field. It can have the following values:
4S when Q = 1, sz = 0

The following encodings are reserved:
• Q = 0, sz = x.
• Q = 1, sz = 1.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bpts(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_FMAX, operand, esize);
C7.2.104 FMIN (vector)

Floating-point minimum (vector). This instruction compares corresponding elements in the vectors in the two source SIMD&FP registers, places the smaller of each of the two floating-point values into a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

V[d] = Reduce(ReduceOp_FMINNUM, operand, esize);
```
C7.2.109 FMINNMP (vector)

Floating-point Minimum Number Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of floating-point values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result is the numerical value, otherwise the result is identical to FMIN (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

      Elem[result, e, esize] = FPMaxNum(element1, element2, FPCR);

V[d] = result;
C7.2.110  FMINNMV

Floating-point Minimum Number across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result of the comparison is the numerical value, otherwise the result is identical to FMIN (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

V[d] = result;
C7.2.115  FMLA (vector)

Floating-point fused Multiply-Add to accumulator (vector). This instruction multiplies corresponding floating-point values in the vectors in the two source SIMD&FP registers, adds the product to the corresponding vector element of the destination SIMD&FP register, and writes the result to the destination SIMD&FP register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

\(<V_d>\) Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\(<T>\) For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- \(4H\) when \(Q = 0\)
- \(8H\) when \(Q = 1\)

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- \(2S\) when \(sz = 0, Q = 0\)
- \(4S\) when \(sz = 0, Q = 1\)
- \(2D\) when \(sz = 1, Q = 1\)

The encoding \(sz = 1, Q = 0\) is reserved.

\(<V_n>\) Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<V_m>\) Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();

    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if sub_op then element1 = FPNeg(element1);
    Elem[result, e, esize] = FPMulAdd(Elem[operand3, e, esize], element1, element2, FPCR);

V[d] = result;
```
C7.2.116  **FMLAL, FMLAL2 (by element)**

Floating-point fused Multiply-Add Long to accumulator (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an optional instruction. From Armv8.4 it is mandatory for all implementations to support it.

______ Note ________
ID_AA64ISAR0_EL1.FHM indicates whether this instruction is supported.

C7.2.120   FMLSL, FMLSL2 (by element)

Floating-point fused Multiply-Subtract Long from accumulator (by element). This instruction multiplies the
negated vector elements in the first source SIMD&FP register by the specified value in the second source
SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP
register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception
results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations
to support it.

Note

ID_AA64ISAR0_EL1.FHM indicates whether this instruction is supported.

FMLSL

ARMv8.2

FMLSL <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.H[<index>]

Decode for this encoding

if !HaveFP16uNoRoundingToFP32Ext() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt('0':Rm);    // Vm can only be in bottom 16 registers.
if sz == '1' then UNDEFINED;
integer index = UInt(H:L:M);
integer esize = 32;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean sub_op = (S == '1');
integer part = 0;

FMLSL2

ARMv8.2

FMLSL2 <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.H[<index>]

0
**Decode for this encoding**

```c
if !HaveFP16MulNoRoundingToFP32Ext() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt('0':Rm); //Vm can only be in bottom 16 registers.
if sz == '1' then UNDEFINED;
integer index = UInt(H:L:M);

integer esize = 32;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean sub_op = (S == '1');
integer part = 1;
```

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Ta>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 2S when Q = 0
  - 4S when Q = 1
- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Tb>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 2H when Q = 0
  - 4H when Q = 1
- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
- `<index>` Is the element index, encoded in the "H:L:M" fields.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize DIV 2) operand1 = Vpart[n, part];
bits(128) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;
bits(esize DIV 2) element1;
bits(esize DIV 2) element2 = Elem[operand2, index, esize DIV 2];

for e = 0 to elements-1
  element1 = Elem[operand1, e, esize DIV 2];
  if sub_op then element1 = FPNeg(element1);
  Elem[result, e, esize] = FPMulAddH(Elem[operand3, e, esize], element1, element2, FPCR);
V[d] = result;
```
C7.2.121 **FMLSL, FMLSL2 (vector)**

Floating-point fused Multiply-Subtract Long from accumulator (vector). This instruction negates the values in the vector of one SIMD&FP register, multiplies these with the corresponding values in another vector, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

--- **Note** ---

ID_AA64ISAR0_EL1.FHM indicates whether this instruction is supported.

V[d] = result;
C7.2.122  FMOV (vector, immediate)

Floating-point move immediate (vector). This instruction copies an immediate floating-point constant into every element of the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Half-precision

**ARMv8.2**

Single-precision and double-precision

The following decodings are specific to the ARMv8.2 architecture for single-precision and double-precision floating-point operations.

#### Decoding for half-precision variant

`FMOV <Vd>.<T>, #<imm>`

**Decode for this encoding**

if !HaveFP16Ext() then UNDEFINED;

integer rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;

imm8 = a:b:c:d:e:f:g:h;
imm16 = imm8<7>:NOT(imm8<6>):Replicate(imm8<6>, 2):imm8<5:0>:Zeros(6);

imm = Replicate(imm16, datasize DIV 16);

### Single-precision variant

Applies when `op == 0`.

`FMOV <Vd>.<T>, #<imm>`

**Decode for all variants of this encoding**

integer rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

if cmode:op == '11111' then
  // FMOV Dn,#imm is in main FP instruction set

### Double-precision variant

Applies when `Q == 1 && op == 1`.

`FMOV <Vd>.2D, #<imm>`

if Q == '0' then UNDEFINED;
imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);

Assembler symbols

<v_d> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0
8H when Q = 1

For the single-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

2S when Q = 0
4S when Q = 1

<imm> Is a signed floating-point constant with 3-bit exponent and normalized 4 bits of precision, encoded in "a:b:c:d:e:f:g:h". For details of the range of constants available and the encoding of <imm>, see Modified immediate constants in A64 floating-point instructions on page C2-166.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
V[rd] = imm;
C7.2.123  FMOV (register)

Floating-point Move register without conversion. This instruction copies the floating-point value in the SIMD&FP source register to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision variant
Applies when ftype == 11.
FMOV <Hd>, <Hn>

Single-precision variant
Applies when ftype == 00.
FMOV <Sd>, <Sn>

Double-precision variant
Applies when ftype == 01.
FMOV <Dd>, <Dn>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize;
case ftype of
when '00' datasize = 32;
when '01' datasize = 64;
when '10' UNDEFINED;
when '11'
if HaveFP16Ext() then
  datasize = 16;
else
  UNDEFINED;

Assembler symbols

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Dn> Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.
Operation

CheckFPAdvSIMDEnabled64();

bits(datasize) operand = V[n];

V[d] = operand;
C7.2.124  FMOV (general)

Floating-point Move to or from general-purpose register without conversion. This instruction transfers the contents of a SIMD&FP register to a general-purpose register, or the contents of a general-purpose register to a SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 16|14 13 12|11 10 9 | 5 4 | 0 |
| sf 0 | 0 | 1 | 1 | 1 | 0 | ftype 1 | 0 | x | 1 | 1 | x | 0 | 0 | 0 | 0 | 0 | Rn | Rd |
```

**Half-precision to 32-bit variant**
Applies when \( sf == 0 \) \&\& \( ftype == 11 \) \&\& \( rmode == 00 \) \&\& \( opcode == 110 \).
FMOV <Wd>, <Hn>

**Half-precision to 64-bit variant**
Applies when \( sf == 1 \) \&\& \( ftype == 11 \) \&\& \( rmode == 00 \) \&\& \( opcode == 110 \).
FMOV <Xd>, <Hn>

**32-bit to half-precision variant**
Applies when \( sf == 0 \) \&\& \( ftype == 11 \) \&\& \( rmode == 00 \) \&\& \( opcode == 111 \).
FMOV <Hd>, <Wn>

**32-bit to single-precision variant**
Applies when \( sf == 0 \) \&\& \( ftype == 00 \) \&\& \( rmode == 00 \) \&\& \( opcode == 111 \).
FMOV <Sd>, <Wn>

**Single-precision to 32-bit variant**
Applies when \( sf == 0 \) \&\& \( ftype == 00 \) \&\& \( rmode == 00 \) \&\& \( opcode == 110 \).
FMOV <Wd>, <Sn>

**64-bit to half-precision variant**
Applies when \( sf == 1 \) \&\& \( ftype == 11 \) \&\& \( rmode == 00 \) \&\& \( opcode == 111 \).
FMOV <Hd>, <Xn>

**64-bit to double-precision variant**
Applies when \( sf == 1 \) \&\& \( ftype == 01 \) \&\& \( rmode == 00 \) \&\& \( opcode == 111 \).
FMOV <Db>, <Xn>

**64-bit to top half of 128-bit variant**
Applies when \( sf == 1 \) \&\& \( ftype == 10 \) \&\& \( rmode == 01 \) \&\& \( opcode == 111 \).
FMOV <Vd>.D[1], <Xn>
Double-precision to 64-bit variant

Applies when \( sf = 1 \) && \( ftype = 01 \) && \( rmode = 00 \) && \( opcode = 110 \).

\[ \text{FMOV} <X_d>, <D_n> \]

Top half of 128-bit to 64-bit variant

Applies when \( sf = 1 \) && \( ftype = 10 \) && \( rmode = 01 \) && \( opcode = 110 \).

\[ \text{FMOV} <X_d>, <V_n>.D[1] \]

\end{align*}
\]
Operation

CheckFPAdvSIMDEnabled64();

V[d] = imm;
C7.2.126  FMSUB

Floating-point Fused Multiply-Subtract (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, negates the product, adds that to the value of the third SIMD&FP source register, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<Sn> Is the 32-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register holding the multiplier, encoded in the "Rm" field.

<Sa> Is the 32-bit name of the third SIMD&FP source register holding the minuend, encoded in the "Ra" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand = V[a];
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

operand1 = FPNeg(operand1);
result = FPMulAdd(operand, operand1, operand2, FPCR);
V[d] = result;
```
**C7.2.127 FMUL (by element)**

Floating-point Multiply (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hn> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<V> Is a width specifier, encoded in the "sz" field. It can have the following values:
    S when sz = 0
    D when sz = 1
<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> For the vector, half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
    4H when Q = 0
    8H when Q = 1
For the vector, single-precision and double-precision variant: is an arrangement specifier, encoded in the "Q:sz" field. It can have the following values:
    2S when Q = 0, sz = 0
    4S when Q = 1, sz = 0
    2D when Q = 1, sz = 1
The encoding Q = 0, sz = 1 is reserved.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> For the half-precision variant: is the name of the second SIMD&FP source register, in the range V0 to V15, encoded in the "Rm" field.
For the single-precision and double-precision variant: is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.
<Ts> Is an element size specifier, encoded in the "sz" field. It can have the following values:
    S when sz = 0
    D when sz = 1
<index> For the half-precision variant: is the element index, in the range 0 to 7, encoded in the "H:L:M" fields.
For the single-precision and double-precision variant: is the element index, encoded in the "sz:L:H" field. It can have the following values:
    H:L when sz = 0, L = x
    H when sz = 1, L = 0
The encoding sz = 1, L = 1 is reserved.

\text{V[d] = result;}
\]
C7.2.130  FMULX (by element)

Floating-point Multiply extended (by element). This instruction multiplies the floating-point values in the vector elements in the first source SIMD&FP register by the specified floating-point value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If one value is zero and the other value is infinite, the result is 2.0. In this case, the result is negative if only one of the values is negative, otherwise the result is positive.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  Elem[result, e, esize] = FPMulX(element1, element2, FPCR);
V[d] = result;
```
C7.2.132   FNEG (vector)

Floating-point Negate (vector). This instruction negates the value of each vector element in the source SIMD&FP register, writes the result to a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Half-precision**

\]

Single-precision and double-precision variant

FRECPX <V><d>, <V><n>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;

Assembler symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<V> Is a width specifier, encoded in the "sz" field. It can have the following values:
  S when sz = 0
  D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

### Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bites(datasize) result;
bits(esize) element;

for e = 0 to elements-1
  element = Elem[operand, e, esize];
  Elem[result, e, esize] = FPrepx(element, FPCR);

V[d] = result;
```
C7.2.140  FRINTA (vector)

Floating-point Round to Integral, to nearest with ties to Away (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the Round to Nearest with Ties to Away rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
    4H when Q = 0
    8H when Q = 1

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
    2S when sz = 0, Q = 0
    4S when sz = 0, Q = 1
    2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPRoundInt(element, FPCR, rounding, exact);

V[d] = result;
C7.2.147   FRINTN (scalar)

Floating-point Round to Integral, to nearest with ties to even (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the Round to Nearest rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  element = Elem[operand, e, esize];
  Elem[result, e, esize] = FPRSqrtEstimate(element, FPCR);

V[d] = result;
C7.2.155  FRSQRTS

Floating-point Reciprocal Square Root Step. This instruction multiplies corresponding floating-point values in the vectors of the two source SIMD&FP registers, subtracts each of the products from 3.0, divides these results by 2.0, places the results into a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

result = FPSub(operand1, operand2, FPCR);
V[d] = result;
```

C7.2.160   INS (element)

Insert vector element from another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (element). The alias is always the preferred disassembly.

Advanced SIMD variant
INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

Decode for this encoding
integer d = UInt(Rd);
integer n = UInt(Rn);
integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;
integer dst_index = UInt(imm5<4:size+1>);
integer src_index = UInt(imm4<3:size>);
integer idxdsize = if imm4<3> == '1' then 128 else 64;
  // imm4<size-1:0> is IGNORED
integer esize = 8 << size;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ts> Is an element size specifier, encoded in the "imm5" field. It can have the following values:
  B when imm5 = xxxx1
  H when imm5 = xxx10
  S when imm5 = xx100
  D when imm5 = x1000
The encoding imm5 = x0000 is reserved.

<index1> Is the destination element index encoded in the "imm5" field. It can have the following values:
imm5<4:1> when imm5 = xxxx1
imm5<4:2> when imm5 = xxx10
imm5<4:3> when imm5 = xx100
imm5<4> when imm5 = x1000
The encoding imm5 = x0000 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<index2> Is the source element index encoded in the "imm5:imm4" field. It can have the following values:

- imm<4:3:0> when imm5 = xxxx1
- imm<4:3:1> when imm5 = xxx10
- imm<4:3:2> when imm5 = xx100
- imm<4:3> when imm5 = x1000

The encoding imm5 = x0000 is reserved.

Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.

**Operation**

```cpp
CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n];
bits(128) result;

result = V[d];
Elem[result, dst_index, esize] = Elem[operand, src_index, esize];
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.161 INS (general)

Insert vector element from general-purpose register. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (from general). The alias is always the preferred disassembly.

imm5 0 0 0 1 1

Rn
Rd
```

**Advanced SIMD variant**

INS <Vd>.<Ts>[<index>], <R><n>

**Decode for this encoding**

```plaintext
text
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;
integer index = UInt(imm5<4:size+1>);
integer esize = 8 << size;
```

**Assembler symbols**

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ts> Is an element size specifier, encoded in the "imm5" field. It can have the following values:

- B when imm5 = xxxx1
- H when imm5 = xxx10
- S when imm5 = xx100
- D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<index> Is the element index encoded in the "imm5" field. It can have the following values:

- imm5<4:1> when imm5 = xxxx1
- imm5<4:2> when imm5 = xxx10
- imm5<4:3> when imm5 = xx100
- imm5<4> when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<R> Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:

- W when imm5 = xxxx1
- W when imm5 = xxx10
```
The encoding imm5 = x0000 is reserved.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
bias(0) element = X[n];
bias(128) result;

result = V[d];
Elem[result, index, esize] = element;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.162   LD1 (multiple structures)

Load multiple single-element structures to one, two, three, or four registers. This instruction loads multiple
single-element structures from memory and writes the result to one, two, three, or four SIMD&FP registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

No offset

|0 |Q| 0 0 1 1 0 0 1 |1 0 x x 1 x | size | Rn | Rt |
```

L opcode

**One register, immediate offset variant**

Applies when Rm == 11111 && opcode == 0111.

LD1 { <Vt>.<T> }, [<Xn|SP>], <imm>

**One register, register offset variant**

Applies when Rm != 11111 && opcode == 0111.

LD1 { <Vt>.<T> }, [<Xn|SP>], <Xn>
Two registers, immediate offset variant
Applies when \( R_m = 11111 \) & opcode \( = 1010 \).
\[
\text{LD1} \{ <V_t>.<T>, <V_t2>.<T> \}, [<X_n|SP>], <\text{imm}>
\]

Two registers, register offset variant
Applies when \( R_m \neq 11111 \) & opcode \( = 1010 \).
\[
\text{LD1} \{ <V_t>.<T>, <V_t2>.<T> \}, [<X_n|SP>], <X_m>
\]

Three registers, immediate offset variant
Applies when \( R_m = 11111 \) & opcode \( = 0110 \).
\[
\text{LD1} \{ <V_t>.<T>, <V_t2>.<T>, <V_t3>.<T> \}, [<X_n|SP>], <\text{imm}>
\]

Three registers, register offset variant
Applies when \( R_m \neq 11111 \) & opcode \( = 0110 \).
\[
\text{LD1} \{ <V_t>.<T>, <V_t2>.<T>, <V_t3>.<T> \}, [<X_n|SP>], <X_m>
\]

Four registers, immediate offset variant
Applies when \( R_m = 11111 \) & opcode \( = 0010 \).
\[
\text{LD1} \{ <V_t>.<T>, <V_t2>.<T>, <V_t3>.<T>, <V_t4>.<T> \}, [<X_n|SP>], <\text{imm}>
\]

Four registers, register offset variant
Applies when \( R_m \neq 11111 \) & opcode \( = 0010 \).
\[
\text{LD1} \{ <V_t>.<T>, <V_t2>.<T>, <V_t3>.<T>, <V_t4>.<T> \}, [<X_n|SP>], <X_m>
\]

Decode for all variants of this encoding

\text{integer } m &= \text{UInt}(R_m); \\
\text{boolean } \text{wback} &= \text{TRUE};
\end{align*}
\]

Assembler symbols
\(<V_t>\) Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
\(<T>\) Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
\[
\begin{align*}
8B & \quad \text{when size} = 00, Q = 0 \\
16B & \quad \text{when size} = 00, Q = 1 \\
4H & \quad \text{when size} = 01, Q = 0 \\
8H & \quad \text{when size} = 01, Q = 1 \\
2S & \quad \text{when size} = 10, Q = 0 \\
4S & \quad \text{when size} = 10, Q = 1 \\
1D & \quad \text{when size} = 11, Q = 0 \\
2D & \quad \text{when size} = 11, Q = 1
\end{align*}
\]
\(<V_t2>\) Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.
\(<V_t3>\) Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.
\(<V_t4>\) Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.
<Xn\SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> For the one register, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#8 \text{ when } Q = 0
#16 \text{ when } Q = 1

For the two registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#16 \text{ when } Q = 0
#32 \text{ when } Q = 1

For the three registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#24 \text{ when } Q = 0
#48 \text{ when } Q = 1

For the four registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#32 \text{ when } Q = 0
#64 \text{ when } Q = 1

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

**Shared decode for all encodings**

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.171  **LD4 (multiple structures)**

Load multiple 4-element structures to four registers. This instruction loads multiple 4-element structures from memory and writes the result to the four SIMD&FP registers, with de-interleaving.

For an example of de-interleaving, see LD3 (multiple structures).

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Immediate offset variant

Applies when Rm == 11111.

Register offset variant

Applies when Rm != 11111.

LD4R { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>

Decode for all variants of this encoding

`integer t = UInt(Rt);`
`integer n = UInt(Rn);`
`integer m = UInt(Rm);`
`boolean wback = TRUE;`

Assembler symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
1D when size = 11, Q = 0
2D when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.
<Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.
<Vt4> Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm> Is the post-index immediate offset, encoded in the "size" field. It can have the following values:

#4 when size = 00
#8 when size = 01
#16 when size = 10
#32 when size = 11
<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.174   LDNP (SIMD&FP)

Load Pair of SIMD&FP registers, with Non-temporal hint. This instruction loads a pair of SIMD&FP registers from memory, issuing a hint to the memory system that the access is non-temporal. The address that is used for the load is calculated from a base register value and an optional immediate offset.

For information about non-temporal pair instructions, see Load/Store SIMD and Floating-point Non-temporal pair on page C3-186.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### 32-bit variant

C7 A64 Advanced SIMD and Floating-point Instruction Descriptions
C7.2 Alphabetical list of A64 Advanced SIMD and floating-point instructions

C7.2.176   LDR (immediate, SIMD&FP)

Load SIMD&FP Register (immediate offset). This instruction loads an element from memory, and writes the result as a scalar to the SIMD&FP register. The address that is used for the load is calculated from a base register value, a signed immediate offset, and an optional offset that is a multiple of the element size.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols
<8t>    Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
<64t>   Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
<ht> Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<qt> Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<st> Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<hm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> For the 8-bit variant: is the index extend specifier, encoded in the "option" field. It can have the following values:

- UXTw when option = 010
- SXTw when option = 110
- SXTx when option = 111

For the 128-bit, 16-bit, 32-bit and 64-bit variant: is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

- UXTw when option = 010
- LSL when option = 011
- SXTw when option = 110
- SXTx when option = 111

<amount> For the 8-bit variant: is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

For the 16-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #1 when S = 1

For the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #2 when S = 1

For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #3 when S = 1

For the 128-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #4 when S = 1
Shared decode for all encodings

integer n = UInt(Rn);

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.184 MOV (scalar)

Move vector element to scalar. This instruction duplicates the specified vector element in the SIMD&FP source register into a scalar, and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the DUP (element) instruction. This means that:

- The encodings in this description are named to match the encodings of DUP (element).
- The description of DUP (element) gives the operational pseudocode for this instruction.

Scalar variant

MOV <V><d>, <Vn>.<T>[<index>]

is equivalent to

DUP <V><d>, <Vn>.<T>[<index>]

and is always the preferred disassembly.

Assembler symbols

<\V> Is the destination width specifier, encoded in the "imm5" field. It can have the following values:
B when imm5 = xxxx1
H when imm5 = xx10
S when imm5 = xx100
D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<\d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<\Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is the element width specifier, encoded in the "imm5" field. It can have the following values:
B when imm5 = xxx1
H when imm5 = xx10
S when imm5 = xx100
D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<\index> Is the element index encoded in the "imm5" field. It can have the following values:
imm5<4:1> when imm5 = xxxx1
imm5<4:2> when imm5 = xx10
imm5<4:3> when imm5 = xx100
imm5<4> when imm5 = x1000

The encoding imm5 = x0000 is reserved.
Operation
The description of DUP (element) gives the operational pseudocode for this instruction.

Operational information
If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.185  MOV (element)

Move vector element to another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the INS (element) instruction. This means that:

- The encodings in this description are named to match the encodings of INS (element).
- The description of INS (element) gives the operational pseudocode for this instruction.

**Advanced SIMD variant**

\[
\text{MOV} \quad <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]
\]

is equivalent to

\[
\text{INS} \quad <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]
\]

and is always the preferred disassembly.

**Assembler symbols**

- \(<Vd>\) Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- \(<Ts>\) Is an element size specifier, encoded in the "imm5" field. It can have the following values:
  - B when \(\text{imm5} = \text{xxxx1}\)

- \(<\text{index2}>\) Is the source element index encoded in the "imm5:imm4" field. It can have the following values:
  - \(\text{imm4<3:0>} \) when \(\text{imm5} = \text{xxxx1}\)
  - \(\text{imm4<3:1>} \) when \(\text{imm5} = \text{xxx10}\)
  - \(\text{imm4<3:2>} \) when \(\text{imm5} = \text{xx100}\)
imm4<3> when imm5 = x1000
The encoding imm5 = x0000 is reserved.
Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.

Operation
The description of INS (element) gives the operational pseudocode for this instruction.

Operational information
If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.186  MOV (from general)

Move general-purpose register to a vector element. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the INS (general) instruction. This means that:

- The encodings in this description are named to match the encodings of INS (general).
- The description of INS (general) gives the operational pseudocode for this instruction.

**Advanced SIMD variant**

MOV <Vd>.<Ts>[<index>], <R><n>

is equivalent to

INS  <Vd>.<Ts>[<index>], <R><n>

and is always the preferred disassembly.

**Assembler symbols**

- **<Vd>**: Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<Ts>**: Is an element size specifier, encoded in the "imm5" field. It can have the following values:
  - B when imm5 = xxxx1
  - H when imm5 = xxx10
  - S when imm5 = xx100
  - D when imm5 = x1000
  - The encoding imm5 = x0000 is reserved.
- **<index>**: Is the element index encoded in the "imm5" field. It can have the following values:
  - imm5<4:1> when imm5 = xxxx1
  - imm5<4:2> when imm5 = xxx10
  - imm5<4:3> when imm5 = xx100
  - imm5<4> when imm5 = x1000
  - The encoding imm5 = x0000 is reserved.
- **<R>**: Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:
  - W when imm5 = xxxx1
  - W when imm5 = xxx10
  - W when imm5 = xx100
  - X when imm5 = x1000
The encoding imm5 = x0000 is reserved.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

**Operation**

The description of **INS (general)** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.187  MOV (vector)

Move vector. This instruction copies the vector in the source SIMD&FP register into the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the ORR (vector, register) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (vector, register).
- The description of ORR (vector, register) gives the operational pseudocode for this instruction.

Three registers of the same type variant

MOV <Vd>.<T>, <Vn>.<T>

is equivalent to

ORR  <Vd>.<T>, <Vn>.<T>, <Vn>.<T>

and is the preferred disassembly when Rm == Rn.

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 8B when Q = 0
- 16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

Operation

The description of ORR (vector, register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.188   MOV (to general)

Move vector element to general-purpose register. This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the UMOV instruction. This means that:

- The encodings in this description are named to match the encodings of UMOV.
- The description of UMOV gives the operational pseudocode for this instruction.

32-bit variant

Applies when Q == 0 && imm5 == xx100.

MOV <Wd>, <Vn>.S[<index>]

is equivalent to

UMOV <Wd>, <Vn>.S[<index>]

and is always the preferred disassembly.

64-reg,UMOV-64-reg variant

Applies when Q == 1 && imm5 == x1000.

MOV <Xd>, <Vn>.D[<index>]

is equivalent to

UMOV <Xd>, <Vn>.D[<index>]

and is always the preferred disassembly.

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<index> For the 32-bit variant: is the element index encoded in "imm5<4:3>".

For the 64-reg,UMOV-64-reg variant: is the element index encoded in "imm5<4>".

Operation

The description of UMOV gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
Move Immediate (vector). This instruction places an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**8-bit variant**

Applies when $op == 0 \land cmode == 1110$.

$MOVI \langle Vd\rangle.\langle T\rangle, \#<imm8>{, LSL \#0}$

**16-bit shifted immediate variant**

Applies when $op == 0 \land cmode == 10x0$.

$MOVI \langle Vd\rangle.\langle T\rangle, \#<imm8>{, LSL \#<amount>}$

**32-bit shifted immediate variant**

Applies when $op == 0 \land cmode == 0xx0$.

$MOVI \langle Vd\rangle.\langle T\rangle, \#<imm8>{, LSL \#<amount>}$

**32-bit shifting ones variant**

Applies when $op == 0 \land cmode == 110x$.

$MOVI \langle Vd\rangle.\langle T\rangle, \#<imm8>, MSL \#<amount>$

**64-bit scalar variant**

Applies when $Q == 0 \land op == 1 \land cmode == 1110$.

$MOVI \langle Dd\rangle, \#<imm>$

**64-bit vector variant**

Applies when $Q == 1 \land op == 1 \land cmode == 1110$.

$MOVI \langle Vd\rangle.2D, \#<imm>$

**Decode for all variants of this encoding**

```plaintext
integer rd = UInt(Rd);
integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);

Assembler symbols

<DD> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<VD> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<imm> Is a 64-bit immediate 'aaaaaaabbbbbbbbbccccccccddddddddeeeeeeeeffffffffffgggggggghhhhhhhhhhh', encoded in "a:b:c:d:e:f:g:h".

<T> For the 8-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  8B when Q = 0
  16B when Q = 1

For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  4H when Q = 0
  8H when Q = 1

For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  2S when Q = 0
  4S when Q = 1

<imm8> Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

<amount> For the 16-bit shifted immediate variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:
  0 when cmode<1> = 0
  8 when cmode<1> = 1
defaulting to 0 if LSL is omitted.

For the 32-bit shifted immediate variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:
  0 when cmode<2:1> = 00
  8 when cmode<2:1> = 01
  16 when cmode<2:1> = 10
  24 when cmode<2:1> = 11
defaulting to 0 if LSL is omitted.

For the 32-bit shifting ones variant: is the shift amount encoded in the "cmode<0>" field. It can have the following values:
  8 when cmode<0> = 0
  16 when cmode<0> = 1

Operation

CheckFPAdvSIMDEnabled64();

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.190   MUL (by element)

Multiply (vector, by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

MUL <Vd>.<T>, <Vn>.<T>, <Vm>.<Ts>[<index>]

Decode for this encoding

integer idxdsiz = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of

integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The following encodings are reserved:

- size = 00, Q = x.
- size = 11, Q = x.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:

- 0:Rm when size = 01
- M:Rm when size = 10
The following encodings are reserved:
• size = 00.
• size = 11.
Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:
H when size = 01
S when size = 10

The following encodings are reserved:
• size = 00.
• size = 11.

<index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:
H:L:M when size = 01
H:L when size = 10

The following encodings are reserved:
• size = 00.
• size = 11.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];

  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
— The values of the NZCV flags.
C7.2.194   NEG (vector)

Negate (vector). This instruction reads each vector element from the source SIMD&FP register, negates each value, puts the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

```
[31 30 29 28] [27 26 25 24] [23 22 21 20] [19 18 17 16] [15 14 13 12] [11 10 9] |  5  4  |  0  |
  0  1  1  1  1  1  0 | size 1 0 0 0 0 1 0 1 1 1 0 | Rn | Rd |
```

Scalar variant

NEG <V><d>, <V><n>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean neg = (U == '1');
```

Vector

```
[31 30 29 28] [27 26 25 24] [23 22 21 20] [19 18 17 16] [15 14 13 12] [11 10 9] |  5  4  |  0  |
  0  1  1  1  1  0 | size 1 0 0 0 0 1 0 1 1 1 0 | Rn | Rd |
```

Vector variant

NEG <Vd>.<T>, <Vn>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean neg = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

D when size = 11

The following encodings are reserved:

- size = 0x.
- size = 10.
<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

</d> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

</n> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B  when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H  when size = 01, Q = 0
- 8H  when size = 01, Q = 1
- 2S  when size = 10, Q = 0
- 4S  when size = 10, Q = 1
- 2D  when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

Op

eration for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;

for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;

Op

erational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.195   NOT

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MVN. The alias is always the preferred disassembly.

Vector variant
NOT <Vd>.<T>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
   element = Elem[operand, e, esize];
   Elem[result, e, esize] = NOT(element);

V[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.196   **ORN (vector)**

Bitwise inclusive OR NOT (vector). This instruction performs a bitwise OR NOT between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

ORN `<Vd>..<T>, <Vn>..<T>, <Vm>..<T>`

### Decode for this encoding

```plaintext
text
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;
```

### Assembler symbols

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  - 8B when `Q` = 0
  - 16B when `Q` = 1
- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```plaintext
checkFPAvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
operand2 = NOT(operand2);
result = operand1 OR operand2;
V[d] = result;
```

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.
C7.2.197 ORR (vector, immediate)

Bitwise inclusive OR (vector, immediate). This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise OR between each result and an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

16-bit variant

Applies when cmode == 10x1.

ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}

32-bit variant

Applies when cmode == 0xx1.

ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}

Decode for all variants of this encoding

```plaintext
integer rd = UInt(Rd);
integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;

case cmode:op of
  when '0xx00' operation = ImmediateOp_MOVI;
  when '0xx10' operation = ImmediateOp_ORR;
  when '10x00' operation = ImmediateOp_MOVI;
  when '10x10' operation = ImmediateOp_ORR;
  when '110x0' operation = ImmediateOp_MOVI;
  when '1110x' operation = ImmediateOp_MOVI;
  when '11110' operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

Assembler symbols

- `<Vd>` is the name of the SIMD&FP register, encoded in the "Rd" field.
- `<T>` is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".
- `<imm8>` is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".
For the 16-bit variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:

- 0 when cmode<1> = 0
- 8 when cmode<1> = 1

defaulting to 0 if LSL is omitted.

For the 32-bit variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:

- 0 when cmode<2:1> = 00
- 8 when cmode<2:1> = 01
- 16 when cmode<2:1> = 10
- 24 when cmode<2:1> = 11

defaulting to 0 if LSL is omitted.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
  when ImmediateOp_MOVI
      result = imm;
  when ImmediateOp_MVNI
      result = NOT(imm);
  when ImmediateOp_ORR
      operand = V[rd];
      result = operand OR imm;
  when ImmediateOp_BIC
      operand = V[rd];
      result = operand AND NOT(imm);

V[rd] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.198  ORR (vector, register)

Bitwise inclusive OR (vector, register). This instruction performs a bitwise OR between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (vector). See Alias conditions for details of when each alias is preferred.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.199   PMUL

Polynomial Multiply. This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

For information about multiplying polynomials see *Polynomial arithmetic over \{0, 1\}* on page A1-48.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant
PMUL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if U == '1' && size != '00' then UNDEFINED;
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean poly = (U == '1');

Assembler symbols

<Vd>    Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T>     Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  8B     when size = 00, Q = 0
  16B     when size = 00, Q = 1
The following encodings are reserved:
  •  size = 01, Q = x.
  •  size = 1x, Q = x.
<Vn>    Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>    Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) product;
for e = 0 to elements-1
  element1 = Elem(operand1, e, esize);
element2 = \texttt{Elem}[\texttt{operand2}, e, esize];
if \texttt{poly} then
  \texttt{product} = \texttt{PolynomialMult} (\texttt{element1}, \texttt{element2})<\texttt{esize}:0>;
else
  \texttt{product} = (\texttt{UInt} (\texttt{element1}) \texttt{+ UInt} (\texttt{element2}))<\texttt{esize}:0>;
\texttt{Elem} [\texttt{result}, e, esize] = \texttt{product};
\texttt{V}[d] = \texttt{result};

\textbf{Operational information}

If \texttt{PSTATE.DIT} is 1:

\begin{itemize}
  \item The execution time of this instruction is independent of:
    \begin{itemize}
      \item The values of the data supplied in any of its registers.
      \item The values of the NZCV flags.
    \end{itemize}
  \item The response of this instruction to asynchronous exceptions does not vary based on:
    \begin{itemize}
      \item The values of the data supplied in any of its registers.
      \item The values of the NZCV flags.
    \end{itemize}
\end{itemize}
C7.2.200  PMULL, PMULL2

Polynomial Multiply Long. This instruction multiplies corresponding elements in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

For information about multiplying polynomials see *Polynomial arithmetic over \{0, 1\}* on page A1-48.

The PMULL instruction extracts each source vector from the lower half of each source register, while the PMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

PMULL[2] <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

if size == '01' || size == '10' then UNDEFINED;
if size == '11' && !HaveBit128PMULLExt() then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

Assembler symbols

2
Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent]  when Q = 0
[present]  when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H  when size = 00
1Q  when size = 11

The following encodings are reserved:

•  size = 01.
•  size = 10.

The '1Q' arrangement is only allocated in an implementation that includes the Cryptographic Extension, and is otherwise RESERVED.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<\textbf{Tb}> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

\begin{itemize}
  \item \textbf{8B} when size = 00, Q = 0
  \item \textbf{16B} when size = 00, Q = 1
  \item \textbf{1D} when size = 11, Q = 0
  \item \textbf{2D} when size = 11, Q = 1
\end{itemize}

The following encodings are reserved:

\begin{itemize}
  \item size = 01, Q = x.
  \item size = 10, Q = x.
\end{itemize}

<\textbf{Vm}> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

\begin{verbatim}
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
bits(esize) element1;
bits(esize) element2;
for e = 0 to elements-1
  element1 = Elem[operand1, e, esize];
  element2 = Elem[operand2, e, esize];
  Elem[result, e, 2*esize] = PolynomialMult(element1, element2);
V[d] = result;
\end{verbatim}

**Operational information**

If PSTATE.DIT is 1:

\begin{itemize}
  \item The execution time of this instruction is independent of:
    \begin{itemize}
      \item The values of the data supplied in any of its registers.
      \item The values of the NZCV flags.
    \end{itemize}
  \item The response of this instruction to asynchronous exceptions does not vary based on:
    \begin{itemize}
      \item The values of the data supplied in any of its registers.
      \item The values of the NZCV flags.
    \end{itemize}
\end{itemize}
### C7.2.201 RADDHN, RADDHN2

Rounding Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see ADDHN, ADDHN2.

The RADDHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

![Instruction Encoding](image)

**Three registers, not all the same type variant**

\[ RADDHN(2) \] <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

**Decode for this encoding**

```plaintext```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');
```

**Assembler symbols**

\[ 2 \] Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

\[ <Vd> \] Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\[ <Tb> \] Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
  8H when size = 00
  4S when size = 01
  2D when size = 10
  The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;
for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;
Vpart[d, part] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.202 RAX1

Rotate and Exclusive OR rotates each 64-bit element of the 128-bit vector in a source SIMD&FP register left by 1, performs a bitwise exclusive OR of the resulting 128-bit vector and the vector in another source SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when ARMv8.2-SHA is implemented.

ARMv8.2

```
<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>

\(V[d] = \text{result};\)

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.204 REV16 (vector)

Reverse elements in 16-bit halfwords (vector). This instruction reverses the order of 8-bit elements in each halfword of the vector in the source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
[31 30 29 28] [27 26 25 24] [23 22 21 20] [19 18 17 16] [15 14 13 12] [11 10 9] [ 5 4 ] [ 0 ]
0  Q  0  0  1  1  0  size 1 0 0 0 0 0 0 0 1 1 0  Rn  Rd  U
```

  - The values of the NZCV flags.
C7.2.207 RSHRN, RSHRN2

Rounding Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the vector in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SHRN, SHRN2.

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
|31 30 29 28|27 26 25 24|23 22 |19 18|16|15 14 13 12|11 10 9 |5 4 |0 |
0 Q 0 0 1 1 1 0 l=0000|immh 1 0 0 0 1 1 |Rn Rd op
```

**Vector variant**

RSHRN[2] <Vd>.<Tb>, <Vn>.<Ta>, #<shift>

boolean round = (op == '1');

**Assembler symbols**

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.
The encoding \( \text{immh} = 1xxx \), \( Q = x \) is reserved.

\(<\text{Vn}>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

\(<\text{Ta}>\) Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- \( 8H \) when \( \text{immh} = 0001 \)
- \( 4S \) when \( \text{immh} = 001x \)
- \( 2D \) when \( \text{immh} = 01xx \)

See Advanced SIMD modified immediate on page C4-319 when \( \text{immh} = 0000 \).

The encoding \( \text{immh} = 1xxx \) is reserved.

\(<\text{shift}>\) Is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- \( (16-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 0001 \)
- \( (32-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 001x \)
- \( (64-\text{UInt}(\text{immh:immb})) \) when \( \text{immh} = 01xx \)

See Advanced SIMD modified immediate on page C4-319 when \( \text{immh} = 0000 \).

The encoding \( \text{immh} = 1xxx \) is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
in integer round_const = if round then (1 << (shift - 1)) else 0;
in integer element;
for e = 0 to elements-1
    element = (\text{UInt}(\text{Elem}(\text{operand}, e, 2\times esize)) + \text{round_const}) >> shift;

Vpart[d, part] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.208   RSUBHN, RSUBHN2

Rounding Subtract returning High Narrow. This instruction subtracts each vector element of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see SUBHN, SUBHN2.

The RSUBHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSUBHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
31 30 29 28|27 26 25 24|23 22 21 20 | 16|15 14 13 12|11 10 9  | 5 4 | 0 |

- 8H when size = 00
- 4S when size = 01
- 2D when size = 10

The encoding size = 11 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<vm>
Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) absdiff;

result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  absdiff = Abs(element1-element2)<<esize-1:0;
  Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + absdiff;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.211 SABD

Signed Absolute Difference. This instruction subtracts the elements of the vector of the second source SIMD&FP register from the corresponding elements of the first source SIMD&FP register, places the absolute values of the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant
SABD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.212  SABDL, SABDL2

Signed Absolute Difference Long. This instruction subtracts the vector elements of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, places the absolute value of the results into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The SABDL instruction writes the vector to the lower half of the destination register and clears the upper half, while the SABDL2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.216 SADDLV

Signed Add Long across Vector. This instruction adds every vector element in the source SIMD&FP register together, and writes the scalar result to the destination SIMD&FP register. The destination scalar is twice as long as the source vector elements. All the values in this instruction are signed integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
[31 30 29 28] [27 26 25 24] [23 22 21 20] [19 18 17 16] [15 14 13 12] [11 10 9] | 5 4 | 0 |
0 | Q | 0 | 1 | 1 | 1 | 0 | size | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | Rd |
   |
U   |
```

**Advanced SIMD variant**

SADDLV <V><d>, <Vn>.<T>

**Decode for this encoding**

```python
integer d = UInt(Rd);
integer n = UInt(Rn);
if size:Q == '100' then UNDEFINED;
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

**Assembler symbols**

- `<V>` Is the destination width specifier, encoded in the "size" field. It can have the following values:
  - H when size = 00
  - S when size = 01
  - D when size = 10

  The encoding size = 11 is reserved.

- `<d>` Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

- `<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 4S when size = 10, Q = 1

  The following encodings are reserved:
  - size = 10, Q = 0.
  - size = 11, Q = x.
Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer sum;

sum = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    sum = sum + Int(Elem[operand, e, esize], unsigned);
V[d] = sum<2*esize-1:0>;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.217  **SADDW, SADDW2**

Signed Add Wide. This instruction adds vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the results in a vector, and writes the vector to the SIMD&FP destination register.

The **SADDW** instruction extracts the second source vector from the lower half of the second source register, while the **SADDW2** instruction extracts the second source vector from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.218  SCVTF (vector, fixed-point)

Signed fixed-point Convert to Floating-point (vector). This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:
    H when immh = 001x
    S when immh = 01xx
    D when immh = 1xxx
The encoding immh = 000x is reserved.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<r> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
    4H when immh = 001x, Q = 0
    8H when immh = 001x, Q = 1
    2S when immh = 01xx, Q = 0
    4S when immh = 01xx, Q = 1
    2D when immh = 1xxx, Q = 1
See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.
The following encodings are reserved:
    • immh = 0001, Q = x.
    • immh = 1xxx, Q = 0.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:
    (32-UInt(immh:immb)) when immh = 001x
    (64-UInt(immh:immb)) when immh = 01xx
    (128-UInt(immh:immb)) when immh = 1xxx
The encoding immh = 000x is reserved.

For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:
    (32-UInt(immh:immb)) when immh = 001x
    (64-UInt(immh:immb)) when immh = 01xx
    (128-UInt(immh:immb)) when immh = 1xxx
See Advanced SIMD modified immediate on page C4-319 when immh = 0000.
The encoding immh = 0001 is reserved.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bites(datasize) operand = V[n];
bites(datasize) result;
bites(esize) element;
for e = 0 to elements-1
element = Elem[operand, e, esize];
Elem[result, e, esize] = FixedToFP(element, fracbits, unsigned, FPCR, rounding);

V[d] = result;
C7.2.219  SCVTF (vector, integer)

Signed integer Convert to Floating-point (vector). This instruction converts each element in a vector from signed integer to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Scalar half precision

```c
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HaveSHA1Ext() then UNDEFINED;
```

**Assembler symbols**

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

```c
AArch64.CheckFPAdvSIMDEnabled();

bits(32) operand = V[n];  // read element [0] only, [1-3] zeroed
V[d] = ROL(operand, 30);
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.226  SHA1M

SHA1 hash update (majority).

Advanced SIMD variant

SHA1M <Qd>, <Sn>, <Vm>.4S

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if !HaveSHA1Ext() then UNDEFINED;

Assembler symbols

<Qd> Is the 128-bit name of the SIMD&FP source and destination, encoded in the "Rd" field.
<Sn> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the third SIMD&FP source register, encoded in the "Rm" field.

Operation

AArch64.CheckFPAdvSIMDEnabled();

bits(128) X = V[d];
bits(32) Y = V[n];  // Note: 32 not 128 bits wide
bits(128) W = V[m];
bits(32) t;

for e = 0 to 3
    t = SHA_majority(X<63:32>, X<95:64>, X<127:96>);
    Y = Y + ROL(X<31:0>, 5) + t + Elem[W, e, 32];
    X<63:32> = ROL(X<63:32>, 30);
    <Y, X> = ROL(Y:X, 32);
    V[d] = X;

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
— The values of the NZCV flags.
Signed Halving Add. This instruction adds corresponding signed integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SRHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### SHADD

Three registers of the same type variant

**SHADD** `<Vd>.<T>, <Vn>.<T>, <Vm>.<T>`

**Decode for this encoding**

- integer `d = UInt(Rd);`
- integer `n = UInt(Rn);`
- integer `m = UInt(Rm);`
- if `size == '11'` then UNDEFINED;
- integer `esize = 8 << UInt(size);`
- integer `datasize = if Q == '1' then 128 else 64;`
- integer `elements = datasize DIV esize;`
- boolean `unsigned = (U == '1');`

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - `8` when `size = 00, Q = 0`
  - `16` when `size = 00, Q = 1`
  - `4` when `size = 01, Q = 0`
  - `8` when `size = 01, Q = 1`
  - `2` when `size = 10, Q = 0`
  - `4` when `size = 10, Q = 1`
  - The encoding `size = 11, Q = x` is reserved.
- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;
```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    sum = element1 + element2;
    Elem[result, e, esize] = sum<esize:1>;
V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.239   SHL

Shift Left (immediate). This instruction reads each value from a vector, left shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

\[
\begin{array}{cccccccccccccccc}
\end{array}
\]

\text{immh}

Scalar variant

SHL <V><d>, <V><n>, #<shift>

Decode for this encoding

integer \( d = \text{UInt}(Rd) \);
integer \( n = \text{UInt}(Rn) \);
if \( \text{immh}<3> != '1' \) then UNDEFINED;
integer esize = 8 \(< < 3\); integer datasize = esize;
integer elements = 1;
integer shift = \text{UInt}(immh:immb) - esize;

Vector

\[
\begin{array}{cccccccccccccccc}
\end{array}
\]

\text{immh}

Vector variant

SHL <Vd>.<T>, <Vn>.<T>, #<shift>

Decode for this encoding

integer \( d = \text{UInt}(Rd) \);
integer \( n = \text{UInt}(Rn) \);
if \( \text{immh} == '0000' \) then SEE "Advanced SIMD modified immediate";
if \( \text{immh}<3>:Q == '10' \) then UNDEFINED;
integer esize = 8 \(< < \text{HighestSetBit}(immh)\);
integer datasize = if \( Q == '1' \) then 128 else 64;
integer elements = datasize DIV esize;
integer shift = \text{UInt}(immh:immb) - esize;

Assembler symbols

\(<V>\) Is a width specifier, encoded in the "immh" field. It can have the following values:

- \( D \) when \( \text{immh} = 1xxx \)

The encoding \( \text{immh} = 0xxx \) is reserved.
<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

</d> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

</T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- **8B** when \( \text{immh} = 0001, Q = 0 \)
- **16B** when \( \text{immh} = 0001, Q = 1 \)
- **4H** when \( \text{immh} = 001x, Q = 0 \)
- **8H** when \( \text{immh} = 001x, Q = 1 \)
- **2S** when \( \text{immh} = 01xx, Q = 0 \)
- **4S** when \( \text{immh} = 01xx, Q = 1 \)
- **2D** when \( \text{immh} = 1xxx, Q = 1 \)

See [Advanced SIMD modified immediate on page C4-319](#) when \( \text{immh} = 0000, Q = x \).

The encoding \( \text{immh} = 1xxx, Q = 0 \) is reserved.

</n> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

</shift> For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in the "immh:immb" field. It can have the following values:

- \( (\text{UInt}(\text{immh:immb})-64) \) when \( \text{immh} = 1xxx \)

The encoding \( \text{immh} = 0xxx \) is reserved.

For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

- \( (\text{UInt}(\text{immh:immb})-8) \) when \( \text{immh} = 0001 \)
- \( (\text{UInt}(\text{immh:immb})-16) \) when \( \text{immh} = 001x \)
- \( (\text{UInt}(\text{immh:immb})-32) \) when \( \text{immh} = 01xx \)
- \( (\text{UInt}(\text{immh:immb})-64) \) when \( \text{immh} = 1xxx \)

See [Advanced SIMD modified immediate on page C4-319](#) when \( \text{immh} = 0000 \).

Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bvts datasize) operand = V[n];
bvts datasize) result;
or e = 0 to elements-1
    Elem[result, e, esize] = LSL(Elem[operand, e, esize], shift);

V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.240 SHLL, SHLL2

Shift Left Long (by element size). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, left shifts each result by the element size, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The SHLL instruction extracts vector elements from the lower half of the source register, while the SHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

SHLL[2] <Vd>,<Ta>, <Vn>,<Tb>, #<shift>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = esize;
boolean unsigned = FALSE;    // Or TRUE without change of functionality

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
8H when size = 00
4S when size = 01
2D when size = 10
The encoding size = 11 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H  when size = 01, Q = 0
8H  when size = 01, Q = 1
2S  when size = 10, Q = 0
4S  when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<shift>  Is the left shift amount, which must be equal to the source element width in bits, encoded in the
"size" field. It can have the following values:
  8  when size = 00
  16 when size = 01
  32 when size = 10

The encoding size = 11 is reserved.

Operation

CheckFPAdvSIMDEnabled64();
bval(datasize) operand = Vpart[n, part];
bval(2*datasize) result;
integer element;

for e = 0 to elements-1
  element = Int(Elem[operand, e, esize], unsigned) << shift;
  Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.241  **SHRN, SHRN2**

Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are truncated. For rounded results, see RSHRN, RSHRN2.

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

---

### Vector variant

SHRN[2] <Vd>,<Tb>, <Vn>,<Ta>, #<shift>

### Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<> == '1' then UNDEFINED;
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
```

### Assembler symbols

2  
Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

`absent` when Q = 0
`present` when Q = 1

<Vd>  
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>  
Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- **8B** when immh = 0001, Q = 0
- **16B** when immh = 0001, Q = 1
- **4H** when immh = 001x, Q = 0
- **8H** when immh = 001x, Q = 1
- **2S** when immh = 01xx, Q = 0
- **4S** when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<n> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<ta> Is an arrangement specifier, encoded in the "imm" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8H</td>
<td>when immh = 0001</td>
</tr>
<tr>
<td>4S</td>
<td>when immh = 001x</td>
</tr>
<tr>
<td>2D</td>
<td>when immh = 01xx</td>
</tr>
</tbody>
</table>

See Advanced SIMD modified immediate on page C4-319 when immh = 0000.

The encoding immh = 1xxx is reserved.

<shift> Is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(16-UInt(immh:immb)) when immh = 0001</td>
<td></td>
</tr>
<tr>
<td>(32-UInt(immh:immb)) when immh = 001x</td>
<td></td>
</tr>
<tr>
<td>(64-UInt(immh:immb)) when immh = 01xx</td>
<td></td>
</tr>
</tbody>
</table>

See Advanced SIMD modified immediate on page C4-319 when immh = 0000.

The encoding immh = 1xxx is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bias(datasize=2) operand = V[n];
bias(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;

Vpart[d, part] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.242  SHSUB

Signed Halving Subtract. This instruction subtracts the elements in the vector in the second source SIMD&FP register from the corresponding elements in the vector in the first source SIMD&FP register, shifts each result right one bit, places each result into elements of a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

SHSUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>8B</th>
<th>16B</th>
<th>4H</th>
<th>8H</th>
<th>2S</th>
<th>4S</th>
</tr>
</thead>
<tbody>
<tr>
<td>when size = 00, Q = 0</td>
<td>when size = 00, Q = 1</td>
<td>when size = 01, Q = 0</td>
<td>when size = 01, Q = 1</td>
<td>when size = 10, Q = 0</td>
<td>when size = 10, Q = 1</td>
</tr>
</tbody>
</table>

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
exteger element1;
exteger element2;
exteger diff;

for e = 0 to elements-1
element1 = Int(Elem[operand1, e, esize], unsigned);
element2 = Int(Elem[operand2, e, esize], unsigned);
diff = element1 - element2;
Elem[result, e, esize] = diff<esize:1>;
V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.243   SLI

Shift Left and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, left shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the left of each vector element in the source register are lost.

The following figure shows the operation of shift left by 3 for an 8-bit vector element.

![Diagram of SLI instruction](image-url)

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Scalar

### Vector variant

SLI <Vd>.<T>, <Vn>.<T>, #<shift>
Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3>:Q == '10' then UNDEFINED;
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer shift = UInt(immh:immb) - esize;
```

Assembler symbols

- `<V>`: Is a width specifier, encoded in the "immh" field. It can have the following values:
  - D when immh = 1xxx
  - The encoding immh = 0xxx is reserved.
- `<d>`: Is the number of the SIMD&FP destination register, in the "Rd" field.
- `<n>`: Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vd>`: Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>`: Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
  - 8 when immh = 0001, Q = 0
  - 16 when immh = 0001, Q = 1
  - 4H when immh = 001x, Q = 0
  - 8H when immh = 001x, Q = 1
  - 2S when immh = 01xx, Q = 0
  - 4S when immh = 01xx, Q = 1
  - 2D when immh = 1xxx, Q = 1
  - See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.
  - The encoding immh = 1xxx, Q = 0 is reserved.
- `<Vn>`: Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- `<shift>`: For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in the "immh:immb" field. It can have the following values:
  - (UInt(immh:immb)-64) when immh = 1xxx
  - The encoding immh = 0xxx is reserved.
  - For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
    - (UInt(immh:immb)-8) when immh = 0001
    - (UInt(immh:immb)-16) when immh = 001x
    - (UInt(immh:immb)-32) when immh = 01xx
    - (UInt(immh:immb)-64) when immh = 1xxx
    - See Advanced SIMD modified immediate on page C4-319 when immh = 0000.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bias(datasize) operand = V[n];
bias(datasize) operand2 = V[d];
bias(datasize) result;
```
bits(esize) mask = LSL(Ones(esize), shift);
bits(esize) shifted;
for e = 0 to elements-1
    shifted = LSL(Elem[operand, e, esize], shift);
    Elem[result, e, esize] = (Elem[operand2, e, esize] AND NOT(mask)) OR shifted;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.244   SM3PARTW1

SM3PARTW1 takes three 128-bit vectors from the three source SIMD&FP registers and returns a 128-bit result in the destination SIMD&FP register. The result is obtained by a three-way exclusive OR of the elements within the input vectors with some fixed rotations, see the Operation pseudocode for more information.

This instruction is implemented only when ARMv8.2-SM is implemented.

ARMv8.2

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
SM3PARTW2 takes three 128-bit vectors from three source SIMD&FP registers and returns a 128-bit result in the destination SIMD&FP register. The result is obtained by a three-way exclusive OR of the elements within the input vectors with some fixed rotations, see the Operation pseudocode for more information.

This instruction is implemented only when ARMv8.2-SM is implemented.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.247   SM3TT1A

SM3TT1A takes three 128-bit vectors from three source SIMD&FP registers and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a three-way exclusive OR of the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the three-way exclusive OR.
- The result of the exclusive OR of the top 32-bit element of the second source vector, Vn, with a rotation left by 12 of the top 32-bit element of the first source vector.
- A 32-bit element indexed out of the third source vector, Vm.

The result of this addition is returned as the top element of the result. The other elements of the result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 9.

This instruction is implemented only when ARMv8.2-SM is implemented.

  element2 = Int(Elem[operand2, e, esize], unsigned);
  maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
  Elem[result, e, esize] = maxmin<esize-1:0>;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.254 SMAXP

Signed Maximum Pairwise. This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers of the same type variant

SMAXP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

### Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');

### Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(2*datasize) concat = operand2:operand1;
integer element1;
integer element2;
integer maxmin;

for e = 0 to elements-1
  element1 = Int(Elem[concat, 2*e, esize], unsigned);
  element2 = Int(Elem[concat, (2*e)+1, esize], unsigned);
  maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
  Elem[result, e, esize] = maxmin<esize-1:0>;

V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.255 SMAXV

Signed Maximum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are signed integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

SMAXV <V><d>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then UNDEFINED;
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean min = (op == '1');

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
  B when size = 00
  H when size = 01
  S when size = 10

The encoding size = 11 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  8B when size = 00, Q = 0
  16B when size = 00, Q = 1
  4H when size = 01, Q = 0
  8H when size = 01, Q = 1
  4S when size = 10, Q = 1

The following encodings are reserved:
  * size = 10, Q = 0.
  * size = 11, Q = x.
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    element = Int(Elem[operand, e, esize], unsigned);
    maxmin = if min then Min(maxmin, element) else Max(maxmin, element);
V[d] = maxmin=esize-1:0;
C7.2.256 SMIN

Signed Minimum (vector). This instruction compares corresponding elements in the vectors in the two source SIMD&FP registers, places the smaller of each of the two signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

SMIN <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

integer d = UInt(Rd);

    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
    Elem[result, e, esize] = maxmin<esize-1:0>;
V[d] = result;

Operational information
If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.258  **SMINV**

Signed Minimum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are signed integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
0 | Q | 1 | 1 | 1 | 1 | 0 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0
  |   |   |   |   |   | U |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
```

**Advanced SIMD variant**

SMINV <V><d>, <Vn>.<T>

**Decode for this encoding**

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '100' then UNDEFINED;
if size == '111' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean min = (op == '1');
```

**Assembler symbols**

<V>  
Is the destination width specifier, encoded in the "size" field. It can have the following values:

- **B** when size = 00
- **H** when size = 01
- **S** when size = 10

The encoding size = 11 is reserved.

<d>  
Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn>  
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T>  
Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- **8B** when size = 00, Q = 0
- **16B** when size = 00, Q = 1
- **4H** when size = 01, Q = 0
- **8H** when size = 01, Q = 1
- **4S** when size = 10, Q = 1

The following encodings are reserved:

- size = 10, Q = 0.
- size = 11, Q = x.
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
  element = Int(Elem[operand, e, esize], unsigned);
  maxmin = if min then Min(maxmin, element) else Max(maxmin, element);

V[d] = maxmin-(esize-1:0);

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.259  SMLAL, SMLAL2 (by element)

Signed Multiply-Add Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element in the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are signed integer values.

The SMLAL instruction extracts vector elements from the lower half of the first source register, while the SMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

SMLAL\{2\} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

Decode for this encoding

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
  when '01' index = UInt(H:L:M); Rmhi = '0';
  when '10' index = UInt(H:L); Rmhi = M;
  otherwise UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  [absent] when Q = 0
  [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
  4S when size = 01
  2D when size = 10
The following encodings are reserved:

- \( \text{size} = 00 \)
- \( \text{size} = 11 \)

\(<Vn>\) is the name of the first SIMD&FP source register, encoded in the "\(Rn\)" field.

\(<Tb>\) is an arrangement specifier, encoded in the "\(\text{size:Q}\)" field. It can have the following values:

- \(4H\) when \(\text{size} = 01\), \(Q = 0\)
- \(8H\) when \(\text{size} = 01\), \(Q = 1\)
- \(2S\) when \(\text{size} = 10\), \(Q = 0\)
- \(4S\) when \(\text{size} = 10\), \(Q = 1\)

The following encodings are reserved:

- \(\text{size} = 00, Q = x\)
- \(\text{size} = 11, Q = x\)

\(<Vm>\) is the name of the second SIMD&FP source register, encoded in the "\(\text{size:M:Rm}\)" field. It can have the following values:

- \(0:Rm\) when \(\text{size} = 01\)
- \(M:Rm\) when \(\text{size} = 10\)

The following encodings are reserved:

- \(\text{size} = 00\)
- \(\text{size} = 11\)

Restricted to \(V0-V15\) when element size \(<Ts>\) is \(H\).

\(<Ts>\) is an element size specifier, encoded in the "\(\text{size}\)" field. It can have the following values:

- \(H\) when \(\text{size} = 01\)
- \(S\) when \(\text{size} = 10\)

The following encodings are reserved:

- \(\text{size} = 00\)
- \(\text{size} = 11\)

\(<\text{index}>\) is the element index, encoded in the "\(\text{size:L:H:M}\)" field. It can have the following values:

- \(H:L:M\) when \(\text{size} = 01\)
- \(H:L\) when \(\text{size} = 10\)

The following encodings are reserved:

- \(\text{size} = 00\)
- \(\text{size} = 11\)

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxdsize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
```
if sub_op then
    Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
else
    Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] + product;

V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.260   SMLAL, SMLAL2 (vector)

Signed Multiply-Add Long (vector). This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLAL instruction extracts each source vector from the lower half of each source register, while the SMLAL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

SMLAL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then UNDEFINED;

for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  product = (element1*element2)<<2*esize-1:0;
  if sub_op then
    accum = Elem[operand3, e, 2*esize] - product;
  else
    accum = Elem[operand3, e, 2*esize] + product;
  Elem[result, e, 2*esize] = accum;

V[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.261 SMLSL, SMLSL2 (by element)

Signed Multiply-Subtract Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLSL instruction extracts vector elements from the lower half of the first source register, while the SMLSL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

SMLSL{2} <Vd>.<Tn>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

Decode for this encoding

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
  when '01' index = UInt(H:L:M); Rmhi = '0';
  when '10' index = UInt(H:L); Rmhi = M;
  otherwise UNDEFINED;

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  [absent] when Q = 0
  [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tn> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
  4S when size = 01
  2D when size = 10

The following encodings are reserved:
  * size = 00.
• size = 11.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1

The following encodings are reserved:
• size = 00, Q = x.
• size = 11, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
0:Rm when size = 01
M:Rm when size = 10

The following encodings are reserved:
• size = 00.
• size = 11.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:
H when size = 01
S when size = 10

The following encodings are reserved:
• size = 00.
• size = 11.

<index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:
H:L:M when size = 01
H:L when size = 10

The following encodings are reserved:
• size = 00.
• size = 11.

Operation

CheckFPAdvSIMDEnabled64();

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
    else
\[ \text{Elem[result, e, 2*esize]} = \text{Elem[operand3, e, 2*esize]} + \text{product}; \]

\[ \text{V[d]} = \text{result}; \]

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.262  SMLSL, SMLSL2 (vector)

Signed Multiply-Subtract Long (vector). This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLSL instruction extracts each source vector from the lower half of each source register, while the SMLSL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

SMLSL{2}  <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>  Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 8H  when size = 00
- 4S  when size = 01
- 2D  when size = 10

The encoding size = 11 is reserved.

<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb>  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B  when size = 00, Q = 0
- 16B when size = 00, Q = 1
4H    when size = 01, Q = 0
8H    when size = 01, Q = 1
2S    when size = 10, Q = 0
4S    when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<\rm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;
bits(2*esize) accum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        accum = Elem[operand3, e, 2*esize] - product;
    else
        accum = Elem[operand3, e, 2*esize] + product;
    Elem[result, e, 2*esize] = accum;

V[d] = result;
```

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### C7.2.263  SMOV

Signed Move vector element to general-purpose register. This instruction reads the signed integer from the source SIMD&FP register, sign-extends it to form a 32-bit or 64-bit value, and writes the result to destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### 32-bit variant

Applies when $Q = 0$.

\[
\text{SMOV} \ <Wd>, \ <Vn>.<Ts>[<index>] \]

#### 64-reg, SMOV-64-reg variant

Applies when $Q = 1$.

\[
\text{SMOV} \ <Xd>, \ <Vn>.<Ts>[<index>] \]

#### Decode for all variants of this encoding

```plaintext
integer d  = UInt(Rd);
integer n  = UInt(Rn);
integer size;

case Q:imm5 of
  when 'xxxxx1' size = 0;    // SMOV [WX]d, Vn.B
  when 'xxxx10' size = 1;    // SMOV [WX]d, Vn.H
  when 'xxx100' size = 2;    // SMOV Xd, Vn.S
  otherwise UNDEFINED;

integer idxdsize = if imm5<4> == '1' then 128 else 64;
integer index   = UInt(imm5<4:size+1>);
integer esize   = 8 << size;
integer datasize = if Q == '1' then 64 else 32;
```

#### Assembler symbols

- **<Wd>** Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Xd>** Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Vn>** Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- **<Ts>** For the 32-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:
  - **B** when imm5 = xxxx1
  - **H** when imm5 = xxxx10
  The encoding imm5 = xxxx00 is reserved.
  For the 64-reg, SMOV-64-reg variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:
  - **B** when imm5 = xxxx1
H when \( \text{imm5} = \text{xxx10} \)
S when \( \text{imm5} = \text{xx100} \)

The encoding \( \text{imm5} = \text{xx000} \) is reserved.

\(<\text{index}>\) For the 32-bit variant: is the element index encoded in the "imm5" field. It can have the following values:
- \( \text{imm5}<4:1> \) when \( \text{imm5} = \text{xxxx1} \)
- \( \text{imm5}<4:2> \) when \( \text{imm5} = \text{xxx10} \)

The encoding \( \text{imm5} = \text{xxx00} \) is reserved.

For the 64-reg,SMOV-64-reg variant: is the element index encoded in the "imm5" field. It can have the following values:
- \( \text{imm5}<4:1> \) when \( \text{imm5} = \text{xxxx1} \)
- \( \text{imm5}<4:2> \) when \( \text{imm5} = \text{xxx10} \)
- \( \text{imm5}<4:3> \) when \( \text{imm5} = \text{xx100} \)

The encoding \( \text{imm5} = \text{xx000} \) is reserved.

**Operation**

\[
\text{CheckFPAdvSIMDEnabled64}();
\]
\[
\text{bits(idxdsize)} \ \text{operand} = V[n];
\]
\[
X[d] = \text{SignExtend}(\text{Elem}[\text{operand}, \text{index}, \text{esize}], \text{datasize});
\]

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.264   SMULL, SMULL2 (by element)

Signed Multiply Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the result in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMULL instruction extracts vector elements from the lower half of the first source register, while the SMULL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant
SMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

Decode for this encoding

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
  when '01' index = UInt(H:L:M); Rmhi = '0';
  when '10' index = UInt(H:L); Rmhi = M;
  otherwise UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  [absent] when Q = 0
  [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
  4S when size = 01
  2D when size = 10

The following encodings are reserved:
  • size = 00.
  • size = 11.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
The following encodings are reserved:
- size = 00, Q = x.
- size = 11, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
- 0:Rm when size = 01
- M:Rm when size = 10
The following encodings are reserved:
- size = 00.
- size = 11.
Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:
- H when size = 01
- S when size = 10
The following encodings are reserved:
- size = 00.
- size = 11.

<index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:
- H:L:M when size = 01
- H:L when size = 10
The following encodings are reserved:
- size = 00.
- size = 11.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxdsize) operand2 = V[m];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2+esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  product = (element1*element2)<2+esize-1:0>;
  Elem[result, e, 2+esize] = product;
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.266   SQABS

Signed saturating Absolute value. This instruction reads each vector element from the source SIMD&FP register, puts the absolute value of the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

V[d] = result;
```

C7.2.268  SQDMLAL, SQDMLAL2 (by element)

Signed saturating Doubling Multiply-Add Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQDMLAL instruction extracts vector elements from the lower half of the first source register, while the SQDMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.269   **SQDMLAL, SQDMLAL2 (vector)**

Signed saturating Doubling Multiply-Add Long. This instruction multiplies corresponding signed integer values in
the lower or upper half of the vectors of the two source SIMD&FP registers, doubles the results, and accumulates
the final results with the vector elements of the destination SIMD&FP register. The destination vector elements
are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation
bit FPSR.QC is set.

The SQDMLAL instruction extracts each source vector from the lower half of each source register, while the SQDMLAL2
instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

```
C7.2.272   SQDMULH (by element)

Signed saturating Doubling Multiply returning High half (by element). This instruction multiplies each vector
element in the first source SIMD&FP register by the specified vector element of the second source SIMD&FP
register, doubles the results, places the most significant half of the final results into a vector, and writes the vector
to the destination SIMD&FP register.

The results are truncated. For rounded results, see SQRDMULH (by element).

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

- **H:L** when size = 10

The following encodings are reserved:

- size = 00
- size = 11

**Operation for all encodings**

```assembly
CheckFPAdvSIMDEnabled64();
operandsize operand1 = V[n];
operandsize operand2 = V[m];
operandsize result;
integer round_const = if round then 1 << (esize - 1) else 0;
integer element1;
integer element2;
integer product;
boolean sat;

element2 = SInt(Elem[operand2, index, esize]);
for e = 0 to elements-1
    element1 = SInt(Elem[operand1, e, esize]);
    product = (2 * element1 * element2) + round_const;
    // The following only saturates if element1 and element2 equal -(2^(esize-1))
    (Elem[result, e, esize], sat) = SignedSatQ(product >> esize, esize);
    if sat then FPSR.QC = '1';

V[d] = result;
```
C7.2.273   SQDMULH (vector)

Signed saturating Doubling Multiply returning High half. This instruction multiplies the values of corresponding
elements of the two source SIMD&FP registers, doubles the results, places the most significant half of the final
results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SQRDMULH (vector).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation
bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

  if sat then FPSR.QC = '1';
V[d] = result;
```

5 when size = 10
C7.2.274   SQDMULL, SQDMULL2 (by element)

Signed saturating Doubling Multiply Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the final results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQDMULL instruction extracts the first source vector from the lower half of the first source register, while the SQDMULL2 instruction extracts the first source vector from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.277 SQRDMLAH (by element)

Signed Saturating Rounding Doubling Multiply Accumulate returning High Half (by element). This instruction multiplies the vector elements of the first source SIMD&FP register with the value of a vector element of the second source SIMD&FP register without saturating the multiply results, doubles the results, and accumulates the most significant half of the final results with the vector elements of the destination SIMD&FP register. The results are rounded.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSR.QC, is set if saturation occurs.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if sat then FPSR.QC = '1';

V[d] = result;
```
C7.2.282  **SQRDMULH (vector)**

Signed saturating Rounding Doubling Multiply returning High half. This instruction multiplies the values of corresponding elements of the two source SIMD&FP registers, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see SQRDMULH (vector).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if sat then FPSR.QC = '1';
V[d] = result;
```
C7.2.283  **SQRSHL**

Signed saturating Rounding Shift Left (register). This instruction takes each vector element in the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see SQSHL (register).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

V[d] = result;
C7.2.284  SQRSHRN, SQRSHRN2

Signed saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SQRSHRN, SQRSHRN2.

The SQRSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper
64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have
the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-319 when immh = 0000.
The encoding immh = 1xxx is reserved.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:
B when immh = 0001
H when immh = 001x
S when immh = 01xx

The following encodings are reserved:
• immh = 0000.
• immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:
H when immh = 0001
S when immh = 001x
D when immh = 01xx
The following encodings are reserved:
- \( \text{immh} = 0000 \).
- \( \text{immh} = 1xxx \).

\(<n>\) Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

\(<\text{shift}>\) For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:
- \(16\)-\(\text{UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 0001\)
- \(32\)-\(\text{UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 001x\)
- \(64\)-\(\text{UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 01xx\)

The following encodings are reserved:
- \( \text{immh} = 0000 \).
- \( \text{immh} = 1xxx \).

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:
- \(16\)-\(\text{UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 0001\)
- \(32\)-\(\text{UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 001x\)
- \(64\)-\(\text{UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 01xx\)

See Advanced SIMD modified immediate on page C4-319 when \(\text{immh} = 0000\).

The encoding \( \text{immh} = 1xxx \) is reserved.

### Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (\text{shift} - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
  element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> \text{shift};
  (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
  if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```
C7.2.285  SQRSHRUN, SQRSHRUN2

Signed saturating Rounded Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are rounded. For truncated results, see SQRSHRUN, SQRSHRUN2.

The SQRSHRUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vpart[d, part] = result;
```

C7.2.286  SQSHL (immediate)

Signed saturating Shift Left (immediate). This instruction reads each vector element in the source SIMD&FP register, shifts each result by an immediate value, places the final result in a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

```
| 31 30 29 28|27 26 25 24|23 22 | 19 18 |16|15 14 13 12|11 10 9 |  5  |4  |0 |

endcase;

Assembler symbols

<\V> Is a width specifier, encoded in the "immh" field. It can have the following values:
- B when immh = 0001
- H when immh = 001x
- S when immh = 01xx
- D when immh = 1xxx

The encoding immh = 0000 is reserved.

<\d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<\n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<\Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1
- 2D when immh = 1xxx, Q = 1

See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = 0 is reserved.

<\Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the left shift amount, in the range 0 to the operand width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
- (UInt(immh:immb)-8) when immh = 0001
- (UInt(immh:immb)-16) when immh = 001x
- (UInt(immh:immb)-32) when immh = 01xx
- (UInt(immh:immb)-64) when immh = 1xxx

The encoding immh = 0000 is reserved.

For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
- (UInt(immh:immb)-8) when immh = 0001
- (UInt(immh:immb)-16) when immh = 001x
- (UInt(immh:immb)-32) when immh = 01xx
- (UInt(immh:immb)-64) when immh = 1xxx
Operation for all encodings

CheckFPAdvSIMDEnabled64();

bits(datasize) result;
integer element;
boolean sat;

for e = 0 to elements - 1
    element = Int(Elem[operand, e, esize, src_unsigned] << shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, dst_unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
C7.2.287   SQSHL (register)

Signed saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see SQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], src_unsigned) << shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, dst_unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
```
C7.2.289 SQSHRN, SQSHRN2

Signed saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts and truncates each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. For rounded results, see SQRSHRN, SQRSHRN2.

The SQSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-319 when immh = 0000.
The encoding immh = 1xxx is reserved.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:

B when immh = 0001
H when immh = 001x
S when immh = 01xx

The following encodings are reserved:

• immh = 0000.
• immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 0001
S when immh = 001x
D when immh = 01xx
The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

- (16-UInt(immh:immb)) when immh = 0001
- (32-UInt(immh:immb)) when immh = 001x
- (64-UInt(immh:immb)) when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- (16-UInt(immh:immb)) when immh = 0001
- (32-UInt(immh:immb)) when immh = 001x
- (64-UInt(immh:immb)) when immh = 01xx

See Advanced SIMD modified immediate on page C4-319 when immh = 0000.

The encoding immh = 1xxx is reserved.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
inumber round_const = if round then (1 << (shift - 1)) else 0;
inumber element;
boolean sat;
for e = 0 to elements-1
  element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
  (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
  if sat then FPSR.QC = '1';
Vpart[d, part] = result;
```
**C7.2.290 SQSHRUN, SQSHRUN2**

Signed saturating Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see SQRSHRUN, SQRSHRUN2.

The SQSHRUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQSHRUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

if immh<3> == '1' then UNDEFINED;
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
```
integer elements = datasize DIV esize;
integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');

**Assembler symbols**

2
Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- **[absent]** when Q = 0
- **[present]** when Q = 1

<Vd>
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>
Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- **8B** when immh = 0001, Q = 0
- **16B** when immh = 0001, Q = 1
- **4H** when immh = 001x, Q = 0
- **8H** when immh = 001x, Q = 1
- **2S** when immh = 01xx, Q = 0
- **4S** when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-319 when immh = 0000, Q = x.

The encoding **immh = 1xxx, Q = x** is reserved.

<Vn>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>
Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- **8H** when immh = 0001
- **4S** when immh = 001x
- **2D** when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-319 when immh = 0000.

The encoding **immh = 1xxx** is reserved.

<Vb>
Is the destination width specifier, encoded in the "immh" field. It can have the following values:

- **B** when immh = 0001
- **H** when immh = 001x
- **S** when immh = 01xx

The following encodings are reserved:

- **immh = 0000.**
- **immh = 1xxx.**

<d>
Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va>
Is the source width specifier, encoded in the "immh" field. It can have the following values:

- **H** when immh = 0001
- **S** when immh = 001x
- **D** when immh = 01xx

The following encodings are reserved:

- **immh = 0000.**
- **immh = 1xxx.**
<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

The following encodings are reserved:

•immh = 0000.
•immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

See Advanced SIMD modified immediate on page C4-319 when immh = 0000.

The encoding immh = 1xxx is reserved.

**Operation for all encodings**

```
CheckFPAdvSIMDEnabled64();
bm(datasmie+2) operand = V[n];
bm(datasmie) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;
for e = 0 to elements-1
  element = (SInt(Elem[operand, e, 2*esize]) + round const) >> shift;
  (Elem[result, e, esize], sat) = UnsignedSatQ(element, esize);
  if sat then FPSR.QC = '1';
Vpart[d, part] = result;
```

C7.2.291 SQSUB

Signed saturating Subtract. This instruction subtracts the element values of the second source SIMD&FP register from the corresponding element values of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

   diff = element1 - element2;
   (Elem[result, e, esize], sat) = SatQ(diff, esize, unsigned);
   if sat then FPSR.QC = '1';

V[d] = result;
```

C7.2.292  **SQXTN, SQXTN2**

Signed saturating extract Narrow. This instruction reads each vector element from the source SIMD&FP register, saturates the value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The **SQXTN** instruction writes the vector to the lower half of the destination register and clears the upper half, while the **SQXTN2** instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
8B  when size = 00, Q = 0
16B when size = 00, Q = 1
4H  when size = 01, Q = 0
8H  when size = 01, Q = 1
2S  when size = 10, Q = 0
4S  when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, esize] = (element1+element2+1)<esize:1>;

V[d] = result;
Shift Right and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the right of each vector element of the source register are lost.

The following figure shows the operation of shift right by 3 for an 8-bit vector element.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

See Advanced SIMD modified immediate on page C4-319 when \(\text{immh} = 0000, Q = x\).

The encoding \(\text{immh} = 1xxx, Q = 0\) is reserved.

\(</Vn>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

\(<\text{shift}>\) For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values:

\[(128-\text{UInt}(\text{immh}:\text{immb})) \text{ when } \text{immh} = 1xxx\]

The encoding \(\text{immh} = 0xxx\) is reserved.

For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values:

\[(16-\text{UInt}(\text{immh}:\text{immb})) \text{ when } \text{immh} = 0001\]

\[(32-\text{UInt}(\text{immh}:\text{immb})) \text{ when } \text{immh} = 001x\]

\[(64-\text{UInt}(\text{immh}:\text{immb})) \text{ when } \text{immh} = 01xx\]

\[(128-\text{UInt}(\text{immh}:\text{immb})) \text{ when } \text{immh} = 1xxx\]

See Advanced SIMD modified immediate on page C4-319 when \(\text{immh} = 0000\).

Operation for all encodings

\[
\text{CheckFPAdvSIMDEnabled64();} \\
\text{bits(datasize) operand} = V[n]; \\
\text{bits(datasize) operand2} = V[d]; \\
\text{bits(datasize) result};
\]
bits(esize) mask = LSR(Ones(esize), shift);
bits(esize) shifted;

for e = 0 to elements-1
    shifted = LSR(Elem[operand, e, esize], shift);
    Elem[result, e, esize] = (Elem[operand2, e, esize] AND NOT(mask)) OR shifted;
    V[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.296 SRSHL

Signed Rounding Shift Left (register). This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see SSHL.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.300 SSHLL, SSHLL2

Signed Shift Left Long (immediate). This instruction reads each vector element from the source SIMD&FP register, left shifts each vector element by the specified shift amount, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The SSHLL instruction extracts vector elements from the lower half of the source register, while the SSHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias SXTL, SXTL2. See Alias conditions for details of when each alias is preferred.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx
See Advanced SIMD modified immediate on page C4-319 when immh = 0000.
The encoding immh = 1xxx is reserved.

<Rn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1
See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<shift> Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
- (UInt(immh:immb)-8) when immh = 0001
- (UInt(immh:immb)-16) when immh = 001x
- (UInt(immh:immb)-32) when immh = 01xx
See Advanced SIMD modified immediate on page C4-319 when immh = 0000.
The encoding immh = 1xxx is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bias(datasize) operand = Vpart[n, part];
bias(datasize*2) result;
integer element;
for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.301  SSHR

Signed Shift Right (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, places the final result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The results are truncated. For rounded results, see SRSR.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.303 SSUBL, SSUBL2

Signed Subtract Long. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are twice as long as the source vector elements.

The SSUBL instruction extracts each source vector from the lower half of each source register, while the SSUBL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- 4S when size = 10, Q = 1
- 1D when size = 11, Q = 0
- 2D when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

<Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.
Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

For the one register, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#8 when Q = 0
#16 when Q = 1

For the two registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#16 when Q = 0
#32 when Q = 1

For the three registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#24 when Q = 0
#48 when Q = 1

For the four registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:

#32 when Q = 0
#64 when Q = 1

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

```

Assembler symbols

- `<Vt>` Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - `8B` when size = 00, Q = 0
  - `16B` when size = 00, Q = 1
  - `4H` when size = 01, Q = 0
  - `8H` when size = 01, Q = 1
25  when size = 10, Q = 0
45  when size = 10, Q = 1
2D  when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<\Vt2>  Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm>  Is the post-index immediate offset, encoded in the "Q" field. It can have the following values:
  #16  when Q = 0
  #32  when Q = 1

<Xm>  Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.310   ST3 (single structure)

Store single 3-element structure from one lane of three registers. This instruction stores a 3-element structure to
memory from corresponding elements of three SIMD&FP registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

No offset

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
### STNP (SIMD&FP)

Store Pair of SIMD&FP registers, with Non-temporal hint. This instruction stores a pair of SIMD&FP registers to memory, issuing a hint to the memory system that the access is non-temporal. The address used for the store is calculated from an address from a base register value and an immediate offset. For information about non-temporal pair instructions, see *Load/Store SIMD and Floating-point Non-temporal pair on page C3-186.*

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### 32-bit variant
Applies when \( \text{opc} == 00 \).

\[
\text{STNP} \ <\text{St1}>, \ <\text{St2}>, \ [\langle\text{Xn}|\text{SP}\rangle\{, \ #\langle\text{imm}\rangle\}]
\]

#### 64-bit variant
Applies when \( \text{opc} == 01 \).

\[
\text{STNP} \ <\text{Dt1}>, \ <\text{Dt2}>, \ [\langle\text{Xn}|\text{SP}\rangle\{, \ #\langle\text{imm}\rangle\}]
\]

#### 128-bit variant
Applies when \( \text{opc} == 10 \).

\[
\text{STNP} \ <\text{Qt1}>, \ <\text{Qt2}>, \ [\langle\text{Xn}|\text{SP}\rangle\{, \ #\langle\text{imm}\rangle\}]
\]

\]

128-bit variant
Applies when $size == 00 && opc == 10$.

\[
\text{STUR} \quad \text{<Qt>}, \quad [\text{<Xn|SP>}{, \ #<simm>}]
\]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer scale} &= \text{UInt}(\text{opc}1):\text{size}; \\
\text{if scale} > 4 \text{ then UNDEFINED; } \\
\text{bits}(64) \text{ offset} &= \text{SignExtend}(\text{imm9}, 64);
\end{align*}
\]

Assembler symbols

- $<Bt>$: Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
- $<Dt>$: Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
- $<Ht>$: Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
- $<Qt>$: Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
- $<St>$: Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
- $<Xn|SP>$: Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<sim> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```plaintext
t: Integer n = Uint(Rn);
Integer t = Uint(Rt);
MemOp memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
Integer datasize = 8 << scale;
```

Operation

```plaintext
CheckFPAdvSIMDEnabled64();
Bits(64) address;
Bits(datasize) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

case memop of
    when MemOp_STORE
        data = V[t];
        Mem[address, datasize DIV 8, AccType_VEC] = data;
    when MemOp_LOAD
        data = Mem[address, datasize DIV 8, AccType_VEC];
        V[t] = data;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C7.2.318  SUB (vector)

Subtract (vector). This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

</tbody>
</table>

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
b bits(datasize) operand1 = V[n];
b bits(datasize) operand2 = V[m];
b bits(datasize) result;
b bits(esize) element1;
b bits(esize) element2;
for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if sub_op then
        Elem[result, e, esize] = element1 - element2;
    else
        Elem[result, e, esize] = element1 + element2;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.319 SUBHN, SUBHN2

Subtract returning High Narrow. This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values.

The results are truncated. For rounded results, see RSUBHN, RSUBHN2.

The SUBHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SUBHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

SUBHN(2) <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

Decode for this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } m &= \text{UInt}(Rm); \\
\text{if } size == '11' \text{ then UNDEFINED; } \\
\text{integer esize} &= 8 << \text{UInt}(size); \\

\text{boolean sub_op} &= (o1 == '1'); \\
\text{boolean round} &= (U == '1'); \\
\end{align*}
\]

Assembler symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

\[
\begin{align*}
\text{[absent]} \quad &\text{when } Q = 0 \\
\text{[present]} \quad &\text{when } Q = 1
\end{align*}
\]

<Vd>

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>

Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

\[
\begin{align*}
8B &\quad \text{when size = 00, Q = 0} \\
16B &\quad \text{when size = 00, Q = 1} \\
4H &\quad \text{when size = 01, Q = 0} \\
8H &\quad \text{when size = 01, Q = 1} \\
2S &\quad \text{when size = 10, Q = 0} \\
4S &\quad \text{when size = 10, Q = 1}
\end{align*}
\]
The encoding size = 11, Q = x is reserved.

\(<Vn>\) Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<Ta>\) Is an arrangement specifier, encoded in the "size" field. It can have the following values:

<table>
<thead>
<tr>
<th>Size</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>8H</td>
</tr>
<tr>
<td>01</td>
<td>4S</td>
</tr>
<tr>
<td>10</td>
<td>2D</td>
</tr>
</tbody>
</table>

The encoding size = 11 is reserved.

\(<Vm>\) Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;

for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.320   SUQADD

Signed saturating Accumulate of Unsigned value. This instruction adds the unsigned integer values of the vector elements in the source SIMD&FP register to corresponding signed integer values of the vector elements in the destination SIMD&FP register, and writes the resulting signed integer values to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

   op2 = Int[Elem[operand2, e, esize], unsigned];
   (Elem[result, e, esize], sat) = SatQ(op1 + op2, esize, unsigned);
   if sat then FPSR.QC = '1';
V[d] = result;
C7.2.321 SXTL, SXTL2

Signed extend Long. This instruction duplicates each vector element in the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The SXTL instruction extracts the source vector from the lower half of the source register, while the SXTL2 instruction extracts the source vector from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the SSHLL, SSHLL2 instruction. This means that:

- The encodings in this description are named to match the encodings of SSHLL, SSHLL2.
- The description of SSHLL, SSHLL2 gives the operational pseudocode for this instruction.

<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22</th>

</tbody>
</table>

**Vector variant**

SXTL{2} <Vd>,<Ta>, <Vn>,<Tb>

is equivalent to

SSHLL{2} <Vd>,<Ta>, <Vn>,<Tb>, #0

and is the preferred disassembly when BitCount(immh) == 1.

**Assembler symbols**

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- 8H when immh = 0001
- 4S when immh = 001x
- 2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-319 when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
25 when immh = 01xx, Q = 0
45 when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

Operation

The description of SSHLL, SSHLL2 gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.322   TBL

Table vector Lookup. This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the result for that lookup is 0. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Two register table variant
Applies when len == 01.
TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B }, <Vm>.<Ta>

Three register table variant
Applies when len == 10.
TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B }, <Vm>.<Ta>

Four register table variant
Applies when len == 11.
TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B, <Vn+3>.16B }, <Vm>.<Ta>

Single register table variant
Applies when len == 00.
TBL <Vd>.<Ta>, { <Vn>.16B }, <Vm>.<Ta>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
integer regs = UInt(len) + 1;
boolean is_tbl = (op == '0');

Assembler symbols

</Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
</Ta> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
  8B when Q = 0
  16B when Q = 1
</Vn> For the four register table, three register table and two register table variant: is the name of the first SIMD&FP table register, encoded in the "Rn" field.
For the single register table variant: is the name of the SIMD&FP table register, encoded in the "Rn" field.

\(<\textit{Rn+1}>\) Is the name of the second SIMD&FP table register, encoded as "Rn" plus 1 modulo 32.

\(<\textit{Rn+2}>\) Is the name of the third SIMD&FP table register, encoded as "Rn" plus 2 modulo 32.

\(<\textit{Rn+3}>\) Is the name of the fourth SIMD&FP table register, encoded as "Rn" plus 3 modulo 32.

\(<\textit{Rm}>\) Is the name of the SIMD&FP index register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) indices = V[m];
bv(128*regs) table = Zeros();
bv(datasize) result;
integer index;

// Create table from registers
for i = 0 to regs-1
    table<128*i+127:128*i> = V[n];
    n = (n + 1) MOD 32;

result = if is_tbl then Zeros() else V[d];
for i = 0 to elements-1
    index = UInt(Elem[indices, i, 8]);
    if index < 16 * regs then
        Elem[result, i, 8] = Elem[table, index, 8];

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.323  TBX  

Table vector lookup extension. This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the existing value in the vector element of the destination register is left unchanged. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Two register table variant  
Applies when len == 01.

TBX <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B }, <Vm>.<Ta>

Three register table variant  
Applies when len == 10.

TBX <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B }, <Vm>.<Ta>

Four register table variant  
Applies when len == 11.

TBX <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B, <Vn+3>.16B }, <Vm>.<Ta>

Single register table variant  
Applies when len == 00.

TBX <Vd>.<Ta>, { <Vn>.16B }, <Vm>.<Ta>

Decode for all variants of this encoding  

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
integer regs = UInt(len) + 1;
boolean is_tbl = (op == '0');

Assembler symbols  

<\vd>  
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>  
Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

<table>
<thead>
<tr>
<th>Q</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>88</td>
</tr>
<tr>
<td>1</td>
<td>168</td>
</tr>
</tbody>
</table>
For the four register table, three register table and two register table variant: is the name of the first SIMD&FP table register, encoded in the "Rn" field.

For the single register table variant: is the name of the SIMD&FP table register, encoded in the "Rn" field.

<\Vn+1> Is the name of the second SIMD&FP table register, encoded as "Rn" plus 1 modulo 32.

<\Vn+2> Is the name of the third SIMD&FP table register, encoded as "Rn" plus 2 modulo 32.

<\Vn+3> Is the name of the fourth SIMD&FP table register, encoded as "Rn" plus 3 modulo 32.

<\Vm> Is the name of the SIMD&FP index register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
b bits(datasize) indices = V[m];

```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.324 TRN1

Transpose vectors (primary). This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places each result into consecutive elements of a vector, and writes the vector to the destination SIMD&FP register. Vector elements from the first source register are placed into even-numbered elements of the destination vector, starting at zero, while vector elements from the second source register are placed into odd-numbered elements of the destination vector.

--- Note ---

By using this instruction with TRN2, a 2 x 2 matrix can be transposed.

The following figure shows the operation of TRN1 and TRN2 halfword operations where Q = 0.

![TRN1 and TRN2 operations](image)

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
| 31 30 29 28 27 26 25 24 23 22 21 20 16 15 14 12 11 10 9 5 4 0 |
|-----------------------|------------------|------------------|
| 0 Q 0 1 1 1 0 size 0 | Rm 0 0 1 0 1 0 | Rn 10 10 Rd |
```

**Advanced SIMD variant**

TRN1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

**Decode for this encoding**

```plaintext```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;
```

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 88 when size = 00, Q = 0
  - 168 when size = 00, Q = 1
4H    when size = 01, Q = 0
8H    when size = 01, Q = 1
2S    when size = 10, Q = 0
4S    when size = 10, Q = 1
2D    when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<n>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<m>  Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```
CheckFPAvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

for p = 0 to pairs-1
    Elem[result, 2*p+0, esize] = Elem[operand1, 2*p+part, esize];
    Elem[result, 2*p+1, esize] = Elem[operand2, 2*p+part, esize];

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- 4S when size = 01
- 2D when size = 10

The encoding size = 11 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

- 8H when size = 00, Q = 0
- 16H when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<\m> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bias(datasize) operand1 = Vpart[n, part];
bias(datasize) operand2 = Vpart[m, part];
bias(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.332  UADDLP

Unsigned Add Long Pairwise. This instruction adds pairs of adjacent unsigned integer values from the vector in the
source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.
The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

Vector variant
UADDLP <Vd>.<Ta>, <Vn>.<Tb>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV (2 * esize);
boolean acc = (op == '1');
boolean unsigned = (U == '1');

Assembler symbols

</Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ta> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  4H when size = 00, Q = 0
  8H when size = 00, Q = 1
  2S when size = 01, Q = 0
  4S when size = 01, Q = 1
  1D when size = 10, Q = 0
  2D when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.
</Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  8B when size = 00, Q = 0
  16B when size = 00, Q = 1
  4H when size = 01, Q = 0
  8H when size = 01, Q = 1
  2S when size = 10, Q = 0
  4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.
**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(2*esize) sum;
integer op1;
integer op2;

result = if acc then V[d] else Zeros();
for e = 0 to elements-1
  op1 = Int(Elem[operand, 2*e+0, esize], unsigned);
  op2 = Int(Elem[operand, 2*e+1, esize], unsigned);
  sum = (op1+op2)<2*esize-1:0>;
  Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + sum;

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.333   UADDLV

Unsigned sum Long across Vector. This instruction adds every vector element in the source SIMD&FP register together, and writes the scalar result to the destination SIMD&FP register. The destination scalar is twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

UADDLV <V><d>, <Vn>.<T>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
if size:Q == '100' then UNDEFINED;
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

Assembler symbols

<V>   Is the destination width specifier, encoded in the "size" field. It can have the following values:

    H when size = 00
    S when size = 01
    D when size = 10

The encoding size = 11 is reserved.

<d>   Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn>  Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T>   Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

    8B when size = 00, Q = 0
    16B when size = 00, Q = 1
    4H when size = 01, Q = 0
    8H when size = 01, Q = 1
    4S when size = 10, Q = 1

The following encodings are reserved:

- size = 10, Q = 0.
- size = 11, Q = x.
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer sum;

sum = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    sum = sum + Int(Elem[operand, e, esize], unsigned);

V[d] = sum<2*esize-1:0>;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.334 UADDW, UADDW2

Unsigned Add Wide. This instruction adds the vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. The vector elements of the destination register and the first source register are twice as long as the vector elements of the second source register. All the values in this instruction are unsigned integer values.

The UADDW instruction extracts vector elements from the lower half of the second source register, while the UADDW2 instruction extracts vector elements from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

</tr>
</tbody>
</table>
```

Three registers, not all the same type variant

UADDW\{2\} <Vd>.<Ta>, <Vn>.<Ta>, <Vm>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

-absent- when Q = 0
-present- when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H when size = 00
4S when size = 01
2D when size = 10

The encoding size = 11 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.335   UCVTF (vector, fixed-point)

Unsigned fixed-point Convert to Floating-point (vector). This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

integer frachbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRoundingMode(FPCR);

Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:
H when immh = 001x
S when immh = 01xx
D when immh = 1xxx
The encoding immh = 000x is reserved.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1
2D when immh = 1xxx, Q = 1
See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.
The following encodings are reserved:
• immh = 0001, Q = x.
• immh = 1xxx, Q = 0.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx
(128-UInt(immh:immb)) when immh = 1xxx
The encoding immh = 000x is reserved.
For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx
(128-UInt(immh:immb)) when immh = 1xxx
See Advanced SIMD modified immediate on page C4-319 when immh = 0000.
The encoding immh = 0001 is reserved.

Operation for all encodings

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;
for e = 0 to elements-1
element = Elem[operand, e, esize];
Elem[result, e, esize] = FixedToFP(element, fracbits, unsigned, FPCR, rounding);
V[d] = result;
C7.2.336   UCVTF (vector, integer)

Unsigned integer Convert to Floating-point (vector). This instruction converts each element in a vector from an
unsigned integer value to a floating-point value using the rounding mode that is specified by the FPCR, and writes
the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception
results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exceptions and exception traps on page D1-2184.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and
Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

```c
integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fsize;
FPRounding rounding;
```
case ftype of
    when '00'
      fltsize = 32;
    when '01'
      fltsize = 64;
    when '10'
      UNDEFINED;
    when '11'
      if HaveFP16Ext() then
        fltsize = 16;
      else
        UNDEFINED;
    rounding = FPRoundingMode(FPCR);

Assembler symbols

<DD>   Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<HD>   Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<SD>   Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Xn>   Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<Wn>   Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();

bits(fltsize) fltval;
bits(intsize) intval;

intval = X[n];
fltval = FixedToFP(intval, 0, TRUE, FPCR, rounding);
V[d] = fltval;
C7.2.339  UDOT (by element)

Dot Product unsigned arithmetic (vector, by element). This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an optional instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note

ID_AA64ISAR0_EL1.DP indicates whether this instruction is supported.

---

ARMv8.2

Vector variant

UDOT <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.4B[<index>]

Decode for this encoding

**Advanced SIMD variant**

UMINV <V><d>, <Vn>.<T>

**Decode for this encoding**

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
if size:Q == '100' then UNDEFINED;
if size == '111' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean min = (op == '1');
```

**Assembler symbols**

- `<V>`: Is the destination width specifier, encoded in the "size" field. It can have the following values:
  - B when size = 00
  - H when size = 01
  - S when size = 10
  The encoding size = 11 is reserved.

- `<d>`: Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

- `<Vn>`: Is the name of the SIMD&FP source register, encoded in the "Rn" field.

- `<T>`: Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 4S when size = 10, Q = 1
  The following encodings are reserved:
  - size = 10, Q = 0.
  - size = 11, Q = x.
**Operation**

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = \text{Int}(\text{Elem}(\text{operand, 0, esize}, \text{unsigned}));
for e = 1 to elements-1
  element = \text{Int}(\text{Elem}(\text{operand, e, esize}, \text{unsigned}));
  maxmin = if min then Min(maxmin, element) else Max(maxmin, element);

V[d] = maxmin-esize-1:0;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.349  **UMLAL, UMLAL2 (by element)**

Unsigned Multiply-Add Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMLAL instruction extracts vector elements from the lower half of the first source register, while the UMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Vector variant**

UMLAL{2} <Vd>,<Ta>,<Vn>,<Tb>,<Vm>,<Ts>[<index>]

**Decode for this encoding**

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;

  when '01' index = UInt(H:L:M); Rmhi = '0';
  when '10' index = UInt(H:L); Rmhi = M;
  otherwise UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');

**Assembler symbols**

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

  [absent] when Q = 0
  [present] when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>  Is an arrangement specifier, encoded in the "size" field. It can have the following values:

  4S  when size = 01
  2D  when size = 10

The following encodings are reserved:

* size = 00.
• `size = 11`.

`<Vn>` is the name of the first SIMD&FP source register, encoded in the "Rn" field.

`<Tb>` is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- `4H` when `size = 01`, `Q = 0`
- `8H` when `size = 01`, `Q = 1`
- `2S` when `size = 10`, `Q = 0`
- `4S` when `size = 10`, `Q = 1`

The following encodings are reserved:
- `size = 00`, `Q = x`.
- `size = 11`, `Q = x`.

`<Vm>` is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
- `0:Rm` when `size = 01`
- `M:Rm` when `size = 10`

The following encodings are reserved:
- `size = 00`.
- `size = 11`.

Restricted to V0-V15 when element size `<Ts>` is H.

`<Ts>` is an element size specifier, encoded in the "size" field. It can have the following values:
- `H` when `size = 01`
- `S` when `size = 10`

The following encodings are reserved:
- `size = 00`.
- `size = 11`.

`<index>` is the element index, encoded in the "size:L:H:M" field. It can have the following values:
- `H:L:M` when `size = 01`
- `H:L` when `size = 10`

The following encodings are reserved:
- `size = 00`.
- `size = 11`.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bias(datasize) operand1 = Vpart[n, part];
bias(idxdsize) operand2 = V[m];
bias(2*datasize) operand3 = V[d];
bias(2*datasize) result;
integer element1;
integer element2;
bias(2*esize) product;
element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<<2*esize-1:0);
    if sub_op then
        Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
    else
        ...
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### C7.2.353 UMOV

Unsigned Move vector element to general-purpose register. This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (to general). See **Alias conditions** for details of when each alias is preferred.

#### 32-bit variant

Applies when \( Q = 0 \).

\[
\text{UMOV } \langle Wd \rangle, \langle Vn \rangle.\langle Ts \rangle[\langle index \rangle]
\]

#### 64-reg, UMOV-64-reg variant

Applies when \( Q = 1 \) \&\& \( \text{imm}5 = \text{x}1000 \).

\[
\text{UMOV } \langle Xd \rangle, \langle Vn \rangle.\langle Ts \rangle[\langle index \rangle]
\]

### Decode for all variants of this encoding

integer \( d = \text{UInt}(\text{Rd}) \);

integer \( n = \text{UInt}(\text{Rn}) \);

integer size;

case \( Q : \text{imm}5 \) of
   when '0xxxx1' size = 0;  // UMOV \( Wd, Vn.B \)
   when '0xxx10' size = 1;  // UMOV \( Wd, Vn.H \)
   when '0xx100' size = 2;  // UMOV \( Wd, Vn.S \)
   when '1x1000' size = 3;  // UMOV \( Xd, Vn.D \)
   otherwise UNDEFINED;

integer \( \text{idxdsize} = \text{if \text{imm}5<4> = '1' then 128 else 64; \}

integer index = UInt(\text{imm}5<4:size+1>);

terger esize = 8 \ll \text{size};

integer datasize = if \( Q = '1' \) then 64 else 32;

### Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV (to general)</td>
<td>( \text{imm}5 = \text{'x}100 )</td>
</tr>
<tr>
<td>MOV (to general)</td>
<td>( \text{imm}5 = \text{'xx}100 )</td>
</tr>
</tbody>
</table>

### Assembler symbols

- \( \langle Wd \rangle \) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( \langle Xd \rangle \) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ts> For the 32-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:

- B when imm5 = xxxx1
- H when imm5 = xx10
- S when imm5 = xx100

The encoding imm5 = xx000 is reserved.

For the 64-reg,UMOV-64-reg variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:

- D when imm5 = x1000

The following encodings are reserved:

- imm5 = x0000.
- imm5 = xxxx1.
- imm5 = xxx10.
- imm5 = xx100.

<index> For the 32-bit variant: is the element index encoded in the "imm5" field. It can have the following values:

- imm5<4:1> when imm5 = xxxx1
- imm5<4:2> when imm5 = xx10
- imm5<4:3> when imm5 = xx100

The encoding imm5 = xx000 is reserved.

For the 64-reg,UMOV-64-reg variant: is the element index encoded in "imm5<4>".

**Operation**

```c
CheckFPAvailable64();
bits(idxdsize) operand = V[n];

X[d] = ZeroExtend(Elem[operand, index, esize], datasize);
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.354 UMULL, UMULL2 (by element)

Unsigned Multiply Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMULL instruction extracts vector elements from the lower half of the first source register, while the UMULL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

UMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

Decode for this encoding

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
  when '01' index = UInt(H:L:M); Rmhi = '0';
  when '10' index = UInt(H:L); Rmhi = M;
  otherwise UNDEFINED;

integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
  [absent] when Q = 0
  [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
  4S when size = 01
  2D when size = 10
The following encodings are reserved:
  • size = 00.
  • size = 11.
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The following encodings are reserved:
- size = 00, Q = x.
- size = 11, Q = x.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
- 0:Rm when size = 01
- M:Rm when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:
- H when size = 01
- S when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

<index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:
- H:L:M when size = 01
- H:L when size = 10

The following encodings are reserved:
- size = 00.
- size = 11.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
b downgrade(operand1 = Vpart[n, part];
b downgrade(operand2 = V[m];
big2datasize(result);
integer element1;
integer element2;
b downgrade(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
element1 = Int(Elem[operand1, e, esize], unsigned);
product = (element1*element2)<2*esize-1:0>;
Elem[result, e, 2*esize] = product;

V[d] = result;
```
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.355 UMULL, UMULL2 (vector)

Unsigned Multiply long (vector). This instruction multiplies corresponding vector elements in the lower or upper half of the two source SIMD&FP registers, places the result in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are unsigned integer values.

The UMULL instruction extracts each source vector from the lower half of each source register, while the UMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

UMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.356   UQADD

Unsigned saturating Add. This instruction adds the values of corresponding elements of the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if sat then FPSR.QC = '1';
V[d] = result;
```
C7.2.357  UQRSHL

Unsigned saturating Rounding Shift Left (register). This instruction takes each vector element of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see UQSHL (immediate).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

\(<Vn>\) Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<Vm>\) Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```c
CheckFPAdvSIMDEnabled64();
bots(datasize) operand1 = V[n];
bots(datasize) operand2 = V[m];
bots(datasize) result;

integer round_const = 0;
integer shift;
integer element;
boolean sat;

for e = 0 to elements-1
    shift = SInt(Elem[operand2, e, esize]<7:0>);
    if rounding then
        round_const = 1 << (-shift - 1);  // 0 for left shift, 2^(n-1) for right shift
        element = (Int(Elem[operand1, e, esize], unsigned) + round_const) << shift;
        if saturating then
            (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
        else
            Elem[result, e, esize] = element<esize-1:0>;
    else
        Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
```
C7.2.358  **UQRSHRN, UQRSHRN2**

Unsigned saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are rounded. For truncated results, see **UQSHRN, UQRSHRN2**.

The **UQRSHRN** instruction writes the vector to the lower half of the destination register and clears the upper half, while the **UQRSHRN2** instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler symbols

2
Is the second and upper half specifier. If present it causes the operation to be performed on the upper
64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have
the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd>
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>
Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

<Vn>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>
Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-319 when immh = 0000.
The encoding immh = 1xxx is reserved.

<Vb>
Is the destination width specifier, encoded in the "immh" field. It can have the following values:
B when immh = 0001
H when immh = 001x
S when immh = 01xx

The following encodings are reserved:
• immh = 0000.
• immh = 1xxx.

<d>
Is the number of the SIMD&FP destination register, in the "Rd" field.

</a>
Is the source width specifier, encoded in the "immh" field. It can have the following values:
H when immh = 0001
S when immh = 001x
D when immh = 01xx
The following encodings are reserved:

- \( \text{immh} = 0000 \).
- \( \text{immh} = 1xxx \).

\(<n>\) Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

\(<\text{shift}>\) For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

- \(16\text{-}\text{UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 0001\)
- \(32\text{-}\text{UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 001x\)
- \(64\text{-}\text{UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 01xx\)

The following encodings are reserved:

- \( \text{immh} = 0000 \).
- \( \text{immh} = 1xxx \).

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- \(16\text{-}\text{UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 0001\)
- \(32\text{-}\text{UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 001x\)
- \(64\text{-}\text{UInt}(\text{immh}:\text{immb})\) when \(\text{immh} = 01xx\)

See Advanced SIMD modified immediate on page C4-319 when \(\text{immh} = 0000\).

The encoding \(\text{immh} = 1xxx\) is reserved.

**Operation for all encodings**

```
CheckFPAdvSIMDEnabled64();

8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1
2D when immh = 1xxx, Q = 1

See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = 0 is reserved.

<Vn>
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<shift>
For the scalar variant: is the left shift amount, in the range 0 to the operand width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
(UInt(immh:immb)-8) when immh = 0001
(UInt(immh:immb)-16) when immh = 001x
(UInt(immh:immb)-32) when immh = 01xx
(UInt(immh:immb)-64) when immh = 1xxx

The encoding immh = 0000 is reserved.

For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
(UInt(immh:immb)-8) when immh = 0001
(UInt(immh:immb)-16) when immh = 001x
(UInt(immh:immb)-32) when immh = 01xx
(UInt(immh:immb)-64) when immh = 1xxx
See *Advanced SIMD modified immediate* on page C4-319 when immh = 0000.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
boolean sat;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], src_unsigned) << shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, dst_unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
```
C7.2.360  UQSHL (register)

Unsigned saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts the element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if sat then FPSR.QC = '1';

V[d] = result;
C7.2.361 UQSHRN, UQSHRN2

Unsigned saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see UQRSHRN, UQRSHRN2.

The UQSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the UQSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Assembler symbols**

2  
Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

    [absent]  when Q = 0
    [present] when Q = 1

<Vd>  
Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>  
Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

    8B  when immh = 0001, Q = 0
    16B when immh = 0001, Q = 1
    4H  when immh = 001x, Q = 0
    8H  when immh = 001x, Q = 1
    2S  when immh = 01xx, Q = 0
    4S  when immh = 01xx, Q = 1

See *Advanced SIMD modified immediate* on page C4-319 when immh = 0000, Q = x. The encoding immh = 1xxx, Q = x is reserved.

<Vn>  
Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>  
Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

    8H  when immh = 0001
    4S  when immh = 001x
    2D  when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-319 when immh = 0000. The encoding immh = 1xxx is reserved.

<Vb>  
Is the destination width specifier, encoded in the "immh" field. It can have the following values:

    B   when immh = 0001
    H   when immh = 001x
    S   when immh = 01xx

The following encodings are reserved:

    • immh = 0000.
    • immh = 1xxx.

<d>  
Is the number of the SIMD&FP destination register, in the "Rd" field.

</a>  
Is the source width specifier, encoded in the "immh" field. It can have the following values:

    H   when immh = 0001
    S   when immh = 001x
    D   when immh = 01xx
The following encodings are reserved:

- $\text{immh} = 0000$
- $\text{immh} = 1xxx$

<n>
Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift>
For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

- $16 \cdot \text{UInt}(\text{immh:immb})$ when $\text{immh} = 0001$
- $32 \cdot \text{UInt}(\text{immh:immb})$ when $\text{immh} = 001x$
- $64 \cdot \text{UInt}(\text{immh:immb})$ when $\text{immh} = 01xx$

The following encodings are reserved:

- $\text{immh} = 0000$
- $\text{immh} = 1xxx$

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

- $16 \cdot \text{UInt}(\text{immh:immb})$ when $\text{immh} = 0001$
- $32 \cdot \text{UInt}(\text{immh:immb})$ when $\text{immh} = 001x$
- $64 \cdot \text{UInt}(\text{immh:immb})$ when $\text{immh} = 01xx$

See Advanced SIMD modified immediate on page C4-319 when $\text{immh} = 0000$.

The encoding $\text{immh} = 1xxx$ is reserved.

**Operation for all encodings**

```c
CheckFPAdvSIMDEnabled64();
biasy, size = 2) operand = V[n];
biasy, size) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;
for e = 0 to elements - 1
    element = (Int(Elem[operand, e, 2 * esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';
Vpart[d, part] = result;
```

C7.2.362   UQSUB

Unsigned saturating Subtract. This instruction subtracts the element values of the second source SIMD&FP register from the corresponding element values of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(32) element;

for e = 0 to elements-1
    element = Elem[operand, e, 32];
    Elem[result, e, 32] = UnsignedRecipEstimate(element);

V[d] = result;
```
C7.2.365 URHADD

Unsigned Rounding Halving Add. This instruction adds corresponding unsigned integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see UHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Three registers of the same type variant**

URHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

**Decode for this encoding**

```plaintext
type = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == "11" then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

**Assembler symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 2S when size = 10, Q = 0
  - 4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vn>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```plaintext
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
```
for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  Elem[result, e, esize] = (element1+element2+1)<esize:1>;

V[d] = result;
C7.2.366  **URSHL**

Unsigned Rounding Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Scalar**

```
[31 30 29 28] [27 26 25 24] [23 22 21 20] 16 15 14 13 12 11 10 9 5 4 0 0 1 1 1 1 0 size 1 Rm 0 1 0 1 0 1 Rn Rd
```

**Scalar variant**

URSHL <V><d>, <V><n>, <V><m>

**Decode for this encoding**

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.371 USHLL, USHLL2

Unsigned Shift Left Long (immediate). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, shifts the unsigned integer value left by the specified number of bits, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The USHLL instruction extracts vector elements from the lower half of the source register, while the USHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias UXTL, UXTL2. See Alias conditions for details of when each alias is preferred.

Vector variant

USHLL[2] <Vd>.<Ta>, <Vn>.<Tb>, #<shift>

Decode for this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh[3] == '1' then UNDEFINED;
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
boolean unsigned = (U == '1');

Alias conditions

<table>

</tbody>
</table>

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See Advanced SIMD modified immediate on page C4-319 when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
- 2S when immh = 01xx, Q = 0
- 4S when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<shift> Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

- (UInt(immh:immb)-8) when immh = 0001
- (UInt(immh:immb)-16) when immh = 001x
- (UInt(immh:immb)-32) when immh = 01xx

See Advanced SIMD modified immediate on page C4-319 when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(datasize*2) result;
integer element;
for e = 0 to elements-1
   element = Int(Elem[operand, e, esize], unsigned) << shift;
   Elem[result, e, 2*esize] = element<2*esize-1:0>;
V[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.372 USHR

Unsigned Shift Right (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see URSHR.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

\[
\begin{array}{c|c}
\text{absent} & \text{when } Q = 0 \\
\text{present} & \text{when } Q = 1 \\
\end{array}
\]

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

\[
\begin{array}{c|c}
8 & \text{when } size = 00 \\
4 & \text{when } size = 01 \\
2 & \text{when } size = 10 \\
\end{array}
\]

The encoding size = 11 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<Tb> is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- The encoding size = 11, Q = x is reserved.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.377 UXTL, UXTL2

Unsigned extend Long. This instruction copies each vector element from the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The UXTL instruction extracts vector elements from the lower half of the source register, while the UXTL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the USHLL, USHLL2 instruction. This means that:

- The encodings in this description are named to match the encodings of USHLL, USHLL2.
- The description of USHLL, USHLL2 gives the operational pseudocode for this instruction.

**Vector variant**

UXTL{2} <Vd>.<Ta>, <Vn>.<Tb>

is equivalent to

USHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #0

and is the preferred disassembly when BitCount(immh) == 1.

**Assembler symbols**

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd>

Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta>

Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- 8H when immh = 0001
- 4S when immh = 001x
- 2D when immh = 01xx

See *Advanced SIMD modified immediate* on page C4-319 when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn>

Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb>

Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1
25 when immh = 01xx, Q = 0
45 when immh = 01xx, Q = 1

See Advanced SIMD modified immediate on page C4-319 when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = x is reserved.

Operation
The description of USHLL, USHLL2 gives the operational pseudocode for this instruction.

Operational information
If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.378  UZP1

Unzip vectors (primary). This instruction reads corresponding even-numbered vector elements from the two source
SIMD&FP registers, starting at zero, places the result from the first source register into consecutive elements in the
lower half of a vector, and the result from the second source register into consecutive elements in the upper half of
a vector, and writes the vector to the destination SIMD&FP register.

--- Note ---
This instruction can be used with UZP2 to de-interleave two vectors.

The following figure shows the operation of UZP1 and UZP2 with the arrangement specifier 8B.

```
Vn  A7  A6  A5  A4  A3  A2  A1  A0
Vm  B7  B6  B5  B4  B3  B2  B1  B0
```

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state
and Exception level, an attempt to execute the instruction might be trapped.

```
<table>
<thead>
<tr>

**Advanced SIMD variant**

UZP1 <Vd>.<t>, <Vn>.<t>, <Vm>.<t>

**Decode for this encoding**

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
```

**Assembler symbols**

- `<Vd>` is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<t>` is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  - 8B when size = 00, Q = 0
  - 16B when size = 00, Q = 1
  - 4H when size = 01, Q = 0
  - 8H when size = 01, Q = 1
  - 2S when size = 10, Q = 0
  - 4S when size = 10, Q = 1
2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<n> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operandh = V[m];
bits(datasize) result;

bits(datasize*2) zipped = operandh:operand1;
for e = 0 to elements-1
    Elem[result, e, esize] = Elem[zipped, 2*e+part, esize];

V[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C7.2.379  UZP2

Unzip vectors (secondary). This instruction reads corresponding odd-numbered vector elements from the two source SIMD&FP registers, places the result from the first source register into consecutive elements in the lower half of a vector, and the result from the second source register into consecutive elements in the upper half of a vector, and writes the vector to the destination SIMD&FP register.

--- Note ---
This instruction can be used with UZP1 to de-interleave two vectors.

The following figure shows the operation of UZP1 and UZP2 with the arrangement specifier 8B.

```
  Vm  A7  A6  A5  A4  A3  A2  A1  A0
  Vm  B7  B6  B5  B4  B3  B2  B1  B0

UZP1.8, doubleword

Vd  B6  B4  B2  B0  A6  A4  A2  A0

UZP2.8, doubleword

Vd  B7  B5  B3  B1  A7  A5  A3  A1
```

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Advanced SIMD variant

UZP2 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>  

**Decode for this encoding**

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
```

**Assembler symbols**

- **<Vd>**  
  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

- **<T>**  
  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
  
  - 8 when size = 00, Q = 0
  - 16 when size = 00, Q = 1
  - 4 when size = 01, Q = 0
  - 8 when size = 01, Q = 1
  - 2 when size = 10, Q = 0
  - 4 when size = 10, Q = 1
2D  when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

\(<Vn>\)  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<Vm>\)  Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operandl = V[n];
bits(datasize) operandh = V[m];
bits(datasize) result;

bits(datasize*2) zipped = operandh:operandl;
for e = 0 to elements-1
    Elem[result, e, esize] = Elem[zipped, 2*e+part, esize];

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.380   XAR

Exclusive OR and Rotate performs a bitwise exclusive OR of the 128-bit vectors in the two source SIMD&FP
registers, rotates each 64-bit element of the resulting 128-bit vector right by the value specified by a 6-bit immediate
value, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when ARMv8.2-SHA is implemented.

ARMv8.2

```

Advanced SIMD variant

XAR <Vd>.2D, <Vn>.2D, <Vm>.2D, #<imm6>

Decode for this encoding

```python
if !HaveSHA3Ext() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
```

Assembler symbols

```markdown
<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>  Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<imm6>  Is a rotation right, encoded in "imm6".
```

Operation

```python
AArch64.CheckFPAdvSIMDEnabled();

bits(128) Vm = V[m];
bits(128) Vn = V[n];
bits(128) tmp;
tmp = Vn EOR Vm;
V[d] = ROR(tmp<127:64>, UInt(imm6)):ROR(tmp<63:0>, UInt(imm6));
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### C7.2.381 XTN, XTN2

Extract Narrow. This instruction reads each vector element from the source SIMD&FP register, narrows each value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements.

The XTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the XTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

#### Vector variant

XTN{2} <Vd>.<Tb>, <Vn>.<Ta>

#### Decode for this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
```

#### Assembler symbols

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
   [absent]  when Q = 0
   [present]  when Q = 1

<Vd>  Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb>  Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
   8B  when size = 00, Q = 0
   16B when size = 00, Q = 1
   4H  when size = 01, Q = 0
   8H  when size = 01, Q = 1
   2S  when size = 10, Q = 0
   4S  when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn>  Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta>  Is an arrangement specifier, encoded in the "size" field. It can have the following values:
   8H  when size = 00
The encoding size = 11 is reserved.

Operation

```c
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;
bits(2*esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, 2*esize];
    Elem[result, e, esize] = element<esize-1:0>;
Vpart[d, part] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C7.2.382 ZIP1

Zip vectors (primary). This instruction reads adjacent vector elements from the upper half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

--- Note ---
This instruction can be used with ZIP2 to interleave two vectors.

The following figure shows the operation of ZIP1 and ZIP2 with the arrangement specifier 8B.

---

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

---

**Advanced SIMD variant**

ZIP1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

**Decode for this encoding**

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;

**Assembler symbols**

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

<table>
<thead>

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Part D

The AArch64 System Level Architecture
This chapter describes the AArch64 system level programmers’ model. It contains the following sections:

- **Exception levels** on page D1-2134.
- **Exception terminology** on page D1-2135.
- **Execution state** on page D1-2137.
- **Security state** on page D1-2138.
- **Virtualization** on page D1-2140.
- **Registers for instruction processing and exception handling** on page D1-2143.
- **Process state, PSTATE** on page D1-2149.
- **Program counter and stack pointer alignment** on page D1-2152.
- **Reset** on page D1-2154.
- **Exception entry** on page D1-2158.
- **Exception return** on page D1-2167.
- **The Exception level hierarchy** on page D1-2171.
- **Synchronous exception types, routing and priorities** on page D1-2178.
- **Asynchronous exception types, routing, masking and priorities** on page D1-2186.
- **Configurable instruction enables and disables, and trap controls** on page D1-2196.
- **System calls** on page D1-2242.
- **Mechanisms for entering a low-power state** on page D1-2243.
- **Self-hosted debug** on page D1-2248.
- **Event monitors** on page D1-2250.
- **Interprocessing** on page D1-2251.
- **The effect of implementation choices on the programmers’ model** on page D1-2264.
D1.1 Exception levels

The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If ELn is the Exception level, increased values of n indicate increased software execution privilege.
- Execution at EL0 is called unprivileged execution.
- EL2 provides support for virtualization.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

Note

A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

The effect of implementation choices on the programmers’ model on page D1-2264 shows some example implementations.

When executing in AArch64 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the target Exception level of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the System registers.

An exception cannot target EL0.

Exception levels exist within a particular Security state. The ARMv8-A security model on page D1-2138 describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then when execution is at EL3, the PE can access all resources available at all Exception levels, for both Security states.

Each Exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see Chapter D5 The AArch64 Virtual Memory System Architecture.

D1.1.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

- EL0 Applications.
- EL1 OS kernel and associated functions that are typically described as privileged.
- EL2 Hypervisor.
- EL3 Secure monitor.
D1.2 Exception terminology

The following subsections define the terms used when describing exceptions:

• Terminology for taking an exception.
• Terminology for returning from an exception.
• Exception levels.
• Definition of a precise exception.
• Definitions of synchronous and asynchronous exceptions on page D1-2136.

D1.2.1 Terminology for taking an exception

An exception is generated when the PE first responds to an exceptional condition. The PE state at this time is the state the exception is taken from. The PE state immediately after taking the exception is the state the exception is taken to.

D1.2.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception returns from. The PE state immediately after the execution of that instruction is the state the exception returns to.

D1.2.3 Exception levels

An Exception level, ELₙ, with a larger value of ℎ than another Exception level, is described as being a higher Exception level than the other Exception level. For example, EL3 is a higher Exception level than EL1.

An Exception level with a smaller value of ℎ than another Exception level is described as being a lower Exception level than the other Exception level. For example, EL0 is a lower Exception level than EL1.

An Exception level is described as:

• Using AArch64 when execution in that Exception level is in the AArch64 Execution state.
• Using AArch32 when execution in that Exception level is in the AArch32 Execution state.

D1.2.4 Definition of a precise exception

An exception is described as precise when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Other than the SError interrupt, all exceptions taken to AArch64 state are required to be precise. For each occurrence of an SError interrupt, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

Where a synchronous exception that is taken to AArch64 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by the instructions can be UNKNOWN, provided that:

• The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
• The registers are not involved in the calculation of the memory address used by the instruction.

Also, for Data Aborts from load or store instructions executed in AArch64 state, where the Data Abort is taken synchronously:

• If the load or store instruction specifies writeback of a new base address, the base address is restored to the original value on taking the exception.
• If the instruction was a load to either the base address register or the offset register, that register is restored to the original value. Any other destination registers become UNKNOWN.
• If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.
Examples of instructions that perform more than one single-copy atomic memory access are the AArch32 LDM and STM instructions and the AArch64 LDP and STP instructions.

--- Note ---
For the definition of a single-copy atomic access, see Properties of single-copy atomic accesses on page B2-93.

D1.2.5 Definitions of synchronous and asynchronous exceptions

An exception is described as synchronous if all of the following apply:

• The exception is generated as a result of direct execution or attempted execution of an instruction.
• The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
• The exception is precise.

For more information about synchronous exceptions, see Synchronous exception types, routing and priorities on page D1-2178.

An exception is described as asynchronous if any of the following apply:

• The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
• The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
• The exception is imprecise.

For more information about asynchronous exceptions, see Asynchronous exception types, routing, masking and priorities on page D1-2186.
D1.3 Execution state

The Execution states are:

- **AArch64** The 64-bit Execution state.
- **AArch32** The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

*Execution state on page A1-36* gives more information about them.

Exception levels *use* Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

--- Note ---

- *Typical Exception level usage model on page D1-2134* shows which Exception levels different software layers might typically use.
- *The effect of implementation choices on the programmers’ model on page D1-2264* gives information on supported configurations of Exception levels and Execution states.

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. *Interprocessing on page D1-2251* describes this.
D1.4 Security state

The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

**Secure state**
When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.

**Non-secure state**
When in this state, the PE:
- Can access only the Non-secure physical address space.
- Cannot access the Secure system control resources.

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see *About the Virtual Memory System Architecture (VMSA)* on page D5-2372.

D1.4.1 The ARMv8-A security model

The principles of the ARMv8-A security model are:

- If the implementation includes EL3, then it has two Security states, Secure and Non-secure, and:
  - EL3 exists only in Secure state.
  - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
  - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
  - If ARMv8.4-SecEL2 is not implemented, EL2 exists only in Non-secure state.
  - If ARMv8.4-SecEL2 is implemented, EL2 can exist in Secure state. It is enabled when the value of SCR_EL3.EEL2 is 1.
- If the implementation does not include EL3, it has one Security state, that is:
  - IMPLEMENTATION DEFINED, if the implementation does not include EL2 or if ARMv8.4-SecEL2 is implemented.
  - Non-secure state, if the implementation includes EL2 and ARMv8.4-SecEL2 is not implemented.

Security model when EL3 is using AArch64 state

Figure D1-1 on page D1-2139 shows the security model when EL3 is using AArch64 state. The figure shows how instances of EL0 and EL1 are present in both Security states. It also shows the expected software usage of the different Exception levels.
For an overview of the Security model when EL3 is using AArch32, see Figure G1-1 on page G1-5224.
D1.5 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2.

When enabled in the current Security state, EL2 provides a set of features that support virtualizing an ARMv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between virtual machines. A virtual machine comprises EL1 and EL0.
- A number of Guest operating systems. A Guest OS runs on a virtual machine in EL1.
- For each Guest operating system, applications, that run on the virtual machine of that Guest OS, usually in EL0.

Note

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

The hypervisor assigns a virtual machine identifier (VMID) to each virtual machine.

EL2 supports Guest OS management and provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.

- Trap various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2. See Configurable instruction enables and disables, and trap controls on page D1-2196.

- Route interrupts to the appropriate one of:
  - The current Guest OS.
  - A Guest OS that is not currently running.
  - The hypervisor.

ARMv8.1 introduces the Virtualization Host Extensions (VHE) that provide enhanced support for Type 2 hypervisors. For more information, see Virtualization Host Extensions on page D5-2474.

In an implementation that includes EL2:

- The implementation provides an independent translation regime for memory accesses from EL2, the EL2 translation regime. An implementation that includes ARMv8.1-VHE also supports an alternative EL2&0 translation regime.

Note

An implementation that includes ARMv8.1-VHE can be configured so that the EL2&0 translation regime is used both for accesses from EL2 and for accesses from EL0.

- For the EL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the virtual address (VA) to an intermediate physical address (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the physical address (PA).
  - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

- When ARMv8.3-NV is implemented, a Guest Hypervisor can be run at EL1. For more information on how this affects address translation, see Nested virtualization on page D5-2480.

- When ARMv8.4-NV is implemented, then accesses of EL1 and EL2 registers that would be trapped are instead transformed into memory accesses. For more information, see Enhanced support for nested virtualization on page D5-2482.
D1.5 Virtualization

D1.5.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- **HVC** on page C6-824.
- Traps to EL2. *EL2 configurable controls* on page D1-2206, describes these.
- All of the virtual interrupts:
  - Virtual SError.
  - Virtual IRQ.
  - Virtual FIQ.

All virtual interrupts are always taken to EL1, and can only be taken from EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See *Virtual interrupts*.

When a virtual interrupt is enabled, its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3.

For more information, see *Asynchronous exception types, routing, masking and priorities* on page D1-2186.

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions. For more information, see:
  - *Routing exceptions from EL0 to EL2* on page D1-2178.
  - *Routing debug exceptions* on page D2-2275.
- Provides mechanisms to trap PE operations to EL2. See *EL2 configurable controls* on page D1-2206.

  When an operation is trapped to EL2, the hypervisor typically either:
  - Emulates the required operation. The application running in the Guest OS is unaware of the trap.
  - Returns an error to the Guest OS.

Virtual interrupts

The virtual interrupts have names that correspond to the physical interrupts, as shown in Table D1-1.

<table>
<thead>
<tr>
<th>Physical interrupt</th>
<th>Corresponding virtual interrupt</th>
</tr>
</thead>
<tbody>
<tr>
<td>SError</td>
<td>Virtual SError</td>
</tr>
<tr>
<td>IRQ</td>
<td>Virtual IRQ</td>
</tr>
<tr>
<td>FIQ</td>
<td>Virtual FIQ</td>
</tr>
</tbody>
</table>

Software executing in EL2 can use virtual interrupts to signal physical interrupts to EL1 and EL0. Example D1-1 shows a usage model for virtual interrupts.

Example D1-1 Virtual interrupt usage model

A virtual interrupt usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.
2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:

- If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
- If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

A hypervisor can prevent EL1 and EL0 from distinguishing a virtual interrupt from a physical interrupt.
D1.6 Registers for instruction processing and exception handling

In the ARM architecture, registers fall into two main categories:

- Registers that provide system control or status reporting. These are described in Chapter D12 AArch64 System Register Descriptions.
- Registers that are used in instruction processing, for example to accumulate a result, and in handling exceptions. This section introduces these registers, for execution in AArch64 state.

This section contains the following subsections:

- The general purpose registers, R0-R30.
- The stack pointer registers.
- The SIMD and floating-point registers, V0-V31.
- Saved Program Status Registers (SPSRs).
- Exception Link Registers (ELRs).

D1.6.1 The general purpose registers, R0-R30

The general purpose register bank is used when processing instructions in the base instruction set. It comprises 31 general purpose registers, R0-R30.

These registers can be accessed as 31 64-bit registers, X0-X30, or 31 32-bit registers, W0-W30. See Register size on page C6-676.

For information on the format of these registers, see Registers in AArch64 state on page B1-81.

D1.6.2 The stack pointer registers

In AArch64 state, in addition to the general purpose registers, a dedicated stack pointer register is implemented for each implemented Exception level. The stack pointer registers are:

- SP_EL0 and SP_EL1.
- If the implementation includes EL2, SP_EL2.
- If the implementation includes EL3, SP_EL3.

Note

The four stack pointer register names define an architecture state requirement for four registers. For information on how to access these registers, and access restrictions, see Special-purpose registers on page C5-354.

For information on stack pointer alignment restrictions, see SP alignment checking on page D1-2152.

Stack pointer register selection

When executing at EL0, the PE uses the EL0 stack pointer, SP_EL0.

When executing at any other Exception level, the PE can be configured to use either SP_EL0 or the stack pointer for that Exception level, SP_ELx.

By default, taking an exception selects the stack pointer for the target Exception level, SP_ELx. For example, taking an exception to EL1 selects SP_EL1. Software executing at the target Exception level can then choose to change the stack pointer to SP_EL0 by updating PSTATE.SP.

This applies even if taking the exception does not change the Exception level. For example, if the PE is executing at EL1 and the PE is using the SP_EL0 stack pointer, then on taking an exception that targets EL1, the stack pointer changes to SP_EL1.

The selected stack pointer can be indicated by a suffix to the Exception level:

- t Indicates use of the SP_EL0 stack pointer.
- h Indicates use of the SP_ELx stack pointer.
D1.6 Registers for instruction processing and exception handling

Note
The t and h suffixes are based on the terminology of thread and handler.

Table D1-2 shows the set of stack pointer options.

<table>
<thead>
<tr>
<th>Exception level (EL)</th>
<th>Stack pointer (SP) options</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0</td>
<td>SP_EL0t</td>
</tr>
<tr>
<td>EL1</td>
<td>SP_EL1t, SP_EL1h</td>
</tr>
<tr>
<td>EL2</td>
<td>SP_EL2t, SP_EL2h</td>
</tr>
<tr>
<td>EL3</td>
<td>SP_EL3t, SP_EL3h</td>
</tr>
</tbody>
</table>

D1.6.3 The SIMD and floating-point registers, V0-V31

The SIMD and floating-point instructions share a common bank of registers for floating-point, vector, and other SIMD-related scalar operations.

The SIMD and floating-point register bank comprises 32 quadword (128-bit) registers, V0-V31.

These registers can be accessed as:
- 32 doubleword (64-bit) registers, D0-D31.
- 32 word (32-bit) registers, S0-S31.
- 32 halfword (16-bit) registers, H0-H31.
- 32 byte (8-bit) registers, B0-B31.

For information on the format of these registers, see Registers in AArch64 state on page B1-81.

D1.6.4 Saved Program Status Registers (SPSRs)

The Saved Program Status Registers (SPSRs) are used to save PE state on taking exceptions.

In AArch64 state, there is an SPSR at each Exception level exceptions can be taken to, as follows:
- SPSR_EL1, for exceptions taken to EL1 using AArch64.
- If EL2 is implemented, SPSR_EL2, for exceptions taken to EL2 using AArch64.
- If EL3 is implemented, SPSR_EL3, for exceptions taken to EL3 using AArch64.

Note
Exceptions cannot be taken to EL0.

When the PE takes an exception, the PE state is saved from PSTATE in the SPSR at the Exception level the exception is taken to. For example, if the PE takes an exception to EL1, the PE state is saved in SPSR_EL1. For more information on PSTATE, see Process state, PSTATE on page D1-2149.

Saving the PE state means the exception handler can:
- On return from the exception, restore the PE state to the state stored in the SPSR at the Exception level the exception is returning from. For example, on returning from EL1, the PE state is restored to the state stored in SPSR_EL1.
- Examine the value that PSTATE had when the exception was taken, for example to determine the Execution state and Exception level in which the instruction that caused an exception was executed.
### Note

- All PSTATE fields are saved, including those which have no direct read and write access, and those that are meaningful only in AArch32 state.
- Those PSTATE fields that are meaningful only in AArch32 state are saved when an exception is taken from AArch32 state to AArch64 state.

The SPSRs are UNKNOWN on reset.

### SPSR format for exceptions taken to AArch64 state

Exceptions can be taken to AArch64 state from AArch64 state or AArch32 state:

- For an exception taken to AArch64 state from AArch64 state, the SPSR bit assignments are:

```
   31 30 29 28 27 25 24 23 22 21 20 19 10 9 8 7 6 5 4 3 0
N  Z  C  V RES0 RES0 D  A  I  F  0  M[3:0]
```

**Condition flags**
- N, Z, C, V, bits[31:28]
  - Shows the values of the PSTATE, {N, Z, C, V} Condition flags immediately before the exception was taken.

**Bits[27:24], for exceptions taken from AArch64 state**
- Reserved, RES0.

**Q, bit[27], for exceptions taken from AArch32 state**
- Shows the value of PSTATE.Q immediately before the exception was taken.

**IT[1:0], bits[26:25], for exceptions taken from AArch32 state**
- See IT[7:2] on page D1-2146.

**DIT, bit[24], from ARMv8.4**
- Shows the value of PSTATE.DIT immediately before the exception was taken.

**UAO, bit[23], from ARMv8.2**
- Shows the value of PSTATE.UAO immediately before the exception was taken.
- This bit is res0 in ARMv8.0 and in ARMv8.1 when ARMv8.2-UAO is not implemented.

The following list describes the bit assignments:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Shows the values of the PSTATE, {N, Z, C, V} Condition flags immediately before the exception was taken.</td>
</tr>
<tr>
<td>Z</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>C</td>
<td>Shows the value of PSTATE.Q immediately before the exception was taken.</td>
</tr>
<tr>
<td>V</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>RES0</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>D</td>
<td>Shows the value of PSTATE.DIT immediately before the exception was taken.</td>
</tr>
<tr>
<td>A</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>I</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>F</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>0</td>
<td>Shows the value of PSTATE.UAO immediately before the exception was taken.</td>
</tr>
<tr>
<td>M[3:0]</td>
<td>Execution State.</td>
</tr>
<tr>
<td>GE[3:0]</td>
<td>Shows the value of PSTATE.GE[3:0] immediately before the exception was taken.</td>
</tr>
</tbody>
</table>
PAN, bit[22], from ARMv8.1
Shows the value of PSTATE.PAN immediately before the exception was taken.
This bit is res0 when ARMv8.1-PAN is not implemented.

SPSR_ELx.SS is used by a debugger to initiate a Software Step exception. The SS bit also indicates
which software step state machine state the PE was in. See Software Step exceptions on
page D2-2317.

IL, bit[20] Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was
taken. See Illegal return events from AArch64 state on page D1-2168.

Bits[19:10], for exceptions taken from AArch64 state
Reserved, RES0.

GE[3:0], bits [19:16], for exceptions taken from AArch32 state
Shows the value of PSTATE.GE immediately before the exception was taken.

IT[7:2], bits [15:10], for exceptions taken from AArch32 state
With IT[1:0] on page D1-2145, shows the value of PSTATE.IT before the exception was taken.

D, bit[9], for exceptions taken from AArch64 state
The debug exception mask bit. Shows the value of PSTATE.D immediately before the exception
was taken. See The PSTATE debug mask bit, D on page D1-2248.

E, bit[9], for exceptions taken from AArch32 state
Endianness of data accesses. Shows the value of PSTATE.E immediately before the exception was
taken.

A, I, F, bits[8:6]
Shows the values of the PSTATE.{A, I, F} exception mask bits immediately before the exception
was taken:
See Asynchronous exception masking on page D1-2190.

Bit[5], for exceptions taken from AArch64 state
Reserved, RES0.

T, bit[5], for exceptions taken from AArch32 state
Shows the value of PSTATE.T immediately before the exception was taken.

M[4:0], bits[4:0], for exceptions taken from AArch64 state

Note
The name of this field is inherited from ARMv7, where the M field specified the PE mode.

M[4] The value of this is 0. M[4] encodes the value of PSTATE.nRW, that indicates the
Execution state from which the exception was taken.
M[3:0] Encodes the Exception level and the stack pointer register selection, as shown in Table D1-3.

Table D1-3 M[3:0] encodings, for exceptions taken from AArch64 state

<table>
<thead>
<tr>
<th>M[3:0]</th>
<th>Exception level and stack pointer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>EL.3h</td>
</tr>
<tr>
<td>0b1110</td>
<td>EL.3t</td>
</tr>
<tr>
<td>0b1101</td>
<td>EL.2h</td>

</tr>
<tr>
<td>0b1000</td>
<td>EL.0t</td>
</tr>
</tbody>
</table>

a. All M[3:0] encodings not shown in the table are reserved.

The M[3:0] encoding comprises:
- M[1] Reserved, RES0. If set to 1 at the time of an exception return, then that exception return is treated as an Illegal Execution state exception return.
- M[0] Selects the SP:
  - 0 SP_EL0. Indicated by a t suffix on the Exception level.
  - 1 SP_ELx, where x is the value of M[3:2]. Indicated by an h suffix on the Exception level.

See Stack pointer register selection on page D1-2143.

M[4:0], bits[4:0], for exceptions taken from AArch32 state
The Mode field. Specifies the AArch32 PE mode.

M[4] The value of this is 1. M[4] encodes the value of PSTATE.nRW, that indicates the Execution state from which the exception was taken.

M[3:0] Encodes the AArch32 PE mode that the PE was in immediately before the exception was taken, as shown in Table D1-4.

Table D1-4 M[3:0] encodings, for exceptions taken from AArch32 state

<table>

### Note

In this description of SPSR:

- For exceptions taken from AArch64 state, PSTATE links to the AArch64 system level description.
- For exceptions taken from AArch32 state, PSTATE links to the AArch32 system level description.

### SPSR bits:

- That are defined as RES0 on an exception taken from AArch32 state are ignored on any exception return to AArch32 state.
- That are defined as RES0 on an exception taken from AArch64 state are ignored on any exception return to AArch64 state.

### Pseudocode description of SPSR operations

The SPSR[] pseudocode function accesses the current SPSR, and is common to AArch32 and AArch64 operations. The SetPSTATEFromPSR() pseudocode function updates PSTATE from an SPSR.

### D1.6.5 Exception Link Registers (ELRs)

Exception Link Registers hold preferred exception return addresses.

Whenever the PE takes an exception, the preferred return address is saved in the ELR at the Exception level the exception is taken to. For example, whenever the PE takes an exception to EL1, the preferred return address is saved in ELR_EL1.

On an exception return, the PC is restored to the address stored in the ELR. For example, on returning from EL1, the PC is restored to the address stored in ELR_EL1.

AArch64 state provides an ELR for each Exception level exceptions can be taken to. The ELRs that AArch64 state provides are:

- ELR_EL1, for exceptions taken to EL1.
- If EL2 is implemented, ELR_EL2, for exceptions taken to EL2.
- If EL3 is implemented, ELR_EL3, for exceptions taken to EL3.

On taking an exception from AArch32 state to AArch64 state, bits[63:32] of the ELR are set to zero.

The preferred return address depends on the nature of the exception. For more information, see Preferred exception return address on page D1-2159.
D1.7 Process state, PSTATE

In the ARMv8-A architecture, Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE includes all of the following:

- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

PSTATE is defined in pseudocode as the PSTATE structure, of type `ProcState`. `ProcState` is defined in Chapter J1 ARMv8 Pseudocode.

The PSTATE fields that are meaningful in AArch64 state are:

The Condition flags

- **N** Negative Condition flag.
- **Z** Zero Condition flag.
- **C** Carry Condition flag.
- **V** Overflow Condition flag.

*Process state, PSTATE on page B1-82* gives more information about these flags.

The Execution state controls

- **SS** Software Step bit, see *Software Step exceptions on page D2-2317*. On a reset or taking an exception to AArch64 state, this bit is set to 0.
- **IL** Illegal Execution state bit, see *The Illegal Execution state exception on page D1-2170*. On a reset or taking an exception to AArch64 state, this bit is set to 0.
- **nRW** Current Execution state, see *Execution state on page D1-2137*. This bit is 0 when the current Execution state is AArch64. This bit is set to 0:
  - On reset into an Exception level that is using AArch64.
  - On taking an exception to an Exception level that is using AArch64.
- **EL** Current Exception level, see *Exception levels on page D1-2134*. On a reset to AArch64 state, this field holds the encoding for the highest implemented Exception level.

  **Note**

  The ARM architecture requires that a PE resets into the highest implemented Exception level.

- **SP** Stack pointer register selection bit, see *Stack pointer register selection on page D1-2143*. On a reset or taking an exception to AArch64 state, this bit is set to 1, meaning that SP_ELx is selected.

The exception mask bits

- **D** Debug exception mask bit, see *The PSTATE debug mask bit, D on page D1-2248*. On a reset or taking an exception to AArch64 state, this bit is set to 1.
- **A, I, F** Asynchronous exception mask bits:
  - **A** SError interrupt mask bit.
  - **I** IRQ interrupt mask bit.
  - **F** FIQ interrupt mask bit.

See *Asynchronous exception types, routing, masking and priorities on page D1-2186*. On a reset or taking an exception to AArch64 state, each of these bits is set to 1.

Access control bits

- **PAN** Privileged Access Never (PAN) state bit. For more information, see *About PSTATE.PAN on page D5-2445*. This bit is implemented only when ARMv8.1-PAN is implemented.
D1.7 Process state, PSTATE

Timing control bits

UAO  
*User Access Override* (UAO) bit. For more information, see *About PSTATE_UAO* on page D5-2446.
This bit is implemented only when ARMv8.2-UAO is implemented.

DIT  
*Data Independent Timing* (DIT) bit. For more information, see *About PSTATE.DIT* on page B1-87.
This bit is implemented only when ARMv8.4-DIT is implemented.

On a reset to AArch64 state, this bit is set to 0.

D1.7.1 Accessing PSTATE fields

In AArch64 state, PSTATE fields can be accessed using Special-purpose registers that can be directly read using the MRS instruction, and directly written using the MSR (register) instructions. Table D1-5 shows the Special-purpose registers that access the PSTATE fields that hold AArch64 state, when the PE is in AArch64 state. All other PSTATE fields do not have direct read and write access.

Table D1-5 Accessing PSTATE fields using MRS and MSR (register)

<table>
<thead>
<tr>
<th>Special-purpose register</th>
<th>PSTATE fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>NZCV</td>
<td>N, Z, C, V</td>
</tr>
<tr>
<td>DAIF</td>
<td>D, A, I, F</td>
</tr>
<tr>
<td>CurrentEL</td>
<td>EL</td>

<tr>
<td>SPSel</td>
<td>SP</td>
</tr>
<tr>
<td>PAN</td>
<td>PAN</td>
</tr>
<tr>
<td>UAO</td>
<td>UAO</td>
</tr>
<tr>
<td>DIT</td>
<td>DIT</td>
</tr>
</tbody>
</table>

Software can also use the MSR (immediate) instruction to directly write to PSTATE. {D, A, I, F, SP, PAN, UAO}. Table D1-6 shows the MSR (immediate) operands that can directly write to these PSTATE fields when the PE is in AArch64 state.

Table D1-6 Accessing PSTATE.{D, A, I, F, SP} using MSR (immediate)

<table>
<thead>
<tr>
<th>Operand</th>
<th>PSTATE fields</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAIFSet</td>
<td>D, A, I, F</td>
<td>Directly sets any of the PSTATE.{D,A, I, F} bits to 1</td>
</tr>
<tr>
<td>DAIFClr</td>
<td>D, A, I, F</td>

<td>UAO</td>
<td>Directly sets PSTATE.UAO to either 1 or 0</td>
</tr>
<tr>
<td>DIT</td>
<td>DIT</td>
<td>Directly sets PSTATE.DIT to either 1 or 0</td>
</tr>
</tbody>
</table>

PSTATE. {N, Z, C, V} can be accessed at EL0. Access to PSTATE. {D, A, I, F} at EL0 using AArch64 depends on SCTLR_EL1.UMA, see *Traps to EL1 of EL0 accesses to the PSTATE. {D, A, I, F} interrupt masks* on page D1-2200. All other PSTATE access instructions can be executed at EL1 or higher and are UNDEFINED at EL0.
Writes to the PSTATE fields have side-effects on various aspects of the PE operation. All of these side-effects are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

D1.7.2 The Saved Program Status Registers (SPSRs)

On taking an exception, PSTATE is preserved in the SPSR of the Exception level the exception is taken to. The SPSRs are described in *Saved Program Status Registers (SPSRs)* on page D1-2144.
D1.8 Program counter and stack pointer alignment

This section contains the following:

• PC alignment checking.
• SP alignment checking.

D1.8.1 PC alignment checking

PC alignment checking generates a PC alignment fault exception associated with the instruction fetch if, in AArch64 state, there is an attempt to architecturally execute an instruction that was fetched with a misaligned PC. A misaligned PC is when bits[1:0] of the PC are not 0b00.

Note

As with Instruction Aborts, speculative fetching of an instruction does not generate an exception. An exception occurs only on an attempt to architecturally execute the instruction.

If an exception is generated as a result of an instruction fetch at EL0, it is taken to EL1. If an exception occurs when HCR_EL2.TGE bit is 1 and EL2 is enabled in the current Security state, it is taken to EL2. If an exception is generated as a result of an instruction fetch at any other Exception level, the Exception level is unchanged.

A PC misalignment sets the EC field in the Exception Syndrome Register (ESR) to 0x22, for the ESR associated with the target Exception level.

When the exception is taken to an Exception level using AArch64, the associated Exception Link Register holds the entire PC in its misaligned form, as does the FAR_ELx for the Exception level that the exception is taken to.

Exception return and PC alignment on page D1-2168 gives more information on PC alignment checking associated with exception returns.

Note

A misalignment of the PC is a common indication of a serious error, for example software corruption of an address.

The pseudocode function AArch64.CheckPCAlignment() performs PC alignment checking in AArch64 state. When necessary it calls AArch64.PCAlignmentFault() to generate an exception.

D1.8.2 SP alignment checking

A misaligned stack pointer is where bits[3:0] of the stack pointer are not 0b0000, when the stack pointer is used as the base address of the calculation, regardless of any offset applied by the instruction.

The PE can be configured so that if a load or store instruction uses a misaligned stack pointer, the PE generates an SP alignment fault exception on the attempt to execute the instruction. In this configuration, CheckSPAlignment() performs the stack pointer check, and calls AArch64.SPAlignmentFault() if a misaligned stack pointer is found.

Note

• As with Data Aborts, a speculative data access to memory using the stack pointer does not generate the exception. The exception occurs only on an attempt to architecturally execute the instruction.
• Prefetch memory abort instructions do not cause synchronous exceptions. See Prefetch memory on page C3-188.

Stack pointer alignment checking is only performed in AArch64 state, and can be enabled for each Exception level as follows:

• SCTLR_EL1.{SA0, SA} controls EL0 and EL1, respectively.
• SCTLR_EL2.SA controls EL2.
• SCTLR_EL3.SA controls EL3.
If an exception is generated as a result of a load or store at EL0, it is taken as an exception to EL1. If an exception occurs when the HCR_EL2.TGE bit is set and EL2 is enabled in the current Security state, it is taken to EL2. If an exception is generated as a result of a load or store at any other Exception level, the Exception level is unchanged.

A stack pointer misalignment sets the EC field to 0x26, in the ESR associated with the target Exception level. If memory alignment checking and stack pointer alignment checking are enabled, then an SP alignment fault has priority in setting the value of the EC field, in the ESR associated with the target Exception level.

The pseudocode function `CheckSPAlignment()` performs the stack pointer alignment check. When necessary it calls `AArch64.SPAlignmentFault()` to generate an exception.
D1.9 Reset

The ARMv8-A architecture supports the following resets:

<table>
<thead>
<tr>
<th>Reset Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cold reset</td>
<td>Resets all of the logic on which the PE executes, including the integrated debug functionality.</td>
</tr>
<tr>
<td>Warm reset</td>
<td>Resets the logic on which the PE executes, but does not reset the integrated debug functionality.</td>
</tr>
</tbody>
</table>

All logic on which the PE executes that is reset by a Warm reset is also reset by a Cold reset.

Note: The ARMv8-A architecture also supports an external debug reset. See External debug register resets on page H8-6558.

The difference between a Cold reset and a Warm reset is relevant only to the debug functionality and the RMR_ELx register, if an RMR_ELx register is implemented:

- A Warm reset permits debugging across a reset of the PE logic.
- Writing 1 to RMR_ELx.RR requests a Warm reset.

The mechanisms, other than RMR_ELx.RR, to assert these resets are IMPLEMENTATION DEFINED. It is IMPLEMENTATION DEFINED whether:

- It is possible to independently assert an External Debug reset and a Cold reset.
- It is possible to assert a Warm reset, as opposed to asserting a Cold reset, other than by the use of RMR_ELx.RR.

Note: ARM recommends that:

- If separate Core and Debug power domains are implemented, as described in Reset and debug on page H6-6531, then a Cold reset can be asserted independently of External Debug reset.
- A Warm reset can be asserted to permit debugging across a reset of the PE logic.

This means that an implementation can define other resets according to the requirements the implementation or system must fulfil. These other resets are outside the scope of the ARMv8-A architecture. However, they can be mapped onto the resets described here.

In the description that follows, the term reset is used in contexts where there is no difference between the effect of a Cold reset and the effect of a Warm reset.

On a reset, the PE enters the highest implemented Exception level.

If the highest implemented Exception level can use either Execution state, then:

- The implementation must include a Reset Management Register (RMR). Only one RMR is implemented. The RMR implemented is the RMR is associated with the highest Exception level.
- On a Cold reset, the Execution state entered is determined by a configuration input signal.
- On a Warm reset, the Execution state entered is determined by RMR_ELx.AA64.

If the highest implemented Exception level is configured to use AArch64 state, then on reset:

- The stack pointer for the highest implemented Exception level, SP_ELx, is selected.
- Execution starts at an IMPLEMENTATION DEFINED address, anywhere in the physical address range. The RVBAR associated with the highest implemented Exception level, RVBAR_EL1, RVBAR_EL2, or RVBAR_EL3, holds this address.
The remainder of this section contains the following:

- **PE state on reset to AArch64 state.**
- **Code sequence to use RMR_ELx.RR to request a Warm reset on page D1-2156.**

For more information about reset see:

- **Behavior of caches at reset on page D4-2347.**
- **TLB behavior at reset on page D5-2501.**
- **Reset and debug on page H6-6531.**

### D1.9.1 PE state on reset to AArch64 state

#### Note

See the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* for the reset requirements for GIC System registers.

Immediately after a reset, much of the PE state is **UNKNOWN**. However, some of the PE state is defined. If the PE resets to AArch64 state using either a Cold or a Warm reset, the PE state that is defined is as follows:

- Each of the PSTATE.\{D, A, I, F\} interrupt masks is set to 1.
- The Software step control bit, PSTATE.SS, is set to 0.
- The IL process state bit, PSTATE.IL, is set to 0.
- All general-purpose, and SIMD and floating-point registers are **UNKNOWN**.
- The ELR and SPSR for each Exception level are **UNKNOWN**.
- The stack pointer register for each Exception level is **UNKNOWN**.
- The global exclusive monitor and local exclusive monitor for the PE are **UNKNOWN**.
- Unless explicitly defined in this subsection, each System register at each Exception level is in an architecturally **UNKNOWN** state.
- The TLBs and caches are in an **IMPLEMENTATION DEFINED** state. This means that the TLBs, the caches, or both, might require invalidation using **IMPLEMENTATION DEFINED** invalidation sequences before the memory management system is enabled or Normal memory accesses are permitted to be Cacheable.

#### Note

- On reset, System register Cacheability control fields force all Normal memory accesses to be treated as Non-cacheable. This applies only for the translation regime used by the Exception level and Security state entered on reset. For information about these controls see *Enabling and disabling the caching of memory accesses on page D4-2345.*
- The implementation might include **IMPLEMENTATION DEFINED** resets. If it does, each of these resets might treat the cache and TLB state differently. The ARMv8-A architecture permits this.
- Different **IMPLEMENTATION DEFINED** invalidation sequences might be required for different **IMPLEMENTATION DEFINED** resets.
- In some implementations, the **IMPLEMENTATION DEFINED** invalidation sequence might be a NOP.

- In the SCTLR_ELx for the highest implemented Exception level:
  - Each of the \{M, C, I\} bits is set to 0
  - The EE bit is set to an **IMPLEMENTATION DEFINED** value, typically defined by a configuration input.
- If an RMR is implemented, RMR_ELx.RR is set to 0. ELx in this context is the highest implemented Exception level.
- The enables for the counter event stream are set to 0. This means that the following bits are set to 0:
  - CNTKCTL_EL1.EVNTEN.
  - If the implementation includes EL2, CNTHTCTL_EL2.EVNTEN.
- PMCR_EL0.E is set to 0.

#### Note

This means the Performance Monitors cannot assert interrupts at reset.
• **OSDLR_EL1.DLK** bit is set to 0.
• Each of **MDCCINT_EL1.{TX, RX}** is set to 0.
• **EDPSCR.CWRR** is set to 0.
• **EDPRSR.SR** is set to 1.
• If the implementation includes EL3, then each of **MDCR_EL3.{EPMAD, EDAD, SPME}** is set to 0.
• If the implementation includes EL2, then **MDCR_EL2.HPMN** is set to the value of **PMCR_EL0.N**.
• **EDESR.OUSC** is set to 0, and **EDESR.{SS, RC}** are set to the values of **EDECR.{SS, RCE}**.

—— Note ————

On an External debug reset, **EDECR.{SS, RCE}** are set to 0.

Additionally, for a Cold reset into AArch64 state:

• If an RMR is implemented, **RMR_ELx.AA64** is set to 1. ELx in this context is the highest implemented Exception level.
• Each of **MDCCSR_EL0.{TXfull, RXfull}** is set to 0.
• The **DBGPRCR_EL1.CORENPRDRQ** is set to the value of **EDPSCR.COREPURQ**.

An External Debug reset sets **EDPSCR.COREPURQ** to 0, see **External debug register resets** on page H8-6558. If an External Debug reset and a Cold reset coincide, both **DBGPRCR_EL1.CORENPRDRQ** and **EDPSCR.COREPURQ** are reset to 0.

• The debug CLAIM bits are reset to 0.

—— Note ————

These are the bits that are set to 1 by writing to **DBGCLAIMSET_EL1.CLAIM**, and cleared to 0 by writing to **DBGCLAIMCLR_EL1.CLAIM**.

—— Note ————

**MDCCSR_EL0.{RXfull, TXfull}** reflect the values in **EDSCR.{RXfull, TXfull}**.

—— Note ————

**OSLSR_EL1.OSLK** is set to 1.

• In the **EDPRSR**:
  — The SPMAD, SDAD fields are set to 0.
  — The SPD field is set to 1.
• Each field of **AMCNTNCLR0_EL0, AMCNTNCLR1_EL0, AMCNTNSET0_EL0**, and **AMCNTNSET1_EL0** is set to 0.
• Each of the implemented architectured activity monitor counters **AMEVCNTR0<\n> EL0** and each of the implemented auxiliary activity monitor counters **AMEVCNTR1<\n> EL0** are set to 0.

For more information about resets in AArch64 System registers, see Chapter D12 AArch64 System Register Descriptions.

**D1.9.2 Code sequence to use RMR_ELx.RR to request a Warm reset**

The following assembler sequence uses **RMR_ELx.RR** to request a Warm reset:

```assembly
MOV Wy, #3 ; for AArch64, #2 for AArch32; y is any register
DSB ; ensure all stores etc are complete
```

### D1.9.3 Pseudocode description of reset

The `AArch64.TakeReset()` pseudocode function performs a reset into AArch64 state.

`AArch64.TakeReset()` calls the functions `AArch64.ResetGeneralRegisters()`, `AArch64.ResetSIMDFPRegisters()`, `AArch64.ResetSpecialRegisters()`, `AArch64.ResetSystemRegisters()`, and `ResetExternalDebugRegisters()`.

`AArch64.ResetSystemRegisters()` resets all System registers to their reset state as defined in the register descriptions in *PE state on reset to AArch64 state* on page D1-2155 and Chapter D12 *AArch64 System Register Descriptions*.

**Note**
The `AArch64.ResetSystemRegisters()` function only resets the System registers.

`ResetExternalDebugRegisters()` resets all external debug registers to their reset state as defined in the register descriptions in Chapter H9 *External Debug Register Descriptions*. 

```assembly
MSR RMR_ELx, Wy ; request the reset
ISB               ; synchronise change to the RMR
Loop
  WFI               ; enter a quiescent state
B Loop
```
D1.10 Exception entry

Exceptions are targeted at particular Exception levels. The Exception level that an exception targets is either programmed by software, or is determined by the nature of the exception.

Under no circumstances do exceptions cause execution to move to a lower Exception level.

If an asynchronous exception targets a lower Exception level, the exception is not taken and remains pending. See *Asynchronous exception routing* on page D1-2187 and *Asynchronous exception masking* on page D1-2190.

--- Note ---
The construction of the architecture means that usually, it is impossible for an exception to target a lower Exception level.

---

The Security state can only change on taking an exception if taken from Non-secure state to EL3.

--- Note ---
Taking an exception to EL3 from any Exception level has no effect on the value of the SCR_EL3.NS bit.

---

On taking an exception to AArch64 state:

- The PE state is saved in the SPSR_ELx at the target Exception level. See *Saved Program Status Registers (SPSRs)* on page D1-2144.
- The preferred return address is saved in the ELR_ELx at the target Exception level. See *Exception Link Registers (ELRs)* on page D1-2148.
- All of PSTATE.{D, A, I, F} are set to 1. See *Process state, PSTATE* on page D1-2149.
- If ARMv8.2-UAO is implemented, PSTATE.UAO is set to 0. See *Process state, PSTATE* on page D1-2149.
- If the exception is a synchronous exception or an SErr or interrupt, information characterizing the reason for the exception is saved in the ESR_ELx at the target Exception level. See *Use of the ESR_EL1, ESR_EL2, and ESR_EL3* on page D1-2160.
- The stack pointer register selected is the dedicated stack pointer register for the target Exception level. See *The stack pointer registers* on page D1-2143.
- For a physical SError interrupt exception, the pending state of the physical SError is cleared when any of:
  - The SError interrupt is edge-triggered.
  - ARMv8.4-DFE is implemented.
  - If the RAS Extension is implemented, and on taking the SError interrupt, the syndrome recorded in ELR_ELx indicates an SError other than IMPLEMENTATION DEFINED or uncategorized SError interrupt syndrome.
- Otherwise, it is IMPLEMENTATION DEFINED whether the pending state of the physical SError is cleared. This IMPLEMENTATION DEFINED behavior may vary according to the nature of the SError interrupt.
- Execution moves to the target Exception level, and starts at the address defined by the exception vector. Which exception vector is used is also an indicator of whether the exception came from a lower Exception level or the current Exception level. See *Exception vectors* on page D1-2159.

The remainder of this section contains the following:

- *Preferred exception return address* on page D1-2159.
D1.10 Exception entry

- Exception vectors.
- Pseudocode description of exception entry to AArch64 state on page D1-2160.
- Exception classes and the ESR_ELx syndrome registers on page D1-2160.
- Summary of register updates on faults taken to an Exception level that is using AArch64 on page D1-2165.

D1.10.1 Preferred exception return address

For an exception taken to an Exception level using AArch64, the Exception Link Register for that Exception level, ELR_ELx, holds the preferred exception return address. The preferred exception return address depends on the nature of the exception, as follows:

- For asynchronous exceptions, it is the address of the instruction following the instruction boundary at which the interrupt occurs. Therefore, it is the address of the first instruction that did not execute, or did not complete execution, as a result of taking the interrupt.
- For synchronous exceptions other than system calls, it is the address of the instruction that generates the exception.
- For exception generating instructions, it is the address of the instruction that follows the exception generating instruction.

--- Note ---

If an exception generating instruction is trapped, disabled, or is UNDEFINED because the Exception level has insufficient privilege to execute the instruction, the preferred exception return address is the address of the exception generating instruction.

---

When an exception is taken from an Exception level using AArch32 to an Exception level using AArch64, the top 32 bits of the modified ELR_ELx are 0.

D1.10.2 Exception vectors

When the PE takes an exception to an Exception level that is using AArch64, execution is forced to an address that is the exception vector for the exception. The exception vector exists in a vector table at the Exception level the exception is taken to.

A vector table occupies a number of consecutive word-aligned addresses in memory, starting at the vector base address.

Each Exception level has an associated Vector Base Address Register (VBAR), that defines the exception base address for the table at that Exception level.

For exceptions taken to AArch64 state, the vector table provides the following information:

- Whether the exception is one of the following:
  - Synchronous exception.
  - SError.
  - IRQ.
  - FIQ.
- Information about the Exception level that the exception came from, combined with information about the stack pointer in use, and the state of the register file.
Reset is treated as a special vector for the highest implemented Exception level. This special vector uses an IMPLEMENTATION DEFINED address that is typically set either by a hardwired configuration of the PE or by configuration input signals. The RVBAR_ELx register contains this reset vector address, where x is the number of the highest implemented Exception level.

### D1.10.3 Pseudocode description of exception entry to AArch64 state

The `AArch64.TakeException()` pseudocode function describes the behavior when the PE takes an exception to an Exception level that is using AArch64. The `AArch64.ExceptionClass()` function determines the EC (Exception class) and IL (Instruction length) values required to report the exception, and `AArch64.ReportException()` reports the exception.

The pseudocode functions `AArch64.TakeException()`, `AArch64.ExceptionClass()`, and `AArch64.ReportException()` are described in Chapter J1 ARMv8 Pseudocode.

### D1.10.4 Exception classes and the ESR_ELx syndrome registers

If the exception is a synchronous exception or an SError interrupt, information characterizing the reason for the exception is saved in the ESR_ELx at the Exception level the exception is taken to. The information saved is determined at the time the exception is taken, and is not changed as a result of the explicit synchronization that takes place at the start of taking the exception. See Synchronization requirements for AArch64 System registers on page D12-2663. The following sections give more information:

- Use of the ESR_EL1, ESR_EL2, and ESR_EL3.
- The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1 on page D1-2165.

#### Use of the ESR_EL1, ESR_EL2, and ESR_EL3

An ESR_ELx holds the syndrome information for an exception that is taken to AArch64 state.

**Note**

This use of a syndrome is also the reporting model used for exceptions taken to Hyp mode when they are taken to EL2 using AArch32.

Figure D1-2 on page D1-2161 shows the general format of the ESR_ELx registers.
The \textit{ESR\_ELx} fields are:

- **EC, bits[31:26]** The Exception class field, that indicates the cause of the exception.
- **IL, bit[25]** The Instruction length bit, for synchronous exceptions, that indicates whether a trapped instruction was a 16-bit or a 32-bit instruction.
- **ISS, bits[24:0]** The Instruction specific syndrome field. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

\textit{ESR\_EL1, Exception Syndrome Register (EL1)} on page D12-2759, \textit{ESR\_EL2, Exception Syndrome Register (EL2)} on page D12-2796 and \textit{ESR\_EL3, Exception Syndrome Register (EL3)} on page D12-2832 describe the registers in full, including:

- Listing the valid EC field values.
- Describing the ISS for each Exception class.
- Giving a full description of the use of the IL field.

Table D1-8 shows the encoding of the \textit{ESR\_ELx}.EC field, the Exception class field. For each EC value, the table references a subsection of the \textit{ESR\_ELx} register definition that describes the ISS format, with links to descriptions of possible causes of the exception, for example the configuration required to enable a trap.

- **a.** See also *Reporting AArch32 synchronous exceptions taken to an Exception level using AArch64 on page D1-2165.*
- **b.** Exceptions caused by configurable traps, enables, or disables.
- **c.** See *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2231.*
- **d.** Only for MCR or MRRC accesses to the PMCCNTR_EL0 or PMCCNTR.
- **e.** Excludes exceptions that are generated because the value of HCR_EL2.TGE is 1, see *The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1 on page D1-2165.*
- **f.** Applies only to traps of accesses to MVFR0, MVFR1, MVFR2, or FPSID. Includes traps of VR8 accesses. Because the MVFR registers are read-only and a VR8 access to the FPSID is ignored and not trapped, there are no MCR or VMSR accesses that can be trapped with this EC value.
- **g.** Only as a result of HCR_EL2.TGE.
- **h.** Only as a result of HCR_EL2.TSC.
- **i.** Only if SVE is implemented. Otherwise the EC value is reserved.
- **j.** Only if ARMv8.3-NV is implemented and HCR_EL2.NV is 1.
- **k.** Used for MMU faults generated by instruction accesses, and for synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.
- **l.** Used for MMU faults generated by data accesses, Alignment faults other than SP alignment faults and PC alignment faults, and for synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.
- **m.** Only as a result of HCR_EL2.TGE ==1 or MDCR_EL2.TDE ==1.
- **n.** Only if the 88K instruction is executed in EL3. This is the only debug exception that can be taken to EL3 when EL3 is using AArch64.

**Reserved EC values**

For EC values not shown in Table D1-8 on page D1-2161:

- Unused EC values in the range 0b000000-0b101100 (0x00-0x2C) are reserved by ARM for future use for synchronous exceptions.
- Unused EC values in the range 0b101100-0b111111 (0x2D-0x3F) are reserved by ARM for future use, and might be used for synchronous or asynchronous exceptions.
The EC used to report an exception routed to EL2 because HCR_EL2.TGE is 1

When an exception is taken from EL0 to EL2 because the value of HCR_EL2.TGE is 1, the exception is reported in ESR_EL2. The EC value and corresponding ISS encoding used to report the exception in ESR_EL2 depend on how an exception of the same class would be reported in ESR_EL1 when the value of HCR_EL2.TGE,RW is {0, 1}:

• If the exception would have been reported in ESR_EL1 using the EC value 0x07 then it is reported in ESR_EL2 using the EC value 0x00 and corresponding ISS encoding.

• Otherwise, the exception is reported in ESR_EL2 using the EC value and ISS encoding that would have been used to report the exception ESR_EL1.

Reporting AArch32 synchronous exceptions taken to an Exception level using AArch64

Although possible exception causes are generally similar for AArch32 state and AArch64 state, AArch32 state has additional exception taxonomy that is not present in AArch64 state. The following sections described named AArch32 exceptions that can, in some contexts, be taken to an Exception level that is using AArch64:

• Undefined Instruction exception on page G1-5282.
• Supervisor Call (SVC) exception on page G1-5286.
• Secure Monitor Call (SMC) exception on page G1-5287.
• Hypervisor Call (HVC) exception on page G1-5288.
• Prefetch Abort exception on page G1-5289.
• Data Abort exception on page G1-5293.

When EL2 is using AArch64 and the value of HCR_EL2.TGE is 1, these exceptions are routed to EL2, and reported in the ESR_EL2. Table D1-9 shows how they are reported.

Table D1-9 Syndrome reporting in ESR_EL2 of HCR_EL2 routing of exceptions

<table>

a. The pseudocode in Operation for all encodings on page F5-4267 identifies when the execution of an SMC instruction in AArch32 state generates an exception that is taken to EL3 using AArch64.

D1.10.5 Summary of register updates on faults taken to an Exception level that is using AArch64

For all exceptions taken to an Exception level using AArch64 that are not listed in Validity of FAR_ELx on page D1-2166, the FAR_ELx for the Exception level the exception is taken to is UNKNOWN.

For all exceptions taken to EL2 using AArch64 that are not listed in Validity of HPFAR_EL2 on page D1-2166, the HPFAR_EL2 is UNKNOWN.

The following sections give more information:

• Validity of FAR_ELx on page D1-2166.
• Validity of HPFAR_EL2 on page D1-2166.
Validity of FAR_ELx

The faulting virtual address is saved in FAR_ELx for the Exception level the exception is taken to if an exception is one of:

- An Instruction Abort exception.
- A Data Abort exception.
- A PC alignment fault exception.
- A Watchpoint exception.

The architecture permits that the FAR_ELx is UNKNOWN for synchronous External aborts other than synchronous External aborts on translation table walks. In this case, the ISS.FnV bit returned in ESR_ELx indicates whether FAR_ELx is valid.

If an exception is taken from an Exception level using AArch32 into an Exception level using AArch64, and that exception writes the FAR_ELx at the Exception level the exception is taken to, the most significant 32 bits of FAR_ELx are all zero, unless both of the following apply, in which case the most significant 32 bits of FAR_ELx are 0x00000001:

- The faulting address was generated by a load or store that sequentially incremented from address 0xFFFFFFFF.
  Such a load or store instruction is CONSTRAINED UNPREDICTABLE, see Out of range VA on page K1-7199.
- The implementation treats such incrementing as setting bit[32] of the virtual address to 1.

The FAR_ELx for an Exception level is made UNKNOWN as a result of an exception return from that Exception level.

Validity of HPFAR_EL2

The faulting IPA is saved in HPFAR_EL2 if the exception is an Instruction Abort or Data Abort taken to EL2 and the fault is one of:

- A Translation or Access Flag fault on a stage 2 translation.
- A stage 2 Address Size fault.
- A fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.

HPFAR_EL2 is made UNKNOWN as a result of an exception return from EL2.
D1.11 Exception return

In the ARMv8-A architecture, an exception return is always to the same Exception level or a lower Exception level. An exception return is used for:

- A return to a previously executing thread.
- Entry to a new execution thread. For example:
  - The initialization of a hypervisor by a Secure monitor.
  - The initialization of an operating system by a hypervisor.
  - Application entry from an operating system or hypervisor.

An exception return requires the simultaneous restoration of the PC and PSTATE to values that are consistent with the desired state of execution on returning from the exception.

In AArch64 state, an ERET instruction causes an exception return, see ERET on page C6-816.

If ARMv8.2-IESB is implemented, when the SCTLR_ELx.IESB bit at the Exception level the exception is returning from is 1, the PE inserts an error synchronization event before the ERET instruction. See ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

On executing an ERET instruction at ELx:

- The PC is restored with the value held in ELR_ELx.
- PSTATE is restored by using the contents of SPSR_ELx.

ELR_ELx and SPSR_ELx are the ELR_ELx and SPSR_ELx at the Exception level the exception is returning from. The exception return makes this ELR_ELx and SPSR_ELx UNKNOWN.

See Address tagging in AArch64 state on page D5-2374 for details of how tagged addresses are handled in an Exception return from an Exception level using AArch64 to an Exception level using AArch64.

**Note**

When returning from an Exception level using AArch64 to an Exception level using AArch32, the top 32 bits of the ELR_ELx are ignored.

An ERET instruction also:

- Sets the Event Register for the PE executing the ERET instruction. See Mechanisms for entering a low-power state on page D1-2243.
- Resets the local Exclusives monitor for the PE executing the ERET instruction. This removes the risk of errors that might be caused when a path to an exception return fails to include a CLREX instruction.

**Note**

This behavior prevents self-hosted debug from software stepping through a Load-Exclusive/Store-Exclusive pair. However, when self-hosted debug is using software step, it is highly probable that the Exclusives monitor state would be lost anyway, for other reasons. Stepping code that uses Exclusives monitors on page D2-2328 describes this.

It is IMPLEMENTATION DEFINED whether the resetting of the local Exclusives monitor also resets the global Exclusives monitor.

The ERET instruction is UNDEFINED in EL0.

When returning from an Exception level using AArch64 to an Exception level using AArch32, the AArch32 context is restored. The ARMv8-A architecture defines the relationship between AArch64 state and AArch32 state, for:

- General-purpose registers.
- Special-purpose registers.
- System registers.

In an implementation that includes EL3, the Security state can only change on returning from an exception if the return is from EL3 to a lower Exception level.
The following sections give more information:

- Exception return and PC alignment.
- Illegal return events from AArch64 state.
- Legal returns that set PSTATE.I to 1 on page D1-2169.
- The Illegal Execution state exception on page D1-2170.
- Pseudocode description of exception return on page D1-2170.

### D1.11 Exception return and PC alignment

When SPSR_ELx.M[4] == 0, indicating an Exception return to AArch64 state, the value of ELR_ELx is transferred to the PC. If this value is misaligned, subsequent execution results in a PC alignment fault exception.

When SPSR_ELx.M[4] == 1, indicating an Exception return to AArch32 state, the value of ELR_ELx is transferred to the PC except that, for a legal exception return:

- If SPSR_ELx.T is 0, ELR_ELx[1:0] are treated as being 0 for restoring the PC.
- If SPSR_ELx.T is 1, ELR_ELx[0] is treated as being 0 for restoring the PC.

This means that a PC alignment fault exception cannot occur following a legal exception return from AArch64 state to AArch32 state. However, where the Exception return with SPSR_ELx.M[4] == 1 is an illegal exception return then it is IMPLEMENTATION DEFINED whether a misaligned value in ELR_ELx is aligned when it is restored to the PC.

---

**Note**

In an implementation that forces the alignment of the PC value restored from SPSR_ELx on an illegal exception return with SPSR_ELx.M[4] == 1, if SPSR_ELx.T == 1 the restored PC value might give rise to a PC alignment fault exception, because the PE remains in AArch64 state and only ELR_ELx[0] is treated as being 0 for restoring the PC.

---

For more information about the illegal exception return cases see *Illegal return events from AArch64 state*.

### D1.11.2 Illegal return events from AArch64 state

In this section:

**Return** In AArch64 state, refers to any of:

- Execution of an ERET instruction.
- Execution of a DRPS instruction in Debug state.
- Exit from Debug state.

**Saved process state value** In AArch64 state, refers to any of:

- The value held in the SPSR_ELx for an ERET instruction.
- The value held in the SPSR_ELx for a DRPS instruction executed in Debug state.
- The value held in the DSPSR_EL0 for a Debug state exit.

**Link address** In AArch64 state, refers to any of:

- The address held in ELR_ELx for an ERET instruction.
- The address held in DLR_EL0 for a Debug state exit.

**Configured from reset** Indicates the state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The ARMv8 architecture has a generic mechanism for handling returns to a mode or state that is illegal. In AArch64 state, this can occur as the result of any of the following situations:

- A return where the Exception level being returned to is higher than the current Exception level.
- A return where the Exception level being returned to is not implemented. For example a return to EL2 when EL2 is not implemented.
• A return to EL2 when EL3 is implemented and the value of the SCR_EL3.NS bit is 0 if ARMv8.4-SecEL2 is not implemented.

• A return to EL1 when EL2 is implemented and the value of the HCR_EL2.TGE bit is 1.

• A return where the value of the saved process state M[4] bit is 0, indicating a return to AArch64 state, and one of the following is true:
  — The M[3:0] bits are 0001.
  — The Exception level being returned to is using AArch32 state, as programmed by the SCR_EL3.RW or HCR_EL2.RW bits, or as configured from reset.

• A return where the value of the saved process state M[4] bit is 1, indicating a return to AArch32 state, and one of the following is true:
  — The M field value is not a valid AArch32 state PE mode. Table D1-4 on page D1-2147 shows the valid M[3:0] values for AArch32 state PE modes. This includes the case where M[3:0] is 0000, indicating User mode, and EL0 does not support AArch32 state.
  — The Exception level being returned to is using AArch64 state as determined by the SCR_EL3.RW or HCR_EL2.RW field or the configuration from reset. This includes the case where the Exception level being returned to does not support AArch32 state.

Note

This means that, in an implementation that supports only AArch64 state, any attempt to return to AArch32 state is an illegal exception return.

• A Debug state exit from EL0 using AArch64 state, to EL0 using AArch32 state.

In these cases:

• PSTATE.IL is set to 1, to indicate an illegal return.

• PSTATE. {EL, nRW, SP} are unchanged. This means the Exception level, Execution state, and stack pointer selection do not change as a result of the return.

• The following PSTATE bits are restored from the saved process state value:
  — The D, A, I, F exception mask bits.

• If the illegal return is an illegal exception return, the PSTATE.SS bit is handled as normal for a return. That is, the SS bit is handled in the same way as an exception return that is not an illegal exception return. See Software Step exceptions on page D2-2317.

In all these cases the PSTATE.SS bit is handled as it would be for a normal return, as described in Entering the active-not-pending state on page D2-2319 and Exiting Debug state on page H2-6454. DRPS never sets the SS bit. This is indicated in Entering the active-not-pending state on page D2-2319.

• If the illegal return is not a DRPS instruction executed in Debug state, the PC is restored from the link address. However, if the value of the M[4] bit of the saved process state is 1, indicating a return to AArch32 state, then:
  — Bits[31:2] of the PC are restored from the link address.
  — Bits[63:32, 1:0] of the PC are UNKNOWN.

When the value of the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See The Illegal Execution state exception on page D1-2170.

All aspects of the illegal return, other than the effects described in this section, occur as they do for a legal return.

D1.11.3 Legal returns that set PSTATE.IL to 1

In this section, return, saved process state value, and link address have the same meaning as defined in Illegal return events from AArch64 state on page D1-2168.
If the value of the IL bit in the saved process state is 1, then it is copied to PSTATE by a return, meaning that PSTATE.IL is set to 1. In this case, if the return is not an illegal return, and targets AArch32 state, then the PSTATE.{IT, T} bits are either:

- Set to 0.
- Copied from the saved process state value.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

The PSTATE.{IT, T} bits are only valid in AArch32 state, see Process state, PSTATE on page G1-5239.

When the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See The Illegal Execution state exception.

### D1.11.4 The Illegal Execution state exception

When the value of the PSTATE.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. In AArch64 state, the PSTATE.IL bit can be set to 1 by any of:

- An illegal return, as described in Illegal return events from AArch64 state on page D1-2168.
- A legal return that sets PSTATE.IL to 1, as described in Legal returns that set PSTATE.IL to 1 on page D1-2169.

If an Illegal Execution state exception is generated at EL0, it is taken to EL1. If the exception occurs when EL2 is implemented and enabled in the current Security state, and HCR_EL2.TGE == 1, then it is taken to EL2. If an Illegal Execution state exception is generated at any other Exception level, the Exception level is unchanged.

An Illegal Execution state exception sets ESR_ELx.EC for the target Exception level to the value of 0x0E.

On taking any exception to an Exception level that is using AArch64 state:

1. The value of the PSTATE.IL bit is copied into the SPSR_ELx.IL bit for the Exception level to which the exception is taken.
2. The PSTATE.IL bit is cleared to 0.

Note

This means that it is not possible for software to observe the value of PSTATE.IL.

For the priority of this exception class, see Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2179.

### D1.11.5 Pseudocode description of exception return

The AArch64.ExceptionReturn() pseudocode function transfers the return address to the PC, and restores PSTATE to its saved value by calling SetPSTATEFromPSR().

The IllegalExceptionReturn() function checks for an Illegal Execution state exception.
D1.12 The Exception level hierarchy

The System registers provide controls that control PE behavior through the Exception level hierarchy.

If EL3 and EL2 are implemented, System registers at EL3 and EL2 provide controls that control the Execution state of lower Exception levels.

Table D1-10 shows the principal System registers.

<table>
<thead>
<tr>
<th>EL3</th>
<th>EL2</th>
<th>EL1</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCTLR_EL3</td>
<td>SCTLR_EL2</td>
<td>SCTLR_EL1</td>
<td>Controls execution for its own Exception level.</td>
</tr>
<tr>
<td>SCR_EL3</td>
<td>HCR_EL2</td>
<td>-</td>
<td>Controls execution at lower Exception levels.</td>
</tr>
<tr>
<td>-</td>
<td>HSTR_EL2</td>
<td>-</td>
<td>Used only if at least one of EL1 and EL0 is using AArch32.</td>
</tr>
</tbody>
</table>

The prioritization of exceptions generated as a result of controls in these registers is described in Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2179.

The following sections describe the Exception level hierarchy:

- The hierarchy of configuration and routing control.
- Control of SIMD, floating-point and trace functionality on page D1-2177.
- Control of IMPLEMENTATION DEFINED features on page D1-2177.
- Routing exceptions from EL0 to EL2 on page D1-2178.

D1.12.1 The hierarchy of configuration and routing control

The following subsections give a summary of the controls available at each Exception level for controlling execution at that Exception level and all lower Exception levels:

- Controls provided at EL3.
- Controls provided at EL2 on page D1-2173.
- Controls provided at EL1 on page D1-2175.

For information on how the controls summarized in these subsections affect PE behavior, see the definitions of the control bits in the register descriptions.

Controls provided at EL3

Controls provided by the SCR_EL3

| SCR_EL3.NS | Determines the Security state of execution at EL1 and EL0.                |
| SCR_EL3.RW | Determines the Execution state of the next-lower Exception level.        |
| SCR_EL3.{EA, FIQ, IRQ} | Route:  |
| EA | Physical SError interrupts and synchronous External aborts to EL3. |
| FIQ | Physical FIQ interrupts to EL3. |
| IRQ | Physical IRQ interrupts to EL3. |
| SCR_EL3.SMD | Disables the Secure Monitor Call exception.                                |
| SCR_EL3.HCE | Enables the Hypervisor Call exception.                                     |
| SCR_EL3.ST | Enables Secure EL1 access to the Secure timer.                            |
SCR_EL3.SIF Secure Instruction Fetch. When in Secure state, disables instruction fetches from Non-secure memory.

SCR_EL3.TW1 Trap Wait-For-Interrupt.

SCR_EL3.TWE Trap Wait-For-Event.

SCR_EL3.TERR Trap Error Record accesses. This field is part of the RAS Extension.

SCR_EL3.FIEN Fault Injection Enable. This field is part of the RAS Common Fault Injection Model Extension.

SCR_EL3.NMEA Non-maskable External aborts. This field is part of ARMv8.4-DFE.

SCR_EL3.EASE External aborts to SError interrupt vector. This field is part of ARMv8.4-DFE.

SCR_EL3.EEL2 Enables Secure EL2 functionality.

Controls provided by the SCTLR_EL3

SCTL_R_EL3.{A, SA} Enable alignment checking:
A On data accesses from EL3.
SA On the SP, when executing at EL3.

SCTL_R_EL3.{M, C, I, WIX} Memory system control bits:
M Enables EL3 stage 1 address translation.
C When set to 0, makes data accesses to Normal memory from EL3, and Normal memory accesses to the EL3 translation tables, Non-cacheable.
I When set to 0, makes instruction accesses to Normal memory from EL3 Non-cacheable.
WIX For accesses from EL3, enables treating all writable memory regions as XN, execute-never.

SCTL_R_EL3EE Defines the endianness of data accesses from EL3, including stage 1 translation table walks at EL3.

Note
Instruction fetches are always little-endian.

Controls provided by the MDCR_EL3

MDCR_EL3.{EPMAD, EDAD} Enable external debugger accesses to:
EPMAD Performance Monitors registers.
EDAD Breakpoint and Watchpoint registers.

MDCR_EL3.{SPME, SDD, SPD32} Secure debug controls:
SPME Secure Performance Monitors enable. Enables event counting in Secure state.
SDD Disables all debug exceptions taken from Secure state, if the debug target Exception level, EL_D, is using AArch64.
SPD32 Enables debug exceptions from Secure EL1 using AArch32.

MDCR_EL3.{TDOSA, TDA, TTRF, TPM} These are trap controls, that control traps to EL3 of EL2, EL1, and EL0 accesses to the following:
TDOSA The OS-related debug registers.
 Those debug registers not included in the MDCR_EL3.TDOSA trap.
TTRF  The trace filter control registers.
TPM   The Performance Monitors registers.

For EL1 and EL0, these traps apply to accesses from both Security states.

**Controls provided at EL2**

When EL2 is enabled in the current Security state and is using AArch64, the following controls apply:

**Controls provided by SCTLR_EL2**

**SCTLR_EL2.[A, SA]** Enable alignment checking:
- **A** On data accesses from EL2.
- **SA** On the SP, when executing at EL2.

**SCTLR_EL2.[M, C, I, WXN]**

Memory system control bits:
- **M** Enables EL2 stage 1 address translation.
- **C** When set to 0, makes data accesses to Normal memory from EL2, and Normal memory accesses to the EL2 translation tables, Non-cacheable.
- **I** When set to 0, makes instruction accesses to Normal memory from EL2 Non-cacheable.
- **WXN** For accesses from EL2, enables treating all writable memory regions as XN, execute-never.

**SCTLR_EL2.EE**

Defines the endianness of data accesses from EL2, including stage 1 translation table walks at EL2.

Also defines the endianness of stage 2 translation table walks at Non-secure EL1 and EL0.

--- **Note** ---

Instruction fetches are always little-endian.

--- **Note** ---

**Controls provided by HCR_EL2**

**HCR_EL2.RW**

Determines the Execution state of the next-lower Exception level.

**HCR_EL2.[AMO, IMO, FMO]**

Route physical interrupts to EL2, and if the value of HCR_EL2.TGE is 0, enable virtual interrupts:
- **AMO** Route physical SError interrupts to EL2 and enable virtual SError interrupts
- **IMO** Route physical IRQ interrupts to EL2 and enable virtual IRQ interrupts.
- **FMO** Route physical FIQ interrupts to EL2 and enable virtual FIQ interrupts.

--- **Note** ---

- If a physical interrupt is routed to both EL3 and EL2, routing to EL3 takes precedence over routing to EL2.
- When the value of HCR_EL2.TGE is 0, the virtual interrupt enables apply regardless of whether the corresponding physical interrupt is routed to EL2 or to EL3.
- In ARMv8.0, when the value of HCR_EL2.TGE is 1 the virtual interrupts are disabled.
- From ARMv8.1, when the value of HCR_EL2.TGE is 1:
  - If ARMv8.1-VHE is not implemented, or if HCR_EL2.E2H is 0, these fields behave as 1 for all purposes other than a direct read of the value of the fields.
If ARMv8.1-VHE is implemented and HCR_EL2.E2H is 1, these fields behave as 0 for all purposes other than a direct read of the value of the fields.

**HCR_EL2.{VSE, VI, VF}**

Cause a virtual interrupt to be pending:
- **VSE** Virtual SError interrupt.
- **VI** Virtual IRQ interrupt.
- **VF** Virtual FIQ interrupt.

**HCR_EL2.VM**

Enable bit for EL1&0 stage 2 address translations.

**HCR_EL2.{SWIO, PTW, FB, BSU, DC, CD, ID}**

Controls for memory system behavior for accesses made from EL1 and EL0:
- **SWIO** Set/Way Invalidate Override.
- **PTW** Protect Table Walk.
- **FB** Force broadcast of TLB and instruction cache maintenance instructions.
- **BSU** Barrier Shareability Upgrade.
- **DC** Default Cacheability control for the EL1&0 translation regime.
- **CD** When set to 1, forces stage 2 translation table walks to Normal memory, and stage 2 translations for data accesses to Normal memory, to be Non-cacheable.
- **ID** When set to 1, forces stage 2 translations for instruction accesses to Normal memory be Non-cacheable.

**HCR_EL2.HCD**

Hypervisor Call Disable.

--- **Note** ---

If an implementation includes EL3, this bit is RES0.

**HCR_EL2.{TRVM, TDZ, TVM, TTLB, TPU, TPC, TSW, TACR, TIDCP, TSC, TID1, TID2, TID3, TWE, TWI, TERR}**

Trap operations performed at EL1 or EL0 to EL2, as follows:
- **TRVM** Trap Read of Virtual Memory controls.
- **TDZ** Trap Data Cache Zero.
- **TVM** Trap Virtual Memory controls.
- **TTLB** Trap TLB maintenance instructions.
- **TPU** Trap cache maintenance to the Point of Unification instructions.
- **TPC** Trap data cache maintenance to the Point of Coherency instructions.
- **TSW** Trap data cache maintenance by Set/Way instructions.
- **TACR** Trap Auxiliary Control Register accesses.
- **TIDCP** Trap Implementation-Dependent functionality.
- **TSC** Trap Secure Monitor Call.
- **TID0** Trap ID Group 0 register accesses.
- **TID1** Trap ID Group 1 register accesses.
- **TID2** Trap ID Group 2 register accesses.
- **TID3** Trap ID Group 3 register accesses.
- **TWI** Trap Wait-For-Interrupt.
- **TWE** Trap Wait-For-Event.
- **TERR** Trap error record accesses. This field is part of the RAS Extension.

—— Note ————

There are no AArch64 System registers in ID Group 0, therefore the TID0 trap is only relevant when EL1 is using AArch32.

SCTLR_EL1.SA0 Enable alignment checking on the SP when executing at EL0.

SCTLR_EL1.{M, C, I, WXN}

Memory system control bits:

M Enables EL1&0 stage 1 address translation.

C When set to 0, makes data accesses to Normal memory from EL0 and EL1, and Normal memory accesses to the EL1&0 stage 1 translation tables, Non-cacheable.

I When set to 0, makes instruction accesses to Normal memory from EL1 and EL0 Non-cacheable.

WXN For accesses from EL1 and EL0, enables treating all writable memory regions as XN, execute-never.

SCTLR_EL1.EE Defines the endianness of data accesses from EL1, including stage 1 translation table walks at EL1 and EL0.

Note Instruction fetches are always little-endian.

SCTLR_EL1.E0E EL0 Endianness. Defines the endianness used for explicit data accesses made from EL0.

SCTLR_EL1.{UCI, UCT, DZE, nTWI, nTWE}

Trap enables:

UCI Unprivileged Cache maintenance Instruction enable.

UCT Unprivileged Cache Type access enable.

DZE Data cache Zero Enable.

nTWI Not Trap Wait-For-Interrupt.

nTWE Not Trap Wait-For-Event.

SCTLR_EL1.UMA Unprivileged Mask Access.

SCTLR_EL1.{SED, ITD, CP15BEN}

These bits control the use, at EL0, of AArch32 functionality that is deprecated, or OPTIONAL and deprecated:

SED Disables use of the SETEND instruction.

ITD If supported, disables some uses of the IT instruction. The register field description identifies the uses that are disabled.

CP15BEN If supported, enables use of the CP15DMB, CP15DSB, and CP15ISB memory barrier instructions.

The deprecated uses of the IT instruction, and use of the CP15DMB, CP15DSB, and CP15ISB instructions, are deprecated for performance reasons. Implementation of the ITD and CP15BEN controls is optional, and if a control is not implemented then the associated AArch32 functionality cannot be disabled.

Note When HCR_EL2.{TGE, E2H} == {1, 1}, the controls provided by SCTLR_EL1 are overridden by the controls in SCTLR_EL2.
**Controls provided by the MDSCR_EL1**

**MDSCR_EL1.{MDE, SS}**

Enable controls for the debug exceptions:

- **MDE**: Enables Breakpoint exceptions, Watchpoint exceptions, and Vector Catch exceptions.
- **SS**: Enables Software Step exceptions.

There is no enable control for Breakpoint Instruction exceptions. Breakpoint Instruction exceptions are always enabled.

**MDSCR_EL1.KDE** Enables debug exceptions from ELD when ELD is using AArch64.

**MDSCR_EL1.TDCC** Enables a trap to EL1 of EL0 accesses to the Debug Communications Channel registers.

**D1.12.2 Control of SIMD, floating-point and trace functionality**

In addition to the controls described in *The hierarchy of configuration and routing control* on page D1-2171, the following registers provide a hierarchy of control of access to SIMD and floating-point functionality, and to trace functionality that is accessible using the System registers:

**CPTR_EL3** Traps operation at lower Exception levels to EL3, if the operation is not trapped to EL2 by CPTR_EL2 and is not trapped to EL1 by CPACR_EL1.

**CPTR_EL2** Traps operation in Non-secure EL1 or EL0 to EL2, if the operation is not trapped to EL1 by CPACR_EL1. CPTR_EL2.{TTA, TFP} also trap operation in EL2.

The trap bits in the CPTR_EL3 and CPTR_EL2 are as follows:

- **TCPAC**: Traps accesses to the registers that control access to SIMD, floating-point, and trace functionality.
- **TTA**: Traps any System register access to trace functionality, unless that access is otherwise trapped to a lower Exception level.
- **TFP**: Traps any execution of an instruction that uses the SIMD and floating-point register bank, unless that access is otherwise trapped to a lower Exception level.

**CPACR_EL1** Traps operation from EL1 or EL0 to EL1. Traps set in the CPACR_EL1 take precedence over any traps set in the CPTR_EL2 or CPTR_EL3. The trap fields are as follows:

- **TTA**: Traps to EL1 any System register access from EL0 or EL1 to trace functionality.
- **FPEN**: Traps to EL1 execution of instructions that uses the SIMD and floating-point register bank.

**D1.12.3 Control of IMPLEMENTATION DEFINED features**

*The hierarchy of configuration and routing control* on page D1-2171 and *Control of SIMD, floating-point and trace functionality* describe the controls of the trapping of architecturally-defined functionality. However, the architecture also defines registers that can be used to provide IMPLEMENTATION DEFINED traps of IMPLEMENTATION DEFINED functionality to the different Exception levels. *Table D1-11* shows these control registers, for AArch64 state controls.

**Table D1-11 Control of traps of IMPLEMENTATION DEFINED functionality**

D1.13  Synchronous exception types, routing and priorities

Synchronous exceptions are:

- Any exception generated by attempting to execute an instruction that is UNDEFINED, including:
  - Attempts to execute instructions at an inappropriate Exception level.
  - Attempts to execute instructions when they are disabled.
  - Attempts to execute instruction bit patterns that have not been allocated.

- Illegal Execution state exceptions. These are caused by attempts to execute an instruction when the value of PSTATE.IL is 1, see Illegal return events from AArch64 state on page D1-2168.

- Exceptions caused by the use of a misaligned SP.

- Exceptions caused by attempting to execute an instruction with a misaligned PC.

- Exceptions caused by the exception-generating instructions SVC, HVC, or SM C.

- Traps on attempts to execute instructions that the System registers define as instructions that are trapped to a higher Exception level. See Configurable instruction enables and disables, and trap controls on page D1-2196.

- Instruction Aborts generated by the memory address translation system that are associated with attempts to execute instructions from areas of memory that generate faults.

- Data Aborts generated by the memory address translation system that are associated with attempts to read or write memory that generate faults.

- Data Aborts caused by a misaligned address.

- All of the debug exceptions:
  - Breakpoint Instruction exceptions.
  - Breakpoint exceptions.
  - Watchpoint exceptions.
  - Vector Catch exceptions.
  - Software Step exceptions.

- In an implementation that supports the trapping of floating-point exceptions, exceptions caused by trapped IEEE floating-point exceptions, see Floating-point exceptions and exception traps on page D1-2184.

- In some implementations, External aborts. External aborts are failed memory accesses, and include accesses to those parts of the memory system that occur during the address translation. The ARMv8 architecture permits, but does not require, implementations to treat such exceptions synchronously. See External aborts on page D4-2365.

This remainder of this section contains the following:

- Routing exceptions from EL0 to EL2.
- Routing debug exceptions to EL2 on page D1-2179.
- Routing synchronous External aborts on page D1-2179
- Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2179.
- Effect of Data Aborts on page D1-2183.
- Floating-point exceptions and exception traps on page D1-2184.

D1.13.1  Routing exceptions from EL0 to EL2

When EL2 is enabled in the current Security state and the value of HCR_EL2.TGE is 1, any exception taken from EL0 that would otherwise be taken to EL1 is, instead, routed to EL2. This means that an application can execute at EL0 without using any functionality at EL1.
### Note
- When EL2 is using AArch64 state, the HCR_EL2.TGE control applies regardless of whether EL0 is using AArch32 state or AArch64 state.
- Implementations typically use the following Exception level and software hierarchy:
  - EL2: Hypervisor.
  - EL1: Operating system.
  - EL0: Application.

In such an implementation, setting HCR_EL2.TGE to 1 means that an application can run at EL0 under the direct control of a hypervisor executing at EL2, with no operating system involvement.

### D1.13 Routing debug exceptions to EL2
When EL2 is enabled in the current Security state and the value of MDCR_EL2.TDE is 1, debug exceptions are routed to EL2. For more information see Routing debug exceptions on page D2-2275.

When the value of MDCR_EL2.TDE is 1, each of the MDCR_EL2.{TDRA, TDOSA, TDA} bits is treated as 1 for all purposes other than direct reads of the MDCR_EL2.

### D1.13.3 Routing synchronous External aborts
When the value of SCR_EL3.EA is 1, synchronous external aborts are taken to EL3.

When the RAS Extension is implemented, EL2 is enabled in the current Security state, and the value of HCR_EL2.TEA is 1, synchronous external aborts from EL0 and EL1 that are not routed to EL3 are routed to EL2.

### D1.13.4 Synchronous exception prioritization for exceptions taken to AArch64 state
In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. For exceptions taken to an Exception level that is using AArch64, these are prioritized as follows, where 1 is the highest priority.

#### Note
The priority numbering in this list correlates with the equivalent AArch32 state list in Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-5251 and the list in Debug state entry and debug event prioritization on page H2-6421.

1-3: These priority numbers represent debug events.

4: Software Step exceptions. See Software Step exceptions on page D2-2317.

5: This priority number represents debug events.

6: PC alignment fault exceptions. See PC alignment checking on page D1-2152.

7: Instruction Abort exceptions. See AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D5-2494.

8: Breakpoint exceptions or Address Matching Vector Catch exceptions. See:
   - Breakpoint exceptions on page D2-2284.
   - Vector Catch exceptions on page D2-2316.

Vector Catch exceptions are only taken from AArch32 state.
Note

An Exception Trapping Vector Catch exception is generated on exception entry for an exception that has been prioritized as described in *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-5251. This means that it is outside the scope of the description of this section.

Illegal Execution state exceptions. See *Illegal return events from AArch64 state* on page D1-2168.

Exceptions taken from EL1 to EL2 because of one of the following configuration settings:

- `HSTR_EL2.Tn`
- `HCR_EL2.TIDCP`
- If ARMv8.3-NV is implemented, `HCR_EL2.NV` or `HCR_EL2.NV1`.

Note

If ARMv8.4-NV is implemented and `HCR_EL2.{NV, NV1, NV2}` are set such that register accesses to EL1 are transformed into memory accesses, then `HCR_EL2{NV, NV1}` do not generate exceptions to EL2.

Software Breakpoint exceptions caused by the execution of a Breakpoint instruction:

- For exceptions taken from AArch64 state, `BRK`.
- For exceptions taken from AArch32 state, `BKPT`.

Exceptions that occur as a result of attempting to execute an instruction that is UNDEFINED for one or more of the following reasons:

- Attempting to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
- Attempting to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.
- Debug state execution of an instruction encoding that is unallocated in Debug state.
- Non-debug state execution of an instruction encoding that is unallocated in Non-debug state.
- Execution of an HVC instruction, when HVC instructions are disabled by `SCR_EL3.HCE` or `HCR_EL2.HCD`.
- Execution of an MSR or MRS instruction to SP_EL0 when the value of SPSel is 0.
- Execution of an HLT instruction when HLT instructions are disabled by `EDSCR.HDE` or halting is prohibited.
- In Debug state:
  - Execution of a DCPS1 instruction in Non-secure EL0 when `HCR_EL2.TGE` is 1.
  - Execution of a DCPS2 instruction in EL1 or EL0 when EL2 is disabled in the current Security state or is not implemented.
  - Execution of a DCPS3 instruction when `EDSCR.SDD` is 1 or when EL3 is not implemented.
  - When the value of `EDSCR.SDD` is 1, execution in EL2, EL1, or EL0 of an instruction that is configured by EL3 control registers to trap to EL3. It is IMPLEMENTATION DEFINED whether this type of exception is prioritized at this level or has the priority of the original trap exception.
- When executing in AArch32 state, execution of an instruction that is UNDEFINED as a result of any of:
  - Being in an IT block when `SCTLR_EL1.ITD` is 1.
  - Executing a seten0 instruction executed `SCTLR_EL1.SED`.
  - Executing a CP15DMB, CP15DSB, or CP15SB barrier instruction when `SCTLR_EL1.CP15BEN` is 0.
Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are SCTLR.[ITD, SED, CP15BEN], with additional controls HSCTLR.[ITD, SED, CP15BEN].

See Disabling or enabling EL0 use of AArch32 deprecated functionality on page D1-2201

• When executing in AArch32 state, execution of an instruction that is UNDEFINED because at least one of FPCR.[Stride, Len] is nonzero, when programming these bits to nonzero values is supported. See Floating-point exceptions and exception traps on page G1-5320.

Note

— This case applies only when EL0 is using AArch32 and EL1 is using AArch64. The exception generated by the attempted execution at EL0 of the UNDEFINED instruction is taken to EL1 using AArch64.
— When EL1 is using AArch32, the corresponding controls are FPSCR.[Stride, Len], and any exception generated by the attempted execution at EL0 or EL1 of an instruction that is UNDEFINED because of a nonzero [Stride, Len] value is taken to EL1 using AArch32.

13

Exceptions taken to EL1, or taken to EL2 because the value of HCR_EL2.TGE is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 4-12.

Note

When EL2 is using AArch32, the equivalent control for routing exceptions to EL2 is HCR.TGE.

14

Exceptions taken from EL0 to EL2 because of one of the following configuration settings:
• HSTR_EL2.Tn.
• HCR_EL2.TIDCP.

Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are HSTR.Tn and HCR.TIDCP.

15

Exceptions taken to EL2 because of configuration settings in CPTR_EL2.

Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state, the equivalent controls are in HCPR.

16

Exceptions taken to EL2 because of one of the following configuration settings:
• Any setting in HCR_EL2 other than the {TIDCP, NV} fields.
• Any setting in CNTHCTL_EL2.
• Any setting in MDCR_EL2.

Note

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state, equivalent controls are:
• Settings in HCR, other than the TIDCP bit.
  For exceptions taken to AArch32 state there is no control equivalent to HCR_EL2.NV.
• Any setting in CNTHCTL or HDCR.
17 Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities 4-16.

18 Exceptions caused by the SMC instruction being UNDEFINED because the value of SCR_EL3.SMD is 1.

19 Exceptions caused by the execution of an Exception generating instruction not covered by priority 11:
   • For exceptions taken from AArch64 state, Branches, Exception generating, and System instructions on page C3-170 defines these and the priority 11 instructions.
   • When executing in AArch32 state, the exception-generating instructions are SVC, HVC, and SMC.

20 Exceptions taken to EL3 because of configuration settings in the CPTR_EL3.

   Note
   When in Debug state and the value of EDSCR.SDD is 1, instructions executed at EL2, EL1 or EL0 that are configured by EL3 control registers to trap to EL3 are treated as UNDEFINED and generate an exception taken to EL2 or EL1. It is IMPLEMENTATION DEFINED whether these exceptions are prioritized as an UNDEFINED instruction or have the priority of the original trap exception.

21 Exceptions taken to EL3 from Secure EL1 using AArch32, because of execution of the instructions listed in Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-2231.

22 Exceptions taken to EL3 from EL0, EL1, or EL2 because of configuration settings in the MDCR_EL3.

   Note
   When in Debug state and the value of EDSCR.SDD is 1, instructions executed at EL2, EL1 or EL0 that are configured by EL3 control registers to trap to EL3 are treated as UNDEFINED and generate an exception taken to EL2 or EL1. It is IMPLEMENTATION DEFINED whether these exceptions are prioritized as an UNDEFINED instruction or have the priority of the original trap exception.

23 Exceptions taken to EL3 because of configurable access to instructions, and that are not covered by any of priorities 4-22.

   Note
   When in Debug state and the value of EDSCR.SDD is 1, instructions executed at EL2, EL1 or EL0 that are configured by EL3 control registers to trap to EL3 are treated as UNDEFINED and generate an exception taken to EL2 or EL1. It is IMPLEMENTATION DEFINED whether these exceptions are prioritized as an UNDEFINED instruction or have the priority of the original trap exception.

24 Trapped floating-point exceptions, if supported. See Floating-point exceptions and exception traps on page D1-2184.

25 This priority number represents debug events.

26 SP alignment faults. See SP alignment checking on page D1-2152.

27 Data Abort exceptions other than a Data Abort exception generated by a synchronous External abort that was not generated by a translation table walk or the update of a page table entry. That is, any Data Abort exception that is not covered by item 29. See AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D5-2494. It is IMPLEMENTATION DEFINED whether synchronous External aborts are prioritized here or as item 29.

28 Watchpoint exceptions. See Watchpoint exceptions on page D2-2302.
Data Abort exception generated by a synchronous External abort that was not generated by a translation table walk or the update of a page table entry, see External aborts on page D4-2365. It is IMPLEMENTATION DEFINED whether synchronous External aborts are prioritized here or as item 27.

For items 27-29, if an instruction results in more than one single-copy atomic memory access, the prioritization between synchronous exceptions generated on each of those different memory accesses is not defined by the architecture.

--- Note ---
Exceptions generated by a translation table walk are reported and prioritized as either an Instruction Abort exception, priority 7 in this list, or a Data Abort exception, priority 27 in this list. See also AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D5-2494.

**D1.13.5 Effect of Data Aborts**

If an instruction that stores to memory generates a Data Abort, the value of each memory location that instruction stores to is either:

- Unchanged, if one of the following applies:
  - An Alignment fault is generated.
  - An MMU fault is generated.
  - A Watchpoint exception is generated.
  - An External abort is generated, if that External abort is taken synchronously.

--- Note ---
If an External abort is taken asynchronously, using the SError interrupt, it is outside the scope of the architecture to define the effect of the store on the memory location, because it depends on the system-specific nature of the External abort. However, in general, ARM recommends that such memory locations are not updated.

- UNKNOWN for any location for which no exception and no debug event is generated.

For External aborts and Watchpoint exceptions, the size of a memory location is defined as being the size for which a memory access is single-copy atomic.

--- Note ---
For the definition of a single-copy atomic access, see Properties of single-copy atomic accesses on page B2-93.

An External abort might signal a data corruption to the PE. For example a memory location might have been corrupted. The error that caused the External abort might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

For Data Aborts from load or store instructions executed in AArch64 state, if the:

**Data Abort is taken synchronously**

- If the load or store instruction specifies writeback of a new base address, the base address is restored to the original value on taking the exception.
- If the instruction was a load to either the base address register or the offset register, that register is restored to the original value. Any other destination registers become UNKNOWN.
- If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.

**Data Abort is taken asynchronously, using the SError interrupt**

If the instruction was a load, the destination registers of the load take an UNKNOWN value if the SError interrupt is taken at a point in the instruction stream after the load.
D1.13.6 Floating-point exceptions and exception traps

Execution of a floating-point instruction, or an Advanced SIMD instruction that performs floating-point operations, can generate an exceptional condition, called a floating-point exception.

Note
In AArch64 state, a floating-point instruction performs only a single floating-point operation. However, an Advanced SIMD instruction that operates on floating-point values can perform multiple floating-point operations. Therefore, this section describes the handling of a floating-point exception on an operation, rather than on an instruction.

The ARMv8-A architecture supports synchronous exception generation in the event of any or all of the following floating-point exceptions:
- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

Whether an implementation includes synchronous exception generation for these floating-point exceptions is IMPLEMENTATION DEFINED:
- For an implementation that does provide this capability, FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} are the control bits that enable synchronous exception generation for each of the different floating-point exceptions.
- For an implementation that does not provide this capability, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits are RAZ/WI.

Note
- An Input Denormal floating-point exception is generated when a single-precision or double-precision floating-point value is flushed-to-zero because the value of FPCR.FZ is 1. However, no Input Denormal exception is generated when a half-precision floating-point value is flushed-to-zero because the value of FPCR.FZ16 is 1.
- The ARMv8-A architecture does not support asynchronous reporting of floating-point exceptions.

When generating synchronous exceptions for one or more floating-point exceptions is enabled, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception, while adhering to the rule that an exception can never be taken to a lower Exception level.

The exception is reported in the ESR_ELx for the Exception level to which it is taken.

In an implementation that includes synchronous exception generation for floating-point exceptions in AArch64 state:
- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception. An implementation is permitted not to restore the cumulative exception bits in the event of such an exception. For more information see Combinations of floating-point exceptions on page D1-2185.
- When the execution of separate operations in separate SIMD elements causes multiple floating-point exceptions, the ESR_ELx reports one exception associated with one element that the instruction uses. The architecture does not specify which element is reported, however the element that is reported is identified in the ESR_ELx.

The AArch64.FPTrappedException() and FPProcessException() pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch64 state.
Combinations of floating-point exceptions

Many pseudocode functions perform `floating-point operations`, including `FixedToFP()`, `FPAdd()`, `FPCompare()`, `FPCompareEQ()`, `FPCompareGE()`, `FPCompareGT()`, `FPDiv()`, `FPMax()`, `FPMin()`, `FPmul()`, `FPmulAdd()`, `FPRecipEstimate()`, `FPRecipStepFused()`, `FPRecipStepFused()`, `FPSqrtStepFused()`, `FPSqrt()`, `FPMulAdd()`, and `FPToFixed()`. All of these operations can generate floating-point exceptions.

--- Note ---

`FPAbs()` and `FPNeg()` are not classified as `floating-point operations` because:

- They cannot generate floating-point exceptions.
- The floating-point operation behavior described in the following sections does not apply to them:

More than one floating-point exception can occur on the same operation. The only combinations of floating-point exceptions that can occur are:

- Overflow with Inexact.
- Underflow with Inexact.
- Input Denormal with other floating-point exceptions.

The priority order of these floating-point exceptions is that the Inexact exception is treated as lowest priority, and the Input Denormal exception is treated as highest priority.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, a floating-point exception on one operation is treated as higher priority than a floating-point exception on another operation if the occurrence of the second floating-point exception depends on the result of the first operation. Otherwise, it is `CONSTRAINED UNPREDICTABLE` which floating-point exception is treated as higher priority, where the exception prioritization might differ between different instances of the same two floating-point exceptions being generated on the same operation during execution of the instruction.

When none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative bit in the `FPSR` to be set to 1.

When a floating-point exception is trapped:

- It is `IMPLEMENTATION DEFINED` whether the `FPSR` is restored when the trapped floating-point exception is taken. If the `FPSR` is not restored then, then it is `CONSTRAINED UNPREDICTABLE` which untrapped floating-point exception, if any, are indicated by the corresponding `FPSR` cumulative exception bits having the value 1.

- In the `ESR_ELx` for the Exception level to which the trapped exception is taken, the value of the floating-point exception trapped bit for the highest priority trapped floating-point exception must be 1.

  In this `ESR_ELx`:
  - The value of the floating-point exception trapped bit for any other untrapped floating-point exception generated by the same operation must be 0. This applies to both higher priority and lower priority untrapped floating point exceptions.
  - The value of the floating-point exception trapped bit for any lower priority trapped floating-point exception generated by the same operation might be 1, but the architecture does not require this.

For trapped floating-point exceptions from Advanced SIMD instructions, the architecture does not define the floating-point exception prioritization between different elements of the instruction. The architectural requirements for floating-point exception prioritization apply only to multiple floating-point exceptions generated on the same element of an Advanced SIMD operation.

--- Note ---

An implementation might provide information about a lower priority or untrapped floating-point exceptions in an `IMPLEMENTATION DEFINED` way, for example using an `IMPLEMENTATION DEFINED` register.
D1.14  Asynchronous exception types, routing, masking and priorities

In the ARMv8-A architecture, asynchronous exceptions that are taken to AArch64 state are also known as interrupts.

There are two types of interrupts:

**Physical interrupts**  Are signals sent to the PE from outside the PE. They are:
- SError. System Error.
- IRQ.
- FIQ.

**Virtual interrupts**  Are interrupts that software executing at EL2 can enable and make pending. A virtual interrupt is taken from EL0 or EL1 to EL1.

Virtual interrupts have names that correspond to the physical interrupts:
- vSError.
- vIRQ.
- vFIQ.

--- Note ---

- For information about how virtual interrupts might be used see *Virtual interrupt usage model* on page D1-2141.
- The SError interrupt replaces the ARMv7 asynchronous abort. The new name better describes the nature of the exception, and means that, in AArch64 state, it is categorized as a unique exception class, with EC encoding 0x2F.

An External abort generated by the memory system might be taken asynchronously using the SError interrupt. These SError interrupts always behave as edge-triggered interrupts. An implementation might include other sources of SError interrupt. It is implementation defined whether these other sources are edge-triggered or level-sensitive. See also *External aborts* on page D4-2365.

Each physical interrupt type can be assigned a target Exception level of EL1, EL2 or EL3, as shown in *Asynchronous exception routing* on page D1-2187.

When an interrupt occurs:

- On taking an SError or a vSError interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is updated to describe an SError interrupt. When the RAS Extension is implemented, the exception syndrome for the vSError interrupt is taken from the values in the VSESR_EL2 register. See *Exception classes and the ESR_ELx syndrome registers* on page D1-2160, and the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.
- On taking an IRQ, vIRQ, FIQ or vFIQ interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is not updated.

The remainder of this section contains the following:

- *Asynchronous exception routing* on page D1-2187.
- *Asynchronous exception masking* on page D1-2190.
- *Virtual interrupts* on page D1-2192.
- *Prioritization and recognition of interrupts* on page D1-2194.
- *Taking an interrupt or other exception during a multiple-register load or store* on page D1-2195.
D1.14.1 Asynchronous exception routing

The following tables show the routing of physical interrupts when the highest implemented Exception level is using AArch64:

- For implementations that include both EL2 and EL3, see Table D1-12.
- For implementations that include EL3 but not EL2, see Table D1-13 on page D1-2188.
- For implementations that include EL2 but not EL3, see Table D1-14 on page D1-2189.

When the highest implemented Exception level is using AArch32, see Table G1-19 on page G1-5280.

In the tables:

SCR This is the Effective value of a field in SCR.

FIQ IRQ EA The Effective value of the field that handles the asynchronous exception type in SCR, if the highest EL is using AArch32, or SCR_EL3, if the highest EL is using AArch64.

HCR This is the Effective value of a field in HCR, if EL2 is using AArch32 or HCR_EL2 if EL2 is using AArch64.

When the value of the TGE is 1, the virtual exceptions are disabled.

When the Effective value of HCR.{E2H,TGE} is:

\{0, 1\} The Effective value of each of the HCR.{AMO,IMO,FMO} fields is 1.

\{1, 1\} The Effective value of each of the HCR.{AMO,IMO,FMO} fields is 0.

FMO IMO AMO The Effective value of the mask override field for the asynchronous exception type in HCR, if EL2 is using AArch32 or HCR_EL2 if EL2 is using AArch64.

EL2 The exception is taken to EL2 using AArch64.

EL3 The exception is taken to EL3 using AArch64.

C The interrupt is not taken and remains pending, regardless of the PSTATE.{A, I, F} interrupt masks.

FIQ IRQ Abt The exception is taken to the FIQ mode, the IRQ mode or the Abort mode according to the type of asynchronous exception.

Hyp The exception is taken to AArch32 Hyp mode.

Mon The exception is taken to AArch32 Monitor mode.

n/a Not applicable. The field does not exist in the register in this configuration or the Exception level is not accessible in this configuration.

FMO = FMO Masking
EL0 = Exception Level 0
EL1 = Exception Level 1
EL2 = Exception Level 2
D1.14.2 Asynchronous exception masking

When an interrupt is masked, it means that it cannot be taken. Instead, it remains pending.

When executing in AArch64 state, interrupts are masked implicitly when the target Exception level of the interrupt is lower than the current Exception level.

In addition, interrupts can be masked when the target Exception level is the current Exception level. The controls for this are:

<table>
<thead>
<tr>
<th>SError</th>
<th>PSTATE.A</th>
</tr>
</thead>
<tbody>
<tr>
<td>IRQ</td>
<td>PSTATE.I</td>
</tr>
<tr>
<td>FIQ</td>
<td>PSTATE.F</td>
</tr>
</tbody>
</table>

When the target Exception level is higher than the current Exception level:

- If the target Exception level is EL3, the interrupt cannot be masked by the PSTATE.{A, I, F} bits.
- If the target Exception level is EL2, and either HCR_EL2.E2H is 0 or HCR_EL2.TGE is 0, the interrupt cannot be masked by the PSTATE.{A, I, F} bits.
- If the target Exception level is EL2, HCR_EL2.E2H is 1, and HCR_EL2.TGE is 1, the interrupt can be masked by the PSTATE.{A, I, F} bits.
- If the target Exception level is EL1, the interrupt can be masked by the PSTATE.{A, I, F} bits.

Note

- The ability to execute in EL0 with interrupts to EL1 masked is required by some user level driver code.
- The PSTATE.{A, I, F} bits can mask both physical interrupts and virtual interrupts.
- The ARMv8-A architecture does not support Non-maskable FIQ (NMFI) operations. This means that it does not provide a configuration option to override the masking of FIQs by PSTATE.F.

On taking any exception to an Exception level using AArch64, all of PSTATE.{A, I, F} are set to 1, masking all interrupts that target that Exception level.

The following tables show the masking of physical interrupts when the highest implemented Exception level is using AArch64:

- For implementations that include both EL2 and EL3, see Table D1-15 on page D1-2191.
- For implementations that include EL3 but not EL2, see Table D1-16 on page D1-2192.
- For implementations that include EL2 but not EL3, see Table D1-17 on page D1-2192.

For the masking of interrupts when the highest implemented Exception level is using AArch32, see Table G1-20 on page G1-5281.

For the masking of virtual interrupts, see Virtual interrupts on page D1-2192.

In the tables:

- **SCR** This is the Effective value of a field in SCR.
- **FIQ IRQ EA** The Effective value of the field that handles the asynchronous exception type in SCR, if the highest EL is using AArch32, or SCR_EL3, if the highest EL is using AArch64.
- **HCR** This is the Effective value of a field in HCR.
  - When the value of HCR.TGE is 1, the virtual exceptions are disabled.
  - When the Effective value of HCR.{E2H, TGE} is:
    - {0, 1} The Effective value of each of the HCR.{AMO, IMO, FMO} fields is 1.
    - {1, 1} The Effective value of each of the HCR.{AMO, IMO, FMO} fields is 0.
- **FMO IMO AMO** The Effective value of the mask override field for the asynchronous exception type in HCR, if EL2 is using AArch32 or HCR_EL2 if EL2 is using AArch64.
- **A** When the interrupt is asserted it is taken regardless of the value of the PSTATE.{A, I, F} interrupt masks.
When the interrupt is asserted it is subject to the corresponding Process state mask. If the value of the mask is 1 then the interrupt is not taken. If the value of the mask is 0 the interrupt is taken.

**A/B**

When ARMv8.4-DFE is implemented, the interrupt is an SError interrupt, and SCR_EL3.NMEA is 1, then the interrupt behaves as A. Otherwise, the interrupt behaves as B.

**C**

When the interrupt is asserted it is not taken, regardless of the value of the PSTATE.{A, I, F} interrupt masks.

**n/a**

Not applicable. The PE cannot be executing at this Exception level for the specified state of HCR and SCR_EL3.

---

a. When the implementation does not include ARMv8.4-SecEL2, the SCR_EL3.EEL2 field is not implemented and the Effective value of EEL2 is 0.

b. When the implementation does not include ARMv8.1-VHE, the HCR_EL2.E2H field is not implemented and the Effective value of E2H is 0.
D1.14.3 Virtual interrupts

When the value of $\text{HCR\_EL2}.TGE$ is 0, setting an $\text{HCR\_EL2}.\{\text{FMO, IMO, AMO}\}$ routing control bit to 1 enables the corresponding virtual interrupt. When the value of $\text{HCR\_EL2}.TGE$ is 1 all virtual interrupts are disabled.

When execution is in Secure state, or at EL2, all types of virtual interrupt are always masked.

Virtual interrupts can only be taken from EL0 or EL1 to EL1. When a virtual interrupt type is enabled, that type of interrupt can be generated by:

- Software setting the corresponding virtual interrupt pending bit, $\text{HCR\_EL2}.\{\text{VSE, VI, VF}\}$, to 1.
- For a $\text{vIRQ}$ or a $\text{vFIQ}$, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller. See, for example, the ARM Generic Interrupt Controller Architecture Specification.

--- Note ---

For a usage model for virtual interrupts, see Virtual interrupt usage model on page D1-2141.

When a virtual interrupt is disabled:

- It cannot be taken.
- It cannot be seen in the $\text{ISR\_EL1}$.

Each virtual interrupt type can be masked when execution is in EL1 or EL0, by using the same Process State mask bits that mask the physical interrupts, $\text{PSTATE}.\{A, I, F\}$.

<td>EL2</td>
<td>B</td>
</tr>
</tbody>
</table>

a. If the implementation does not include ARMv8.1-VHE, the HCR.E2H field is not implemented and behavior is as if the value of E2H is 0.
Table D1-18 summarizes the bits that enable virtual interrupts and the bits that cause virtual interrupts to be pending.

<table>
<thead>
<tr>
<th>Virtual interrupt type</th>
<th>Enable controla</th>
<th>Cause a virtual interrupt to be pending</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSError</td>
<td>HCR_EL2.AMO</td>
<td>HCR_EL2.VSE</td>
</tr>
<tr>
<td>vIRQ</td>
<td>HCR_EL2.IMO</td>
<td>HCR_EL2.VI</td>
</tr>
<tr>
<td>vFIQ</td>
<td>HCR_EL2.FMO</td>
<td>HCR_EL2.VF</td>
</tr>
</tbody>
</table>

a. Applies only when the value of HCR_EL2.TGE is 0, otherwise the virtual interrupts are disabled.

On taking a vIRQ or a vFIQ interrupt, the corresponding virtual interrupt pending bit in the HCR_EL2 retains its state.

On taking a vSError interrupt, HCR_EL2.VSE is cleared to 0.

**Note**
This means that if the virtual interrupt pending bits are used, the vIRQ or vFIQ exception handler must cause software executing at EL2 or EL3 to set their corresponding virtual interrupt pending bits to 0.

Taking a vSError interrupt to an Exception level using AArch64 updates ESR_EL1 with the encoding for an SError interrupt. For the encoding, see Exception classes and the ESR_ELx syndrome registers on page D1-2160. When the RAS Extension is implemented, the exception syndrome for the vSError interrupt is taken from the values in the VSESR_EL2 register, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile. Taking a vIRQ or a vFIQ interrupt to an Exception level using AArch64 does not update the ESR_EL1.

The following table shows the masking of virtual interrupts when the highest implemented Exception level is using AArch64. In the table:

- **B** When the interrupt is asserted it is subject to the corresponding Process state mask. If the value of the mask is 1 then the interrupt is taken. If the value of the mask is 0 the interrupt is taken.
- **C** When the interrupt is asserted it is not taken, regardless of the value of the Process state mask.
- **n/a** Not applicable. The PE cannot be executing at this Exception level for the specified state of HCR and SCR_EL3.

**HCR** In Table D1-19, including in the table footnote:
- When EL2 is using AArch64 HCR refers to the AArch64 register HCR_EL2.
- When EL2 is using AArch32 HCR refers to the AArch32 register HCR.

When the value of HCR.TGE is 1, the virtual exceptions are disabled.

When the Effective value of HCR.{E2H, TGE} is:

- \(\{0, 1\}\) The Effective value of each of the HCR.{AMO, IMO, FMO} fields is 1.
- \(\{1, 1\}\) The Effective value of each of the HCR.{AMO, IMO, FMO} fields is 0.

Table D1-19 Virtual interrupt masking
D1.14.4 Prioritization and recognition of interrupts

The prioritization of interrupts, including virtual interrupts, is implementation defined.

--- Note ---
As indicated at the start of *Asynchronous exception types, routing, masking and priorities on page D1-2186*, in AArch64 state all possible asynchronous exceptions are defined as interrupts.

--- Note ---
Any interrupt that is pending before one of the following context synchronizing events is taken before the first instruction after the context synchronizing event, provided that the pending interrupt is not masked:

- Execution of an ISB instruction.
- Exception entry.
- Exception return.
- Exit from Debug state.

--- Note ---
If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define whether the PE takes the interrupt or the synchronous exception first.

- The ISR_EL1 identifies any pending interrupts.
- Interrupts are masked when the PE is in Debug state, and therefore this list of context synchronizing events does not include the DCPS and DRPS instructions.

An error synchronization event defines additional requirements for taking an SError interrupt, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

In the absence of a specific requirement to take an interrupt, the architecture only requires that unmasked pending interrupts are taken in finite time.

If an unmasked interrupt was pending but is changed to not pending before it is taken, then the architecture permits the interrupt to be taken, but does not require this to happen. If the interrupt is taken then it must be taken before the first Context synchronization event after the interrupt was changed to not pending.
D1.14.5 Taking an interrupt or other exception during a multiple-register load or store

In AArch64 state, interrupts can be taken during a sequence of memory accesses caused by a single load or store instruction. This is true regardless of the memory type being accessed.

If an interrupt, or another exception, is taken from AArch64 during the execution of an instruction that performs a sequence of memory accesses, rather than a single single-copy atomic access, then:

- For a load, any register being loaded by the instruction other than ones used in the generation of the address by the instruction, can contain an **UNKNOWN** value. Registers used in the generation of the address are restored to their initial value.

- For a store, any data location being stored to by the instruction can contain an **UNKNOWN** value.

- For either a load or a store, if the instruction specifies writeback of the base address, then that register is restored to its initial value.

--- Note ---

- This interrupt behavior is in contrast to behavior in AArch32 state, when interrupts cannot be taken during a sequence of memory accesses caused by a single load or store instruction.

- In both Execution states, synchronous data abort exceptions can be taken during the execution of an instruction that performs a sequence of memory accesses.

- Software must avoid using multiple-register load and store instructions for accesses to Device memory, particularly to Device memory with the non-Gathering attribute, because an exception taken during the load or store can result in repeated accesses.
D1.15 Configurable instruction enables and disables, and trap controls

This section describes the controls provided by AArch64 state for enabling, disabling, and trapping particular instructions. Each control is categorized as an instruction enable, an instruction disable, or a trap control.

Instruction enables and instruction disables

Enable or disable the use of one or more particular instructions at a particular Exception level and Security state.

When an instruction is disabled as a result of an instruction enable or disable, it is UNDEFINED.

Trap controls

A trap control determines whether one or more particular instructions, whenever executed at a particular Exception level, are trapped.

A trapped instruction generates a Trap exception.

For trap controls provided by:

<table>
<thead>
<tr>
<th>EL1</th>
<th>Trap exceptions are taken to EL1, unless routed from EL0 to EL2 because HCR_EL2.TGE is 1 as described in Routing exceptions from EL0 to EL2 on page D1-2178. For descriptions of these controls see EL1 configurable controls on page D1-2197.</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL2</td>
<td>Trap exceptions are taken to EL2. For descriptions of these controls see EL2 configurable controls on page D1-2206.</td>
</tr>
<tr>
<td>EL3</td>
<td>Trap exceptions are taken to EL3. For descriptions of these controls see EL3 configurable controls on page D1-2229.</td>
</tr>
</tbody>
</table>

Note

The definitions of traps and enables and disables overlap, and the classification of some controls is historical. In AArch64 state, the most significant characteristic of an exception report is the ESR_ELx.EC value with which it is reported. Describing a register control field as an instruction enable, an instruction disable, or a trap control, gives no indication of how an exception that is generated as a consequence of the value of that field is handled or reported.

An exception generated as a result of an instruction enable or disable, or a trap control, is only taken if both of the following apply:

- The instruction generating the exception does not also generate a higher priority exception. Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2179 defines the prioritization of different exceptions on the same instruction.

- The instruction is not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in the PE state it is executed in. UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions can generate exceptions as a result of these controls, but the architecture does not require them to do so.

Exceptions generated as a result of these controls are synchronous exceptions.

Exceptions are reported in the ESR_ELx, with an EC value that indicates the Exception class. and:

- Many cases, including all traps, are reported with a non-zero EC value and an associated syndrome.

- Some cases where an instruction is UNDEFINED are reported with an EC value 0x00, the value for an exception for an unknown or uncategorized reason, and in these cases no syndrome is provided. ISS encoding for exceptions with an unknown reason on page D12-2763 identifies the cases that are reported with EC value 0x00.

Table D1-8 on page D1-2161 lists the EC values that are used for exceptions that result from traps, enables, and disables.

Note

- A particular control might have a mnemonic that suggests it is different type of control to the control type it is categorized as. For example, SCTLR_EL1.DZE is a trap control even though DZE means DC ZVA Enable.
In addition to the controls described in this section, a *routing control*, HCR_EL2.TGE, can be used to route exceptions from EL0 to EL2. See *Routing exceptions from EL0 to EL2* on page D1-2178.

An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.

This section is organized as follows:
- Register access instructions.
- EL1 configurable controls.
- EL2 configurable controls on page D1-2206.
- EL3 configurable controls on page D1-2229.

### D1.15 Register access instructions

When an instruction is disabled or trapped, the exception is taken before execution of the instruction. This means that if the instruction is a register access instruction:
- No access is made before the exception is taken.
- Side-effects that are normally associated with the access do not occur before the exception is taken.

### D1.15.1 Register access instructions

These controls are in _EL0 and _EL1 System registers. The resulting exceptions might be taken from either Execution state. SPSR_EL1.M[4] indicates which Execution state the exception was taken from.

Table D1-20 shows the _EL0 and _EL1 System registers that contain these controls.

Traps to EL1 of EL0 execution of cache maintenance instructions

SCTLR_EL1.ICI traps EL0 execution of cache maintenance instructions to EL1:
1. EL0 execution of cache maintenance instructions is not trapped to EL1.
0. Any attempt to execute a cache maintenance instruction at EL0 is trapped to EL1.
Table D1-23 shows the instructions that are trapped to EL1, and how the exceptions are reported in ESR_EL1:

### Table D1-23 Instructions trapped to EL1 when SCTLR_EL1.UCl is 0

<table>
<thead>
<tr>
<th>Traps from AArch64 state</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>DC CVAU, DC CIVAC, DC CVAC, DC CVAP, IC IVAU</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18&lt;sup&gt;a&lt;/sup&gt;</td>
<td></td>
</tr>
<tr>
<td>AArch32 state</td>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

<sup>a</sup> If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

### Traps to EL1 of EL0 accesses to the CTR_EL0

SCTLR_EL1.UCT traps EL0 accesses to the CTR_EL0 to EL1:

- **1** EL0 accesses to the CTR_EL0 are not trapped to EL1.
- **0** EL0 accesses to the CTR_EL0 are trapped to EL1.

Table D1-24 shows how the exceptions are reported in ESR_EL1:

### Table D1-24 Register accesses trapped to EL1 when SCTLR_EL1.UCT is 0

<table>
<thead>
<tr>
<th>Traps from AArch64 state</th>
<th>Register</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTR_EL0</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18&lt;sup&gt;a&lt;/sup&gt;</td>
<td></td>
</tr>
<tr>
<td>n/a</td>
<td>n/a</td>
<td></td>
</tr>
</tbody>
</table>

<sup>a</sup> If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

### Traps to EL1 of EL0 execution of WFE and WFI instructions

SCTLR_EL1.{nTWE, nTWI} trap EL0 execution of WFE and WFI instructions to EL1:

#### SCTLR_EL1.nTWE

- **1** EL0 execution of WFE instructions is not trapped to EL1.
- **0** Any attempt to execute a WFE instruction at EL0 is trapped to EL1, if the instruction would otherwise have caused the PE to enter a low-power state.

#### SCTLR_EL1.nTWI

- **1** EL0 execution of WFI instructions is not trapped to EL1.
- **0** Any attempt to execute a WFI instruction at EL0 is trapped EL1, if the instruction would otherwise have caused the PE to enter a low-power state.

Table D1-25 shows how the exceptions are reported in ESR_EL1:

### Table D1-25 Instructions trapped to EL1 when SCTLR_EL1.{nTWE, nTWI} are 0

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Traps from AArch64 state</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>WFE</td>
<td>WFI</td>
<td>Trapped WFI or WFE instruction, using EC value 0x01&lt;sup&gt;a&lt;/sup&gt;</td>
<td></td>
</tr>
</tbody>
</table>

<sup>a</sup> If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.
In AArch32 state, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its Condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- Wait for Event mechanism and Send event on page D1-2243.
- Wait For Interrupt on page D1-2246.

Traps to EL1 of EL0 execution of DC ZVA instructions

SCTLR_EL1.DZE traps EL0 execution of DC ZVA instructions to EL1:

1  EL0 execution of DC ZVA instructions is not trapped to EL1.

0  Any attempt to execute a DC ZVA instruction at EL0 is trapped to EL1. Reading the DCZID_EL0 returns a value that indicates that DC ZVA instructions are not implemented.

Table D1-26 shows how the exceptions are reported in ESR_EL1:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instruction</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>DC ZVA</td>
<td>Trapped AArch64 MSR, MSR, or System instruction, using EC value 0x18^a</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

a. If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks

SCTLR_EL1.UMA traps EL0 execution of MSR and MRS instructions that access the PSTATE.{D, A, I, F} masks to EL1:

1  EL0 execution of MSR or MRS instructions that access the DAIF is not trapped to EL1.

0  Any attempt at EL0 to execute an MSR or an MRS instruction that accesses the DAIF is trapped to EL1.

Table D1-27 shows how the exceptions are reported in ESR_EL1:

<table>
<thead>
<tr>
<th>Taken from</th>
<th>Disabled instructions</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>MRS, MSR (register), MSR (immediate), that access the DAIF</td>
<td>Trapped AArch64 MSR, MSR, or System instruction, using EC value 0x18^a</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

a. If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.
Disabling or enabling EL0 use of AArch32 deprecated functionality

Table D1-28 shows the deprecated AArch32 functionality that might have disable controls in the SCTLR_EL1:

- The SED control is always implemented.
- Whether each of the ITD, CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented then the associated functionality cannot be disabled.

These SCTLR_EL1 controls apply only to execution at EL0 using AArch32. When an instruction is disabled by one of these controls, it is UNDEFINED at EL0 using AArch32. Table D1-28 shows how the exceptions are reported in ESR_EL1:

Table D1-28 EL1 controls for disabling and enabling EL0 use of AArch32 deprecated functionality

<table>
<thead>
<tr>
<th>Deprecated AArch32 functionality</th>
<th>Instruction enable or disable in the SCTLR_EL1</th>
<th>Disabled instructions</th>
<th>Syndrome reporting in ESR_EL1(^a)</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETEND instructions</td>
<td>SED(^b)</td>
<td>SETEND instructions</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td>Some uses of IT instructions</td>
<td>ITD(^c)</td>
<td>See the SCTLR_EL1.IT description</td>
<td></td>
</tr>
<tr>
<td>Accesses to the CP15DMB, CP15DSB, and CP15ISB barrier instructions</td>
<td>CP15BEN(^d)</td>
<td>MCR accesses to the CP15DMB, CP15DSB, and CP15ISB instructions</td>
<td></td>
</tr>
</tbody>
</table>

\(^a\) If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, the exception is routed to EL2 and reported in ESR_EL2 using the EC value shown in the table.

\(^b\) SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.

\(^c\) IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.

\(^d\) System register (coproc==0b1111) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.

--- Note ---

- The uses of the IT instruction, and use of the CP15DMB, CP15DSB, and CP15ISB barrier instructions, are deprecated for performance reasons.

- The SCTLR provides similar controls that apply when EL1 is using AArch32, and the HSCTLR provides similar controls that apply when EL2 is using AArch32.

---

Traps to EL1 of EL0 and EL1 System register accesses to the trace registers

CPACR_EL1.TTA traps EL0 and EL1 System register accesses to the trace registers to EL1.

1  EL0 and EL1 System register accesses to the trace registers are trapped to EL1.
0  This control has no effect on accesses to the trace registers.

--- Note ---

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and the resulting exception is higher priority than a CPACR_EL1.TTA Trap exception.

- The ARMv8-A architecture does not provide traps on trace register accesses through the optional Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see Register access instructions on page D1-2197.
Table D1-29 shows the registers for which accesses are trapped to EL1 when CPACR_EL1.TTA is 1, and how the exceptions are reported in ESR_EL1:

**Table D1-29 Register accesses trapped to EL1 when CPACR_EL1.TTA is 1**

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>All implemented trace registers</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18.(^a)</td>
</tr>
</tbody>
</table>
| AArch32 state | All implemented trace registers | For accesses using:  
  - MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.\(^a\)  
  - MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C.\(^a\) |

\(^a\) If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

**Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality**

When EL1 is using AArch64, CPACR_EL1.FPEN traps EL0 and EL1 accesses to the SIMD and floating-point registers to EL1:

- **00** Causes any instructions in EL0 or EL1 that use the registers that are associated with Advanced SIMD and floating-point execution to be trapped.
- **01** Causes any instructions in EL0 that use the registers that are associated with Advanced SIMD and floating-point execution to be trapped, but does not cause any instruction in EL1 to be trapped.
- **10** Causes any instructions in EL0 or EL1 that use the registers that are associated with Advanced SIMD and floating-point execution to be trapped.
- **11** Does not cause any instruction to be trapped.

Table D1-30 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL1:

**Table D1-30 Register accesses trapped to EL1 by CPACR_EL1.FPEN**

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>EL0 and EL1 using AArch64, or EL0 using AArch64 only(^a),</td>
<td>FPSCR, FPSR, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See <em>The SIMD and floating-point registers, V0-V31 on page D1-2144</em>.</td>
<td>Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP, using EC value 0x07(^b)</td>
</tr>
<tr>
<td>EL0 using AArch32</td>
<td>FPSCR, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See Advanced SIMD and floating-point System registers on page G1-5318.</td>
<td>Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP, using EC value 0x07(^b)</td>
</tr>
</tbody>
</table>

\(^a\) As described at the start of this subsection, the value of CPACR_EL1.FPEN determines whether the trap applies only to accesses from EL0, or applies to both accesses from EL1 and accesses from EL0.

\(^b\) If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using EC value 0x00.

**Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers**

MDSCR_EL1.TDCC traps EL0 accesses to the DCC registers to EL1:

- **1** EL0 accesses to the DCC registers are trapped to EL1.
- **0** This control has no effect on accesses to the DCC registers.
Traps of AArch32 accesses to DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

Traps of AArch64 accesses to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0 are ignored in Debug state.

Table D1-31 shows the accesses that are trapped, and how the exceptions are reported in ESR_EL1:

**Table D1-31 Accesses trapped to EL1 when MDSCR_EL1.TDCC is 1**

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>Accesses to the MDCCSR_EL0, DBGDTR_EL0, DBGDTRTX_EL0 and DBGDTRRX_EL0</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18a</td>
</tr>
</tbody>
</table>
| AArch32 state | • MRC of DBGDSCRint, DBGDTRRXint, and, if implemented, DBGDIR, DBGDSAR and DBGDRAR.  
| | • MCR to DBGDTRXint. | Trapped MCR or MRC access (coproc==0b11110), using EC value 0x05a |
| | • LDC access to DBGDTRRXint.  
| | • STC access to DBGDTRRXint. | Trapped LDC or STC access, using EC value 0x06a |
| | If implemented, MRC of DBGDSAR and DBGDRAR. | Trapped MCR or MRC access (coproc==0b11110), using EC value 0x0Ca |

a. If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

**Traps to EL1 of EL0 accesses to the Generic Timer registers**

CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} trap EL0 accesses to the Generic Timer registers to EL1, as follows:

• **CNTKCTL_EL1.EL0PTEN** traps EL0 accesses to the physical timer registers.

• **CNTKCTL_EL1.EL0VTEN** traps EL0 accesses to the virtual timer registers.

• **CNTKCTL_EL1.EL0PCTEN** traps EL0 accesses to the frequency register and physical counter register.

• **CNTKCTL_EL1.EL0VCTEN** traps EL0 accesses to the frequency register and virtual counter register.

For all of these controls:

1  EL0 accesses are not trapped to EL1.
0  EL0 accesses are trapped to EL1.

Accesses to the frequency register, CNTFRQ_EL0 or CNTFRQ, are only trapped if CNTKCTL_EL1.EL0PCTEN and CNTKCTL_EL1.EL0VCTEN are both 0.

Table D1-32 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL1:

**Table D1-32 Register accesses trapped from EL0 to EL1 by CNTKCTL_EL1 trap controls**

<table>
<thead>
<tr>

</tbody>
</table>
Traps to EL1 of EL0 accesses to Performance Monitors registers

PMUSERENR_EL0. {ER, CR, SW, EN} trap EL0 accesses to the Performance Monitors registers to EL1. For each of these controls:

- **1** EL0 accesses are not trapped to EL1.
- **0** EL0 accesses are trapped to EL1.

For those Performance Monitors registers that more than one PMUSERENR_EL0. {ER, CR, SW, EN} control applies to, accesses are only trapped if all controls that apply are set to 0.

The accesses that these trap controls trap might be reads, writes, or both.

Table D1-33 shows:

- The registers for which EL0 accesses are trapped. For each register, the table shows the type of access trapped.
- How the exceptions are reported in ESR_EL1.

### Table D1-32 Register accesses trapped from EL0 to EL1 by CNTKCTL_EL1 trap controls (continued)

Traps to EL1 of EL0 accesses to Activity Monitors registers

AMUSERENR_EL0.EN traps EL0 accesses to the Activity Monitors registers to EL1:

1. EL0 accesses are not trapped to EL1.
2. EL0 accesses are trapped to EL1.

Table D1-34 on page D1-2206 shows:

- The registers for which EL0 accesses are trapped.

---

a. If HCR_EL2.TGE is 1 EL2 is enabled in the current Security state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

b. The EL0 access is trapped only if the corresponding EL1 accesses is permitted. For example, the PMSWINC_EL0 and PMSWINC registers are WO at EL1, and therefore, when the value of EN is 0:
- Write accesses to these registers from EL0 are trapped.
- Read accesses to these registers from EL0 are UNDEFINED, because read accesses to the registers from EL1 are UNDEFINED.
• How the exceptions are reported in ESR_EL1.

### Table D1-34 Register accesses trapped to EL1 when AMUSERENR_EL0.EN is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64</td>
<td>AMCFGFR_EL0, AMCGCR_EL0, AMCNTENCLR0_EL0,</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18a</td>
</tr>
<tr>
<td>state</td>
<td>AMCNTENCLR1_EL0, AMCNTENSET0_EL0,</td>

<td></td>
</tr>
<tr>
<td></td>
<td>AMEVCTR0&lt;n&gt; or AMEVCTR1&lt;n&gt;.</td>
<td></td>
</tr>
</tbody>
</table>

a. If HCR_EL2.TGE is 1 and EL2 is enabled in the current Security state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

### Enabling use of the Pointer authentication instructions, EL1&0 translation regime

This control is implemented when ARMv8.3-PAuth is implemented.

Each of the SCTLR_EL1.{EnDA, EnDB, EnIA, EnIB} fields enables the pointer authentication functionality for the corresponding Pointer authentication instructions for the EL1&0 translation regime. For more information see System register control of pointer authentication on page D5-2378.

**Note**

These controls cause the pointer authentication instructions to execute as NOPs. They never cause an exception to be generated.

### Disabling Address tagging for instruction accesses, EL1&0 translation regime

This control is implemented when ARMv8.3-PAuth is implemented.

When a TCR_EL1.{TBI0, TBI1} field enables the use of address tagging for the EL1&0 translation regime, the corresponding TCR_EL1.{TBI0, TBI1} field determines whether address tagging is used for both data and instruction addresses, or only for data addresses. For more information see Address tagging in AArch64 state on page D5-2374.

**Note**

These controls determine the scope of address tagging. They never cause an exception to be generated.

### D1.15.3 EL2 configurable controls

These controls are in _EL2 System registers. The resulting exceptions might be taken from either Execution state. SPSR_EL2.M[4] indicates which Execution state the exception was taken from.

These controls are ignored in Secure state.
Table D1-35 shows the _EL2 System registers that contain these controls.

Table D1-35 _EL2 registers that contain instruction disables and trap controls

Also see the following for more general information about traps to EL2:

- Register access instructions on page D1-2197.
- For traps from an Exception level using AArch32:
  - Instructions that fail their Condition code check on page G1-5333.
  - Trapping to EL2 of instructions that are UNPREDICTABLE on page G1-5333.

Traps to EL2 of EL1 accesses to virtual memory control registers

HCR_EL2.(TRVM, TVM) trap EL1 accesses to the virtual memory control registers to EL2, if enabled in the current Security state:

HCR_EL2.TRVM, for read accesses:
- 1 EL1 reads of the virtual memory control registers are trapped to EL2.
- 0 This control has no effect on reads of the virtual memory control registers.

HCR_EL2.TVM, for write access:
- 1 EL1 writes to the virtual memory control registers are trapped to EL2.
- 0 This control has no effect on writes to the virtual memory control registers.

Table D1-38 shows:
- The registers for which reads are trapped to EL2 when HCR_EL2.TRVM is 1.
- The registers for which writes are trapped to EL2 when HCR_EL2.TVM is 1.
- How the exceptions are reported in ESR_EL2.

Table D1-38 Register read and write accesses trapped when HCR_EL2.(TRVM, TVM) are 1

<table>
<thead>
<tr>
<th>Traps from</th>

</tr>
</tbody>
</table>

— Note —

EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by a Guest OS to write to the registers that control the Non-secure memory system. A hypervisor might use this trap as part of its virtualization of memory management.
Disabling Non-secure state execution of HVC instructions

HCR_EL2.HCD disables execution of HVC instructions:

1  HVC instructions are UNDEFINED at EL2 and EL1, and any resulting exception is taken from the current Exception level to the current Exception level.
0  HVC instruction execution is enabled at EL2 and EL1.

--- Note ---
HVC instructions are always UNDEFINED at EL0.

HCR_EL2.HCD is only implemented if EL3 is not implemented. Otherwise, it is RES0.

Table D1-39 shows how the exceptions are reported in ESR_ELx:

<table>
<thead>
<tr>
<th>Taken from</th>
<th>Disabled instruction</th>
<th>Syndrome reporting in ESR_ELx</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

Traps to EL2 of EL0 and EL1 execution of DC ZVA instructions

HCR_EL2.TDZ traps EL0 and EL1 execution of DC ZVA instructions to EL2:

1  Any attempt to execute a DC ZVA instruction at EL0 or EL1 is trapped to EL2 if enabled in the current Security state. Reading the DCZID_EL0 returns a value that indicates that DC ZVA instructions are not implemented.
0  This control has no effect on execution of DC ZVA instructions.

Table D1-40 shows how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instruction</th>
<th>Syndrome reporting in ESR_EL2</th>

<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

Traps to EL2 of EL1 execution of TLB maintenance instructions

In the ARMv8-A architecture, the System instruction encoding space includes TLB maintenance instructions.

HCR_EL2.TTLB traps EL1 execution of TLB maintenance instructions to EL2 if enabled in the current Security state:

1  Any attempt to execute a TLBI instruction at EL1 is trapped to EL2.
0  This control has no effect on execution of TLBI instructions.
D1 The AArch64 System Level Programmers’ Model
D1.15 Configurable instruction enables and disables, and trap controls

Table D1-41 shows the instructions that are trapped, and how the exceptions are reported in ESR_EL2:

TLB maintenance instructions on page D5-2506, for the AArch64 state instructions.
•
The scope of TLB maintenance instructions on page G5-5546, for the AArch32 state instructions.

Traps to EL2 of EL0 and EL1 execution of cache maintenance instructions
HCR_EL2.{TSW, TPC, TPU} trap cache maintenance instructions to EL2, if enabled in the current Security state,
as follows:
0

The control has no effect on the execution of cache maintenance instructions.

1

Any attempt to execute a corresponding cache maintenance instruction at EL1, or at EL0 if
permitted by SCTLR_EL1.UCI, is trapped to EL2.
Table D1-42 Controls for trapping cache maintenance instructions to EL2
Trap control

Trapped instructions

HCR_EL2.TSW

<td>ICIMVAU, ICIALLU, ICIALLUIIS, DCCMVAU</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

Note

IC IALLUIS and IC IALLU are always UNDEFINED at EL0 using AArch64.

ICIMVAU, ICIALLU, ICIALLUIIS, and DCCMVAU are always UNDEFINED at EL0 using AArch32.

For more information about these instructions, see:

- Cache maintenance instructions, and data cache zero operation on page C5-347 for the AArch64 instructions.
- Cache maintenance system instructions on page K13-7413 for the AArch32 instructions.

Traps to EL2 of EL1 accesses to the Auxiliary Control Register

HCR_EL2.TACR traps EL1 accesses to the Auxiliary Control Registers to EL2 if enabled in the current Security state:

- 1: EL1 accesses to the Auxiliary Control Registers are trapped to EL2.
- 0: This control has no effect on accesses to the Auxiliary Control Registers.
Table D1-46 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL2:

### Table D1-46 Register accesses trapped to EL2 when HCR_EL2.TACR is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>

<tr>
<td>AArch32 state</td>
<td>ACTLR and, if implemented, ACTLR2</td>
<td>Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

---

**Note**
- The ACTLR_EL1, ACTLR, and ACTLR2 are not accessible at EL0.
- The Auxiliary Control Registers are IMPLEMENTATION DEFINED registers that might implement global control bits for the PE.

---

### Traps to EL2 of EL0 and EL1 accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features of the ARMv8-A architecture are IMPLEMENTATION DEFINED. The architecture reserves the encodings of a number of System registers for control of these features.

HCR_EL2.TIDCP traps the execution of System register access instructions that access these registers, as follows:

1. At EL1, any attempt to execute a System register access instruction with a reserved register encoding is trapped to EL2, if enabled in the current Security state.
   - At EL0, it is IMPLEMENTATION DEFINED whether attempts to execute System register access instructions with reserved register encodings are:
     - Trapped to EL2.
     - UNDEFINED, and any resulting exception is taken to EL1.

0. This control has no effect on register access instructions with reserved register encodings.

Table D1-47 shows the register encodings for which accesses are trapped, and how the exceptions are reported in ESR_EL2:

### Table D1-47 Encodings trapped to EL2 when HCR_EL2.TIDCP is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Register encodings</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>Any access to any of the encodings described in Reserved encodings for IMPLEMENTATION DEFINED registers on page D11-2659.</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18</td>
</tr>
</tbody>
</table>
| AArch32 state | An access to any of the following encodings:
- \( \text{Crn}==c9, \text{opc1}==\{0-7\}, \text{Crn}\in\{c0-c2, c5-c8\}, \text{opc2}==\{0-7\}. \)
- \( \text{Crn}==c10, \text{opc1}==\{0-7\}, \text{Crn}\in\{c0, c1, c4, c8\}, \text{opc2}==\{0-7\}. \)
- \( \text{Crn}==c11, \text{opc1}==\{0-7\}, \text{Crn}\in\{c0-c8, c15\}, \text{opc2}==\{0-7\}. \) | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

---

**Note**
- ARM expects the trapping of EL0 accesses to these functions to EL2 to be unusual, and used only when the hypervisor is virtualizing EL0 operation. ARM strongly recommends that unless the hypervisor must virtualize EL0 operation, a EL0 access to any of these functions is UNDEFINED, as it would be if the implementation did not include EL2. The PE then takes any resulting exception to EL1.
• The trapping of accesses to these registers from EL1 is higher priority than an exception resulting from the
register access being UNDEFINED.

Traps to EL2 of EL1 execution of SMC instructions

HCR_EL2.TSC traps EL1 execution of SMC instructions to EL2 if enabled in the current Security state:

1 Any attempt to execute an SMC instruction at EL1 is trapped to EL2, regardless of the value of
SCR_EL3.SMD.

0 This control has no effect on execution of SMC instructions.

If EL3 is not implemented, HCR_EL2.TSC is RES0.

Table D1-48 shows how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped instruction</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td><strong>SMC</strong> on page C6-1085</td>
<td>Trapped SMC instruction execution in AArch64 state, using EC value 0x17</td>
</tr>
<tr>
<td>AArch32 state</td>
<td><strong>SMC</strong> on page F5-4266</td>
<td>Trapped SMC instruction execution in AArch32 state, using EC value 0x13</td>
</tr>
</tbody>
</table>

In AArch32 state, the ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC
instructions that fail their Condition code check, in the same way as with traps on other conditional instructions.

For more information about SMC instructions, see **SMC** on page C6-1085.

--- Note ---

• This trap is implemented only if the implementation includes EL3.
• SMC instructions are UNDEFINED at EL0.
• HCR_EL2.TSC traps execution of the SMC instruction. It is not a routing control for the SMC exception. Trap
exceptions and SMC exceptions have different preferred return addresses.

Traps to EL2 of EL0 and EL1 accesses to the ID registers

Other than the MIDR_EL1, MPIDR_EL1, and PMCR_EL0.N, the ID registers are divided into groups, with a trap
control in the HCR_EL2 for each group.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Register group</th>

</tr>
<tr>
<td>HCR_EL2.TID3</td>
<td><strong>ID group 3, Detailed feature identification registers on page D1-2216</strong></td>
</tr>
</tbody>
</table>

These controls trap register accesses to EL2, as follows:

**HCR_EL2.TID0**

0 This control has no effect on EL1 reads of the ID group 0 registers.

1 Any attempt at EL0 or EL1 to read any register in ID group 0 is trapped to EL2 if
enabled in the current Security state.
HCR_EL2.TID1
0  This control has no effect on EL1 reads of the ID group 1 registers.
1  Any attempt at EL1 to read any register in ID group 1 is trapped to EL2 if enabled in the current Security state.

HCR_EL2.TID2
0  This control has no effect on EL1 and EL0 accesses to the ID group 2 registers.
1  Any attempt at EL0 or EL1 to read any register in ID group 2, and any attempt at EL0 or EL1 to write to the CSSELR or CSSELR_EL1, is trapped to EL2 if enabled in the current Security state.

HCR_EL2.TID3
0  This control has no effect on EL1 reads of the ID group 3 registers.
1  Any attempt at EL1 to read any register in ID group 3 is trapped to EL2 if enabled in the current Security state.

For the MIDR_EL1 and MPIDR_EL1, and for PMCR_EL0.N, the architecture provides read/write aliases. The original register becomes accessible only from EL2 or Secure state, and an EL0 or EL1 read of the original register returns the value of the read/write alias. This substitution is invisible to the EL0 or EL1 software reading the register.

Table D1-50 ID register substitution

<table>
<thead>
<tr>
<th>Register</th>
<th>Original</th>
<th>Alias, EL2 using AArch64</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main ID</td>
<td>MIDR_EL1</td>
<td>VPIDR_EL2</td>
</tr>
<tr>
<td>Multiprocessor Affinity</td>
<td>MPIDR_EL1</td>
<td>VMPIDR_EL2</td>
</tr>
<tr>
<td>Performance Monitors Control Register</td>
<td>PMCR_EL0.N</td>
<td>MDCR_EL2.HPMN</td>
</tr>
</tbody>
</table>

--- Note ---

- If the optional Performance Monitors Extension is not implemented, MDCR_EL2.HPMN is RES0 and PMCR_EL0 is reserved.
- MDCR_EL2.HPMN also affects whether a Performance Monitors counter can be accessed from EL0 or EL1. See the register description of MDCR_EL2 for more information.
- PMCR_EL0 contains other fields that identify the implementation. For more information about trapping accesses to the PMCR_EL0, see Traps to EL2 of EL0 and EL1 accesses to Performance Monitors registers on page D1-2225.

**ID group 0, Primary device identification registers**

In:
- AArch64 state, there are no ID group 0 registers.
- AArch32 state, these registers identify some top-level implementation choices.
Table D1-51 shows the registers that are in ID group 0 for traps to EL2, and how the exceptions are reported in ESR_EL2:

Table D1-51 ID group 0 registers

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 0 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>n/a</td>
<td>n/a</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>FPSID</td>
<td>Trapped VMRS System register access, using EC value 0x08</td>
</tr>
<tr>
<td></td>
<td>JIDR</td>
<td>Trapped MRC System register access (coproc==0b1110), using EC value 0x05</td>
</tr>
</tbody>
</table>

Note

The FPSID is not accessible from EL0 using AArch32.

When the FPSID is accessible, a T32 or A32 VMRS FPSID, <r> instruction is permitted but is ignored. The execution of this VMRS instruction execution is not trapped by the ID group 0 trap.

**ID group 1, Implementation identification registers**

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

Table D1-52 shows the registers that are in ID group 1 for traps to EL2, and how the exceptions are reported in ESR_EL2:

Table D1-52 ID group 1 registers

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 1 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>

<td>TCMTR, TLBTR, REVIDR, AIDR</td>
<td>Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

**ID group 2, Cache identification registers**

These registers describe and control the cache implementation.

Table D1-53 shows the registers that are in ID group 2 for traps to EL2, and how the exceptions are reported in ESR_EL2:

Table D1-53 ID group 2 registers

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 2 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>CTR_EL0, CCSIDR_EL1, CLIDR_EL1, CSSELAR_EL1, and, if implemented, CCSIDR2_EL1</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>CTR, CCSIDR, CLIDR, CSSELAR, and, if implemented, CCSIDR2.</td>
<td>Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03</td>
</tr>
</tbody>
</table>

**ID group 3, Detailed feature identification registers**

These registers provide detailed information about the features of the implementation.
Note

In AArch32 state, these registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See The CPUID identification scheme on page G8-5637.

Table D1-54 shows the registers that are in ID group 3 for traps to EL2, and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Group 3 registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td></td>
<td>ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0. ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3 and, ID_MMFR4, except that if ID_MMFR4 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether reads of the register are trapped. ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5. Any MRC access to any of the following encodings in the (coproc==0b1111) encoding space:</td>
<td>Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03</td>
</tr>
<tr>
<td></td>
<td>• CRn == c0, opc1 == 0, CRm == {c3-c7}, opc2 == {0, 1}.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• CRn == c0, opc1 == 0, CRm == c3, opc2 == 2.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• CRn == c0, opc1 == 0, CRm == c5, opc2 == {4, 5}.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>It is IMPLEMENTATION DEFINED whether HCR_EL2.TID3 traps MRC accesses to in the (coproc==0b1111) encoding space in the following range that are not already mentioned in this table:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• CRn == c0, opc1 == 0, CRm == {c2-c7}, opc2 == {0-7}.</td>
<td></td>
</tr>
</tbody>
</table>

Traps to EL2 of EL0 and EL1 execution of WFE and WFI instructions

HCR_EL2.{TWE, TWI} trap EL0 and EL1 execution of WFE and WFI instructions to EL2:

HCR_EL2.TWE

1 Any attempt to execute a WFE instruction at EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.

0 This control has no effect on execution of WFE instructions.
Any attempt to execute a \texttt{WFI} instruction at EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.

This control has no effect on execution of \texttt{WFI} instructions.

Table D1-55 shows how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Traps from</th>
<th>Trapped instructions</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCR_EL2.TWE</td>
<td>Both Execution states</td>
<td>\texttt{WFE}</td>
<td>Trapped \texttt{WFI} or \texttt{WFE} instruction, using EC value 0x01</td>
</tr>
<tr>
<td>HCR_EL2.TWI</td>
<td>\texttt{WFI}</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In AArch32 state, the attempted execution of a conditional \texttt{WFE} or \texttt{WFI} instruction is only trapped if the instruction passes its Condition code check.

\textbf{Note}

Since a \texttt{WFE} or \texttt{WFI} can complete at any time, even without a Wakeup event, the traps on \texttt{WFE} or \texttt{WFI} are not guaranteed to be taken, even if the \texttt{WFE} or \texttt{WFI} is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- \textit{Wait for Event mechanism and Send event} on page D1-2243.
- \textit{Wait For Interrupt} on page D1-2246.

**Traps to EL2 of EL1 and EL0 accesses to Activity Monitors registers**

CPTR_EL2.TAM traps EL1 and EL0 accesses to the Activity Monitor registers to EL2.

1  
Accesses from EL1 and EL0 to Activity Monitor registers are trapped to EL2

0  
This control has no effect on accesses to Activity Monitor registers.

Table D1-56 shows the registers for which accesses are trapped and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>AMCFGR_EL0, AMCGCR_EL0, AMCNTENCLR0_EL0, AMCNTENCLR1_EL0, AMCNTENSET0_EL0, AMCNTENSET1_EL0, AMCR_EL0, AMEVCNTR0&lt;n&gt;_EL0, AMEVCNTR1&lt;n&gt;_EL0, AMEVTYPE0&lt;n&gt;_EL0, AMEVTYPE1&lt;n&gt;_EL0, AMUSERENR_EL0.</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>AMCFGR, AMCGCR, AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, AMCNTENSET1, AMCR, AMEVTYPE0&lt;n&gt;, AMEVTYPE1&lt;n&gt;, AMUSERENR.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18</td>
</tr>
<tr>
<td>Trapped MCR or MR for \texttt{MRR} access (\texttt{coproc} == 0b1111), using EC value 0x03</td>
</tr>
<tr>
<td>Trapped MCR or MR for \texttt{MRR} access (\texttt{coproc} == 0b1111), using EC value 0x04</td>
</tr>
</tbody>
</table>
Trapping to EL2 of EL1 accesses to the CPACR_EL1 or CPACR

\texttt{CPTR\_EL2.TCPAC} traps EL1 accesses to the \texttt{CPACR\_EL1} or \texttt{CPACR} to EL2:

1  EL1 accesses to the \texttt{CPACR\_EL1} or \texttt{CPACR} are trapped to EL2.
0  This control has no effect on accesses to \texttt{CPACR\_EL1} or \texttt{CPACR}.

Table D1-57 shows how the exceptions are reported in \texttt{ESR\_EL2}:

\begin{table}[h]
\centering
\begin{tabular}{|c|c|p{0.8\textwidth}|}
\hline
\textbf{Traps from} & \textbf{Registers} & \textbf{Syndrome reporting in \texttt{ESR\_EL2}} \\
\hline
AArch64 state & \texttt{CPACR\_EL1} & Trapped AArch64 MSR, MRS, or System instruction, using EC value \texttt{0x18} \\
AArch32 state & \texttt{CPACR} & Trapped \texttt{MCR} or \texttt{MRC} System register access (\texttt{coproc==0b1111}), using EC value \texttt{0x03} \\
\hline
\end{tabular}
\end{table}

---

\textbf{Note}

1. The \texttt{CPACR\_EL1} or \texttt{CPACR} is not accessible at EL0.
2. In ARMv7 and earlier versions of the ARM architecture, one function of the \texttt{CPACR} is as an ID register that identifies what coprocessor or conceptual coprocessor functionality is implemented. Legacy software might use this identification mechanism, and a hypervisor can use this trap to emulate this mechanism. For more information about this coprocessor model see \textit{Background to the System register interface} on page G1-5314.

---

General trapping to EL2 of accesses to the SIMD and floating-point registers

\texttt{CPTR\_EL2.TFP} traps accesses to SIMD and floating-point registers to EL2:

1  Any attempt at EL2, or EL0 or EL1, to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL2.
0  This control has no effect on the execution of instructions that access the SIMD or floating-point registers.

Table D1-58 shows the registers for which accesses are trapped, and how the exceptions are reported in \texttt{ESR\_EL2}:

\begin{table}[h]
\centering
\begin{tabular}{|c|c|p{0.8\textwidth}|}
\hline
\textbf{Traps from} & \textbf{Registers} & \textbf{Syndrome reporting in \texttt{ESR\_EL2}} \\
\hline
AArch64 state & \texttt{FPCR, FPSR, FPEXC32\_EL2}, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See \textit{The SIMD and floating-point registers}, \texttt{V0-V31} on page D1-2144. & Trapped access to a SIMD or floating-point register, resulting from CPACR\_EL1.FPEN or CPTR\_ELx.TFP, using EC value \texttt{0x07} \\
AArch32 state & \texttt{FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC}, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See \textit{Advanced SIMD and floating-point System registers} on page G1-5318. & Trapped access to a SIMD or floating-point register, resulting from CPACR\_EL1.FPEN or CPTR\_ELx.TFP, using EC value \texttt{0x07} \\
\hline
\end{tabular}
\end{table}

\textbf{a.} Permitted \texttt{VMSR} accesses to the \texttt{FPSID} are ignored, but for the purposes of this trap the architecture defines a \texttt{VMSR} access to the \texttt{FPSID} from EL1 or higher as an access to a SIMD and floating-point register.

Traps to EL2 of System register accesses to the trace registers

\texttt{CPTR\_EL2.TTA} traps System register accesses to the trace registers to EL2.

When \texttt{CPTR\_EL2.TTA} is:

1  System register accesses to the trace registers are trapped to EL2.
0  This control has no effect on System register accesses to the trace registers.
**Note**

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are **UNDEFINED**, and any resulting exception is higher priority than a **CPTR_EL2.TTA** Trap exception.
- EL2 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see *Register access instructions on page D1-2197*.

Table D1-59 shows the registers for which accesses are trapped to EL2 when **CPTR_EL2.TTA** is 1, and how the exceptions are reported in **ESR_EL2**:

**Table D1-59 Register accesses trapped to EL2 when **CPTR_EL2.TTA** is 1**

<table>

**Traps to EL2 of System register accesses to the trace filter control registers**

**MDCR_EL2.TTRF** traps System register accesses to the trace filter control registers to EL2, if enabled in the current Security state.

When **MDCR_EL2.TTRF** is:

1  EL1 System register accesses to the trace filter control registers are trapped to EL2.
0  This control has no effect on System register accesses to the trace filter control registers.

Table D1-60 shows the registers for which accesses are trapped to EL2 when **MDCR_EL2.TTRF** is 1, and how the exceptions are reported in **ESR_EL2**.

**Table D1-60 Register accesses trapped to EL2 when **MDCR_EL2.TTRF** is 1**

</tr>
</tbody>
</table>

**General trapping to EL2 of EL0 and EL1 accesses to System registers, from AArch32 state only**

**HSTR_EL2.(T0-T3, T5-T13, T15)** trap accesses to the AArch32 System registers in the coproc==0b1111 encoding space, by the register number, {c0-c3, c5-c13, c15} used for:

- The **Cn** argument used when accessing the register using an MC or MR instruction.
- The **Cn** argument used when accessing the register using an MCRR or MRRC instruction.

These traps are from AArch32 state only. They are from both:

- EL1 using AArch32.
- EL0 using AArch32.
When an HSTR_EL2.Tx trap control is:

1 Any AArch32 state EL1 or EL0 access to the corresponding register is trapped to EL2.

0 This control has no effect on accesses to the corresponding register.

Table D1-61 shows the accesses that are trapped, and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from AArch64 state</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>n/a</td>

</tr>
<tr>
<td></td>
<td>Trapped MCRR or MRRC instructions, where Crm in the instruction identifies the trapped encodings in the (coproc==0b1111) encoding space</td>
<td>Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04</td>
</tr>
</tbody>
</table>

---

**Note**

HSTR_EL2[4, 14] is reserved, RES0. Although the Generic Timer AArch32 System registers are implemented in the coproc==0b1111 encoding space and accessed using a Crn or Crm value of c14, EL2 does not provide a trap on accesses to the Generic Timer System registers.

---

**System registers in the (coproc==0b1111) encoding space with IMPLEMENTATION DEFINED access permission from EL0**

For an AArch32 System register in the (coproc==0b1111) encoding space, which is accessed using a Crn or Crm value that can be trapped by a HSTR_EL2.Tn control, if an access to the register from EL0 is UNDEFINED when the value of the corresponding HSTR_EL2.Tn trap control is 0, then when that HSTR_EL2.Tn trap control is 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure EL0 using AArch32:

- Generates a Trap exception that is taken to EL2.
- Is UNDEFINED and generates an exception that is taken to Non-secure EL1.

If the instruction is treated as UNDEFINED and generates an exception that is taken to Non-secure EL1, and Non-secure EL1 is using AArch64, the exception is reported in ESR_EL1 as an exception for an unknown reason, using EC value 0x00.

---

**Note**

ARM expects that trapping to EL2 of Non-secure EL0 accesses to AArch32 System register in the (coproc==0b1111) encoding space will be unusual, and used only when the hypervisor must virtualize EL0 operation. ARM recommends that, whenever possible, Non-secure EL0 accesses to the System registers behave as they would if the implementation did not include EL2. This means that, if the architecture does not support the Non-secure EL0 access, then the register access instruction is treated as UNDEFINED and generates an exception that is taken to Non-secure EL1.

---

**Traps to EL2 of EL0 and EL1 System register accesses to debug registers**

MDCR_EL2.(TDRA, TDOSA, TDA) trap System register accesses to the debug registers to EL2 if enabled in the current Security state, as follows:

- MDCR_EL2.(TDRA, TDA) trap EL0 and EL1 accesses.
- MDCR_EL2.TDOSA traps EL1 accesses.

---

**Note**

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.
System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2. See *Register access instructions on page D1-2197.*

Table D1-62 shows the subsections that list the accesses trapped. The subsections describe how the traps are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Subsection</th>
</tr>
</thead>
</table>
| MDCR_EL2.TDRA | Traps EL0 and EL1 System register accesses to debug registers to EL2  
if enabled in the current Security state:  
1 | EL0 and EL1 System register accesses to the Debug ROM registers are trapped to EL2.  
0 | This control has no effect on System register accesses to the Debug ROM registers. |
| MDCR_EL2.TDOSA | Trapping System register accesses to powerdown debug registers to EL2  
if enabled in the current Security state:  
1 | EL1 System register accesses to the powerdown debug registers are trapped to EL2.  
0 | This control has no effect on accesses to the powerdown debug registers. |
| MDCR_EL2.TDA | Trapping general System register accesses to debug registers to EL2 |

Table D1-63 shows the register accesses that are trapped, and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>MDRAR_EL1</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18.</td>
</tr>
</tbody>
</table>
| AArch32 state | DBGDRAR, DBGDSAR | For accesses using:  
• MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05.  
• MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C. |

If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDRA is 1 other than for the purpose of a direct read.

**Trapping System register accesses to powerdown debug registers to EL2**

MDCR_EL2.TDOSA traps EL1 System register accesses to the powerdown debug registers to EL2 if enabled in the current Security state:  
1 | EL1 System register accesses to the powerdown debug registers are trapped to EL2.  
0 | This control has no effect on accesses to the powerdown debug registers.
Table D1-64 shows the register accesses that are trapped, and how the exceptions are reported in ESR_EL2:

### Table D1-64 Register accesses trapped to EL2 when MDCR_EL2.TDOSA is 1

<table>
<thead>
<tr>
<th>Traps from Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, DBGPRCR_EL1. Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by MDCR_EL2.TDOSA</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18.</td>
</tr>
<tr>
<td>AArch32 state DBGOSLSR, DBGOSLAR, DBGOSDLR, DBGPRCR. Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by HDCR.TDOSA</td>
<td>Trapped MCR or MRC access (coproc==0b11110), using EC value 0x05.</td>
</tr>
</tbody>
</table>

**Note**

These registers are not accessible at EL0.

If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDOSA is 1 other than for the purpose of a direct read.

**Trapping general System register accesses to debug registers to EL2**

MDCR_EL2.TDA traps EL0 and EL1 System register accesses to those debug System registers that are not mentioned in either of the following:

- Traps to EL2 of EL0 and EL1 System register accesses to debug registers on page D1-2221.
- Trapping System register accesses to powerdown debug registers to EL2 on page D1-2222.

This means that MDCR_EL2.TDA traps EL0 and EL1 System register accesses to all debug System registers to EL2 if enabled in the current Security state, except the following:

- Any access from:
  - AArch64 state to the MDRAR_EL1.
  - AArch32 state to the DBGDRAR or DBGDSAR.
  
  MDCR_EL2.TDRA traps these accesses.

- Any access from:
  - AArch64 state to the OSLAR_EL1, OSLSR_EL1, OSDLR_EL1 or DBGPRCR_EL1.
  - AArch32 state to the DBGOSLSR, DBGOSLAR, DBGOSDLR or DBGPRCR.
  
  MDCR_EL2.TDOSA traps these accesses.

When the PE is in Debug state, MDCR_EL2.TDA does not trap any access from:

- AArch32 state to DBGDTRRXint and DBGDTRTXint.
- AArch64 state to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0.

When MDCR_EL2.TDA is:

1. EL0 or EL1 System register accesses to any of the registers shown in Table D1-65 on page D1-2224 are trapped to EL2.
2. 0. This control has no effect on accesses to the registers shown in Table D1-65 on page D1-2224.
Table D1-65 shows how the exceptions are reported in ESR_EL2:

### Table D1-65 Accesses trapped to EL2 when MDCR_EL2.TDA is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trapped accesses</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>Accesses to the MDCCSR_EL0, MDCCINT_EL1, DBGDTR_EL0, DBGDTRRX_EL0, DBGDTRTX_EL0, OSDTRRX_EL1, MDSCR_EL1, OSDTRTX_EL1, OSECCR_EL1, DBGVR&lt;n&gt;_EL1, DBGBCR&lt;n&gt;_EL1, DBGWVR&lt;n&gt;_EL1, DBGWCR&lt;n&gt;_EL1, DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, and DBGAUTHSTATUS_EL1.</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>Accesses to the DBGIDIR, DBGIDSRInt, DBGIDCCINT, DBGIDTRRXInt, DBGIDTRTXInt, DBGWCounter, DBGVCR, DBGIDSRExt, DBGIDTRRXExt, DBGIDTRTXExt, DBGVR&lt;n&gt;, DBGBCR&lt;n&gt;, DBGWVR&lt;n&gt;, DBGWCR&lt;n&gt;, DBGCLAIMSET, DBGCLAIMCLR, DBGAUTHSTATUS, DBGDEVID, DBGDEVID1, DBGDEVID2, and DBGOSECCR.</td>
<td>For accesses using MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05</td>
</tr>
</tbody>
</table>

If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDA is 1 other than for the purpose of a direct read.

### Traps to EL2 of EL0 and EL1 accesses to the Generic Timer registers

CNTHCTL_EL2 {EL1PCEN, EL1PCTEN} trap EL0 and EL1 accesses to the Generic Timer registers to EL2 if enabled for the current Security state, as follows:

- CNTHCTL_EL2.EL1PCEN traps EL0 and EL1 accesses to the physical timer registers.
- CNTHCTL_EL2.EL1PCTEN traps EL0 and EL1 accesses to the physical counter register.

For each of these controls:

- **1**: EL0 and EL1 accesses are not trapped to EL2.
- **0**: EL0 and EL1 accesses are trapped to EL2.

Table D1-66 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL2.

### Table D1-66 Register accesses trapped to EL2 by CNTHCTL_EL2 trap controls

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Trap control</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>

</tr>
</tbody>
</table>
Traps to EL2 of EL0 and EL1 accesses to Performance Monitors registers

MDCR_EL2.{TPM, TPMCR} trap EL0 and EL1 accesses to the Performance Monitors registers to EL2 if enabled in the current Security state:

**MDCR_EL2.TPM**

| 1 | EL0 and EL1 accesses to the Performance Monitors registers are trapped to EL2. |
| 0 | This control has no effect on accesses to the Performance Monitors registers. |

**MDCR_EL2.TPMCR**

| 1 | EL0 and EL1 accesses to the Performance Monitors Control Registers are trapped to EL2. |
| 0 | This control has no effect on accesses to the Performance Monitors Control Registers. |

--- **Note** ---

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

For:

- **MDCR_EL2.TPM == 1**, Table D1-67 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL2.
- **MDCR_EL2.TPMCR == 1**, Table D1-68 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL2.

### Table D1-67 Register accesses trapped to EL2 when MDCR_EL2.TPM is 1

<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18</td>
</tr>
</tbody>
</table>

Enabling use of the Pointer authentication instructions, EL2 translation regime

This control is implemented when ARMv8.3-PAuth is implemented.

Each of the SCTLR_EL2.{EnDA, EnDB, EnIA, EnIB} fields enables the pointer authentication functionality for the corresponding Pointer authentication instructions for the EL2 or EL2&0 translation regime. For more information see System register control of pointer authentication on page D5-2378.

Note

These controls cause the pointer authentication instructions to execute as NOPs. They never cause an exception to be generated.

Trap to EL2 of EL1 accesses to Pointer authentication key registers

This control is implemented when ARMv8.3-PAuth is implemented.
HCR_EL2.APK traps, to EL2 if enabled in the current Security state, accesses to the Pointer authentication key registers from EL1 to EL2. Because pointer authentication is supported only in AArch64 state this control only traps from AArch64 state. Table D1-71 shows the register accesses that are trapped and how the exceptions are reported in ESR_EL2:

Table D1-71 Register accesses trapped to EL2 when HCR_EL2.APK is 0

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>APDAKeyLo_EL1, APDAKeyHi_EL1, APDBKeyLo_EL1, APDBKeyHi_EL1, APIAKeyLo_EL1, APIAKeyHi_EL1</td>
<td>Trapped AArch64 MSR, MSR5, or System instruction, using EC value 0x18.</td>
</tr>
</tbody>
</table>

For more information see System register control of pointer authentication on page D5-2378.

Trap to EL2 of EL0 accesses to Pointer authentication instructions

This control is implemented when ARMv8.3-PAuth is implemented.

HCR_EL2.API traps, to EL2 if enabled in the current Security state, accesses to any of the Pointer authentication instructions for which pointer authentication is enabled, for instructions executed either:

- At EL1.
- If the Effective value of HCR_EL2.{TGE, E2H} is not \{1, 1\}, at EL0.

Because pointer authentication is supported only in AArch64 state, this control only traps from AArch64 state. Table D1-72 shows the instructions that might be trapped and how the exceptions are reported in ESR_EL2:

Table D1-72 Instructions that might be trapped to EL2 when HCR_EL2.API is 0

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Instructions that might be a trapped</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>AUTIASP, AUTIAZ, AUTIA1716, AUTIB5P, AUTIBZ, AUTIB1716, AUTIA, AUTDA, AUTIB, AUTDB, AUTIZA, AUTIDZA, AUTIZB, AUTIDZB, PACIASP, PACIAZ, PACIA1716, PACIB5P, PACIBZ, PACIB1716, PACIA, PACDA, PACIB, PACDB, PACIZA, PACIDZA, PACIDZB, PACGA, XPACLRI, XPARI, XPARD, RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ, ERETAA, ERETAB, LDRAA, LDRAB.</td>
<td>Trapped Pointer authentication instruction, using EC value 0x09.</td>
</tr>
</tbody>
</table>

- An instruction is trapped only if Pointer authentication is enabled for that instruction.

For more information, including the description of when pointer authentication is enabled for an instruction, see System register control of pointer authentication on page D5-2378.

Disabling Address tagging for instruction accesses, EL2 translation regime

This control is implemented when ARMv8.3-PAuth is implemented.

When a TCR_EL2.TBI or TCR_EL2.{TBI0, TBI1} field enables the use of address tagging for the EL2 translation regime, the corresponding TCR_EL2.TBID or TCR_EL2.{TBID0, TBID1} field determines whether address tagging is used for both data and instruction addresses, or only for data addresses. For more information see Address tagging in AArch64 state on page D5-2374.

--- Note ---

These controls determine the scope of address tagging. They never cause an exception to be generated.
Traps to EL2 for Nested virtualization

These controls are implemented when ARMv8.3-NV is implemented.

___ Note ___

When ARMv8.4-NV is implemented and HCR_EL2.NV2 is 1, the redirection of register accesses to memory accesses has priority over the trapping of register accesses by HCR_EL2.{NV, NV1}, see Enhanced support for nested virtualization on page D5-2482.

HCR_EL2.NV traps the following to EL2, if enabled in the current Security state, from EL1:

- Some System register, System instruction, and Special-purpose register accesses that are UNDEFINED at EL1 when ARMv8.3-NV is not implemented. Only accesses that are not UNDEFINED at EL2 are trapped.

___ Note ___

This means that, for a register that is RO at EL2, and UNDEFINED at Non-secure EL1 when ARMv8.3-NV is not implemented, when ARMv8.3-NV is implemented and this trap is enabled:
- Read accesses to the register from EL1 are trapped to EL2.
- Write accesses to the register from EL1 remain UNDEFINED.

- The execution of some instructions that are UNDEFINED at EL1 when ARMv8.3-NV is not implemented.

Because nested virtualization is supported only in AArch64 state this control only traps from AArch64 state. Table D1-73 shows the registers and instructions that are trapped and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from AArch64 state</th>
<th>Trapped register accesses or instructions</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Any System or Special-purpose register named *_EL2, *_EL02, or *_EL12, except SP_EL2.</td>
<td>Trapped AArch64 MSR, MSR, or System instruction, using EC value 0x18.</td>
</tr>
<tr>
<td></td>
<td>SPSR_abt, SPSR_fiq, SPSR_irq, SPSR_und, using an MSR or MSR instruction.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>SP_EL1 using the dedicated MSR or MSR instruction.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>AT S1E2R, AT S1E2W, TLBI ALLE2, TLBI ALLE2IS, TLBI VAE2, TLBI VAEO2IS, TLBI VAEL2, TLBI VALE2IS.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>AT S1E0R, AT S1E0W, AT S1E1R, AT S1E1W, TLBI ALLE1, TLBI ALLE1IS, TLBI IPAS2E1, TLBI IPAS2E1S, TLBI IPAS2E1S, TLBI VMAALLS12E1, TLBI VMALLS12E1S</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ERET, ERETA, ERETAB.</td>
<td>Trapped ERET, ERETA, or ERETAB instruction execution, using EC value 0x1A.</td>
</tr>
<tr>
<td></td>
<td>When EL3 is not implemented and HCR_EL2.TSC==1, SMC.</td>
<td>Trapped AArch64 SMC instruction, using EC value 0x17.</td>
</tr>
</tbody>
</table>

a. ERETA and ERETAB are implemented when ARMv8.3-PAuth is implemented.

___ Note ___

In addition, when the value of HCR_EL2.NV is 1, a read of CurrentEL returns the value 0bh10 for bits[3:2].
The AArch64 System Level Programmers' Model

D1.15 Configurable instruction enables and disables, and trap controls

HCR_EL2.NV1 traps to EL2, if enabled in the current Security state, from EL1 accesses to some System registers and Special-purpose registers. Because nested virtualization is supported only in AArch64 state this control only traps from AArch64 state. Table D1-74 shows the registers that are trapped and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>VBAR_EL1, ELR_EL1, SPSR_EL1</td>
<td>Trapped AArch64 MSR, MSR, or System instruction, using EC value 0x18.</td>
</tr>
</tbody>
</table>

For more information see Effect of HCR_EL2.(NV, NV1) on page D5-2480.

**Trap to EL2 of EL1 accesses to AT S1E* instructions**

This control is implemented when ARMv8.3-NV is implemented.

HCR_EL2.AT traps to EL2, if enabled in the current Security state, from EL1 accesses to some Address translation instructions. Because nested virtualization is supported only in AArch64 state this control only traps from AArch64 state. Table D1-75 shows the registers that are trapped and how the exceptions are reported in ESR_EL2:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>AT S1E0R, AT S1E0W, AT S1E1R, AT S1E1W, AT S1E1RP, AT S1E1WP</td>
<td>Trapped AArch64 MSR, MSR, or System instruction, using EC value 0x18.</td>
</tr>
</tbody>
</table>

For more information see Effect of HCR_EL2.(NV, NV1) on page D5-2480.

D1.15.4 EL3 configurable controls

These controls are in _EL3 System registers. The resulting exceptions might be taken from either Execution state. SPSR_EL3.M[4] indicates which Execution state the exception was taken from.

Table D1-76 shows the _EL3 System registers that contain these controls.

<sup>a</sup> See Table D1-78 on page D1-2231.
Also see the following for more general information about traps to EL3:

- Register access instructions on page D1-2197.
- Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32.

### Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32

If EL1 is using AArch32, all of the following are trapped to EL3:

- Secure EL1 reads and writes to any of the SCR, NSACR, MVBAR or SDCR.
- Any attempt at Secure EL1 to execute any of the following:
  - ATS12NSO** instructions.
  - SRS instructions that use the R13_mon banked register.
  - MRS or MSR instructions that access any of the SPSR_mon, R13_mon or R14_mon banked registers.

In addition, if EL1 is using AArch32:

- Secure EL1 write accesses to the CNTFRQ register are UNDEFINED. They are not trapped to EL3.
- Any attempt at Secure EL1 to change the PE mode to Monitor mode, by using a CPS or an MSR instruction, or by performing an exception return, is treated as an illegal change of the CPSR.M field. See Illegal changes to PSTATE.M on page G1-5243.

Table D1-79 shows the accesses that are trapped to EL3, and how the exceptions are reported in ESR_EL3.

<td></td>
</tr>
</tbody>
</table>

**Note**

- Reads of the NSACR from either Non-secure EL1 using AArch32 or Non-secure EL2 using AArch32 return the value 0x00000000. See Restricted access System registers on page G5-5595.
- These operations are not available at EL0.
Traps to EL3 of EL2, EL1, and EL0 execution of \texttt{WFE} and \texttt{WFI} instructions

\texttt{SCR_EL3.\{TWE, TWI\}} trap EL2, EL1, and EL0 execution of \texttt{WFE} and \texttt{WFI} instructions to EL3:

\textbf{SCR\_EL3.TWE}

\begin{itemize}
\item 1 Any attempt to execute a \texttt{WFE} instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.
\item 0 This control has no effect on execution of \texttt{WFE} instructions.
\end{itemize}

\textbf{SCR\_EL3.TWI}

\begin{itemize}
\item 1 Any attempt to execute a \texttt{WFI} instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.
\item 0 This control has no effect on execution of \texttt{WFI} instructions.
\end{itemize}

For EL0 and EL1, these traps apply to \texttt{WFE} and \texttt{WFI} execution in both Security states.

Table D1-80 shows how the exceptions are reported in \texttt{ESR\_EL3}.

<table>

<tbody>
<tr>
<td>SCR_EL3.TWE</td>
<td>Both Execution states</td>
<td>\texttt{WFE}</td>
<td>Trapped \texttt{WFE} or \texttt{WFE} instruction, using EC value 0x01</td>
</tr>
<tr>
<td>SCR_EL3.TWI</td>
<td>\texttt{WFI}</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In AArch32 state, the attempted execution of a conditional \texttt{WFE} or \texttt{WFI} instruction is only trapped if the instruction passes its Condition code check.

\begin{itemize}
\item \textbf{Note} \textit{———}
\end{itemize}

Since a \texttt{WFE} or \texttt{WFI} can complete at any time, even without a Wakeup event, the traps on \texttt{WFE} or \texttt{WFI} are not guaranteed to be taken, even if the \texttt{WFE} or \texttt{WFI} is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

\begin{itemize}
\item \textbf{Note} \textit{———}
\end{itemize}

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- \textit{Wait for Event mechanism and Send event} on page D1-2243.
- \textit{Wait For Interrupt} on page D1-2246.

Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers

\texttt{SCR\_EL3.ST} traps Secure EL1 accesses to the Counter-timer Physical Secure timer registers to EL3:

\begin{itemize}
\item 1 Secure EL1 accesses to the Counter-timer Physical Secure timer registers are not trapped to EL3.
\item 0 Secure EL1 accesses to the Counter-timer Physical Secure timer registers are trapped to EL3.
\end{itemize}

\begin{itemize}
\item \textbf{Note} \textit{———}
\end{itemize}

Accesses to the Counter-timer Physical Secure timer registers are always enabled at EL3.
Table D1-81 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in ESR_EL3.

### Table D1-81 Register accesses trapped to EL3 when SCR_EL3.ST is 0

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>

</tr>
<tr>
<td></td>
<td>CNTPS_CTL_EL1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CNTPS_CVAL_EL1</td>
<td></td>
</tr>
<tr>
<td>AArch32 state</td>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Note**

These registers are not accessible at EL0.

### Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions

**SCR_EL3.HCE** enables HVC instruction execution at EL1 and above:

1. HVC instruction execution is enabled at EL1 and above.
2. HVC instructions are UNDEFINED at EL1, EL2, and EL3, and any resulting exception is taken from the current Exception level to the current Exception level.

For EL1, this enable control applies to HVC instructions in Non-secure state only.

If EL2 is not implemented, this bit is RES0.

**Note**

HVC instructions are always UNDEFINED at EL0.

Table D1-82 shows how the exceptions are reported in ESR_ELx:

### Table D1-82 Instruction disabled when SCR_EL3.HCE is 0

<table>
<thead>
<tr>
<th>Taken from</th>
<th>Disabled instruction</th>
<th>Syndrome reporting in ESR_ELx</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>HVC</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td>AArch32 state</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Disabling EL3, EL2, and EL1 execution of SMC instructions

**SCR_EL3.SMD** disables SMC instruction execution at EL1 and above:

1. SMC instructions are UNDEFINED at EL1 and above, and any resulting exception is taken from the current Exception level to the current Exception level.
2. SMC instruction execution is enabled at EL1 and above.

For EL1, this disable control applies to SMC instructions in both Security states.

**Note**

SMC instructions are always UNDEFINED at EL0.
Table D1-83 shows how the exceptions are reported in ESR_ELx:

<table>
<thead>
<tr>
<th>Taken from</th>
<th>Disabled Instruction</th>
<th>Syndrome reporting in ESR_ELx</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>SMC</td>
<td>Exception for an unknown reason, using EC value 0x00</td>
</tr>
<tr>
<td>AArch32 state</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note

If HCR_EL2.TSC or HCR.TSC traps attempted EL1 execution of SMC instructions to EL2, that trap has priority over this disable.

Traps to EL3 of EL2, EL1, and EL0 accesses to Activity Monitors registers

CPTR_EL3.TAM traps EL2, EL1, and EL0 accesses to the Activity Monitor registers to EL3.
1  EL2, EL1, and EL0 System register accesses to all Activity Monitor registers are trapped to EL3.
0  This control has no effect on accesses to Activity Monitor registers.

Table D1-56 on page D1-2218 shows the registers for which the accesses are trapped and how the exceptions are reported in ESR_EL3.

Table D1-84 Register accesses trapped to EL3 when CPTR_EL3.TAM is 1

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPtr, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR

CPTR_EL3.TCPAC traps all of the following to EL3:
•  EL2 accesses to the CPTR_EL2 or HCPtr.
•  EL2 and EL1 accesses to the CPACR_EL1 or CPACR.

When CPTR_EL3.TCPAC is:
1  EL2 accesses to the CPTR_EL2 or HCPtr, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR, are trapped to EL3.
0  This control has no effect on accesses to CPTR_EL2, HCPtr, CPACR_EL1 or CPACR.

For EL1, this trap control applies to accesses from both Security states.
Table D1-85 shows how the exceptions are reported in ESR_EL3.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>CPTR_EL2, CPACR_EL1</td>

</tr>
</tbody>
</table>

**Traps to EL3 of System register accesses to the trace registers**

**CPTR_EL3.TTA** traps System register accesses to the trace registers, from all Exception levels, to EL3:

1. System register accesses to the trace registers are trapped to EL3.
2. This control has no effect on accesses to the trace registers.

**Note**

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than a CPTR_EL3.TTA Trap exception.

- EL3 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see Register access instructions on page D1-2197.

For EL0 and EL1, this trap control applies to accesses from both Security states.

Table D1-86 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in ESR_EL3.

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>

**Traps to EL3 of all System register accesses to the filter trace control registers**

**MDCR_EL3.TTRF** traps System register accesses to the trace registers, from all Exception levels, to EL3:

1. System register accesses to the filter trace registers are trapped to EL3.
2. This control has no effect on accesses to the filter trace registers.

For EL0 and EL1, this trap control applies to accesses from both Security states.
Table D1-87 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in ESR_EL3.

Table D1-87 Register accesses trapped to EL3 when MDCR_EL3.TTRF is 1

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Traps to EL3 of all accesses to the SIMD and floating-point registers

CPTR_EL3.TFP traps all accesses to SIMD and floating-point registers, from all Exception levels, to EL3:

1. Any attempt at any Exception level to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL3
2. This control has no effect on the execution of instructions that access the SIMD or floating-point registers.

For EL0 and EL1, this trap control applies to accesses from both Security states.

Table D1-88 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in ESR_EL3.

Table D1-88 Register accesses trapped to EL3 when CPTR_EL3.TFP is 1

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>FPCR, FPSR, FPEXC32_EL2, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See The SIMD and floating-point registers, V0-V31 on page D1-2144.</td>
<td>Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP, using EC value 0x07</td>
</tr>
<tr>
<td>AArch32 state</td>
<td>FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See Advanced SIMD and floating-point System registers on page G1-5318.</td>
<td>Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP, using EC value 0x07a</td>
</tr>
</tbody>
</table>

a. Permitted VMSR accesses to the FPSID are ignored, but for the purposes of this trap the architecture defines a VMSR access to the FPSID from EL1 or higher as an access to a SIMD and floating-point register.

Note

• FPEXC32_EL2 is not accessible from EL0 using AArch64.
• FPSID, MVFR0, MVFR1, and FPEXC are not accessible from EL0 using AArch32.

Traps to EL3 of EL2, EL1, and EL0 System register accesses to debug registers

MDCR_EL3. {TDOSA, TDA} trap EL2, EL1, and EL0 System register accesses to the debug registers to EL3, from both Security states.

Note

EL3 does not provide traps on debug register accesses through the Memory-mapped or External debug interfaces.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL3, no side-effects occur before the exception is taken to EL3. See Register access instructions on page D1-2197.
Table D1-89 shows the subsections that list the accesses trapped.

<table>
<thead>
<tr>
<th>Trap control</th>
<th>Subsection</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDCR_EL3.TDOSA</td>
<td>Trapping System register accesses to powerdown debug registers to EL3</td>
</tr>
<tr>
<td>MDCR_EL3.TDA</td>
<td>Trapping general System register accesses to debug registers to EL3</td>
</tr>
</tbody>
</table>

**Trapping System register accesses to powerdown debug registers to EL3**

MDCR_EL3.TDOSA traps EL2 and EL1 accesses to the powerdown debug registers to EL3:

- **1** EL2 and EL1 System register accesses to the powerdown debug registers are trapped to EL3.
- **0** This control has no effect on accesses to the powerdown debug registers.

For EL1, this trap control applies to accesses from both Security states.

Table D1-90 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL3.

**Trapping general System register accesses to debug registers to EL3**

MDCR_EL3.TDA traps EL2, EL1, and EL0 System register accesses to the debug System registers that are not mentioned in **Trapping System register accesses to powerdown debug registers to EL3**.

This means that MDCR_EL3.TDA traps EL2, EL1, and EL0 System register accesses to all debug System registers, except the following:

- Accesses from AArch64 state to the OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, or DBGPRCR_EL1.
- Accesses from AArch32 state to the DBGOSLSR, DBGOSLAR, DBGOSDLR, or DBGPRCR.

When MDCR_EL3.TDA is:

- **1** EL2, EL1, and EL0 System register accesses to any of the registers shown in Table D1-91 on page D1-2238 are trapped to EL3.
- **0** This control has no effect on accesses to the registers shown in Table D1-91 on page D1-2238.

For EL0 and EL1, this trap control applies to accesses from both Security states.

---

**Note**

These registers are not accessible at EL0.
When the PE is in Debug state, MDCR_EL3.TDA does not trap any access from:

- AArch32 state to DBGDTRRXint and DBGDTRTXint.
- AArch64 state to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0.

Table D1-91 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL3.

### Table D1-91 Accesses trapped to EL3 when MDCR_EL3.TDA is 1

### Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers

**MDCR_EL3.TPM** traps EL2, EL1, and EL0 accesses to the Performance Monitors registers to EL3:

- **1** EL2, EL1, and EL0 System register accesses to all Performance Monitors registers are trapped to EL3.
- **0** This control has no effect on accesses to Performance Monitors registers.

For EL0 and EL1, this trap control applies to accesses from both Security states.
Table D1-92 shows the registers for which accesses are trapped, and how the exceptions are reported in ESR_EL3.

### Table D1-92 Register accesses trapped to EL3 when MDCR_EL3.TPM is 1

### Enabling use of the Pointer authentication instructions, EL3 translation regime

This control is implemented when ARMv8.3-PAuth is implemented.

Each of the SCTLR_EL3. {EnDA, EnDB, EnIA, EnIB} fields enables the pointer authentication functionality for the corresponding Pointer authentication instructions for the EL3 translation regime. For more information see System register control of pointer authentication on page D5-2378.
Note

These controls cause the pointer authentication instructions to execute as NOPs. They never cause an exception to be generated.

Trap to EL3 accesses to Pointer authentication key registers

This control is implemented when ARMv8.3-PAuth is implemented.

SCR_EL3.APK traps, to EL3, accesses to the Pointer authentication key registers from EL2 or from Secure or Non-secure EL1. Because pointer authentication is supported only in AArch64 state this control only traps from AArch64 state. Table D1-95 shows the register accesses that are trapped and how the exceptions are reported in ESR_EL3:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Registers</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>APDKeyLo_EL1, APDKeyHi_EL1, APDBKeyLo_EL1, APDBKeyHi_EL1, APGKeyLo_EL1, APGKeyHi_EL1, APIAKeyLo_EL1, APIAKeyHi_EL1, APIBKeyLo_EL1, APIBKeyHi_EL1</td>
<td>Trapped AArch64 MSR, MRS, or System instruction, using EC value 0x18.</td>
</tr>
</tbody>
</table>

For more information see System register control of pointer authentication on page D5-2378.

Trap to EL3 accesses to Pointer authentication instructions

This control is implemented when ARMv8.3-PAuth is implemented.

SCR_EL3.API traps, to EL3, accesses to any of the Pointer authentication instructions for which pointer authentication is enabled, for instructions executed at an Exception level lower than EL3, in either Security state.

Because pointer authentication is supported only in AArch64 state this control only traps from AArch64 state. Table D1-96 shows the instructions that might be trapped and how the exceptions are reported in ESR_EL3:

<table>
<thead>
<tr>
<th>Traps from</th>
<th>Instructions that might be a trapped</th>
<th>Syndrome reporting in ESR_EL3</th>
</tr>
</thead>
<tbody>
<tr>
<td>AArch64 state</td>
<td>AUTIASP, AUTIAZ, AUTIA1716, AUTIB5P, AUTIBZ, AUTIB1716, AUTIA, AUTDA, AUTIB, AUTDB, AUTIZA, AUTIZB, AUTI2B, PACIASP, PACIAZ, PACIA1716, PACIB5P, PACIBZ, PACIB1716, PACIA, PACDA, PAC18, PACDB, PACI2A, PACDA, PAC1ZB, PAC2DB, PACCA, XPACLRI, XPCAI, XPACD, RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ, ERETA, ERETAB, LDLRA, LDLRB</td>
<td>Trapped Pointer authentication instruction, using EC value 0x89.</td>
</tr>
</tbody>
</table>

a. An instruction is trapped only if Pointer authentication is enabled for that instruction.

For more information, including the description of when pointer authentication is enabled for an instruction, see System register control of pointer authentication on page D5-2378.

Disabling Address tagging for instruction accesses, EL3 translation regime

This control is implemented when ARMv8.3-PAuth is implemented.

When the TCR_EL3.TBI field enables the use of address tagging for the EL3 translation regime, the TCR_EL3.TBID field determines whether address tagging is used for both data and instruction addresses, or only for data addresses. For more information see Address tagging in AArch64 state on page D5-2374.
--- Note ---

This control determines the scope of address tagging. It never causes an exception to be generated.

---
D1.16 System calls

A system call is generated by the execution of an SVC, HVC, or SMC instruction:

- By default, the execution of an SVC instruction generates a Supervisor Call, a synchronous exception that targets EL1. This provides a mechanism for software executing at EL0 to make a call to an operating system or other software executing at EL1.

- In an implementation that includes EL2, the execution of an HVC instruction generates a Hypervisor Call, a synchronous exception that targets EL2 by default. The HVC instruction is UNDEFINED:
  - At EL0.
  - At EL1 in Secure state.

    **Note**
    Software executing at EL0 cannot directly generate a Hypervisor Call.

- In an implementation that includes EL3, by default the execution of an SMC instruction generates a Secure Monitor Call, a synchronous exception that targets EL3. The SMC instruction is UNDEFINED at EL0, meaning software executing at EL0 cannot directly generate a Secure Monitor Call.

The default behavior applies when the instruction is not UNDEFINED and both of the following are true:

- The instruction is executed at an Exception level that is the same as or lower than the target Exception level.
- The instruction is not trapped to a different Exception level.

If an SVC or HVC instruction is executed at an Exception level that is higher than the target Exception then it generates a synchronous exception that is taken to the current Exception level.

EL2 and EL3 can disable Hypervisor Call exceptions, see:

- *Disabling Non-secure state execution of HVC instructions* on page D1-2210.
- *Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions* on page D1-2233.

EL2 can trap use of the SMC instruction, see *Traps to EL2 of EL1 execution of SMC instructions* on page D1-2214.

EL3 can disable Secure Monitor Call exceptions, see *Disabling EL3, EL2, and EL1 execution of SMC instructions* on page D1-2233.

D1.16.1 Pseudocode description of system calls

The `AArch64.CallSupervisor()` pseudocode function performs an SVC call in AArch64 state.

The `AArch64.CallHypervisor()` pseudocode function performs an HVC call in AArch64 state.

The `AArch64.CallSecureMonitor()` pseudocode function performs an SMC call in AArch64 state.

The `AArch64.CallSupervisor()`, `AArch64.CallHypervisor()`, and `AArch64.CallSecureMonitor()` functions are described in Chapter J1 *ARMv8 Pseudocode*. 
D1.17 Mechanisms for entering a low-power state

The ARM architecture provides mechanisms that software can use to indicate that the PE can enter a low-power state, if it supports that state. The following sections describe those mechanisms:

- **Wait for Event mechanism and Send event.**
- **Wait For Interrupt** on page D1-2246.

D1.17.1 Wait for Event mechanism and Send event

A PE can use the Wait for Event (WFE) mechanism to enter a low-power state, depending on the value of the Event Register for that PE. To enter the low-power state, the PE executes a Wait For Event instruction, WFE, and if the Event Register is clear, the PE can enter the low-power state.

If the PE does enter the low-power state, it remains in that low-power state until it receives a WFE wake-up event.

The architecture does not define the exact nature of the low-power state, except that the execution of a WFE instruction must not cause a loss of memory coherency.

WFE mechanism behavior depends on the interaction of all of the following, that are described in the subsections that follow:

- The Event Register for the PE. See subsection **The Event Register** on page D1-2244.
- The Wait For Event instruction, WFE. See subsection **The Wait For Event instruction** on page D1-2244.
- **WFE wake-up events.** See subsection **WFE wake-up events in AArch64 state** on page D1-2245.
- The Send Event instructions, SEV and SEVL that can cause WFE wake-up events. See subsection **The Send Event instructions** on page D1-2245.

--- Note ---

Because the Wait for Event mechanism is associated with suspending execution on a PE for the purpose of power saving, ARM recommends that the Event Register is set only infrequently. However, software must only use the setting of the Event Register as a hint, and must not assume that any particular message is sent as a result of the setting of the Event Register.

--- Example D1-2 ---

Example D1-2 describes how a spinlock implementation might use the WFE mechanism to save energy.

--- Example D1-2 Spinlock as an example of using Wait For Event and Send Event ---

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device, it might need to add data received from the device to a queue. If another PE is removing data from the same queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the second PE has released the lock. The first PE cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in **Synchronization and semaphores** on page B2-135.
- If the PE obtains the lock it performs its memory operation and then releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. When the lock becomes available, the PE again attempts to obtain it.

A spin-lock mechanism is not ideal for all situations:

- In a low-power system the tight read loop is undesirable because it uses energy to no effect.
In a multiprocessor system the execution of spin-locks by multiple waiting PEs can degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock:

- A PE that fails to obtain a lock executes a `WFE` instruction to request entry to a low-power state, at the time when the Exclusives monitor is set holding the address of the location holding the lock.

- When a PE releases a lock, the write to the lock location causes the Exclusives monitor of any PE monitoring the lock location to be cleared. This clearing of the Exclusives monitors generates a WFE wake-up event for each of those PEs. Then, these PEs can attempt to obtain the lock again.

For large systems, more advanced locking systems, such as ticket locks, can avoid unfairness caused by having multiple PEs simultaneously reading the lock. In such systems, the WFE mechanism can be used in a similar way to monitor the next ticket value.

---

**The Event Register**

The Event Register is a single bit register for each PE. When set, an Event Register indicates that an event has occurred since the register was last cleared, that might require some action by the PE. Therefore, when the Event Register is set, the PE must not suspend operation on executing a `WFE` instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by any of the following:

- A Send Event instruction, `SEV`, executed by any PE in the system.
- A Send Event Local instruction, `SEVL`, executed by the PE.
- An exception return.
- The clearing of the global monitor for the PE.
- An event from a Generic Timer event stream, see Event streams on page D10-2639.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

The Event Register is cleared only by a Wait For Event instruction.

---

**Note**

Software cannot read or write the value of the Event Register directly.

---

**The Wait For Event instruction**

The action of the Wait For Event instruction, `WFE`, depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately.
- If the Event Register is clear the PE can suspend execution and enter a low-power state. It remains in that state until the PE detects a WFE wake-up event, or earlier if the implementation chooses, or until a reset. When the PE detects a WFE wake-up event, or earlier if chosen, the WFE instruction completes. If the wake-up event sets the Event Register, it is IMPLEMENTATION DEFINED whether on restarting execution, the Event Register is cleared.

The `WFE` instruction is available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 might be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-2199.
- Traps to EL2 of EL0 and EL1 execution of WFE and WFI instructions on page D1-2217.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-2232.

---

**Note**

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake-ups.
WFE wake-up events in AArch64 state

The following are WFE wake-up events:

- The execution of an SEV instruction on any PE in the multiprocessor system.
- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is not disabled by EDSCR.INTdis and:
  - Is marked as A in the tables in Asynchronous exception masking on page D1-2190, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.
  - Is marked as B in the tables in Asynchronous exception masking on page D1-2190, if the value of the corresponding PSTATE.{A, I, F} mask bit is 0.

______ Note ________
Any physical SError interrupt, IRQ interrupt, or FIQ interrupt that is marked as A/B behaves as A or B. See A/B on page D1-2191.

- In EL1 or EL0, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is not disabled by EDSCR.INTdis and is marked as B in Table D1-19 on page D1-2193 in Virtual interrupts on page D1-2192, if the value of the corresponding PSTATE.{A, I, F} mask bit is 0.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed see Halting allowed and halting prohibited on page H2-6419.
  See also External Debug Request debug event on page H3-6475.
- An event sent by the timer event stream for the PE. See Event streams on page D10-2639.
- An event caused by the clearing of the global monitor for the PE.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

Not all of these wake-up events set the Event Register.

______ Note ________
The disabling of interrupts, and WFE wake-up events, by EDSCR.INTdis is possible only when external debug is enabled.

The Send Event instructions

The Send Event instructions are:

**SEV, Send Event**  
This causes an event to be signaled to all PEs in the multiprocessor system.

**SEVL, Send Event Local**  
This must set the local Event Register.

______ Note ________
It might signal an event to other PEs by some IMPLEMENTATION DEFINED mechanism, but is not required to do so.

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the SEV instruction. Therefore, ARM recommends that software includes a DSB instruction before any SEV instruction.
Note

A DSB instruction ensures that no instructions, including any SEV instructions, that appear in program order after the DSB instruction, can execute until the DSB instruction has completed. See Data Synchronization Barrier (DSB) on page B2-106.

The SEVL instruction appears to execute in program order relative to any subsequent WFE instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.

The receipt of a signaled SEV or SEVL event by a PE sets the Event Register on that PE.

The SEV and SEVL instructions are available at all Exception levels.

Pseudocode description of the Wait For Event mechanism

This section identifies pseudocode functions that describe the behavior of the Wait For Event mechanism.

The ClearEventRegister() pseudocode function clears the Event Register of the current PE.

The IsEventRegisterSet() pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear.

The WaitForEvent() pseudocode function optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes ClearEventRegister() to be called.

The SendEvent() pseudocode function sets the Event Register of every PE in the multiprocessor system.

The SendEventLocal() pseudocode function sets the event register for the local PE.

D1.17.2 Wait For Interrupt

Software can use the Wait for Interrupt (WFI) instruction to cause the PE to enter a low-power state. The PE then remains in that low-power state until it receives a WFI wake-up event, or until some other IMPLEMENTATION DEFINED reason causes it to leave the low-power state. The architecture permits a PE to leave the low-power state for any reason, but requires that it must leave the low-power state on receipt of any architected WFI wake-up event.

Note

Because the architecture permits a PE to leave the low-power state for any reason, it is permissible for a PE to treat WFI as a NOP, but this is not recommended for lowest power operation.

When the PE leaves a low-power state that was entered as a result of a WFI instruction, that WFI instruction completes.

The architecture does not define the exact nature of the low-power state, except that the execution of a WFI instruction must not cause a loss of memory coherency.

Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 might be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-2199.
- Traps to EL2 of EL0 and EL1 execution of WFE and WFI instructions on page D1-2217.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-2232.

WFI wake-up events

The following are WFI wake-up events:

- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as A, B or A/B in the tables in Asynchronous exception masking on page D1-2190, regardless of the value of the corresponding PSTATE. (A, I, F) mask bit.
• In EL1 or EL0, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as B in Table D1-19 on page D1-2193 in Virtual interrupts on page D1-2192, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.

• An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed see Halting allowed and halting prohibited on page H2-6419.

See also External Debug Request debug event on page H3-6475.

• An event sent by some IMPLEMENTATION DEFINED mechanism.

--- Note ---

• WFI wake-up events are never disabled by EDSCR.INTdis, and are never masked by the PSTATE.{A, I, F} mask bits. If wake-up is invoked by an interrupt that is disabled or masked the interrupt is not taken.

• Because debug events are WFI wake-up events, ARM recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures that the intervention of debug while waiting does not significantly change the function of the program being debugged.

• Some implementations of the WFI mechanism drain down any pending memory activity before suspending execution. This increases power saving, by increasing the area over which clocks can be stopped. The architecture does not require this operation, therefore software must not rely on the WFI mechanism operating in this way.

--- Using WFI to indicate an idle state on bus interfaces ---

Software can use the WFI mechanism to force quiescence on a PE, and, combined with preventing any possible WFI wakeup events, this can be used to complete an entry into a powerdown state.

Because mechanisms for entering powerdown states are inherently IMPLEMENTATION DEFINED, whether an implementation uses the WFI mechanism is IMPLEMENTATION DEFINED. If it does, the WFI instruction forces the suspension of execution, and of all associated bus activity.

The control logic that does this also tracks the activity on the bus interfaces of the PE, so that when the PE has completed all current operations and any associated bus activity has completed, it can signal to an external power controller that there is no ongoing bus activity.

However, the PE must continue to process memory-mapped and external debug interface accesses to debug registers when in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

If the OS Double Lock control is implemented and OSDLR_EL1.DLK is 1, the PE must not signal this idle state to the control logic unless it can also guarantee that the debug interface is idle. For more information about the OS Double Lock, see Debug behavior when the OS Double Lock is locked on page H6-6529.

--- Note ---

In a PE that implements separate core and debug power domains, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains see Power domains and debug on page H6-6521.

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

--- Pseudocode description of Wait For Interrupt ---

The WaitForInterrupt() pseudocode function optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.
Self-hosted debug

The ARMv8-A architecture supports both of the following:

**Self-hosted debug**

The PE itself hosts a debugger. The debugger programs the PE to generate debug exceptions. Debug exceptions are accommodated in the ARMv8-A Exception model.

**External debug**

The PE is controlled by an external debugger. The debugger programs the PE to generate Debug events, that cause the PE to enter Debug state. In Debug state, the PE is halted.

This section describes self-hosted debug. It includes:

- Debug exceptions.
- The PSTATE debug mask bit, D.

For external debug, see part E.

### D1.18.1 Debug exceptions

Debug exceptions occur during normal program flow, if a debugger has programmed the PE to generate them.

For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions.

The possible debug exceptions are:

- Breakpoint Instruction exceptions.
- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

Chapter D2 AArch64 Self-hosted Debug describes these in detail for AArch64.

For the PE to generate a debug exception requires that:

- The debug exception is enabled. The debug exception enable controls on page D2-2274 gives the controls for the different debug exceptions.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level on page D2-2277.

Debug exceptions are synchronous exceptions, and are accommodated in the ARMv8 Exception model.

**Note**

Breakpoints and Watchpoints can cause entry to Debug state instead of causing debug exceptions. See Chapter H1 About External Debug.

### D1.18.2 The PSTATE debug mask bit, D

As with all other exceptions, when a debug exception is taken, software must take care to avoid generating another instance of an exception within the exception handler, to avoid recursive entry into the exception handler and loss of return state.

To help avoid this, the ARMv8 architecture provides a debug exception mask bit, PSTATE.D, that can mask Watchpoint, Breakpoint, and Software Step exceptions when the target Exception level is the current Exception level.
PSTATE.D is set to 1 on taking an exception. This means that while handling an exception in AArch64 state, Watchpoint, Breakpoint, and Software Step exceptions are masked. This prevents recursive entry at the Exception level that debug exceptions are targeted to.

When execution is in AArch64 state, debug exceptions are also masked implicitly when the target Exception level is lower than the current Exception level.

When the target Exception level is higher than the current Exception level, debug exceptions cannot be masked by PSTATE.D.

Because debug exceptions are synchronous, the architecture requires that debug exceptions are not generated when PSTATE.D is 1. By preventing debug exception generation, debug exceptions cannot be taken at a subsequent time when the Process state D mask bit is cleared to 0.

--- Note ---

This differs from the behavior for interrupts, where the PSTATE.{A, I, F} mask has the effect of preventing the interrupt from being taken, but instead the interrupt remains pending.
D1.19 Event monitors

The ARMv8-A architecture supports the following non-invasive architectural components that allow for event monitoring:

**Performance Monitors**

The Performance Monitors have a wide feature set, flexible selection of counted events, and are read/write in operation. See *The Performance Monitors Extension*.

**Activity Monitors**

The Activity Monitors have a narrow feature set, limited selection of counted events, and are read-only in operation. See *The Activity Monitors Extension*.

D1.19.1 The Performance Monitors Extension

The System registers provide access to a Performance Monitors Unit (PMU), defined as the OPTIONAL Performance Monitors Extension to the architecture, a non-invasive debug resource that provides information about the operation of the PE. The PMU provides:

- A 64-bit cycle counter.
- An IMPLEMENTATION DEFINED number of 32-bit event counters. Each event counter can be configured to count occurrences of a specified event. The events that can be counted are:
  - Architectural and microarchitectural events that are likely to be consistent across many microarchitectures. The PMU architecture uses event numbers to identify an event, and the PMU specification defines which event number must be used for each of these architectural and microarchitectural events.
  - Implementation-specific events. The PMU specification reserves event numbers for implementation-specific events. See Appendix K3 *Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events*.

For more information, see Chapter D6 *The Performance Monitors Extension*.

D1.19.2 The Activity Monitors Extension

When the OPTIONAL Activity Monitors Extension is implemented, the System registers provide access to controls and counters for the Activity Monitors Unit (AMU). For more information, see Chapter D7 *The Activity Monitors Extension*. 
D1.20 Interprocessing

Interprocessing is the term used to describe moving between the AArch64 and AArch32 Execution states.

The Execution state can change only on a change of Exception level. This means that the Execution state can change only on taking an exception to a higher Exception level, or returning from an exception to a lower Exception level.

On taking an exception to a higher Exception level, the Execution state either:
• Remains unchanged.
• Changes from AArch32 state to AArch64 state.

On returning from an exception to a lower Exception level, the Execution state either:
• Remains unchanged.
• Changes from AArch64 state to AArch32 state.

Note

If, on taking or returning from an exception, the Exception level remains the same, the Execution state cannot change.

For the description of:
• Exception entry to an Exception level using AArch64, see Exception entry on page D1-2158.
• Exception return from an Exception level using AArch64 state, see Exception return on page D1-2167.
• Exception return to AArch32 state, see Exception return to an Exception level using AArch32 on page G1-5269.

Note

The description in Handling exceptions that are taken to an Exception level using AArch32 on page G1-5247 is outside the scope of interprocessing, because such exceptions must have been taken from an Exception level that is using AArch32, and therefore there is no change of Execution state.

The following sections describe the behavior associated with interprocessing.
• Register mappings between AArch32 state and AArch64 state.
• State of the general-purpose registers on taking an exception to AArch64 state on page D1-2261.
• SPSR, ELR, and AArch64 SP relationships on changing Execution state on page D1-2263.

D1.20.1 Register mappings between AArch32 state and AArch64 state

This section defines the architectural mappings between AArch32 state registers and AArch64 state registers.

The mappings describe:
• For exceptions taken from AArch32 state to AArch64 state, where the AArch32 register content is found.
• For exception returns from AArch64 state to AArch32 state, how the AArch32 register content is derived.

The general model is:
• The AArch32 register contents are situated in the bottom 32 bits of the AArch64 registers.
• In AArch32 state, the upper 32 bits of AArch64 registers are inaccessible and are ignored.

Note

System software that executes in AArch64 state, such as an OS or Hypervisor, can use these mappings for context save and restore, or to interpret and modify the AArch32 registers of an application or virtual machine.

For more information see the following subsections:
• Mapping of the general-purpose registers between the Execution states on page D1-2252.
• Mapping of the SIMD and floating-point registers between the Execution states on page D1-2253.
• Mapping of the System registers between the Execution states on page D1-2254.
Mapping of the general-purpose registers between the Execution states

Table D1-97 shows how each of the AArch32 general-purpose registers, R0-R12, SP, and LR, including the banked copies of these registers, maps to an AArch64 general-purpose register. A register in the AArch64 register column of the table provides the AArch64 view of the corresponding register in the AArch32 register column.

--- Note ---

For some exceptions, the exception syndrome given in the ESR_ELx identifies one or more register numbers from the issued instruction that generated the exception. Where the exception is taken from an Exception level using AArch32 these register numbers give the AArch64 view of the register. For example, if an exception is taken from AArch32 Abort mode, and the faulting instruction specified R14, the ESR_ELx.ISS field would report this using the EC value 0b10100, because register X20 provides the AArch64 view of LR_abt which is the copy of R14 used in Abort mode.

<td>Q15</td>
</tr>
</tbody>
</table>

The AArch64 registers V16-V31 are not accessible from AArch32 state.

The mapping between the V, D, and S registers in AArch64 state is not the same as the mapping between the Q, D, and S registers in AArch32 state:

- In AArch64 state, there are:
  - 32 64-bit D registers, D0-D31.
  - 32 32-bit S registers, S0-S31.

A smaller register occupies the least-significant bytes of the corresponding larger register. For example, S5 is the least-significant word of D5 and V5. Figure D1-3 on page D1-2254 shows this mapping.
In AArch32 state:
- There are no S registers that correspond to Q8-Q15.
- D16-D31 pack into Q8-Q15. For example, D16 and D17 pack into Q8.

**Note**
A consequence of this mapping is that if software executing in AArch64 state interprets D or S registers from AArch32 state, it must unpack the D or S registers from the V registers before it uses them.

**Mapping of the System registers between the Execution states**

ARMv8 architecturally defines the relationship between the AArch64 System registers and the AArch32 System registers, to allow supervisory code such as a hypervisor, that is executing in AArch64 state, to save, restore, and interpret the System registers belonging to a lower Exception level that is using AArch32.

Any modifications made to AArch32 System registers affects only those parts of those AArch64 registers that are mapped to the AArch32 System registers. Bits[63:32] of AArch64 registers, where they are not mapped to AArch32 registers, are unchanged by AArch32 state execution.

**Note**
This model is different to the model for the general-purpose registers described in Mapping of the general-purpose registers between the Execution states on page D1-2252. In this model, there are several cases where two AArch32 System registers are packed into a single AArch64 System register.

When EL3 is implemented and is using AArch32, some System registers are banked between the two Security states. When a register is banked in this way, there is an instance of the register in Secure state, and another instance of the register in Non-secure state. In Table D1-99 on page D1-2255 these banked registers are identified by footnotea. This banking is not supported when EL3 is using AArch64 or if EL3 is not implemented. This means that when EL3 is implemented and is using AArch64, exactly the same registers are accessed in the following states:
- Secure EL1 with EL1 using AArch32.
- Non-secure EL1 with EL1 using AArch32.

This means that, architecturally, it is not possible to determine whether an AArch64 register is mapped onto the Secure instance of the corresponding AArch32 register, or onto the Non-secure instance of that register. When EL3 is using AArch64, the interrupt asserted by the AArch64 CNTP_* timer is the same interrupt as is asserted by the Non-secure AArch32 CNTP_* timer when EL3 is using AArch32.
Note

Although the architecture does not require this, because it is not architecturally visible, ARM expects that implementations will map many of the AArch64 registers for use by EL3 to the Secure instances of the banked AArch32 registers, and will map many of the AArch64 registers for use by EL1 to the Non-secure instances of the banked AArch32 registers. However, if EL2 and EL3 are implemented and both support use of AArch32, this is not possible for the following registers:

- **IFAR**: This is because when EL3 is using AArch32, HIFAR is an alias of the Secure IFAR.
- **DFAR**: This is because when EL3 is using AArch32, HDFAR is an alias of the Secure DFAR.

Table D1-99 shows the mappings between the writable AArch64 System registers and the AArch32 System registers.

There are a small number of AArch32 System registers that are not mapped to any AArch64 System registers. The AArch64 registers listed in Table D1-100 can be used to access these from a higher Exception level that is using AArch64. The registers shown in the table are UNDEFINED if EL1 cannot use AArch32.

D1.20.2 State of the general-purpose registers on taking an exception to AArch64 state

When an exception is taken from AArch32 state to AArch64 state, the state of a general-purpose register depends on whether, immediately before the exception, the register was accessible from AArch32 state, as follows:

If the general-purpose register was accessible from AArch32 state

The upper 32 bits either become zero, or hold the value that the same architectural register held before any AArch32 execution. The choice between these two options is IMPLEMENTATION DEFINED, and might vary dynamically within an implementation. Correspondingly, software must regard the value as being a CONSTRAINED UNPREDICTABLE choice between these two values.

This behavior applies regardless of whether any execution occurred at the Exception level that was using AArch32. That is, this behavior applies even if AArch32 state was entered by an exception return from AArch64 state, and another exception was immediately taken to AArch64 state without any instruction execution in AArch32 state.

Which general-purpose registers have their upper 32 bits affected in this way depends on both:

• The AArch64 state target Exception level.

• The values of both:
  — SCR_EL3.RW.
  — HCR_EL2.RW or HCR.RW, where HCR.RW is a notional bit that is RES0.

Table D1-102 shows which general-purpose registers can have their upper 32 bits set to zero.

### Table D1-101 AArch64 registers that access the AArch32 ID registers (continued)

<td>X0-X14, X16-X30</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>X0-X14</td>
</tr>
</tbody>
</table>

- a. HCR.RW is a notional bit that is RES0.
- b. The RW bit values are not valid for the targeted Exception level.
- c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.
Note

If EL2 is not implemented, or the SCR_EL3.NS or SCR.NS bit prevents its use, then as described in *The effects of supporting fewer than four Exception levels* on page D1-2266, the behavior is consistent with HCR_EL2.RW taking the value of SCR_EL3.RW.

If the general-purpose register was not accessible from AArch32 state

The general rule is that the register retains the state it had before any AArch32 execution.

There is one exception to this rule, that is when taking an exception to EL3 using AArch64 when either EL2 is not implemented or EL1 is in Secure state. In these cases, the X15 register must be treated as if it is accessible when the value of SCR_EL3.RW is 0, and therefore the upper bits of X15 might either be set to zero or retain their previous value.

Which general-purpose registers retain their state depends on both:

- The AArch64 state target Exception level.
- The values of both:
  - SCR_EL3.RW.
  - HCR_EL2.RW or HCR.RW, where HCR.RW is a notional bit that is RES0.

Table D1-103 shows which general-purpose registers can retain their state.

Table D1-103 General-purpose registers that can retain their state on taking an exception to AArch64 from AArch32

<table>

</tr>
</tbody>
</table>

a. HCR.RW is a notional bit that is RES0.
b. The RW bit values are not valid for the targeted Exception level.
c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.

Note

If EL2 is not implemented, or the SCR_EL3.NS bit prevents its use, then as described in *The effects of supporting fewer than four Exception levels* on page D1-2266, the behavior is consistent with HCR_EL2.RW taking the value of SCR_EL3.RW.
D1.20.3 SPSR, ELR, and AArch64 SP relationships on changing Execution state

Table D1-104 shows the SPSR and ELR registers that are architecturally mapped between AArch32 state and AArch64 state.

Table D1-104 SPSR and ELR mappings between AArch32 state and AArch64 state

<table>
<thead>
<tr>
<th>AArch32 register</th>
<th>AArch64 register</th>
</tr>
</thead>
<tbody>
<tr>

<td>SPSR_EL2</td>
</tr>
<tr>
<td>ELR_hyp</td>
<td>ELR_EL2</td>
</tr>
</tbody>
</table>

On exception entry to EL3 using AArch64 state from an Exception level using AArch32 state, when EL2 has been using AArch32 state, the upper 32-bits of ELR_EL2 are either set to zero or they retain the value before the AArch32 state execution. The implementation determines the choice between these two options, and the choice might vary dynamically within an implementation. Therefore, software must regard the upper 32-bits as being UNKNOWN.

On exception entry to an Exception level using AArch64 state from an Exception level using AArch32 state, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during execution in AArch32 state at that Exception level, retain the state that they had before the execution in AArch32 state.

The following AArch32 registers are used only during execution in AArch32 state. However, they retain their state when there is execution at EL1 with EL1 using AArch64 state:

- SPSR_abt.
- SPSR_und.
- SPSR_irq.
- SPSR_fiq.

Note

- These registers are accessible during execution in AArch64 state at Exception levels higher than EL1, for context switching.

- If EL1 does not support execution in AArch32 state then these registers are RES0.

On exception entry to an Exception level using AArch64 from an Exception level using AArch32, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during AArch32 execution at that Exception level retain the state that they had before AArch32 execution. This applies to the following registers:

- SP_EL0.
- SP_EL1.
- SP_EL2.
- ELR_EL1.
D1.21 The effect of implementation choices on the programmers’ model

Three of the implementation choices in ARMv8 are:

• The number of Exception levels implemented.
• Which Exception levels support AArch32 and which Exception levels support AArch64.
• Whether SIMD and floating-point support is implemented.

The following subsections give more information about how these choices affect the programmers’ model:

• Implication of Exception levels implemented.
• Support for Exception levels and Execution states on page D1-2265.
• Implementations not including Advanced SIMD and floating-point instructions on page D1-2265.
• The effects of supporting fewer than four Exception levels on page D1-2266.

D1.21.1 Implication of Exception levels implemented

All implementations must include EL0 and EL1.

EL2 and EL3 are optional. The architecture permits all combinations of EL2 and EL3.

See also Implementations not including Advanced SIMD and floating-point instructions on page D1-2265 and The effects of supporting fewer than four Exception levels on page D1-2266.

For an implementation that includes all of the Exception levels Figure D1-5 shows the implemented Exception levels and the possible Execution states at lower Exception levels when EL3 is using AArch64. Figure D1-5 applies regardless of whether EL3 also supports use of AArch32.

Figure D1-5 ARMv8-A security model when EL3 is using AArch64

† AArch64 permitted only if EL1 is using AArch64
‡ AArch64 permitted only if EL2 is using AArch64
The possible combinations of Exception levels are as follows:

- **EL0, EL1, and EL2.** The implementation supports only a single Security state. This might be either Secure state or Non-secure state.

- **EL0, EL1, and EL3.** The implementation does not support Virtualization. The Exception levels and Execution states depend on whether EL3 is using AArch64 state or AArch32 state, as follows:
  - If EL3 is using AArch64, the Exception levels and Execution states are as shown in Figure D1-5 on page D1-2264 with EL2 removed and no virtualization of EL1 and EL0.
  - If EL3 is using AArch32, the Exception levels and Execution states are as shown in Figure G1-1 on page G1-5224 with EL2 removed and no virtualization of EL1 and EL0.

- **EL0 and EL1 only.** The implementation supports only a single Security state. This might be either Secure state or Non-secure state, see Behavior when only EL1 and EL0 are implemented on page D1-2267.

- **EL0, EL1, EL2, and EL3,** as described in this section.

For more information, see The effects of supporting fewer than four Exception levels on page D1-2266.

### D1.21.2 Support for Exception levels and Execution states

Subject to the interprocessing rules defined in Interprocessing on page D1-2251, an implementation of the ARM architecture could support:

- AArch64 state only.
- AArch64 and AArch32 states.
- AArch32 state only.

This means the ARMv8-A architecture can, potentially, support implementations with very large number of combinations of Execution state and Exception level. ARM intends to license only a subset of the possible combinations.

In an implementation that:

- Supports AArch64 state, all Exception levels are included.
- Has Secure and Non-secure states, EL3 should be implemented.
- Includes all Exception levels, EL3 cannot be included in AArch32 state.

### D1.21.3 Implementations not including Advanced SIMD and floating-point instructions

In general, ARMv8-A requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. Exceptionally, for implementations targeting specialized markets that do not require support for floating-point or use of Advanced SIMD, ARM might produce or license an ARMv8-A implementation that does not provide any support for Advanced SIMD and floating-point instructions. In such an implementation:

**In AArch64 state**

- The CPACR_EL1.FPEN field is RES0.
- The CPTR_EL2.TFP bit is RES1.
- The CPTR_EL3.TFP bit is RES1.
- Each of the ID_AA64PFR0_EL1.{AdvSIMD, FP} fields is 0b1111.
- The FPEXC32_EL2, FPCR, and FPSR registers are not implemented, and their encodings are UNDEFINED.
- Attempted accesses to Advanced SIMD and floating-point functionality are UNDEFINED. This means:
  - All Advanced SIMD and floating-point instructions are UNDEFINED.
  - Attempts to access the Advanced SIMD and floating-point System registers are UNDEFINED.
• If at least one Exception level supports execution in AArch32 state, the MVFR0_EL1, MVFR1_EL1 and MVFR2_EL1 registers are RAZ. When no Exception level supports execution in AArch32 state these registers are UNKNOWN.

In AArch32 state

See AArch32 implications of not including support for Advanced SIMD and floating-point on page G1-5316.

D1.21.4 The effects of supporting fewer than four Exception levels

The effect of implementation choices on the programmers’ model on page D1-2264 defines the permitted combinations of Exception levels in an ARMv8-A implementation.

In every implementation that supports the highest Exception level using either AArch64 state or AArch32 state, an IMPLEMENTATION DEFINED mechanism determines whether the highest implemented Exception level uses AArch64 state or AArch32 state from a Cold reset. Typically, this mechanism is a configuration input. When the highest level is configured to be AArch64 state, then after a Cold reset execution starts at the reset vector in that Exception level.

The unimplemented Exception levels have no effect on execution:
• No interrupts are routed to these Exception levels.
• No traps that target these Exception levels are active.
• All systems calls to unimplemented Exception levels from lower Exception levels are treated as UNDEFINED.
• There is no support for address translation from these Exception levels.
• Any exception return that targets an unimplemented Exception level is treated as an illegal exception return as described in Illegal return events from AArch64 state on page D1-2168.
• Every accessible register associated with an unimplemented Exception level is RES0 unless the register is associated with the Exception level only to provide the ability to transfer execution to a lower Exception level.

—— Note ———
If, for example, EL3 is not implemented and EL2 is the highest implemented Exception level, then because none of the EL3 registers are accessible from EL2, the content of those registers is not architecturally visible.

The following subsections give more information about each of the permitted combinations of Exception levels that do not include all Exception levels.

Behavior when EL3 is not implemented

If EL3 is not implemented:
• If EL2 is implemented and Secure EL2 is not implemented, the Effective value of SCR_EL3.NS is 0b1.
• If Secure EL2 is implemented, the Effective value of SCR_EL3.EEL2 is 0b1 and the Effective value of SCR_EL3.NS is 0b0.
• If EL2 is not implemented, it is IMPLEMENTATION DEFINED whether the Effective value of SCR_EL3.NS is 0b1 or 0b0.

Behavior when EL2 is not implemented

If EL2 is not implemented and EL3 is implemented:
• If EL1 can use AArch32 then the following registers are not RES0:
  — DACR32_EL2.
  — IFSR32_EL2.
  — FPEXC32_EL2.
  — DBGVCR32_EL2.
• The VMPIDR_EL2 and VPIDR_EL2 behave as follows:
  — Reads of VMPIDR_EL2 return the value of MPIDR_EL1, writes to VMPIDR_EL2 are ignored.
  — Reads of VPIDR_EL2 return the value of MIDR_EL1, writes to VPIDR_EL2 are ignored.

• Behavior is consistent with the HCR_EL2.RW bit taking the value of the SCR_EL3.RW bit for all purposes other than reading the HCR_EL2.

• Virtual interrupts are disabled.

• The following address translation and TLB invalidation instructions are UNDEFINED:
  — AT S1E2R and AT S1E2W.
  — TLBI VA2E, TLBI VALE2, TLBI VAE2IS, TLBI VALE2IS, TLBI ALLE2, TLBI ALLE2IS.

  Note

  No other TLB or address translation instructions become UNDEFINED with this combination of Exception levels.

• The SCR_EL3.HCE bit is RES0.

If EL2 is not implemented, regardless of whether EL3 is implemented:
• The Effective value of CNTHCTL_EL2[1:0] is 0b11.
• The Effective value of MDCR_EL2.HPMN is the value of PMCR_EL0.N.

Behavior when only EL1 and EL0 are implemented

If EL3 and EL2 are not implemented, it is IMPLEMENTATION DEFINED whether the Effective value of the SCR_EL3.NS bit is 0b1 or 0b0.

This means that if the PE is part of a system that supports two Security states:
• When the Effective value of the SCR_EL3.NS bit is 0b1, the PE can only access Non-secure memory.
• When the Effective value of the SCR_EL3.NS bit is 0b0, the PE can access both Secure memory and Non-secure memory.

If the Effective value of the SCR_EL3.NS bit is 0b0, then:
• The Effective value of MDCR_EL3.{EPMAD, EDAD} is {0b1, 0b1}.
• The Effective value of MDCR_EL3.{SPME, NSPB} is {0b1, 0b01}.
• The Effective value of MDCR_EL3.SPD32 is 0b11.

If EL3 is not implemented, regardless of whether EL2 is implemented, the Effective value of MDCR_EL3.STE is the inverse of the Effective value of SCR_EL3.NS.

  Note

  • The behavior described in this subsection still applies if EL1 is configured to use AArch32.
  • The implementation can provide a configuration input that determines, from reset, the Effective value of the SCR_EL3.NS bit.
Chapter D2
AArch64 Self-hosted Debug

When the PE is using self-hosted debug, it generates debug exceptions. This chapter describes the AArch64 self-hosted debug exception model. It is organized as follows:

Introductory information
- About self-hosted debug on page D2-2270.
- The debug exception enable controls on page D2-2274.

The debug Exception model
- Routing debug exceptions on page D2-2275.
- Enabling debug exceptions from the current Exception level on page D2-2277.
- The effect of powerdown on debug exceptions on page D2-2279.
- Summary of the routing and enabling of debug exceptions on page D2-2280.
- Pseudocode description of debug exceptions on page D2-2281.

The debug exceptions
- Breakpoint Instruction exceptions on page D2-2282.
- Breakpoint exceptions on page D2-2284.
- Watchpoint exceptions on page D2-2302.
- Vector Catch exceptions on page D2-2316.
- Software Step exceptions on page D2-2317.

Synchronization requirements
The behavior of self-hosted debug after changes to System registers, or after changes to the authentication interface, but before a Context synchronization event guarantees the effects of the changes:
- Synchronization and debug exceptions on page D2-2330.
D2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of debug exceptions, that are taken using the exception model described in Chapter D1 The AArch64 System Level Programmers’ Model. This section introduces some terms that are used in describing self-hosted debug, and then introduces the debug exceptions. See:

- Definition of a debugger in the context of self-hosted debug.
- Context ID and Process ID.
- About debug exceptions.

D2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, debugger means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

D2.1.2 Context ID and Process ID

A CONTEXTIDR_ELx identifies the current Context ID, that is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

In AArch64 state, the CONTEXTIDR_ELx has a single field, PROCID, that is defined as the Process Identifier (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical.

D2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger enables one or more debug exceptions. The debug exceptions that can be generated in stage 1 of an AArch64 translation regime are:

- Breakpoint Instruction exceptions on page D2-2271.
- Breakpoint exceptions on page D2-2271, generated by hardware breakpoints.
- Watchpoint exceptions on page D2-2271, generated by hardware watchpoints.
- Software Step exceptions on page D2-2272.

In addition, debug exceptions generated in an AArch32 translation regime might be routed to EL2 using AArch64. See Routing debug exceptions on page D2-2275. Chapter G2 describes the debug exceptions that can be generated in an AArch32 translation regime.

Vector Catch exceptions are exceptions that cannot be generated in an AArch64 translation regime but can be generated in stage 1 of an AArch32 translation regime and routed to EL2 using AArch64. Vector Catch exceptions on page D2-2316 describes the behavior for this case.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level on page D2-2277. Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

2. A debugger has enabled that particular debug exception.

All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the MDSCR_EL1. See The debug exception enable controls on page D2-2274.

Note

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.
For the definition of halting is allowed, see *Halting allowed and halting prohibited* on page H2-6419.

The following list summarizes each of the debug exceptions:

**Breakpoint Instruction exceptions**

*Breakpoint instructions* generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A64 instruction set is `BRK #<immediate>`. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

**PE behavior**

Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:

• The current Exception level.
• The current Security state.

For more information, see *Breakpoint Instruction exceptions* on page D2-2282.

**Breakpoint exceptions**

The ARMv8-A architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address 0x1000 is committed for execution.

The ARMv8-A architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch64 translation regime:

• Address.
  — Comparisons are made with the virtual address of each instruction in the program flow.
• Context:
  — Context ID Match. Matches with the Context ID held in the CONTEXTIDR_EL1.
  — VMID Match. Matches with the VMID value held in the VTTBR_EL2.
  — Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

**PE behavior**

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State.

Otherwise:

• If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
• If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see *Breakpoint exceptions* on page D2-2284.

**Watchpoint exceptions**

The ARMv8-A architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range 0x1000 - 0x101F.

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a *Linked Context* type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.
The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

**PE behavior**

If halting is allowed and EDSCR.HDE is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 Debug State.

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see *Watchpoint exceptions on page D2-2302.*

**Vector Catch exceptions**

These are not generated in an AArch64 translation regime. They can only be generated in an AArch32 translation regime. See *Vector Catch exceptions on page D2-2316.*

**Software Step exceptions**

Software step is a resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can debug software executing at a lower Exception level, by making it single-step instructions.

After the software being debugged has single-stepped an instruction, the PE takes a Software Step exception.

**PE behavior**

Software step can only be used by a debugger executing in an Exception level that is using AArch64. However, the instruction stepped might be executed in either Execution state, and therefore Software Step exceptions can be taken from either Execution state.

If debug exceptions are enabled, Software Step exceptions can be generated.

If debug exceptions are disabled, software step is inactive.

For more information, see *Software Step exceptions on page D2-2317.*

Table D2-1 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

<table>
<thead>
<tr>
<th>Debug exception</th>
<th>PE behavior if debug exceptions are:</th>
<th>Pseudocode</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
<tr>

<td>Takes the exception</td>
<td>Takes the exception</td>
</tr>
<tr>
<td>Breakpoint exceptions</td>
<td>Takes the exception^a</td>
<td>Ignored</td>
</tr>
<tr>
<td>Watchpoint exceptions</td>
<td>Takes the exception^a</td>
<td>Ignored</td>
</tr>
<tr>
<td>Vector Catch exceptions</td>
<td>Takes the exception</td>
<td>Ignored</td>
</tr>
<tr>
<td>Software Step exceptions</td>
<td>Takes the exception</td>
<td>Not applicable^b</td>
</tr>
</tbody>
</table>
a. If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See Chapter H2 Debug State.

b. Software Step is inactive if debug exceptions are disabled. No Software Step exceptions can be generated.
D2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

**Breakpoint Instruction exceptions**

None. Breakpoint Instruction exceptions are always enabled.

**Breakpoint exceptions**

MDSCR_EL1.MDE, plus an enable control for each breakpoint, DBGBCR<n>_EL1.E.

**Watchpoint exceptions**

MDSCR_EL1.MDE, plus an enable control for each watchpoint, DBGWCR<n>_EL1.E.

**Vector Catch exceptions**

MDSCR_EL1.MDE.

**Software Step exceptions**

MDSCR_EL1.SS.

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level on page D2-2277.

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
D2.3 Routing debug exceptions

Debug exceptions are enabled and routed according to the following controls:

- MDCR_EL2.TDE.
- HCR_EL2.TGE.
- MDCR_EL3.SDD.
- The Security state when the exception is taken.
- The Exception level where the exception is taken.

Breakpoint Instructions are enabled in some situations where other Debug exceptions are disabled.

If the OS Lock is locked, or if DoubleLockStatus() == TRUE, a Debug exception cannot be taken.

Note

If EL2 is not implemented, the Effective value of HCR_EL2.TGE is 0 and the Effective value of MDCR_EL2.TDE is 0. Throughout this section, references to the values of these fields are to the Effective values of the fields.

If EL3 is not implemented, and the implementation is a Secure state only implementation, the Effective value of MDCR_EL3.SDD is 0.

The routing of debug exceptions is as follows:

Table D2-2 shows when debug exceptions are enabled from the current Security state.

### Table D2-2 Whether debug exceptions are enabled from the current Security state

<table>
<thead>
<tr>
<th>Current Security state</th>
<th>Breakpoint Instruction exceptions</th>
<th>All other debug exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>Secure</td>
<td>Enabled</td>
<td>Disabled if MDCR_EL3.SDD is 1. See Disabling debug exceptions from Secure state on page D2-2277. Otherwise enabled.</td>
</tr>
</tbody>
</table>

Debug exceptions taken when EL2 is implemented and enabled in the current Security state

The routing of debug exceptions taken depends on the values of MDCR_EL2.TDE and HCR_EL2.TGE:

If the Effective value of \{MDCR_EL2.TDE, HCR_EL2.TGE\} is not \{0, 0\}

Debug exceptions are routed to EL2, ELD is EL2.

Otherwise

Debug exceptions behave as follows:

- Debug exceptions taken from EL1 and EL0 are routed to EL1. ELD is EL1
- Breakpoint Instruction exceptions taken from EL2 are routed to EL2.
- All other debug exceptions are disabled from EL2 using AArch64.

When EL3 is implemented

Breakpoint Instruction exceptions taken from EL3 are routed to EL3.

All other debug exceptions are disabled from EL3 using AArch64.

Otherwise

Debug exceptions are routed to EL1.

This means that, for all debug exceptions, the Debug target Exception level, EL_D, is either EL1 or EL2. When executing in the same exception level as ELD, see Enabling debug exceptions from the current Exception level on page D2-2277.
Table D2-3, Table D2-4, and Table D2-5 show the routing of debug exceptions. In these tables:

TDE  
Means the logical OR of the Effective value of MDCR_EL2.TDE and the Effective value of HCR_EL2.TGE.

(ELx)  
Means ELD is ELx. However:
- All debug exceptions other than Breakpoint Instruction exceptions are disabled from this Exception level.
- Breakpoint Instruction exceptions taken when executing in this Exception level are routed to the same Exception level. This may not be the same as the ELD Exception level.

ELx  
Means ELD is ELx.

### Table D2-3 Routing when both EL3 and EL2 are implemented

</tr>
</tbody>
</table>

### D2.3.1 Pseudocode description of routing debug exceptions

*DebugTarget()* returns the current debug target Exception level.

*DebugTargetFrom()* returns the debug target Exception level for the specified Security state.

These functions are described in Chapter J1 *ARMv8 Pseudocode*.
D2.4 Enabling debug exceptions from the current Exception level

A debug exception can only be taken if all of the following are true:

- The OS Lock is unlocked.
- `DoubleLockStatus()` == FALSE.
- The debug exception is enabled from the current Exception level.
- The debug exception is enabled from the current Security state.

Table D2-6 shows when debug exceptions are enabled from the current Exception level. In the table, $\text{EL}_D$ is the Exception level that Table D2-3 on page D2-2276 defines.

### Table D2-6 Whether debug exceptions are enabled from the current Exception level

<table>
<thead>
<tr>
<th>Current Exception level</th>
<th>Breakpoint Instruction exceptions</th>
<th>All other debug exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any Exception level that is higher than $\text{EL}_P$, $\text{EL}_D$</td>
<td>Enabled</td>
<td>Disabled</td>
</tr>
<tr>
<td></td>
<td>Enabled</td>
<td>Disabled if either of the following is true:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The Local (kernel) Debug Enable bit, $\text{MDSCR}_\text{EL1}.\text{KDE}$, is 0.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The Debug exception mask bit, $\text{PSTATE}.D$, is 1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Otherwise enabled.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This means that a debugger must explicitly enable these debug exceptions from $\text{EL}<em>D$ by setting $\text{MDSCR}</em>\text{EL1}.\text{KDE}$ to 1 and $\text{PSTATE}.D$ to 0.</td>
</tr>
<tr>
<td>Any Exception level that is lower than $\text{EL}_D$</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

Note

$\text{PSTATE}.D$ is set to 1 at reset and on exception entry.

D2.4.1 Disabling debug exceptions from Secure state

If EL3 is implemented, software executing at EL3 can set the Secure Debug Disable bit, $\text{MDCR}_\text{EL3}.\text{SDD}$, to 1 to disable all debug exceptions taken from AArch64 Secure state other than Breakpoint Instruction exceptions.

The ARMv8-A architecture does not support disabling debug in Non-secure state.

Note

- If the boot software executed when reset is deasserted sets $\text{MDCR}_\text{EL3}.\text{SDD}$ to 1, software operating at EL3 never has to switch the debug registers between Secure state and Non-secure state.
- The PE cannot take a debug exception unless it is enabled from the current Exception level. See Table D2-6.
- If either the OS Lock or the OS Double Lock is locked, debug exceptions other than Breakpoint Instruction exceptions are disabled.
- If EL3 and EL2 are not implemented, and the implementation is a Secure state only implementation, the PE behaves as if $\text{MDCR}_\text{EL3}.\text{SDD}$ is 0.

D2.4.2 Pseudocode description of enabling debug exceptions

`AArch64.GenerateDebugExceptions()` determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the current Exception level and Security state.
AArch64.GenerateDebugExceptionsFrom() determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the specified Exception level and Security state.

These functions are described in Chapter J1 ARMv8 Pseudocode.
D2.5 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences on page H6-6527 describes the powerdown save routine and the restore routine.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

If the OS Lock is unlocked, and DoubleLockStatus() == FALSE, debug exceptions other than Breakpoint Instruction exceptions are enabled.

If OS Lock is locked, or if DoubleLockStatus() == TRUE, debug exceptions other than Breakpoint Instruction exceptions are disabled.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.
D2.6 Summary of the routing and enabling of debug exceptions

Behavior is as follows:

**Breakpoint Instruction exceptions**

These are always enabled, regardless of the current Exception level and Security state. A Breakpoint Instruction exception taken from EL3 is always routed to EL3. A Breakpoint Instruction exception taken from EL2 is routed to EL2. A Breakpoint Instruction exception taken from EL0 or EL1 is always routed to ELD.

**All other debug exceptions**

Table D2-7 shows the valid combinations of MDCR_EL3.SDD, MDCR_EL2.TDE, MDSCR_EL1.KDE, and PSTATE.D, and for each combination shows where these exceptions are enabled from and where they are taken to.

In the table, n/a means not applicable and a dash, -, means that debug exceptions are disabled from that Exception level.

a. The value of (OSLSR_EL1.OSLK == ’1’ || DoubleLockStatus()).
b. If HCR_EL2.TGE is 1, this bit is treated as being 1 other than for a direct read of MDCR_EL2. If EL2 is not implemented, behavior is as if TDE is 0.
c. If EL3 is not implemented, the Effective value of MDCR_EL3.SDD is 0.
D2.7  Pseudocode description of debug exceptions

`AArch64.DebugFault()` returns a `FaultRecord` object that indicates that a memory access has generated a debug exception:

The `AArch64.Abort()` function processes `FaultRecord` objects, as described in *Abort exceptions* on page D4-2370, and generates a debug exception.

`AArch64.Abort()` calls one of the following:

- `AArch64.BreakpointException()`.
- `AArch64.WatchpointException()`.
- `AArch64.VectorCatchException()`.
- `AArch64.SoftwareStepException()`.

These functions are defined in *Chapter J1 ARMv8 Pseudocode.*
D2.8 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:
- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.

For software executing in an Exception level that is using AArch64, a Breakpoint Instruction exception results from the execution of an A64 BRK instruction. However, within the AArch64 EL1&0 translation regime, executing a T32 or A32 BKPT instruction at EL0 using AArch32 generates a Breakpoint Instruction exception.

For more information about the T32 and A32 BKPT instructions, see:
- Breakpoint instruction in the A32 and T32 instruction sets on page G2-5371.
- BKPT instructions as the first instruction in an IT block on page G2-5372.

The following subsections describe Breakpoint Instruction exceptions in an AArch64 translation regime:
- About Breakpoint Instruction exceptions.
- Breakpoint instructions.
- Exception syndrome information and preferred return address on page D2-2283.
- Pseudocode description of Breakpoint Instruction exceptions on page D2-2283.

D2.8.1 About Breakpoint Instruction exceptions

A breakpoint is an event that results from the execution of an instruction, which is based on either:
- The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
- The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Breakpoint Instruction exceptions, that this section describes, are software breakpoints. Breakpoint exceptions on page D2-2284 describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:
- The current Exception level.
- The current Security state.
- Whether the debug target Exception level, EL_D, is using AArch64 or AArch32.

Note
- The debug target Exception level, EL_D, is the Exception level that debug exceptions are targeting. Routing debug exceptions on page D2-2275 describes how EL_D is derived.
- Debuggers using breakpoint instructions must be aware of the ARMv8 rules for concurrent modification and execution of instructions. See Concurrent modification and execution of instructions on page B2-94.

D2.8.2 Breakpoint instructions

The breakpoint instruction in the A64 instruction set is BRK #<immediate>. It is unconditional.

For details of the instruction encoding, see BRK on page C6-742.

The breakpoint instruction in the A32 and T32 instruction sets is BKPT #<immediate>.

For more information about the A32 and T32 breakpoint instruction, see Breakpoint instruction in the A32 and T32 instruction sets on page G2-5371.
D2.8.3 Exception syndrome information and preferred return address

See the following:

- Exception syndrome information.
- Preferred return address.

Exception syndrome information

On taking a Breakpoint Instruction exception, the PE records information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- ESR_EL1.
- ESR_EL2.
- ESR_EL3.

--- Note ---

Breakpoint Instruction exceptions are the only debug exception that can be taken to EL3 using AArch64.

--- Table D2-8 shows the information that the PE records. ---

<table>
<thead>
<tr>
<th>ESR_ELx field</th>
<th>Information recorded in ESR_EL1, ESR_EL2, or ESR_EL3.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception Class, EC</td>
<td>Whether the breakpoint instruction was executed in AArch64 state or AArch32 state. The PE sets this to:</td>
</tr>
<tr>
<td></td>
<td>• 0x3C for an A64 BRK instruction.</td>
</tr>
<tr>
<td></td>
<td>• 0x38 for an A32 or T32 BKPT instruction.</td>
</tr>
<tr>
<td>Instruction Length, IL</td>
<td>The PE sets this to:</td>
</tr>
<tr>
<td></td>
<td>• 0 for a 16-bit T32 BKPT instruction.</td>
</tr>
<tr>
<td></td>
<td>• 1 for an A64 BRK instruction, or an A32 BKPT instruction.</td>
</tr>
<tr>
<td>Instruction Specific Syndrome, ISS</td>
<td>The PE copies the instruction Comment field value into here, zero extended as necessary.</td>
</tr>
<tr>
<td>ISS[24:16]</td>
<td>RES0.</td>
</tr>
<tr>
<td>ISS[15:0]</td>
<td>RES0.</td>
</tr>
</tbody>
</table>

--- Note ---

- If debug exceptions are routed to EL2, it is the exception that is routed, not the instruction that is trapped. Therefore, if a Breakpoint Instruction exception is routed to EL2, ESR_EL2.EC is set to the same value as if the exception was taken to EL1.
- For information about how debug exceptions can be routed to EL2, see Routing debug exceptions on page D2-2275.

Preferred return address

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like SVC.

D2.8.4 Pseudocode description of Breakpoint Instruction exceptions

AArch64.SoftwareBreakpoint() generates a Breakpoint Instruction exception that is taken to AArch64 state.

This function is defined in Chapter J1 ARMv8 Pseudocode.
D2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:
• In an Exception level that is using AArch64.
• At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:
• About Breakpoint exceptions.
• Breakpoint types and linking of breakpoints on page D2-2285.
• Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2293.
• Breakpoint instruction address comparisons on page D2-2295.
• Breakpoint context comparisons on page D2-2296.
• Breakpoint usage constraints on page D2-2297.
• Exception syndrome information and preferred return address on page D2-2300.
• Pseudocode description of Breakpoint exceptions taken from AArch64 state on page D2-2300.

D2.9.1 About Breakpoint exceptions

A breakpoint is an event that results from the execution of an instruction, which is based on either:
• The instruction address, the PE context, or both. This type of breakpoint is called a hardware breakpoint.
• The instruction itself. That is, the instruction is a breakpoint instruction. These can be included in the program that the PE executes. This type of breakpoint is called a software breakpoint.

Breakpoint exceptions are generated by Breakpoint debug events. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in Breakpoint Instruction exceptions on page D2-2282.

An implementation can include between 2-16 hardware breakpoints. ID_AA64DFR0_EL1.BRPs shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:
• The Breakpoint Control Register, DBGBCR<\text{n}>_EL1. This contains controls for the breakpoint, for example an enable control.
• The Breakpoint Value Register, DBGVBV<\text{n}>_EL1. This holds the value used for breakpoint matching, that is one of:
  — An instruction virtual address.
  — A Context ID.
  — A VMID value.
  — A concatenation of both a Context ID value and a VMID value.

These registers are numbered, so that:
• DBGBCR1_EL1 and DBGVBV1_EL1 are for breakpoint number one.
• DBGBCR2_EL1 and DBGVBV2_EL1 are for breakpoint number two.
• …
• …
• DBGBCR<\text{n}>_EL1 and DBGVBV<\text{n}>_EL1 are for breakpoint number n.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:
• The breakpoint is enabled. That is, the breakpoint enable control for it, DBGBCR<\text{n}>_EL1.E, is 1.
• The conditions specified in the DBGBCR<\text{n}>_EL1 are met.
• The comparison with the value held in the DBGBVR<n>_EL1 is successful.
• If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
• The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:
• Whether the instruction passes its Condition code check.
• The instruction type.

If halting is allowed and EDSCR.HDE is 1, Breakpoint debug events cause entry to Debug state. Otherwise, if debug exceptions are:
• Enabled, Breakpoint debug events generate Breakpoint exceptions.
• Disabled, Breakpoint debug events are ignored.

Note
The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions. However, the behavior described also applies if breakpoints are causing entry to Debug state.

The debug exception enable controls on page D2-2274 describes the enable controls for Breakpoint debug events.

D2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:
• A context-aware breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  — An instruction address match.
  — A Context ID match, with the value held in the CONTEXTIDR_EL1.
  — A VMID match, with the VMID value held in the VTTBR_EL2.
  — Both a Context ID match and a VMID match.
• A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match.

ID_AA64DFR0_EL1.CTX_CMPs shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match is categorized as an Address breakpoint. Breakpoints that are programmed to match on anything else are categorized as Context breakpoints.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:
• Used in isolation. In this case, the breakpoint is called an Unlinked breakpoint.
• Enabled for linking to another breakpoint. In this case, the breakpoint is called a Linked breakpoint.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match occurs. For example, a debugger might:
1. Program breakpoint number one to be a Linked Address Match breakpoint.
2. Program breakpoint number five to be a Linked Context ID Match breakpoint.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The Breakpoint Type field for a breakpoint, DBGBCR<\(n\)>_EL1.BT, controls the breakpoint type and whether the breakpoint is enabled for linking. If BT[0] is 1, the breakpoint is enabled for linking.

If AArch32 state is implemented, Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See Specifying the halfword-aligned address that an Address breakpoint matches on page D2-2295.

Note
Stage 1 of an AArch32 translation regimes supports two additional breakpoint types, Unlinked and Linked Address Mismatch breakpoints, BT == 0b0100 and BT == 0b101. For information about these, see Chapter G2 AArch32 Self-hosted Debug. These types are reserved in stage 1 of an AArch64 translation regime. See Reserved BT values on page D2-2297.

Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.
- Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, DBGBCR<\(n\)>_EL1.LBN, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
  - DBGBCR<\(n\)>_EL1.{SSC, HMC, PMC} for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2293.
  - DBGBCR<\(n\)>_EL1.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.
- Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.
- Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.
- If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See Other usage constraints for Address breakpoints on page D2-2299.
- If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.
- Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

Note
Multiple Linked watchpoints can also link to a single Linked Context breakpoint. Watchpoint exceptions on page D2-2302 describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:
- Multiple Linked Address Match breakpoints.
- Multiple Linked watchpoints.

Note
If ARMv8.4-NV is implemented, the hypervisor must use the 0b1101, Linked CONTEXTIDR_EL2 Match breakpoint type to guarantee a linked match, see Interaction with self-hosted and External debug on page D5-2485.
It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

Figure D2-1 shows an example of permitted breakpoint and watchpoint linking.

In Figure D2-1, each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

**Breakpoint types defined by DBGBCRn_EL1.BT**

The following list provides more detail about each breakpoint type:

- **0b0000, Unlinked Address Match breakpoint**
  
  Generation of a Breakpoint exception depends on both:
  
  - **DBGBCR<n>_EL1.(SSC, HMC, PMC)**. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See **Execution conditions for which a breakpoint generates Breakpoint exceptions** on page D2-2293.
  
  - A successful address match, as described in **Breakpoint instruction address comparisons** on page D2-2295.

  **DBGBCR<n>_EL1.LBN** for this breakpoint is ignored.
0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<ν>_EL1.(SSC, HMC, PMC)** for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2293.
- A successful address match defined by this breakpoint, as described in *Breakpoint instruction address comparisons* on page D2-2295.
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

**DBGBCR<ν>_EL1.LBN** for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0010, Unlinked Context ID Match breakpoint

BT == 0b0010 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<ν>_EL1.(SSC, HMC, PMC)**. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2293.
- A successful Context ID match, as described in *Breakpoint context comparisons* on page D2-2296.

The value of DBGBVR<ν>_EL1.ContextID is compared with the current Context ID.

**CONTEXTIDR_EL2** holds the current Context ID when all of:

- The implementation includes ARMv8.1-VHE.
- EL2 is implemented and enabled in the current Security state.
- EL2 using AArch64 and **HCR_EL2.E2H** is set to 1.
- The PE is executing at EL0 and **HCR_EL2.TGE** is 1, or the PE is executing at EL2.

Otherwise, **CONTEXTIDR_EL1** holds the current Context ID.

**DBGBCR<ν>_EL1.(LBN, BAS)** for this breakpoint are ignored.

0b0011, Linked Context ID Match breakpoint

BT == 0b0011 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see *Breakpoint instruction address comparisons* on page D2-2295.
  - A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons* on page D2-2296.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons* on page D2-2307.
  - A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons* on page D2-2296.

The value of DBGBVR<ν>_EL1.ContextID is compared with the current Context ID.

**CONTEXTIDR_EL2** holds the current Context ID when all of:

- The implementation includes ARMv8.1-VHE.
- EL2 is implemented and enabled in the current Security state.
- EL2 using AArch64 and **HCR_EL2.E2H** is set to 1.
• The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2. Otherwise, CONTEXTIDR_EL1 holds the current Context ID. DBGBCR<el1>({LBN, SSC, HMC, BAS, PMC}) for this breakpoint are ignored.

0b0100, Unlinked Address Mismatch breakpoint

BT == 0b0100 is a reserved value in stage 1 of an AArch64 translation regime. See Reserved BT values on page D2-2297.

0b0100, Unlinked Address Mismatch breakpoint on page G2-5379 describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

0b0101, Linked Address Mismatch breakpoint

BT == 0b0101 is a reserved value in stage 1 of an AArch64 translation regime. See Reserved BT values on page D2-2297.

0b0101, Linked Address Mismatch breakpoint on page G2-5379 describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

0b0110, Unlinked CONTEXTIDR_EL1 Match breakpoint

BT == 0b0110 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• The implementation does not include ARMv8.1-VHE.

In an implementation that includes ARMv8.1-VHE, for context-aware breakpoints, generation of a Breakpoint exception depends on both:
• DBGBCR<el1>({SSC, HMC, PMC}). These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
• A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2296.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGBVR<el1>.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1.

Note

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

0b0111, Linked CONTEXTIDR_EL1 Match breakpoint

BT == 0b0111 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• The implementation does not include ARMv8.1-VHE.

In an implementation that includes ARMv8.1-VHE, for context-aware breakpoints, one of the following applies:
• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-2295.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2296.
• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-2307.
D2 AArch64 Self-hosted Debug

D2.9 Breakpoint exceptions

— A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2296.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGVR<n>_EL1.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1.

Note

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGVR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1000, Unlinked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:
• DBGVR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2293.
• A successful VMID match, as described in Breakpoint context comparisons on page D2-2296.

DBGVR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1001, Linked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:
• The breakpoint is not a context-matching breakpoint.
• EL2 is not implemented.

For context-aware breakpoints, one of the following applies:
• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
• Generation of a Breakpoint exception depends on both:
  — A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See Breakpoint instruction address comparisons on page D2-2295.
  — A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2296.
• Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-2307.
  — A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons on page D2-2296.

DBGVR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1010, Unlinked Context ID and VMID Match breakpoint

BT == 0b1010 is a reserved value if either:
• The breakpoint is not a context-aware breakpoint.
• EL2 is not implemented.

When EL2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on all of the following:
• DBGVR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates a Breakpoint exception for. See Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-2293.
• A successful Context ID match, as described in *Breakpoint context comparisons on page D2-2296.*

• A successful VMID match.

The value of $\text{DBGBVR}_n._\text{EL1}.\text{ContextID}$ is compared with $\text{CONTEXTIDR}_\text{EL1}$. *Breakpoint context comparisons on page D2-2296* describes the requirements for a successful Context ID match and a successful VMID match.

$\text{DBGBCR}_n._\text{EL1}.\{\text{LBN, BAS}\}$ for this breakpoint are ignored.

### 0b1011, Linked Context ID and VMID Match breakpoint

**BT == 0b1011** is a reserved value if either:

• The breakpoint is not a context-aware breakpoint.

• EL2 is not implemented.

When EL2 is implemented, for context-aware breakpoints, one of the following applies:

• If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.

• Generation of a Breakpoint exception depends on all of the following:
  — A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see *Breakpoint instruction address comparisons on page D2-2295.*
  — A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons on page D2-2296.*
  — A successful VMID match defined by this breakpoint.

• Generation of a Watchpoint exception depends on all of the following:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons on page D2-2307.*
  — A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons on page D2-2296.*
  — A successful VMID match defined by this breakpoint.

The value of $\text{DBGBVR}_n._\text{EL1}.\text{ContextID}$ is compared with $\text{CONTEXTIDR}_\text{EL1}$. *Breakpoint context comparisons on page D2-2296* describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

$\text{DBGBCR}_n._\text{EL1}.\{\text{LBN, SSC, HMC, BAS, PMC}\}$ for this breakpoint are ignored.

### 0b1100, Unlinked CONTEXTIDR_EL2 Match breakpoint

**BT == 0b1100** is a reserved value if either:

• The breakpoint is not a context-aware breakpoint.

• The implementation does not include ARMv8.1-VHE.

In an implementation that includes ARMv8.1-VHE, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

• $\text{DBGBCR}_n._\text{EL1}.\{\text{SSC, HMC, PMC}\}$. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.

• A successful $\text{CONTEXTIDR}_\text{EL2}$ match, as described in *Breakpoint context comparisons on page D2-2296.*

The Context ID check is made against the value in $\text{CONTEXTIDR}_\text{EL2}$. The value of $\text{DBGBVR}_n._\text{EL1}$ is compared with the Context ID value held in $\text{CONTEXTIDR}_\text{EL2}$.

#### Note

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

$\text{DBGBCR}_n._\text{EL1}.\{\text{LBN, BAS}\}$ for this breakpoint are ignored.
0b1101, Linked CONTEXTIDR_EL2 Match breakpoint

BT == 0b1101 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include ARMv8.1-VHE.

In an implementation that includes ARMv8.1-VHE, for context-aware breakpoints, either:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-2295.
  - A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons on page D2-2296.

- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-2307.
  - A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons on page D2-2296.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

Note

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

0b1110, Unlinked Full Context ID Match breakpoint

BT == 0b1110 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include ARMv8.1-VHE.

In an implementation that includes ARMv8.1-VHE, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, BAS, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in Breakpoint context comparisons on page D2-2296.

The Context ID check is made against the values in both CONTEXTIDR_EL1 and CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1[31:0] is compared with the Context ID value held in CONTEXTIDR_EL1, and the value of DBGBVR<n>_EL1[63:32] is compared with the Context ID value held in CONTEXTIDR_EL2. Both comparisons must match for the Context ID check.

Note

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

0b1111, Linked Full Context ID Match breakpoint

BT == 0b1111 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include ARMv8.1-VHE.
In an implementation that includes ARMv8.1-VHE, for context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.

- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons on page D2-2295.
  - A successful Context ID match, as described in Breakpoint context comparisons on page D2-2296.

- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons on page D2-2307.
  - A successful Context ID match, as described in Breakpoint context comparisons on page D2-2296.

The Context ID check is made against the values in both CONTEXTIDR_EL1 and CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1[31:0] is compared with the Context ID value held in CONTEXTIDR_EL1, and the value of DBGBVR<n>_EL1[63:32] is compared with the Context ID value held in CONTEXTIDR_EL2. Both comparisons must match for the Context ID check.

Note

The operation of this breakpoint does not depend on the value of HCR_EL2.E2H.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

Note

See Reserved DBGBCR<n>_EL1.BT values on page D2-2297 for the behavior of breakpoints programmed with reserved BT values.

**D2.9.3 Execution conditions for which a breakpoint generates Breakpoint exceptions**

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at EL0 in Secure state.

DBGBCR<n>_EL1.{SSC, HMC, PMC} defines the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

**Security State Control, SSC**

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

Note

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the breakpoint is set.

**Higher Mode Control, HMC, and Privileged Mode Control, PMC**

HMC and PMC together control which Exception levels the breakpoint generates Breakpoint exceptions in.

Table D2-9 on page D2-2294 shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Exception levels breakpoints generate Breakpoint exceptions in.
In the table:

Y  Means that a breakpoint programmed with the values of HMC, SSC, and PMC shown in that row can generate Breakpoint exceptions in that Exception level and Security state.

-  Means that a breakpoint programmed with the values of HMC, SSC, and PMC shown in that row cannot generate Breakpoint exceptions in that Exception level and Security state.

For information about which combinations of HMC, SSC and PMC are reserved if an Exception level or Security state are not implemented or enabled, see Reserved DBGBCR<n>_EL1\{SSC, HMC, PMC\} values on page D2-2298.

a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at EL3 using AArch64.
D2.9.4 Breakpoint instruction address comparisons

In this subsection, the term maxAddressSize represents the maximum supported virtual address size, which is 52 bits in an implementation that includes ARMv8.2-LVA and uses the 64KB translation granule, and 48 bits otherwise.

An address comparison is successful if bits [maxAddressSize:2] of the current instruction virtual address are equal to DBGBVR<n>_EL1[maxAddressSize:2].

--- Note ---

DBGBVR<n>_EL1 is a 64-bit register. The most significant bits of this register are sign-extension bits. DBGBVR<n>_EL1[1:0] are RES0 and are ignored.

---

If EL1 is using AArch64 and EL0 is using AArch32, A32 and T32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, the instruction addresses are zero-extended before comparison with the breakpoint.

Specifying the halfword-aligned address that an Address breakpoint matches on

For Address Match breakpoints, if the implementation supports AArch32 state, a debugger must program the Byte Address Selection field, DBGBCR<n>_EL1.BAS.

Table D2-10 Programmable BAS values

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0011</td>
<td>DBGBCR&lt;n&gt;_EL1</td>
<td>Use for T32 instructions.</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBCR&lt;n&gt;_EL1 + 2</td>
<td>Use for T32 instructions.</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBCR&lt;n&gt;_EL1</td>
<td>Use for A64 and A32 instructions.</td>
</tr>
</tbody>
</table>

If the implementation is an AArch64-only implementation, all instructions are word-aligned and DBGBCR<n>_EL1.BAS is RES1.

Figure D2-2 on page D2-2296 shows a summary of when Address Match breakpoints programmed with particular BAS values generate Breakpoint exceptions. The figure contains four parts:

• A column showing the row number, on the left.
• An instruction set and instruction size table.
• A location of instruction figure.
• A BAS field values table, on the right.

To use the figure, read across the rows. For example, row 7 shows that a breakpoint with DBGBCR<n>_EL1.BAS programmed as either 0b0011 or 0b1111 generates Breakpoint exceptions for A64 instructions. A64 instructions are always at word-aligned addresses.

--- Note ---

To breakpoint on an A64 instruction, ARM recommends that the debugger programs DBGBCR<n>_EL1.BAS as 0b1111.

---

In the figure:

Yes Means that the breakpoint generates a Breakpoint exception.
No Means that the breakpoint does not generate a Breakpoint exception.
UNP Means that it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints on page D2-2299.
D2.9.5 Breakpoint context comparisons

The breakpoint type defined by DBGBCR<n>.BT determines what context comparison is required, if any. Table D2-11 shows the BT values that require a comparison, and the match required for the comparison to be successful.

Table D2-11 Breakpoint Context ID and VMID comparison tests

<table>
<thead>
<tr>
<th>DBGBCR&lt;n&gt;.BT</th>
<th>Test required for successful context comparison</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b001x</td>
<td>When ARMv8.1-VHE is implemented, EL2 is using AArch64, the Effective value of HCR_EL2.E2H is 1, and either the PE is executing at EL0 with HCR_EL2.TGE set to 1, or the PE is executing at EL2, CONTEXTIDR_EL2 must match the DBGBVR&lt;n&gt;_EL1.ContextID value. Otherwise, CONTEXTIDR_EL1 must match the DBGBVR&lt;n&gt;_EL1.ContextID value.</td>
</tr>
<tr>
<td>0b011x</td>
<td>CONTEXTIDR_EL1 must match the DBGBVR&lt;n&gt;_EL1.ContextID value.</td>
</tr>
<tr>
<td>0b100x</td>
<td>VTTBR_EL2.VMID must match the DBGBVR&lt;n&gt;_EL1.VMID value.</td>
</tr>
<tr>
<td>0b101x</td>
<td>CONTEXTIDR_EL1 must match the DBGBVR&lt;n&gt;_EL1.ContextID value and VTTBR_EL2.VMID must match the DBGBVR&lt;n&gt;_EL1.VMID value.</td>
</tr>
<tr>
<td>0b110x</td>
<td>CONTEXTIDR_EL2 must match the DBGBVR&lt;n&gt;_EL1.ContextID2 value, DBGBVR&lt;n&gt;_EL1[63:32].</td>
</tr>
<tr>
<td>0b111x</td>
<td>Both: CONTEXTIDR_EL1 must match the DBGBVR&lt;n&gt;_EL1.ContextID value, DBGBVR&lt;n&gt;_EL1[31:0]. CONTEXTIDR_EL2 must match the DBGBVR&lt;n&gt;_EL1.ContextID2 value, DBGBVR&lt;n&gt;_EL1[63:32].</td>
</tr>
</tbody>
</table>

No Context ID or VMID comparison is required for other valid DBGBCR<n>.BT values.

Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of CONTEXTIDR_EL1 and any of:
  - The PE is executing at EL3 using AArch64.
  - The PE is executing at EL2.
ARMv8.1-VHE is implemented, EL2 is using AArch64, the PE is executing in Non-secure state, and HCR_EL2.{E2H, TGE} == {1, 1}.

- The comparison uses the value of CONTEXTIDR_EL2 and any of:
  - ARMv8.1-VHE is not implemented.
  - If ARMv8.4-SecEL2 is not implemented, the PE is in Secure state.
  - EL2 is using AArch32.

- The comparison uses the current VMID value and any of:
  - EL2 is not implemented.
  - If ARMv8.4-SecEL2 is not implemented, the PE is in Secure state.
  - The PE is executing at EL2.
  - ARMv8.1-VHE is implemented, EL2 is using AArch64, the PE is executing in Non-secure state, and HCR_EL2.{E2H, TGE} == {1, 1}.

The following Context breakpoint types do not generate Breakpoint exceptions if EL2 is not implemented or not enabled in the current Security state:

- VMID Match breakpoints.
- VMID and Context ID Match breakpoints.

Note

- For all Context breakpoints, DBGBCR<n>_EL1.BAS is RES1 and is ignored.
- For Linked Context breakpoints, DBGBCR<n>_EL1.{LBN, SSC, HMC, PMC} are RES0 and are ignored.

### D2.9.6 Breakpoint usage constraints

See the following sections:

- Reserved DBGBCR<n>_EL1.BT values.
- Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values on page D2-2298.
- Reserved DBGBCR<n>_EL1.BAS values on page D2-2299.
- Reserved DBGBCR<n>_EL1.LBN values on page D2-2299.
- Other usage constraints for Address breakpoints on page D2-2299.
- Other usage constraints for Context breakpoints on page D2-2300.

#### Reserved DBGBCR<n>_EL1.BT values

Table D2-12 shows when particular DBGBCR<n>_EL1.BT values are reserved.

<table>
<thead>
<tr>
<th>BT value</th>
<th>Breakpoint type</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>

<td>If ARMv8.1-VHE is not implemented, or the breakpoint is not context-aware</td>
</tr>
<tr>
<td>0b111x</td>
<td>Full Context ID Match</td>
<td>If ARMv8.1-VHE is not implemented, or the breakpoint is not context-aware</td>
</tr>
</tbody>
</table>
If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BT value that is not reserved, other than for a direct or external read of \texttt{DBGBCR<n>\_EL1}.

- For a direct or external read of \texttt{DBGBCR<n>\_EL1}, if the reserved BT value:
  - Has no function for any execution conditions, the value read back is \texttt{UNKNOWN}.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values**

Table D2-13 shows when particular combinations of \texttt{DBGBCR<n>_EL1.{SSC, HMC, PMC}} are reserved in stage 1 of an AArch64 translation regime.

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to \texttt{0b01} or \texttt{0b10}, except for the combination with HMC set to 1, SSC set to \texttt{0b01}, and PMC set to \texttt{0b00}</td>
<td>When EL3 is not implemented and EL2 is implemented</td>
</tr>
<tr>
<td>Any combination where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to \texttt{0b01}, and PMC set to \texttt{0b00}, or combinations when SSC is set to \texttt{0b11}</td>
<td>When both of EL2 and EL3 are not implemented</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to \texttt{0b11}, and PMC set to \texttt{0b00}</td>
<td>When EL2 is not implemented</td>
</tr>
<tr>
<td>The combinations with SSC set to \texttt{0b11} except the combination with HMC set to 1, SSC set to \texttt{0b11} and PMC set to \texttt{0b00}</td>
<td>When Secure EL2 is not implemented</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to \texttt{0b01} and PMC set to \texttt{0b00}</td>
<td>When Secure EL2 is not implemented</td>
</tr>
<tr>
<td>Combinations not included in Table D2-9 on page D2-2294</td>
<td>Always</td>
</tr>
</tbody>
</table>

For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
  - The breakpoint must behave as if it is is disabled.
  - A direct or external read of \texttt{DBGBCR<n>_EL1.{SSC, HMC, PMC}} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.

- If the reserved combination does not have a function for other execution conditions:
  - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
  - A direct or external read of \texttt{DBGBCR<n>_EL1.{SSC, HMC, PMC}} returns \texttt{UNKNOWN} values.

If the breakpoint is a Linked Context breakpoint, then:

- The values of HMC, SSC, and PMC are ignored.
• A direct or external read of \texttt{DBGBCR<n>\_EL1.\{SSC, HMC, PMC\}} returns UNKNOWN values

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved DBGBCR<n>\_EL1.BAS values**

In an AArch64-only implementation, \texttt{DBGBCR<n>\_EL1.BAS} for all breakpoints is \texttt{RES1}.

Otherwise:

**For all Context breakpoints**

\texttt{DBGBCR<n>\_EL1.BAS} is \texttt{RES1} and is ignored.

**For all Address breakpoints**

Table D2-10 on page D2-2295 gives the valid values of the \texttt{DBGBCR<n>\_EL1.BAS} field.

If a breakpoint is programmed with a reserved BAS value:

• The breakpoint must behave as if it is either:
  — Disabled.
  — Programmed with a BAS value that is not reserved, other than for a direct or external read of \texttt{DBGBCR<n>\_EL1}.

• A direct or external read of \texttt{DBGBCR<n>\_EL1.BAS} returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

**Reserved DBGBCR<n>\_EL1.LBN values**

**For all Context breakpoints**

\texttt{DBGBCR<n>\_EL1.LBN} reads UNKNOWN and its value is ignored.

**For Linked Address breakpoints**

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any \texttt{DBGBCR<n>\_EL1.LBN} value that is not for a context-aware breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of \texttt{DBGBCR<n>\_EL1.LBN} return an unknown value and behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

• Disabled.

• Linked to an UNKNOWN context-aware breakpoint.

If a Linked Address breakpoint links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

**For Unlinked Address breakpoints**

\texttt{DBGBCR<n>\_EL1.LBN} reads UNKNOWN and its value is ignored.

**Other usage constraints for Address breakpoints**

**For all Address breakpoints**

• \texttt{DBGBVR<n>\_EL1[1:0]} are \texttt{RES0} and are ignored.

• If the implementation supports AArch32 state:
  — For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
If DBGBCR<n>.BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address \((DBGBVR<n>[48:2]:00) + 2\). For T32 instructions, ARM recommends that the debugger programs the BAS field with either 0b0011 or 0b1100.

Other usage constraints for Context breakpoints

For all Context breakpoints

Any bits of DBGBVR<n>_EL1 that are not used to specify Context ID or VMID are RES0 and are ignored.

For Linked Context breakpoints

If no Linked Address breakpoints or Linked watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

D2.9.7 Exception syndrome information and preferred return address

See the following:

• Exception syndrome information.
• Preferred return address.

Exception syndrome information

On taking a Breakpoint exception, the PE records information about the exception in the Exception Syndrome Register (ESR_ELx) at the Exception level the exception is taken to. See ISS encoding for an exception from a Breakpoint or Vector Catch debug exception on page D12-2789 for more information.

Preferred return address

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.9.8 Pseudocode description of Breakpoint exceptions taken from AArch64 state

AArch64.BreakpointValueMatch() tests the value in DBGBVR<n>_EL1.

AArch64.StateMatch() tests the values in DBGBCR<n>_EL1.{SSC, HMC, PMC} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

For a watchpoint, AArch64.StateMatch() tests the values in DBGWCR<n>_EL1.{SSC, HMC, PAC} and, if the watchpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

AArch64.BreakpointMatch() tests a committed instruction against all breakpoints.

AArch64.CheckBreakpoint() generates a Breakpoint exception if all of the following are true:

• MDSCR_EL1.MDE is 1.

• Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level on page D2-2277.

• All of the conditions required for Breakpoint exception generation are met. See About Breakpoint exceptions on page D2-2284.

Note

AArch64.CheckBreakpoint() might halt the PE and cause it to enter Debug state. External debug uses Debug state.
AArch64.BreakpointException() is called to generate a Breakpoint exception.

These functions are defined in Chapter J1 ARMv8 Pseudocode.
D2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:
• In an Exception level that is using AArch64.
• At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:
• About Watchpoint exceptions.
• Watchpoint types and linking of watchpoints on page D2-2303.
• Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-2304.
• Watchpoint data address comparisons on page D2-2307.
• Determining the memory location that caused a Watchpoint exception on page D2-2310.
• Watchpoint behavior on other instructions on page D2-2311.
• Watchpoint usage constraints on page D2-2312.
• Exception syndrome information and preferred return address on page D2-2314.
• Pseudocode description of Watchpoint exceptions taken from AArch64 state on page D2-2315.

D2.10.1 About Watchpoint exceptions

A watchpoint is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as data breakpoints.

A watchpoint operates as follows:
1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a Watchpoint debug event on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, ID_AA64DFR0_EL1.WRPs shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:
• The Watchpoint Control Register, DBGWCR<\(n\)>_EL1. This contains controls for the watchpoint, for example an enable control.
• The Watchpoint Value Register, DBGWVR<\(n\)>_EL1. This holds the data virtual address used for watchpoint matching.

These registers are numbered, so that:
• DBGWCR1_EL1 and DBGWVR1_EL1 are for watchpoint number one.
• DBGWCR2_EL2 and DBGWVR2_EL1 are for watchpoint number two.
• …
• …
• DBGWCR<\(n\)>_EL1 and DBGWVR<\(n\)>_EL1 are for watchpoint number \(n\).

A watchpoint can:
• Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
• Link to a Linked Context breakpoint, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.
A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the Byte Address Select field, DBGWCR<n>_EL1.BAS, to select the bytes. See Programming a watchpoint with eight bytes or fewer on page D2-2308.

- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.

A debugger uses the MASK field, DBGWCR<n>_EL1.MASK, to program a watchpoint with eight bytes to 2GB. See Programming a watchpoint with eight or more bytes on page D2-2309.

A debugger must use either the BAS field or the MASK field. If it uses both, whether the watchpoint generates Watchpoint debug events is CONSTRAINED UNPREDICTABLE. See Programming dependencies of the BAS and MASK fields on page D2-2313.

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, DBGWCR<n>_EL1.E, is 1.
- The conditions specified in the DBGWCR<n>_EL1 are met.
- The comparison with the address held in the DBGWVR<n>_EL1 is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint also are successful. See Figure D2-1 on page D2-2287. See also Breakpoint context comparisons on page D2-2296.
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its Condition code check.

If halting is allowed and EDSCR.HDE is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

Note

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.

However, the behavior described also applies if watchpoints are causing entry to Debug state.

The debug exception enable controls on page D2-2274 describes the enable controls for Watchpoint debug events.

D2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case, the watchpoint is called an Unlinked watchpoint.
- Enabled for linking to a Linked Context breakpoint. In this case, the watchpoint is called a Linked watchpoint.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a Linked VMID Match breakpoint.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the VMID matches.

The Watchpoint Type field for a watchpoint, `DBGWCR<n>_EL1.WT`, controls whether the watchpoint is enabled for linking. If `DBGWCR<n>_EL1.WT` is 1, the watchpoint is enabled for linking.

### Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The Linked Breakpoint Number field, `DBGWCR<n>_EL1.LBN`, for the linked watchpoint specifies the particular Linked Context breakpoint that the linked watchpoint links to, and:
  - `DBGWCR<n>_EL1.WT.{SSC, HMC, PAC}` for the linked watchpoint defines the execution conditions that the watchpoint generates Watchpoint exceptions for. See Execution conditions for which a watchpoint generates Watchpoint exceptions.
  - `DBGBCR<n>_EL1.{SSC, HMC, PMC}` for the Linked Context breakpoint are ignored.
- A linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a linked watchpoint links to a breakpoint that is not context-aware, the behavior of the linked watchpoint is CONSTRAINED UNPREDICTABLE. See Watchpoint usage constraints on page D2-2312.
- If a linked watchpoint links to an Unlinked Context breakpoint, the linked watchpoint never generates any Watchpoint exceptions.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

Note

Multiple Address breakpoints can also link to a single Linked Context breakpoint. Breakpoint exceptions on page D2-2284 describes breakpoints.

Figure D2-1 on page D2-2287 shows an example of permitted watchpoint linking.

### D2.10.3 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at EL2 in Non-secure state.

`DBGWCR<n>_EL1.{SSC, HMC, PAC}` define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

**Security State Control, SSC**

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

Note

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the watchpoint is set.

**Higher Mode Control, HMC, and Privileged Access Control, PAC**

HMC and PAC together control which Exception levels the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access, not to the Exception level at which the access was made.
Note

This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at EL1, the resulting data access triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on EL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A64 Load unprivileged and Store unprivileged instructions are LDTR and STTR.

Table D2-14 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Exception levels watchpoints generate Watchpoint exceptions in.

In the table:

Y or - Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:

Y Can generate Watchpoint exceptions in that Exception level and Security state.
- Cannot generate Watchpoint exceptions in that Exception level and Security state.

For information about which combinations of HMC, SSC and PMC are reserved if an Exception level or Security state are not implemented or enabled, see Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values on page D2-2312.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See Reserved DBGWCR<\text{n}>_EL1_[SSC, HMC, PAC] values on page D2-2312.
D2.10.4 Watchpoint data address comparisons

In this subsection, the term `maxAddressSize` represents the maximum supported virtual address size, which is:

- 52 bits in an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule.
- 48 bits otherwise.

An address comparison is successful if bits `[maxAddressSize:2]` of the current data virtual address are equal to `DBGWVR<n>_EL1[maxAddressSize:2]`, taking into account all of the following:

- The size of the access. See Size of the data access.

  If EL1 is using AArch64 and EL0 is using AArch32, AArch32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, data addresses are zero-extended before comparison with the watchpoint.

- The bytes selected by `DBGWVR<n>_EL1.BAS`. See Programming a watchpoint with eight bytes or fewer on page D2-2308.

- Any address ranges indicated by `DBGWVR<n>_EL1.MASK`. See Programming a watchpoint with eight or more bytes on page D2-2309.

---

**Note**

- `DBGWVR<n>_EL1` is a 64-bit register. The most significant bits of this register are sign-extension bits.
- `DBGWVR<n>_EL1[1:0]` are RES0 and are ignored

---

Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each data access must be taken into account. See Example D2-1.

**Example D2-1**

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address 0x1009 is accessed.
2. The PE accesses the unaligned doubleword starting at address 0x1003.

In this scenario, the watchpoint must generate a Watchpoint exception.

The size of data accesses initiated by `DC ZVA` instructions is the DC ZVA block size that `DCZID_EL0.BS` defines.

The size of data accesses initiated by `DC IVAC` instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
  - The size that `CTR_EL0.DminLine` defines.
  - 2KB.
- A power-of-two.

For both of these instructions:

- The lowest address accessed by the instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.
- The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction on page D2-2312.
Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, DBGWCR<\(n\)\_EL1.BAS, selects which bytes in the doubleword starting at the address contained in the DBGWVR<\(n\)\_EL1 the watchpoint generates Watchpoint exceptions for.

If the address programmed into the DBGWVR<\(n\)\_EL1 is:

- Doubleword-aligned:
  - All eight bits of DBGWCR<\(n\)\_EL1.BAS are used, and the descriptions given in Table D2-15 apply.

- Word-aligned but not doubleword-aligned:
  - Only DBGWCR<\(n\)\_EL1.BAS[3:0] are used, and the descriptions given in Table D2-16 apply. In this case, DBGWCR<\(n\)\_EL1.BAS[7:4] are RES0.

If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see Other usage constraints on page D2-2314.

### Table D2-15 Supported BAS values when the DBGWVRn\_EL1 address alignment is doubleword

<table>
<thead>
<tr>
<th>BAS value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000000</td>
<td>Watchpoint never generates a Watchpoint exception.</td>
</tr>
<tr>
<td>BAS[0] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;(n)_EL1[maxAddressSize(a)_3]:000 is accessed.</td>
</tr>
<tr>
<td>BAS[1] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;(n)_EL1[maxAddressSize(a)_3]:001 is accessed.</td>
</tr>
<tr>
<td>BAS[2] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;(n)_EL1[maxAddressSize(a)_3]:010 is accessed.</td>
</tr>
<tr>
<td>BAS[3] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;(n)_EL1[maxAddressSize(a)_3]:011 is accessed.</td>
</tr>
<tr>
<td>BAS[4] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;(n)_EL1[maxAddressSize(a)_3]:100 is accessed.</td>
</tr>
<tr>
<td>BAS[5] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;(n)_EL1[maxAddressSize(a)_3]:101 is accessed.</td>
</tr>
<tr>
<td>BAS[6] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;(n)_EL1[maxAddressSize(a)_3]:110 is accessed.</td>
</tr>
<tr>
<td>BAS[7] == 1</td>
<td>Generates a Watchpoint exception if the byte at address DBGWVR&lt;(n)_EL1[maxAddressSize(a)_3]:111 is accessed.</td>
</tr>
</tbody>
</table>

*a. maxAddressSize is 52 bits in an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule, and 48 bits otherwise.*

### Table D2-16 Supported BAS values when the DBGWVRn\_EL1 address alignment is word

<table>
<thead>
<tr>
<th>BAS value(b)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000000</td>
<td>Watchpoint never generates a Watchpoint exception</td>
</tr>
<tr>
<td>BAS[0] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;(n)_EL1[maxAddressSize(b)_2]:00 is accessed.</td>
</tr>
<tr>
<td>BAS[1] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;(n)_EL1[maxAddressSize(b)_2]:01 is accessed.</td>
</tr>
<tr>
<td>BAS[2] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;(n)_EL1[maxAddressSize(b)_2]:10 is accessed.</td>
</tr>
<tr>
<td>BAS[3] == 1</td>
<td>Generates a Watchpoint exception if byte at address DBGWVR&lt;(n)_EL1[maxAddressSize(b)_2]:11 is accessed.</td>
</tr>
</tbody>
</table>

*a. DBGWCR<\(n\)\_EL1.BAS[7:4] are RES0.*

*b. maxAddressSize is 52 bits in an implementation that includes ARMv8.2-LVA and is using the 64KB translation granule, and 48 bits otherwise.*
When programming the BAS field with anything other than 0b11111111, a debugger must program DBGWCR<n>_EL1.MASK to be 0b00000. See Programming dependencies of the BAS and MASK fields on page D2-2313.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the DBGWVR<n>_EL1[maxAddressSize:3]. See Example D2-1 on page D2-2307.

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
  - DBGWVR<n>_EL1 with 0x1000.
  - DBGWCR<n>_EL1.BAS to be 0b00001000.

- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
  - DBGWVR<n>_EL1 with 0x2000.
  - DBGWCR<n>_EL1.BAS to be 0b00111000.

- If the address programmed into the DBGWVR<n>_EL1 is doubleword-aligned:
  - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program DBGWCR<n>_EL1.BAS to be 0b00001111.
  - To generate a Watchpoint exception when any byte in the word starting at address DBGWVR<n>_EL1[31:3]:100 is accessed, program DBGWCR<n>_EL1.BAS to be 0b11110000.

--- Note ---

ARM deprecates programming a DBGWVR<n>_EL1 with an address that is not doubleword-aligned.

---

### Programming a watchpoint with eight or more bytes

A debugger can use the MASK field, DBGWCR<n>_EL1.MASK, to program a single watchpoint with a data address range. The range must meet all of the following criteria:

- It is a size that is:
  - A power-of-two.
  - A minimum of eight bytes.
  - A maximum of 2GB.
- It starts at an address that is aligned to the size.

The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

<table>
<thead>
<tr>
<th>MASK</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00000</td>
<td>No bits are masked.</td>
</tr>
<tr>
<td>0b00001</td>
<td>Reserved.</td>
</tr>
<tr>
<td>0b00010</td>
<td>Reserved.</td>
</tr>
<tr>
<td>0b00011</td>
<td>Three least significant bits are masked.</td>
</tr>
<tr>
<td>0b00100</td>
<td>Four least significant bits are masked.</td>
</tr>
<tr>
<td>0b00101</td>
<td>Five least significant bits are masked.</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>0b11111</td>
<td>31 least significant bits are masked.</td>
</tr>
</tbody>
</table>

If n least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address DBGWVR<n>_EL1[maxAddressSize:n]:000...
- Address DBGWVR<n>_EL1[maxAddressSize:n]:111...
- Any address between these two addresses.
For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between \( \text{DBGWVR}_n\text{-EL1}[\text{maxAddressSize:4}]:0000 \) and \( \text{DBGWVR}_n\text{-EL1}[\text{maxAddressSize:4}]:1111 \), including these addresses.

--- Note ---

- The 17 most significant bits cannot be masked. This means that the full address cannot be masked.
- For watchpoint behavior when its MASK field is programmed with a reserved value, see *Reserved DBGWCR\( \_n\text{-EL1.MASK values on page D2-2314}.*

When masking address bits, a debugger must both:

- Program \( \text{DBGWCR}_n\text{-EL1.BAS} \) to be 0b11111111. See *Programming dependencies of the BAS and MASK fields on page D2-2313.*

- In the \( \text{DBGWVR}_n\text{-EL1} \), set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see *Other usage constraints on page D2-2314.*

### D2.10.5 Determining the memory location that caused a Watchpoint exception

On taking a Watchpoint exception, the PE records an address in a *Fault Address Register* that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- \( \text{FAR\_EL1} \), if the exception is taken to EL1.
- \( \text{FAR\_EL2} \), if the exception is taken to EL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the EDWAR.

For more information, see the subsections that follow. These are:

- *Address recorded for Watchpoint exceptions generated by instructions other than data cache maintenance instructions*

- *Address recorded for Watchpoint exceptions generated by data cache maintenance instructions on page D2-2311*

#### Address recorded for Watchpoint exceptions generated by instructions other than data cache maintenance instructions

--- Note ---

Despite its mnemonic, the *DC ZVA, Data Cache Zero by VA* instruction is not a data cache maintenance instruction.

The address recorded must be both:

- From the inclusive range between:
  - The lowest address accessed by the memory access that triggered the watchpoint.
  - The highest *watchpointed address* accessed by the memory access. A watchpointed address is an address that the watchpoint is watching.

- Within a naturally-aligned block of memory that is all of the following:
  - A power-of-two size.
  - No larger than the *DC ZVA* block size.
  - Contains a watchpointed address accessed by the memory access.

The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.
Example D2-2 Address recorded for a watchpoint programmed on 0x8019

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte 0x8019.

An A32 load multiple instruction then loads nine registers starting from address 0x8004 upwards. This triggers the watchpoint.

If the DC ZVA block size is:
- 32 bytes, the address that the PE records must be between 0x8004 and 0x8019 inclusive.
- 16 bytes, the address that the PE records must be between 0x8010 and 0x8019 inclusive.

Address recorded for Watchpoint exceptions generated by data cache maintenance instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

D2.10.6 Watchpoint behavior on other instructions

Under normal operating conditions, the following do not generate Watchpoint exceptions:
- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Prefetch memory instructions.
- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a DC IVAC instruction can generate a Watchpoint.
- All data cache maintenance instructions except DC IVAC.

Note

Despite its mnemonic, the DC ZVA, Data Cache Zero by VA instruction is not a data cache maintenance instruction.

However, the debug architecture allows for implementation defined controls, such as those in ACTLR registers, to enable watchpoints on an implementation defined subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache, address translation, and TLB operations are implementation defined.

The access size of the IMPLEMENTATION DEFINED instruction cache, address translation, and TLB operations which generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

See also the following subsections:
- Watchpoint behavior on accesses by Store-Exclusive instructions.
- Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction on page D2-2312.

Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:
- If the store fails because an Exclusives monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
- Otherwise, the watchpoint generates a Watchpoint exception.
Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction

DC IVAC and DC ZVA operations are treated as data stores. This means that for a watchpoint to match on an access caused by one of these instructions, the debugger must program DBGWCR<n>_EL1.LSC to be one of the following:

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Match on data stores.</td>
</tr>
<tr>
<td>11</td>
<td>Match on data stores and data loads.</td>
</tr>
</tbody>
</table>

**Note**

For the size of data accesses performed by the DC IVAC instruction and the DC ZVA instruction, see Watchpoint data address comparisons on page D2-2307. The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

### D2.10.7 Watchpoint usage constraints

See the following:

- Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values.
- Reserved DBGWCR<n>_EL1.LBN values on page D2-2313.
- Programming dependencies of the BAS and MASK fields on page D2-2313.
- Reserved DBGWCR<n>_EL1.BAS values on page D2-2313.
- Reserved DBGWCR<n>_EL1.MASK values on page D2-2314.
- Other usage constraints on page D2-2314.

#### Reserved DBGWCR<n>_EL1.(SSC, HMC, PAC) values

Table D2-17 shows when particular combinations of DBGWCR<n>_EL1.{SSC, HMC, PAC} are reserved.

**Table D2-17 Reserved SSC, HMC, and PAC combinations**

<table>
<thead>
<tr>
<th>HMC, SSC, and PMC combination</th>
<th>Reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>All combinations with SSC set to 0b01 or 0b10 except for the combination with</td>
<td>When EL3 is not implemented and EL2 is implemented.</td>
</tr>
<tr>
<td>HMC set to 1, SSC set to 0b01, and PMC set to 0b00.</td>
<td>-----------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>All combinations where HMC or SSC is nonzero, except for the combination with HMC set to</td>
<td>When both of EL2 and EL3 are not implemented</td>
</tr>
<tr>
<td>1, SSC set to 0b01, and PMC set to 0b00 or combinations with SSC set to 0b01.</td>
<td>-----------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00.</td>
<td>When EL2 is not implemented</td>
</tr>
<tr>
<td>The combinations with SSC set to 0b11 except the combination with HMC set to 1, SSC set to</td>
<td>When Secure EL2 is not implemented</td>
</tr>
<tr>
<td>0b11, and PMC set to 0b00.</td>
<td>-----------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>The combination with HMC set to 1, SSC set to 0b01, and PMC set to 0b00.</td>
<td>When Secure EL2 is not implemented</td>
</tr>
<tr>
<td>Combinations not included in Table D2-14 on page D2-2305.</td>
<td>Always</td>
</tr>
</tbody>
</table>

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct or external read of DBGWCR<n>_EL1.
- For a direct or external read of DBGWCR<n>_EL1, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of SSC, HMC, and PMC is UNKNOWN.
— Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

**Reserved DBGWCR<n>_EL1.LBN values**

**For Linked Watchpoints**

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any DBGWCR<n>_EL1.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGWCR<n>_EL1.LBN return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:

- Disabled
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

**For Unlinked Watchpoints**

For Unlinked watchpoints, DBGWCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

**Programming dependencies of the BAS and MASK fields**

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the DBGWVR<n>_EL1 the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be 0b11111111, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be 0b00000, so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is non-zero and a BAS field that is not set to 0b11111111, then for each byte in the address range, it is CONSTRAINED UNPREDICTABLE whether or not a Watchpoint exception is generated.

**Reserved DBGWCR<n>_EL1.BAS values**

The BAS field must be programmed with a value Zeros(8-n-m):Ones(n):Zeros(m), where:

- n is a non-zero positive integer less-than-or-equal-to 8.
- m is a positive integer less-than 8.
- n+m is less-than-or-equal-to 8.

All other values are reserved.

**Note**

If x is zero, then Zeros(x) is an empty bitstring.

If DBGWVR<n>_EL1[2] is 1, DBGWCR<n>_EL1.BAS[7:4] are RES0 and are ignored.

If a watchpoint is programmed with a reserved BAS value:

- It is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the DBGWVR<n>_EL1.
• A direct or external read of DBGWCR<n>_EL1.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

Reserved DBGWCR<n>_EL1.MASK values

If a watchpoint is programmed with a reserved MASK value:
• The watchpoint must behave as if it is either:
  — Disabled.
  — Programmed with an UNKNOWN value that is not reserved, that might be 0b00000, other than for a direct or external read of DBGWCR<n>_EL1.
• A direct or external read of DBGWCR<n>_EL1.MASK returns an UNKNOWN value.

Other usage constraints

For all watchpoints:
• DBGWVR<n>_EL1[1:0] are RES0 and are ignored.
• If DBGWCR<n>_EL1.MASK is nonzero, and any masked bits of DBGWVR<n>_EL1 are not 0, it is constrained unpredictable whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
• A watchpoint never generates any Watchpoint exceptions if DBGWCR<n>_EL1.LSC is 0b00.

D2.10.8 Exception syndrome information and preferred return address

See the following:
• Exception syndrome information.
• Preferred return address.

Exception syndrome information

On taking a Watchpoint exception, the PE records all of the following:
• Information about the exception in the Exception Syndrome Register (ESR_ELx) at the Exception level the exception is taken to.
• An address that the debugger can use to determine the memory location that caused the exception. The PE records this in a Fault Address Register (FAR).

The ESR and FAR used is either:
• ESR_EL1 and FAR_EL1, if the exception is taken to EL1.
• ESR_EL2 and FAR_EL2, if the exception is taken to EL2.

Note

Watchpoint exceptions cannot be taken to EL3 using AArch64.

See ISS encoding for an exception from a Watchpoint exception on page D12-2790 for more information.

Preferred return address

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.
D2.10.9  Pseudocode description of Watchpoint exceptions taken from AArch64 state

AArch64.WatchpointByteMatch() tests an individual byte accessed by an operation.

AArch64.StateMatch() tests the values in DBGWCR<\n>_EL1.{HMC, SSC, PAC}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to.

AArch64.WatchpointMatch() tests the value in DBGWVR<\n>_EL1.

AArch64.CheckWatchpoint() generates a FaultRecord that AArch64.Abort() raises a Watchpoint exception for if all of the following are true:

• MDSCR_EL1.MDE is 1.

• Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level on page D2-2277.

• All of the conditions required for Watchpoint exception generation are met. See About Watchpoint exceptions on page D2-2302.

—— Note ———
AArch64.CheckWatchpoint() might halt the PE and cause it to enter Debug state. External debug uses Debug state.

AArch64.WatchpointException() is called to generate a Watchpoint exception.

These functions are defined in Chapter J1 ARMv8 Pseudocode.
D2.11  Vector Catch exceptions

Vector Catch exceptions are not generated in AArch64 translation regimes.

Note

This means that they are never taken to EL1 using AArch64 and are only supported if at least EL1 using AArch32 is supported.

A debugger that is executing in EL2 using AArch64 can route Vector Catch exceptions to EL2 using AArch64. See Routing debug exceptions on page D2-2275.

AArch64.VectorCatchException() is called to generate a Vector Catch exception.

Vector Catch exceptions on page G2-5413 describes Vector Catch exceptions.
D2.12  Software Step exceptions

The following subsections describe Software Step exceptions:

- About Software Step exceptions.
- Rules for setting MDSCR_EL1.SS to 1.
- The software step state machine on page D2-2318.
- Entering the active-not-pending state on page D2-2319.
- Behavior in the active-not-pending state on page D2-2322.
- Entering the active-pending state on page D2-2324.
- Behavior in the active-pending state on page D2-2325.
- Stepping T32 IT instructions on page D2-2325.
- Exception syndrome information and preferred return address on page D2-2325.
- Additional considerations on page D2-2327.
- Pseudocode description of Software Step exceptions on page D2-2329.

D2.12.1  About Software Step exceptions

Software step is an ARMv8-A resource that a debugger can use to make the PE single-step instructions. For example, by using software step, debugger software executing at a higher Exception level can single-step instructions at a lower Exception level.

Operation is as follows:

1. A debugger:
   a. Enables software step by setting MDSCR_EL1.SS to 1. See The debug exception enable controls on page D2-2274.
   b. Executes an exception return instruction, ERET, to branch to the instruction to be single-stepped in the software being debugged.

2. The PE then:
   a. Executes the instruction to be single-stepped.
   b. Takes a Software Step exception on the next instruction, returning control to the debugger.

However, another exception might be generated while the instruction is being stepped. This exception is either:

- A synchronous exception that is generated by the instruction being stepped.
- An asynchronous exception that is taken before or after the instruction being stepped.

The PE can only take a Software Step exception if debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level on page D2-2277.

A state machine describes the behavior of software step, shown in The software step state machine on page D2-2318.

Throughout this Software Step exceptions section, including in all subsections, ELD means the Exception level that Software Step exceptions are targeting. Routing debug exceptions on page D2-2275 defines ELD as the debug target Exception level.

D2.12.2  Rules for setting MDSCR_EL1.SS to 1

Debugger software must be executing in an Exception level and Security state that debug exceptions are disabled from when it sets MDSCR_EL1.SS to 1.

The Exception level that hosts the debugger software must be using AArch64.
D2.12.3 The software step state machine

In Figure D2-3:

- The OS Lock is unlocked and DoubleLockStatus() == FALSE.
- The PE is not in Secure state with MDCR_EL3.SDD set to 1. That is, the PE is in Non-secure state, or is in Secure state with MDCR_EL3.SDD set to 0, or the implementation does not include EL3.

![Software step state machine diagram]

Execution is at either:
- An Exception level that is higher than EL0.
- EL0 with (PSTATE.D == 1 | MDSCR_EL1.KDE == 0).

This is termed execution in a debugger or above.

To make the PE single-step an instruction, the debugger:
1. Sets SPSR_ELx.SS to 1.
2. Programs the ELR_ELx to point to the instruction to be stepped.
3. Executes an ERET instruction.

Execution is in the software being debugged, at either:
- An Exception level that is lower than EL0.
- EL0 with (PSTATE.D == 0 & MDSCR_EL1.KDE == 1).

Execution is in a debugger or above

Execution in a debugger or above

Inactive

By a debugger setting MDSCR_EL1.SS to 1

Inactive

MDSCR_EL1.SS == 0

MDSCR_EL1.SS == 1

Execution has returned to the debugger.

Active-not-pending PSTATE.SS==1

Step completeda

By ERET setting PSTATE.SS to 1

Active-pending PSTATE.SS==0

Step completedb

By an asynchronous exception taken to an Exception level that debug exceptions are enabled from

Inactive PSTATE.SS=0

A Software Step exception is pending.

By a debugger setting MDSCR_EL1.SS to 1

Execution in a debugger or above

Execution is at either:
- An Exception level that is higher than EL0.
- EL0 with (PSTATE.D == 0 & MDSCR_EL1.KDE == 1).

A Software Step exception is pending.

b. The step is the PE either:
   - Executing the instruction to be stepped without taking an exception.
   - Taking an exception to an Exception level that debug exceptions are enabled from. The Exception level might be using AArch64 or AArch32.

c. Or, if execution is at EL0 with MDSCR_EL1.KDE == 1, by software setting PSTATE.D to 0.

d. The step is the PE either:
   - Taking an exception to an Exception level that debug exceptions are disabled from.
   - If execution is at EL0 with MDSCR_EL1.KDE == 1, executing an instruction that sets PSTATE.D to 1.

Software step is inactive when debug exceptions are disabled from the current Exception level, and debug exceptions are disabled from EL0 when PSTATE.D is 1.

For a description of when debug exceptions are enabled or disabled from an Exception level, see Enabling debug exceptions from the current Exception level on page D2-2277.
For more information about how a step is completed, see *Behavior in the active-not-pending state on page D2-2322.*

The software step states are:

**Inactive**  
Software step is inactive. It cannot generate any Software Step exceptions or affect PE execution. Software step is inactive whenever any of the following are true:
- MDSCR_EL1.SS is 0.
- EL₂ is using AArch32.
- Debug exceptions are disabled from the current Exception level or Security state.

**Active-not-pending**  
None of the conditions mentioned in *Inactive* are true, therefore software step is active. The current instruction is the instruction to be stepped.

**Active-pending**  
None of the conditions mentioned in *Inactive* are true, therefore software step is active. A Software Step exception is pending on the current instruction.

Whenever software step is active, whether the state machine is in the active-not-pending state or the active-pending state depends on PSTATE.SS. Table D2-18 shows this.

### Table D2-18 State machine states

</tbody>
</table>

#### D2.12.4 Entering the active-not-pending state

Software step can only enter the active-not-pending state from the inactive state.

Software step:
- Enters the active-not-pending state when an ERET instruction writes 1 to PSTATE.SS, by copying from SPSR_ELx.SS when it restores PSTATE.
- Might enter the active-not-pending state on exiting Debug state when DSPSR_EL0.SS or DSPSR.SS is 1. See *Exiting Debug state on page H2-6454.*

An ERET instruction only copies 1 from SPSR_ELx.SS to PSTATE.SS if all of the following are true:
- MDSCR_EL1.SS is 1.
- EL₂ is using AArch64.
- Debug exceptions are disabled from the current Exception level.
- Debug exceptions are enabled from the Exception level that the ERET instruction targets.

Otherwise, ERET instructions set PSTATE.SS to 0, regardless of the value of SPSR_ELx.SS.

Table D2-19 on page D2-2320 shows this. In the table:
- **Lock** Means the value of (OSLSR_EL1.OSLK == '1' || DoubleLockStatus()).
- **NS** Means SCR_EL3.NS.
SDD
Means MDCR_EL3.SDD. See Disabling debug exceptions from Secure state on page D2-2277.

TDE
Means the Effective value of MDCR_EL2.TDE. See Routing debug exceptions on page D2-2275.

EL1 is using
The Execution state when the ELD is EL1.

EL2 is using
The Execution state when the ELD is EL2.

For:

- If the Effective value of MDCR_EL2.TDE == 0, and EL1 is using AArch64, so that ELD is EL1 using AArch64, Table D2-20 on page D2-2321 shows the value an ERET writes to PSTATE.SS.

- If the Effective value of MDCR_EL2.TDE == 1 and EL2 using AArch64, so that ELD is EL2 using AArch64, Table D2-21 on page D2-2322 shows the value an ERET writes to PSTATE.SS.

In both tables:

**From EL**
Means the Exception level at which the PE executes the ERET instruction.

**Target EL**
Is the target Exception level of the ERET.

---
**Note**
If the ERET is an illegal exception return, the target Exception level of the ERET is the current Exception level. See Illegal return events from AArch64 state on page D1-2168.

**KDE**
Is MDSCR_EL1.KDE. See Enabling debug exceptions from the current Exception level on page D2-2277.
Table D2-20 Value an ERET writes to PSTATE.SS if EL_D is EL1 using AArch64

a. Because MDSCR_EL1.SS == 1, it means that the ERET is itself being stepped.
b. Depends on SPSR_EL1.D.
D2.12.5 Behavior in the active-not-pending state

In this state, the PE does one of the following:

- Executes the instruction to be stepped and either:
  - Completes it without taking a synchronous exception.
  - Takes a synchronous exception if the instruction generates one.
- Takes an asynchronous exception without executing any instructions.
- Enters Debug state because of a Halting debug event.

---

**Note**

No AArch32 instruction can set `PSTATE.SS` to 1.

</tbody>
</table>

a. Because `MDSCR_EL1.SS` == 1, it means that the ERET is itself being stepped.
b. Depends on `SPSR_EL2.D`.
If the PE executes the instruction without taking any exceptions, then the PE sets **PSTATE.SS** to 0, meaning that after the instruction has been executed:

- If the instruction has disabled debug by setting **PSTATE.D** to 1 then software step advances to the inactive state.
- If the instruction disables software step by a direct write to a System register, for example a write to **MDSCR_EL1.KDE** or **MDSCR_EL1.SS**, then software step might advance to the inactive state. These writes require explicit synchronization to guarantee their effect. See *Synchronization and the software step state machine* on page D2-2328.
- Otherwise, software step advances to the active-pending state. See *Behavior in the active-pending state* on page D2-2325.

If the PE takes either a synchronous or an asynchronous exception, behavior is as described in one of the following:

- *If the PE takes an exception to an Exception level that is using AArch64.*
- *If the PE takes an exception to an Exception level that is using AArch32.*

If the PE enters Debug state because of a Halting debug event, behavior is as described in *Entering Debug state and Software Step* on page H2-6428.

### If the PE takes an exception to an Exception level that is using AArch64

As part of exception entry, the PE does all of the following:

- Sets **SPSR_ELx.SS** to 0 or 1, depending on the exception. See *Table D2-22*.
- Sets **PSTATE.SS** to 0. This causes software step to enter either the active-pending state or the inactive state, depending on whether debug exceptions are enabled or disabled from the Exception level that the exception is taken to:
  - **Enabled** Software step enters the active-pending state.
  - **Disabled** Software step enters the inactive state.

In either case, on taking the exception, a step is complete.

- Sets **PSTATE.D** to 1.

<table>
<thead>
<tr>
<th>Exception description</th>
<th>Exceptions</th>
<th>SPSR_ELx.SS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exceptions whose preferred return address is for the instruction that follows the instruction to be stepped.</td>
<td>Supervisor Call (SVC) exceptions. Hypervisor Call (HVC) exceptions. Secure Monitor Call (SMC) exceptions.</td>
<td>0</td>
</tr>
<tr>
<td>Exceptions whose preferred return address is the address of the instruction to be stepped.</td>
<td>All other synchronous exceptions, and asynchronous exceptions that are taken before the instruction to be stepped.</td>
<td>1</td>
</tr>
</tbody>
</table>

---

**Note**

If an SMC instruction executed at Non-secure EL1 is trapped to EL2 because **HCR_EL2.TSC** is 1, the exception is a Trap exception, not a Secure Monitor Call exception, and so **SPSR_ELx.SS** is set to 1, not 0.

---

### If the PE takes an exception to an Exception level that is using AArch32

This can only happen when all of the following is true:

- EL2 is implemented and is using AArch64, and the *Effective value* of **MDCR_EL2.TDE** is 1. Because **MDCR_EL2.TDE** is 1, **ELD** is EL2.
- The exception is taken to EL1 using AArch32.
As part of exception entry, the PE sets PSTATE.SS to 0. This causes software step to enter the active-pending state.

--- Note ---

- Software step always enters the active-pending state because the exception is taken to an Exception level that debug exceptions are enabled from, EL1. Debug exceptions are enabled from EL1 because ELD is EL2, and debug exceptions are always enabled from Exception levels that are lower than EL-D.

- AArch32 SPSRs have no SS bit.

Summary of behavior in the active-not-pending state

Table D2-23 summarizes behavior in the active-not-pending state.

<table>
<thead>

\(^a\) For the No exception rows, this column shows the effect of the event. For the Exception rows, this column shows the exception taken.

\(^b\) Which state software step enters depends on whether debug exceptions are enabled or disabled from the target Exception level. See Figure D2-3 on page D2-2318.

### D2.12.6 Entering the active-pending state

Software step enters the active-pending state after any of the following operations, provided that both:

- MDSCR_EL1.SS is 1.
- Debug exceptions are enabled from the Exception level and Security state that execution is in after the operation.

The operations are:

**While software step is in the active-not-pending state**

The PE either:

- Executing the instruction to be stepped without taking any exceptions.
- Taking an exception.

**While software step is in the active-pending state**

The PE takes an asynchronous exception.

**While software step is in the inactive state**

The PE executes either:

- An ERET instruction when SPSR_ELx.SS is 0.
- An instruction that enables debug by setting PSTATE.D to 0.
Note

If entry to the active-pending state is because of the PE taking an exception, it means that the exception is one that is taken to EL1 when MDCR_EL2.TDE is 1 and EL2 is implemented and enabled in the current Security state. Otherwise, debug exceptions are masked by PSTATE.D, therefore they would be disabled from the target Exception level of the exception.

In addition, software step might enter the active-pending state either:

- After a direct write to a System register, for example a write to MDSCR_EL1.KDE or MDSCR_EL1.SS. These writes require explicit synchronization to guarantee their effect. See Synchronization and the software step state machine on page D2-2328.

- On exiting Debug state when DSPSR_EL0.SS or DSPSR.SS is 0. See Exiting Debug state on page H2-6454.

### D2.12 Behavior in the active-pending state

When the PE is in the active-pending state, a Software Step exception is taken before the PE executes an instruction.

The Software Step exception has higher priority than all other types of synchronous exception. However, the prioritization of this exception with respect to any unmasked pending asynchronous exception is not defined by the architecture.

For more information, see the following:
- Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2179.
- Prioritization and recognition of interrupts on page D1-2194.
- Architectural requirements for taking asynchronous exceptions on page G1-5253.

### D2.12.8 Stepping T32 IT instructions

The ARMv8-A architecture permits a combination of an IT instruction and another 16-bit T32 instruction to comprise one 32-bit instruction.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:
- The PE considers this combination to be one instruction.
- The PE considers this combination to be two instructions.

In an implementation that supports the ITD control, that can disable some uses of the IT instruction, it is then IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD field. For example:
- The PE might consider this combination to be one instruction, regardless of the state of the applicable ITD field.
- The PE might consider this combination to be two instructions, regardless of the state of the applicable ITD field.
- The PE might consider this combination to be one instruction when the applicable ITD field is 1, and two instructions when it is 0.

The applicable ITD field is one of:
- SCTLR_EL1.ITD if execution is at EL0 using AArch32 when EL1 is using AArch64.
- SCTLR.ITD if execution is at EL0 or EL1 when EL1 is using AArch32.
- HSCTLR.ITD if execution is at Non-secure EL2 using AArch32.

### D2.12.9 Exception syndrome information and preferred return address

See the following:
- Exception syndrome information on page D2-2326.
- Preferred return address on page D2-2327.
Exception syndrome information

On taking a Software Step exception, the PE records information about the exception in the Exception Syndrome Register (ESR_ELx) at the Exception level the exception is taken to. See ISS encoding for an exception from a Software Step exception on page D12-2789 for more information.

When an instruction has been stepped, the PE sets:

• The value of ESR_ELx.ISV to 1, to indicate that the EX bit is valid.
• The value of ESR_ELx.EX to indicate whether the instruction stepped was a Load-Exclusive instruction, using the ESR_ELx.EX values shown in ISS encoding for an exception from a Software Step exception on page D12-2789, if this bit is valid.

If no instruction was stepped because software step entered the active-pending state from the inactive state without passing through the active-not-pending state, the PE sets both ESR_ELx.{ISV, EX} to 0.

Note

An implementation that always sets ISV to 0 and never sets EX is not compliant.

ESR_ELx.ISV is UNKNOWN if, in the active-not-pending state, either:

• The instruction stepped was an ERET or an ISB. In these cases, ESR_ELx.EX is set to 0.
• MDCR_EL2.TDE was set to 1, EL2 is implemented and enabled in the current Security state, and either:
  — The instruction to be stepped generated a synchronous exception that was taken to EL1. In this case, the instruction to be stepped never completed.
  — The PE took an asynchronous exception to EL1 before it could execute the instruction to be stepped. In this case, the instruction to be stepped was never executed.

In both of these cases:
• If ESR_ELx.ISV is set to 1, then ESR_ELx.EX must be set to the correct value for the instruction.
• If ESR_ELx.ISV is set to 0, then ESR_ELx.EX must be set to zero.

Table D2-24 shows the permitted scenarios.

Table D2-24 Values that the PE can record in ESR_ELx.{ISV, EX}

<table>
<thead>
<tr>
<th>Description</th>
<th>ESR_ELx.ISV</th>
<th>ESR_ELx.EX</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syndrome data is not available because no instruction was stepped.</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Syndrome data is available because an instruction was stepped. The instruction stepped was an instruction other than a Load-Exclusive instruction.</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Syndrome data is available because an instruction was stepped. The instruction stepped was a Load-Exclusive instruction.</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>The instruction stepped was an ERET or an ISB.</td>
<td>UNKNOWN</td>
<td>0</td>
</tr>
<tr>
<td>The instruction to be stepped generated a synchronous exception that was taken to EL1.</td>
<td>UNKNOWN</td>
<td>Set to the correct value for the instruction.</td>
</tr>
<tr>
<td>The PE took an asynchronous exception before it could execute the instruction to be stepped.</td>
<td>UNKNOWN</td>
<td>Set to the correct value for the instruction.</td>
</tr>
</tbody>
</table>

ESR_ELx.EX is UNKNOWN if the stepped instruction was a conditional Load-Exclusive instruction that failed its Condition code test.

Note

A Load-Exclusive instruction is any one of the following:
• In the A64 instruction set, any instruction that has a mnemonic starting with either LDX or LDAX.
• In the A32 and T32 instruction sets, any instruction that has a mnemonic starting with either LDREX or LDAEX.

Preferred return address

The preferred return of a Software Step exception is the address of the instruction that was not executed because the PE took the Software Step exception instead.

D2.12.10 Additional considerations

This section contains the following:
• Behavior when an ERET instruction is an illegal exception return.
• Behavior when the instruction stepped writes a misaligned PC value on page D2-2328.
• Stepping code that uses Exclusives monitors on page D2-2328.
• Synchronization and the software step state machine on page D2-2328.

Behavior when an ERET instruction is an illegal exception return

If the conditions for entering the active-not-pending state in Entering the active-not-pending state on page D2-2319 are met, but the PE executes an ERET instruction that is an illegal exception return, the exception return must be taken to the same Exception level that it was taken from. In this scenario, even though the Exception level remains the same before and after the ERET, software step can advance from the inactive state to one of the active states. Consider the following case:

1. MDSCR_EL1.SS is 1 and software step is inactive. The current Exception level is EL1 using AArch64, the OS Lock and OS Double Lock are unlocked, and MDCR_EL2.TDE is 0, MDSCR_EL1.KDE is 1, and PSTATE.D is 1.

   PSTATE.D == 1 is the reason why software step is inactive, because PSTATE.D == 1 means that debug exceptions are disabled from the current Exception level.

2. The PE executes an ERET instruction.

3. The intended target of the ERET is EL2. This means that the ERET is an illegal exception return because the intended target is higher than the Exception level the ERET it is executed at. In this case, the ERET must target EL1 instead of EL2.

   If SPSR_EL1.D is 0, then on the ERET PSTATE.D becomes 0 and debug exceptions become enabled from the current Exception level. Software step therefore advances from the inactive state to one of the active states.

Which active state software step advances to depends on whether SPSR_ELx.SS is 1 or 0:

• If SPSR_ELx.SS is 1, software step advances to the active-not-pending state.

   In this case, an Illegal Execution state exception is pending on the instruction to be stepped, and the PE takes the Illegal Execution state exception instead of executing the instruction to be stepped.

• If SPSR_ELx.SS is 0, software step advances to the active-pending state.

   In this case, a Software Step exception and an Illegal Execution state exception are both pending. The Software Step exception has higher priority. On taking the Software Step exception, the PE sets SPSR_ELx.IL to 1.

Note

Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2179 shows the relative priorities of synchronous exceptions.
Behavior when the instruction stepped writes a misaligned PC value

An indirect branch that writes a misaligned PC value might generate a PC alignment fault exception at the target of the branch. However, if the indirect branch is stepped using software step, the PE takes a Software Step exception instead, because the Software Step exception has higher priority. Behavior on returning from the Software Step exception depends on which Execution state the Exception level being returned to is using:

**AArch64**  
A PC alignment fault exception is generated.

**AArch32**  
The return from the Software Step exception forces the PC to the correct alignment, and no PC alignment fault exception is generated.

Debugger software must therefore take care when using software step to single-step an indirect branch instruction executed in AArch32 state, that it does not hide a PC alignment fault exception.

Stepping code that uses Exclusives monitors

The ARMv8-A architecture provides no mechanism for preserving the state of the Exclusives monitors when a Load-Exclusive or a Store-Exclusive instruction is stepped.

However, for certain progressions through the software step state machine, on taking a Software Step exception, the PE provides an indication of whether the instruction stepped was a Load-Exclusive instruction.

Debugger software can use this to detect the state of the Exclusives monitors. For example, if the PE reports that the instruction stepped was a Load-Exclusive instruction, the debugger is aware that the next Store-Exclusive operation will fail, because all Exclusives monitors are cleared on returning from the Software Step exception. The debugger must then take action to ensure that the code being stepped makes forwards progress.

For more information on how the PE reports whether the instruction stepped was a Load-Exclusive instruction, see *Exception syndrome information and preferred return address* on page D2-2325.

Synchronization and the software step state machine

Any of the following can cause transitions between software step states:

- A direct write to a System register.
- A direct write to a Special-purpose register.
- A write to an external debug register that affects the routing of debug exceptions.

Because the software step state machine indirectly reads these registers, it is not guaranteed to observe any new values until after a **Context synchronization event** has occurred.

In the time between a write to one of these registers and the next **Context synchronization event**, it is **CONSTRAINED UNPREDICTABLE** whether software step uses the state of the PE before the write, or the state of the PE after the write.

After a **Context synchronization event**, the state machine must use the state of the PE after the write.

**Example D2-3**

1. Software changes MDSCR_EL1.SS from 0 to 1 when debug exceptions are enabled.
2. The PE executes some instructions.
3. A **Context synchronization event** occurs.

During step 2, it is **CONSTRAINED UNPREDICTABLE** whether software step remains in the inactive state, as if MDSCR_EL1.SS is 0, or enters the active-pending state because MDSCR_EL1.SS is 1. If it is in the:

- Inactive state, then after the **Context synchronization event**, it must enter the active-pending state.
- Active-pending state, the PE might take a Software Step exception before the **Context synchronization event**.
Note

A direct write to a Special-purpose register does not require explicit synchronization.

D2.12.11 Pseudocode description of Software Step exceptions

SSAdvance() advances software step from the active-not-pending state to the active-pending state, by setting PSTATE.SS to 0. It is called on completing execution of each instruction.

CheckSoftwareStep() checks whether software step is in the active-pending state, and if it is, generates a Software Step exception. It is called before each instruction executed, regardless of Execution state, before checking for any other synchronous exceptions.

DebugExceptionReturnSS() returns the value to write to PSTATE.SS on an exception return or an exit from Debug state. See Entering the active-not-pending state on page D2-2319.

These functions are defined in Chapter J1 ARMv8 Pseudocode.
D2.13 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a Context synchronization event has occurred. Similarly, the effect of the change on the software step state machine cannot be relied on until after a Context synchronization event has occurred.

For any instructions executed between the time when the change is made and the time when the next Context synchronization event occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

---

**Example D2-4**

1. Software changes MDSCR_EL1.MDE from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A Context synchronization event occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

---

**Example D2-5**

1. Software unlocks the OS Lock.
2. The PE executes some instructions.
3. A Context synchronization event occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

---

**Note**

Some register updates are self-synchronizing. Others require an explicit Context synchronization event. For more information, see:

- Accessing PSTATE fields on page D1-2150.
- Synchronization requirements for AArch64 System registers on page D12-2663.
- Synchronization of changes to the external debug registers on page H8-6540.
Chapter D3
AArch64 Self-hosted Trace

This chapter describes the AArch64 self-hosted trace:

Introductory information:
  • About self-hosted trace on page D3-2332.
  • Trace sinks on page D3-2332.
  • Register controls to enable self-hosted trace on page D3-2332.

Prohibited regions in trace:
  • Controls to prohibit trace at Exception levels on page D3-2333.
  • Self-hosted trace and visibility of virtual data on page D3-2333.

Timestamps and Synchronization:
  • Self-hosted trace timestamps on page D3-2334.
  • Synchronization in self-hosted trace on page D3-2335.
D3.1 About self-hosted trace

A PE Trace Unit generates trace data to describe the program flow of the PE.

The PE Trace Unit may be an implementation of a standard ARM Embedded Trace Macrocell (ETM), or another type of ARM Trace Architecture, or an IMPLEMENTATION DEFINED trace function.

If an ARMv8.4-compliant PE implements an ETM Architecture PE Trace Unit, ARMv8.4-Trace extension must be implemented.

If an ARMv8.4-compliant PE implements a Trace Unit that is not an ETM Architecture PE Trace Unit, ARM recommends that ARMv8.4-Trace extension is implemented, but this is not mandatory.

Self-hosted trace happens when the agent controlling the trace collection is part of the same software stack as the software being traced. The agent controls prohibited regions. The information collected by the agent is sent to a trace sink.

If the self-hosted trace extensions are implemented, the PE Trace Unit must implement the system register interface. The PE Trace Unit and the PE must have the same view of the debug authentication interface. If ARMv8.4-Trace is implemented, ExternalNoninvasiveDebugEnabled() is always TRUE.

D3.1.1 Trace sinks

The PE Trace Unit sends the trace data to a trace sink. A system might include multiple trace sinks, and allow software to configure which trace sink or sinks are used.

An example of an internal trace sink is an Embedded Trace Router (ETR), which allows software to define a buffer in memory. Trace data is written to this buffer.

ARM recommends that a system that includes ARMv8.4-Trace incorporates an ETR, and follows the system architecture described by the CoreSight Base System Architecture (CS-BSA).

The self-hosted trace extensions do not describe the programmers’ model trace sinks.

D3.1.2 Register controls to enable self-hosted trace

It is IMPLEMENTATION DEFINED whether the PE Trace Unit implements an external debug interface or a self-hosted interface.

If ARMv8.4-Trace is implemented, and external self-hosted trace is not implemented, self-hosted trace is always enabled.

If ARMv8.4-Trace is implemented, and external self-hosted trace is implemented, self-hosted trace is also enabled if one of the following is true:

- EDSCR.TFO == 0.
- EDSCR.TFO == 1, EL3 is implemented, MDCR_EL3.STE == 1 and ExternalSecureNoninvasiveDebugEnabled() == FALSE.
- EDSCR.TFO == 1, EL3 is not implemented, the PE executes in Secure state and ExternalSecureNoninvasiveDebugEnabled() = FALSE.

The pseudocode function SelfHostedTraceEnabled() shows these rules.

If ARMv8.4-Trace is not implemented, SelfHostedTraceEnabled() returns FALSE.

While SelfHostedTraceEnabled() == FALSE, ExternalSecureNoninvasiveDebugEnabled() and ExternalNoninvasiveDebugEnabled() control whether external tracing is prohibited or allowed in each Security state.

The self-hosted trace extensions do not provide any mechanism to control software access to the PE Trace Unit external debug interface.
D3.2 Prohibited regions in self-hosted trace

Trace is not generated in prohibited regions. The pseudocode function `TraceAllowed()` indicates whether tracing is allowed in the current Security state and Exception level.

The IMPLEMENTATION DEFINED debug authentication interface can allow an external agent to disable the self-hosted trace extension.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited in Secure state when `MDCR_EL3.STE == 0`. If `ARMv8.4-Trace` is implemented but not enabled, tracing is prohibited in Secure state when `ExternalSecureNoninvasiveDebugEnabled()` == FALSE.

D3.2.1 Controls to prohibit trace at Exception levels

If `SelfHostedTraceEnabled()` == TRUE, `TRFCR_EL1` and `TRFCR_EL2` control whether trace is prohibited at an Exception level. While `SelfHostedTraceEnabled()` == FALSE, the registers `TRFCR_EL1` and `TRFCR_EL2` are ignored.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited at EL0 if one of the following is true:

- The Effective value of `HCR_EL2.TGE == 0` and `TRFCR_EL2.E0TRE == 0`.
- The Effective value of `HCR_EL2.TGE == 1` and `TRFCR_EL1.E0HTRE == 0`.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited at EL1 if `TRFCR_EL1.E1TRE == 0`.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited at EL2 if `TRFCR_EL2.E2TRE == 0`.

If `SelfHostedTraceEnabled()` == TRUE, tracing is prohibited at EL3 if one of the following is true:

- EL3 is using AArch64 state.
- EL3 is using AArch32 state and `TRFCR.E1TRE == 0`.

The pseudocode `TraceAllowed()` shows the above rules.

If `SelfHostedTraceEnabled()` == TRUE, Table D3-1 shows when export of PMU events Attributable to an Exception level is prohibited.

<table>
<thead>
<tr>
<th>HCR_EL2.TGE</th>
<th>Tracing prohibited in</th>
<th>Export of PMU events Attributable to this Exception level prohibited</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>EL0, EL2, EL3</td>
<td>EL0</td>
</tr>
<tr>
<td>x</td>
<td>EL0, EL1, EL2, EL3</td>
<td>EL0</td>
</tr>
<tr>
<td>x</td>
<td>EL1, EL2, EL3</td>
<td>EL1</td>
</tr>
<tr>
<td>x</td>
<td>EL2, EL3</td>
<td>EL2</td>
</tr>
<tr>
<td>x</td>
<td>EL3</td>
<td>EL3</td>
</tr>
</tbody>
</table>

D3.2.2 Self-hosted trace and visibility of virtual data

A hypervisor can use `TRFCR_EL2.CX` to control visibility of `CONTEXTIDR_EL2` and `VTTBR_EL2.VMID`.

If `SelfHostedTraceEnabled()` == TRUE and `TRFCR_EL2.CX == 0`, or if EL2 is not implemented:

- The values of `CONTEXTIDR_EL2` and `VTTBR_EL2.VMID` are not traced.
- Comparisons between `CONTEXTIDR_EL2` and `VTTBR_EL2.VMID` do not match and results of comparison are not exposed through the comparators.

The PE Trace Unit may either prohibit trace for these values, or may record a `CONTEXTIDR_EL2` or `VTTBR_EL2.VMID` value of zero in the trace.
D3.3 Self-hosted trace timestamps

The trace timestamp is a value that represents the passage of time in real-time. It is calculated from a counter which increments all the time, when the PE is generating trace and when the PE is in a prohibited region.

While `SelfHostedTraceEnabled()` == FALSE, the external trace provides the trace timestamp. If the external trace is a standard CoreSight system, the relationship between CoreSight time and the Generic Timer counter is IMPLEMENTATION DEFINED.

When `SelfHostedTraceEnabled()` == TRUE, the trace timestamp is one of the following:

- The physical counter value `CNTPCT_EL0`.
- A virtual counter value, which is calculated from the physical counter value `CNTPCT_EL0`, minus an offset `CNTVOFF_EL2`.

The fields `TRFCR_EL2.TS`, `HTRFCR.TS`, `TRFCR_EL1.TS` and `TRFCR.TS` control which counter is used for self-hosted trace.

The timestamp used for trace is shown in Table D3-2.

<table>
<thead>
<tr>
<th><code>SelfHostedTraceEnabled()</code></th>
<th>TRFCR_EL2.TS</th>
<th>TRFCR_EL1.TS</th>
<th>Timestamp traced</th>
</tr>
</thead>
<tbody>
<tr>
<td>FALSE</td>
<td>xx</td>
<td>xx</td>
<td>CoreSight time</td>
</tr>
<tr>
<td>TRUE</td>
<td>0b00</td>
<td>0b01</td>
<td>CNTPCT - CNTVOFF</td>
</tr>
<tr>
<td></td>
<td>0b00</td>
<td>0b11</td>
<td>CNTPCT</td>
</tr>
<tr>
<td></td>
<td>0b01</td>
<td>xx</td>
<td>CNTPCT - CNTVOFF</td>
</tr>
<tr>
<td></td>
<td>0b11</td>
<td>xx</td>
<td>CNTPCT</td>
</tr>
</tbody>
</table>

**Note**
The counter value used for the trace timestamp is not affected by the value of `HCR_EL2.E2H`, or whether EL2 is enabled or disabled in the current Security state.
D3.4 Synchronization in self-hosted trace

The PE Trace Unit is an indirect observer of the System registers.

While `SelfHostedTraceEnabled()` == TRUE, indirect reads of the trace filter control fields, TRFCR_EL1.{E1TRE, E0TRE} and TRFCR_EL2.{E2TRE, E0HTRE} are treated as indirect reads made by the instruction being traced, and are subject to the standard requirements for synchronization of System register accesses.

The `TSB CSYNC` operation is used to ensure that a trace operation, due to a PE Trace Unit generating trace for an instruction has completed. The `TSB CSYNC` operation may be reordered with respect to other instructions, so must be combined with at least one context synchronization event to ensure the operations are executed in the required order. This means that a direct write to TRFCR_EL1 or TRFCR_EL2 is guaranteed to be observed by the PE Trace Unit only after a subsequent Context synchronization event. For more information, see *Trace Synchronization Barrier (TSB CSYNC)* on page B2-106.

While `SelfHostedTraceEnabled()` == FALSE, the PE Trace Unit might impose stronger synchronization requirements.
D3 AArch64 Self-hosted Trace
D3.4 Synchronization in self-hosted trace
Chapter D4
The AArch64 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- *About the memory system architecture* on page D4-2338.
- *Address space* on page D4-2339.
- *Mixed-endian support* on page D4-2340.
- *Cache support* on page D4-2341.
- *External aborts* on page D4-2365.
- *Memory barrier instructions* on page D4-2367.
- *Pseudocode description of general memory System instructions* on page D4-2368.
D4.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see Memory hierarchy on page B2-111.

D4.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a Virtual Memory System Architecture (VMSA). Chapter D5 The AArch64 Virtual Memory System Architecture describes the AArch64 view of the VMSA.

D4.1.2 Memory attributes

Memory types and attributes on page B2-122 describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

Table D4-1 shows the memory attributes that are visible at the system level.

<table>
<thead>
<tr>
<th>Memory type</th>
<th>Shareability</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Devicea</td>

</tr>
<tr>
<td></td>
<td>• Outer Shareable.</td>
<td>• Write-Back Cacheable.</td>
</tr>
</tbody>
</table>

a. Takes additional attributes, see Device memory on page B2-126.
b. See also Cacheability, cache allocation hints, and cache transient hints on page D4-2344.

For more information on cachability and shareability see Shareable Normal memory on page B2-123, Non-shareable Normal memory on page B2-124, and Caches and memory hierarchy on page B2-111.
D4.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of physical address (PA) sizes, and provides associated control and identification mechanisms. For more information, see Address size configuration on page D5-2387.

D4.2.1 Virtual address space overflow

When a PE performs a Simple sequential execution of instructions, it calculates:

\[(\text{address of current instruction}) + (\text{size of executed instruction})\]

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an instruction overflows 0xFFFF FFFF FFFF FFFF, the program counter becomes UNKNOWN.

Note

Address tags are not propagated to the program counter, so the tag does not affect the address calculation.

Where an instruction accesses a sequential set of bytes that crosses the 0xFFFF_FFFF_FFFF_FFFF boundary when tagged addresses are not used, or the 0xFFFF_FFFF_FFFF_FFFF boundary when tagged addresses are used, then the virtual address accessed for the bytes above this boundary is UNKNOWN. When tagged addresses are used, the value of the tag associated with the address also becomes UNKNOWN.
D4.3 Mixed-endian support

A control bit, SCTLR_EL1.E0E is provided to allow the endianness of explicit data accesses made while executing at EL0 to be controlled independently of those made while executing at EL1. Table D4-2 shows the endianness of explicit data accesses and translation table walks.

Note
SCTLR_EL1.E0E has no effect on the endianness of the LDTR, LDTRH, LDTRSH, and LDTRSW instructions, or on the endianness of the STTR and STTRH instructions, when these are executed at EL1.

AArch64 state provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - SCTLR_ELx.EE is RW and SCTLR_EL1.E0E is RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - SCTLR_ELx.EE is RES0 and SCTLR_EL1.E0E is RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - SCTLR_ELx.EE is RES1 and SCTLR_EL1.E0E is RW.
- All Exception levels support only little-endianness:
  - SCTLR_ELx.EE is RES0 and SCTLR_EL1.E0E is RES0.
- All Exception levels support only big-endianness:
  - SCTLR_ELx.EE is RES1 and SCTLR_EL1.E0E is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by PSTATE.E. For exception returns to AArch32 state, PSTATE.E is copied from SPSR_ELx.E. If the target Exception level supports only little-endian accesses, SPSR_ELx.E is RES0. If the target Exception level supports only big-endian accesses, SPSR_ELx.E is RES1. PSTATE.E is ignored in AArch64 state.

The BigEndian() function determines whether the current Exception level and Execution state are using big-endian data. This function is defined in Chapter J1 ARMv8 Pseudocode.

For more information about endianness in the ARM architecture see Endian support on page B2-119.
D4.4 Cache support

This section describes the ARMv8 cache identification and control mechanisms, and the A64 cache maintenance instructions, in the following sections:

- General behavior of the caches.
- Cache identification on page D4-2342.
- Cacheability, cache allocation hints, and cache transient hints on page D4-2344.
- Enabling and disabling the caching of memory accesses on page D4-2345.

D4.4.1 General behavior of the caches

When a memory location has a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  - A particular implementation.
  - Some memory attributes.

- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

Note

For more information, see The interaction of cache lockdown with cache maintenance instructions on page D4-2363.

- Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.
• It is guaranteed that no memory location that does not have a Normal Cacheable attribute is allocated into the cache.

• It is guaranteed that no memory location is allocated to the cache if it has a Normal Non-cacheable attribute or any type of Device memory attribute in both:
  — The translation regime at the current Exception level.
  — The translation regime at any higher Exception level.

• For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all masters in its shareability domain.

• Any memory location is not guaranteed to remain incoherent with the rest of memory.

• The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the Cache Write-back Granule. In some implementations the CTR_EL0 identifies the Cache Write-back Granule.

• The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer if it was previously visible to that observer.

--- Note ---

The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR_EL1.{I, C} controls.

---

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.

D4.4.2 Cache identification

The ARMv8 cache identification registers describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes the cache maintenance instructions that:

• Affect the entire cache, for example IC IALLU.

• Operate by VA, for example IC IVAU.

• Operate by set/way, for example DC ISW.

The cache identification registers are:

• The Cache Type Register, CTR_EL0, that defines:
  — The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  — The minimum line length of any of the data or unified caches, affected by the data cache maintenance instruction.
  — The cache indexing and tagging policy of the Level 1 instruction cache.

--- Note ---

It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches see System level caches on page D4-2364.

---

• A single Cache Level ID Register, CLIDR_EL1, that defines:
  — The type of cache that is implemented and can be maintained using the architected cache maintenance instructions that operate by set/way or operate on the entire cache at each cache level, up to the maximum of seven levels.
  — The Level of Coherence (LoC) for the caches. See Terms used in describing the cache maintenance instructions on page D4-2348 for the definition of LoC.
— The Level of Unification Uniprocessor (LoUU) for the caches. See Terms used in describing the cache maintenance instructions on page D4-2348 for the definition of LoUU.
— An optional ICB field to indicate the boundary between the caches used for caching Inner Cacheable memory regions and those used only for caching Outer Cacheable regions.

• A single Cache Size Selection Register, CSSELR_EL1, that selects the cache level and cache type of the current Cache Size Identification Register.

• For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache Size Identification Register, CCSIDR_EL1, that defines:
  — Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
  — The number of sets, associativity and line length of the cache. See Terms used in describing the cache maintenance instructions on page D4-2348 for a definition of these terms.

Note
From ARMv8.3, multiple formats of the Cache Size Identification Register are supported. For more information, see Possible formats of the Cache Size Identification Register, CCSIDR_EL1.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.

2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.

3. For each cache identified at stage 2:
   • Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
     — An instruction cache.
     — A data or unified cache.
   • Read the Cache Size Identification Register to find details of the cache.

Possible formats of the Cache Size Identification Register, CCSIDR_EL1

From ARMv8.3, the Cache Size Identification Register, CCSIDR_EL1 has two different formats available for defining the number of sets and associativity of the cache. For a definition of these terms, see Terms used in describing the cache maintenance instructions on page D4-2348.

When ARMv8.3-CCIDX is implemented:

• CCSIDR_EL1 is a 64-bit register.
• The length of the CCSIDR_EL1.Assoc field is 21 bits. This limits the associativity of the currently selected cache to $2^{21}$.
• The length of the CCSIDR_EL1.NumSets field is 24 bits. This limits the number of sets in the currently selected cache to $2^{24}$.

This is the 64-bit format of the Cache Size Identification Register.

When ARMv8.3-CCIDX is not implemented:

• CCSIDR_EL1 is a 32-bit register.
• The length of the CCSIDR_EL1.Assoc field is 10 bits. This limits the associativity of the currently selected cache to $2^{10}$.
• The length of the CCSIDR_EL1.NumSets field is 15 bits. This limits the number of sets in the currently 
selected cache to $2^{15}$.

This is the 32-bit format of the Cache Size Identification Register.

When one of these formats is implemented, it is implemented across all the levels of caching.

D4.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and can be defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in Memory types and attributes on page B2-122, the memory attributes include a cacheability attribute that is one of:

• Non-cacheable.
• Write-Through cacheable.
• Write-Back cacheable.

In ARMv8, Cacheability attributes other than Non-cacheable can be complemented by a cache allocation hint. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a cache transient hint is supported, see Transient cacheability hint.

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hit is supported the following cache allocation hints can be assigned:

For read accesses: Read-Allocate, Transient Read-Allocate, or No Read-Allocate.

For write accesses: Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

_____ Note _______

• A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.

• Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.

• For VMSAv8-64 translation table walks, the TCR_ELx.{IRGNn, ORGNn} fields define the memory attributes of the translation tables, including the cacheability. However, this assignment supports only a subset of the cacheability attributes described in this section.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

Transient cacheability hint

In ARMv8, it is IMPLEMENTATION DEFINED whether a Transient hint is supported. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

_____ Note _______

The architecture does not specify what is meant by a relatively short period.

The description of the AArch64 MAIR_EL1, MAIR_EL2, and MAIR_EL3 registers, and the AArch32 MAIR0, MAIR1, HMAIR0, and HMAIR1 registers, includes the assignment of the Transient hint in an implementation that supports this option. In this assignment:

• The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.
D4.4 Cache support

D4.4.4 Enabling and disabling the caching of memory accesses

In ARMv8, Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:

- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

**Note**

These Cacheability controls replace the cache enable controls provided in previous versions of the ARM architecture.

The Cacheability control fields and their effects are as follows:

**For the EL1&0 translation regime**

- When the value of `SCTLR_EL1.C` is 0:
  - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the EL1&0 stage 1 translation tables are Non-cacheable.
- When the value of `SCTLR_EL1.I` is 0:
  - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of `HCR_EL2.CD` is 1:
  - All stage 2 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the EL1&0 stage 2 translation tables are Non-cacheable.
- When the value of `HCR_EL2.ID` is 1:
  - All stage 2 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of `HCR_EL2.DC` is 1, all stage 1 translations and all accesses to the EL1&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of `SCTLR_EL1.{I, C}`. This applies to translations for both data and instruction accesses.

**Note**

- The stage 1 and stage 2 cacheability attributes are combined as described in *Combining the stage 1 and stage 2 cacheability attributes for Normal memory* on page D5-2472.
- The `SCTLR_EL1.{C, I}` and `HCR_EL2.DC` fields have no effect on the EL2, EL2&0, and EL3 translation regimes.
- The `HCR_EL2.{ID, CD}` fields affect only stage 2 of the EL1&0 translation regime.
- When EL2 is using AArch64 and EL1 is using AArch32, the `HCR_EL2.{ID, CD, DC}` controls apply as described here, but the EL1 controls are `SCTLR.{C, I}`.

**For the EL2 translation regime**

- When the value of `SCTLR_EL2.C` is 0:
  - All data accesses to Normal memory using the EL2 translation regime are Non-cacheable.
  - All accesses to the EL2 translation tables are Non-cacheable.
- When the value of `SCTLR_EL2.I` is 0:
  - All instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.
Note
The SCTLR_EL2.{I, C} fields have no effect on the EL1&0 and EL3 translation regimes.

For the EL2&0 translation regime
- When the value of SCTLR_EL2.C is 0:
  - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the EL2&0 stage 1 translation tables are Non-cacheable.
- When the value of SCTLR_EL2.I is 0:
  - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.

For the EL3 translation regime
- When the value of SCTLR_EL3.C is 0:
  - All data accesses to Normal memory using the EL3 translation regime are Non-cacheable.
  - All accesses to the EL3 translation tables are Non-cacheable.
- When the value of SCTLR_EL3.I is 0:
  - All instruction accesses to Normal memory using the EL3 translation regime are Non-cacheable.

Note
The SCTLR_EL3.{I, C} fields have no effect on the EL1&0, EL2, and EL2&0 translation regimes.

In addition:
- For translation regimes other than the EL1&0 translation regime, if the value of SCTLR_ELx.M is 0, indicating that stage 1 translations are disabled for that translation regime, then:
  - If the value of SCTLR_ELx.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
  - If the value of SCTLR_ELx.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.
- For the EL1&0 translation regime, if the value of SCTLR_EL1.M is 0, indicating that stage 1 translations are disabled for that translation regime, and the value of HCR_EL2.DC is 0:
  - If the value of SCTLR_EL1.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
  - If the value of SCTLR_EL1.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through Cacheable, Outer Write-Through Cacheable.

The effect of SCTLR_ELx.C, HCR_EL2.DC and HCR_EL2.CD is reflected in the result of the address translation instructions in the PAR when these bits have an effect on the stages of translation being reported in the PAR.

Note
- In conjunction with the requirements in Non-cacheable accesses and instruction caches on page D4-2347, the requirements in this section mean the architecturally required effect of SCTLR_ELx.I is limited to its effect on caching instruction accesses in unified caches.
- This specification can give rise to different cacheability attributes between instruction and data accesses to the same location. Where this occurs, the measures for mismatch memory attributes described in Mismatched memory attributes on page B2-132 must be followed to manage the corresponding loss of coherency.
D4.4.5 Behavior of caches at reset

In ARMv8:

- All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.

- The Cacheability control fields described in Enabling and disabling the caching of memory accesses on page D4-2345 reset to values that force all memory locations to be treated as Non-cacheable.

--- Note ---

This applies only to the controls that apply to the Translation regime that is used by the Exception level and Security state entered on reset.

---

- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.

- If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
  - Provide a mechanism to ensure the correct initialization of the caches.
  - Be documented clearly as part of the documentation of the device.

In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

See also TLB behavior at reset on page D5-2501.

D4.4.6 Non-cacheable accesses and instruction caches

In AArch64 state, instruction accesses to Non-cacheable Normal memory can be held in instruction caches.

Correspondingly, the sequence for ensuring that modifications to instructions are available for execution must include invalidation of the modified locations from the instruction cache, even if the instructions are held in Normal Non-cacheable memory. This includes cases where System register Cacheability control fields force instruction accesses to memory to be Non-cacheable.

Therefore when using self-modified code in Non-cacheable space in a uniprocessor system, the following sequence is required:

; Enter this code with <Wt> containing the new 32-bit instruction
; to be held at a location pointed to by <Xn> in Normal Non-cacheable memory.
STR <Wt>, [Xn]
DSB ISH; Ensure visibility of the data stored
IC IVAU, [Xn]; Invalidate instruction cache by VA to PoU
DSB ISH; Ensure completion of the invalidations
ISB ;

In a multiprocessor system, the IC IVAU is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence, but additional software steps might be required to synchronize the threads with other PEs. This might be necessary so that the PEs executing the modified instructions can execute an ISB after completing the invalidation, and to avoid issues associated with concurrent modification and execution of instruction sequences.

Larger blocks of instructions can be modified using the IC IALLU instruction for a uniprocessor system, or a IC IALLUIS for a multiprocessor system.
D4.4 Cache support

--- Note ---
This section applies even when the Cacheability control fields force instruction accesses to memory in AArch64 state to be Non-cacheable, as described in Enabling and disabling the caching of memory accesses on page D4-2345.

D4.4.7 About cache maintenance in AArch64 state

The following sections give general information about cache maintenance:

• Terms used in describing the cache maintenance instructions.
• The ARMv8 abstraction of the cache hierarchy on page D4-2351.

The following sections describe the A64 cache maintenance instructions:

• The instruction cache maintenance instruction (IC) on page D4-2353.
• The data cache maintenance instruction (DC) on page D4-2353.

--- Note ---
Some descriptions of the cache maintenance instructions refer to the cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR_EL1.{I, C} controls.

Terms used in describing the cache maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instruction scope can be defined:

• By the virtual address of the memory location to be maintained, referred to as operating by VA.
• By a mechanism that describes the location in the hardware of the cache, referred to as operating by set/way.

In addition, for instruction caches, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

• Terminology for cache maintenance instructions operating by set/way.
• Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page D4-2349.

--- Note ---
There is no terminology specific to cache maintenance instructions that operate by VA. When all applicable stages of translation are disabled, the VA used is identical to the PA. For more information about memory system behavior when address translation is disabled, see The effects of disabling a stage of address translation on page D5-2425.

Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

Level
The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the CLIDR_EL1.

In the ARM architecture, the lower numbered cache levels are those closest to the PE. See Memory hierarchy on page B2-111.

Set
Each level of a cache is split up into a number of sets. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.

In the ARM architecture, sets are numbered from 0.
Way

The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The way number specifies one of these locations.

In the ARM architecture, ways are numbered from 0.

--- Note ---

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

--- Terminology for Clean, Invalidate, and Clean and Invalidate instructions ---

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.

2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or stale, copy of the memory location that has been updated.

The Clean and Invalidate instructions address these two issues. The definitions of these instructions are:

**Clean**

A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the shareability domain of that memory location.

**Invalidate**

A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

--- Note ---

Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.

**Clean and Invalidate**

A cache clean and invalidate instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

• For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.
For instructions operating by VA, the following conceptual points are defined:

**Point of Coherency (PoC)**

The point at which all agents that can access memory are guaranteed to see the same copy of a memory location for accesses of any memory type or cacheability attribute. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

--- Note ---

The presence of system caches can affect the determination of the point of coherency as described in *System level caches* on page D4-2364.

---

**Point of Unification (PoU)**

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

--- Note ---

• Such memory is sometimes called non-volatile memory. For example, the Storage-class memory shown in Figure B2-1 on page B2-112 could be used as target memory for this feature.

• The PoP is relevant to the behavior of a PE only when ARMv8.2-DCPoP is implemented, see DC CVAP.

---

The following fields in the CLIDR_EL1 relate to the PoC and PoU:

**LoC, Level of Coherency**

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

• A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.

• Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is 0x0, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

**LoUU, Level of Unification, uniprocessor**

This field defines the last level of data cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is 0x0, this means that no levels of data cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification.
If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

LoUIS, Level of Unification, Inner Shareable

In any implementation:

• This field defines the last level of data or unified cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain. As with LoC, the LoUIS value is a cache level.
• If the LoUIS field value is 0x0, this means that no levels of data or unified cache need to cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain.
• If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

The ARMv8 abstraction of the cache hierarchy

The following subsections describe the ARMv8 abstraction of the cache hierarchy:

• Cache maintenance instructions that operate by VA.
• Cache maintenance instructions that operate by set/way.

Cache maintenance instructions that operate by VA

The VA-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being one of:

• Performed to the Point of Coherency.
• Performed to the Point of Unification.
• When ARMv8.2-DCPoP is implemented, performed to the Point of Persistence.

See Terms used in describing the cache maintenance instructions on page D4-2348 for definitions of these terms, and for more information about possible meanings of VA.

A64 Cache maintenance instructions on page D4-2352 lists the VA-based maintenance instructions.

The CTR_EL0 holds minimum line length values for:

• The instruction caches.
• The data and unified caches.

These values support efficient invalidation of a range of VAs, because this value is the most efficient address stride to use to apply a sequence of VA-based maintenance instructions to a range of VAs.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the CTR_EL0 defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

Cache maintenance instructions that operate by set/way

A64 Cache maintenance instructions on page D4-2352 lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

• A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
• An invalidate instruction invalidates only at the level specified.
D4.4.8 A64 Cache maintenance instructions

The A64 cache maintenance instructions are part of the A64 System instruction class in the register encoding space. For encoding details and other general information on these System instructions, see System instructions on page C3-172, SYS on page C6-1222 and Cache maintenance instructions, and data cache zero operation on page C5-347.

Table D4-3 shows the AArch64 System instructions that perform instruction or data cache maintenance. Instructions that take an argument include \( \text{x}_t \) in the entry in the System instruction column.

---

\( a \). When HCR_EL2.{E2H,TGE} == \{1, 1\}, the control is from SCTLR_EL2.

\( b \). Supported only when ARMv8.2-DCPoP is implemented.

---

A DSB or DMB instruction intended to ensure the completion of cache or branch predictor maintenance instructions must have an access type of both loads and stores.
The following subsections give more information about these instructions:

- The instruction cache maintenance instruction (IC).
- The data cache maintenance instruction (DC).
- EL0 accessibility of cache maintenance instructions on page D4-2355.
- General requirements for the scope of maintenance instructions on page D4-2355.
- Effects of instructions that operate by VA to the PoC on page D4-2355.
- Effects of instructions that operate by VA to the PoP on page D4-2356.
- Effects of instructions that operate by VA to the PoU on page D4-2356.
- Effects of All and set/way maintenance instructions on page D4-2357.
- Effects of virtualization and Security state on the cache maintenance instructions on page D4-2357.
- Boundary conditions for cache maintenance instructions on page D4-2359.
- Ordering and completion of data and instruction cache instructions on page D4-2359.
- Performing cache maintenance instructions on page D4-2360.

The instruction cache maintenance instruction (IC)

System instructions on page C3-172 describes the A64 assembly syntax for this instruction.

When an IC instruction requires an address argument this takes the form of a 64-bit register that holds the VA argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, or at EL2 when HCR_EL2.E2H==1, the current ASID.
- The current Security state.
- Whether the instruction was executed at EL1 or EL2.
- For an instruction executed at EL1, the current VMID.

That VA to PA translation might fault. However, for an instruction cache maintenance instruction that operates by VA:

- It is IMPLEMENTATION DEFINED whether the instruction can generate:
  - An Access flag fault.
  - A Translation fault.
- The instruction cannot generate a Permission fault, except for:
  - The possible generation of a Permission fault by the execution of an IC IVAU instruction at EL0 when the specified address does not have read access at EL0, as described in EL0 accessibility of cache maintenance instructions on page D4-2355.
  - The possible Permission fault on a Stage 2 fault on a stage 1 translation table walk.

For more information about possible faults on a cache maintenance instruction that operates by VA see VMSAv8-64 memory aborts on page D5-2487.

See also Ordering and completion of data and instruction cache instructions on page D4-2359.

The data cache maintenance instruction (DC)

System instructions on page C3-172 describes the A64 assembly syntax for this instruction.

When a DC instruction requires a set/way/level argument this takes the form of a 64-bit register, the upper 32 bits of which are RES0.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-7227 or the instruction description.

When a DC instruction requires an address argument this takes the form of a 64-bit register that holds the VA argument. No alignment restrictions apply for this address.
Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, or at EL2 when HCR_EL2.E2H is 1, the current ASID.
- The current Security state.
- Whether the instruction is executed at EL1 or EL2.
- For an instruction executed at EL1, the current VMID.

That VA to PA translation might fault. However, a data or unified cache maintenance instruction that operates by VA cannot generate a Permission fault except in the following cases:

- The possible generation of a Permission fault by:
  - The execution of a DC IVAC instruction when the specified address does not have write permission.
  - The execution of an enabled DC * instruction at EL0 when the specified address does not have read access at EL0, as described in EL0 accessibility of cache maintenance instructions on page D4-2355.

The description of Permission faults includes possible constraints on the generation of Permission faults on cache maintenance by VA instructions.

- The possible Permission fault on a Stage 2 fault on a stage 1 translation table walk.

For more information about possible faults on a VA to PA translation see VMSAv8-64 memory aborts on page D4-2355.

When executed at EL1, a DC ISW instruction performs a clean and invalidate, meaning it performs the same maintenance as a DC CISW instruction, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- Either:
  - The value of HCR_EL2.SWIO is 1, forcing a cache clean to perform a clean and invalidate.
  - The value of HCR_EL2.VM is 1, meaning EL1&0 stage two address translation is enabled.

When executed at EL1, a DC IVAC instruction performs a clean and invalidate, meaning it performs the same maintenance as a DC CIVAC instruction, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- The value of HCR_EL2.VM is 1, meaning EL1&0 stage two address translation is enabled.

--- Note ---

The forcing of a clean instruction to perform a clean invalidate applies to the AArch32 cache maintenance instructions DCIMVAC and DCISW. See "AArch32 data cache maintenance instructions (DC*)" on page G4-5445.

--- Note ---

When ARMv8.2-DCPoP is implemented, meaning the DC CVAP instruction is implemented, if the memory system does not support the Point of Persistence, a data cache clean to the PoP, DC CVAP, behaves as a data cache clean to the PoC, DC CVAC.

--- Note ---

- Support for the Point of Persistence does not change the definition or behavior of the CLIDR_EL1 System register.

- Because a DSB SYS instruction will not complete until all previous DC CVAP instructions have completed, the following sequence can be used to ensure the completion of any store to the Point of Persistence, where the store might be to Non-cacheable memory:

```
DMB ; Note this can be any DMB that applies to both loads and stores
DC CVAP, Xt
DSB SYS
```

- If caches that are invisible to the programmer exist beyond the Point of Coherency but before the Point of Persistence and hold data that is marked as Non-cacheable, the DC CVAP operation causes the Non-cacheable locations to be cleaned from those caches.

---

If a memory fault that sets the FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.
--- Note ---
Despite its mnemonic, DC ZVA is not a cache maintenance instruction.

See also *EL0 accessibility of cache maintenance instructions* and *Ordering and completion of data and instruction cache instructions* on page D4-2359.

**EL0 accessibility of cache maintenance instructions**

The SCTLR_EL1.UCI bit enables EL0 access for the DC CVAU, DC CVAC, DC CVAP, DC CVAC, and IC IVAU instructions. When EL0 use of these instructions is disabled because SCTLR_EL1.UCI == 0, executing one of these instructions at EL0 generates a trap to EL1, that is reported using EC = 0x18. When HCR_EL2.{E2H,TGE} == 1, the control is from SCTLR_EL2.

--- Note ---
DC CVAP is implemented only if ARMv8.2-DCPoP is implemented.

For these instructions read access permission is required. When the value of SCTLR_EL1.UCI is 1:

- For the DC CVAU, DC CVAC, DC CVAP, and DC CVAC instructions, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, a Permission fault might be generated.
- For the IC IVAU instruction, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, it is IMPLEMENTATION DEFINED whether a Permission fault is generated.

For more information see the description of *Permission faults*. In the case of a DC * instruction executed at EL0 when the address specified cannot be read at EL0 the Permission fault is generated unless one of the permitted constraints described in that section applies and means the fault cannot be generated.

Software can read the CTR_EL0 to discover the stride needed for cache maintenance instructions. The SCTLR_EL1.UCT bit enables EL0 access to the CTR_EL0. When EL0 access to the Cache Type register is disabled, a register access instruction executed at EL0 is trapped to EL1 using EC = 0x18.

**General requirements for the scope of maintenance instructions**

The ARMv8 specification of the cache maintenance instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in *General behavior of the caches* on page D4-2341, *Behavior of caches at reset* on page D4-2347, and *Preloading caches* on page B2-115.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

--- Note ---
ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

**Effects of instructions that operate by VA to the PoC**

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoC must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.
In all cases, for any affected PE, these instructions affect all data and unified caches to the PoC. Table D4-4 shows the scope of these Data and unified cache maintenance instructions.

**Table D4-4 PEs affected by cache maintenance instructions to the PoC**

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The PoC of the entire system</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>All PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
<td>The PoC of the entire system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>All PEs in the same Outer Shareable shareability domain as the PE executing the instruction</td>
<td>The PoC of the entire system</td>
</tr>
</tbody>
</table>

**Effects of instructions that operate by VA to the PoP**

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoP must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the PoP. Table D4-5 shows the scope of these Data and unified cache maintenance to the PoP instructions.

**Table D4-5 PEs affected by cache maintenance instructions to the PoP**

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The PoP of the entire system</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>All PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
<td>The PoP of the entire system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>All PEs in the same Outer Shareable shareability domain as the PE executing the instruction</td>
<td>The PoP of the entire system</td>
</tr>
</tbody>
</table>

**Effects of instructions that operate by VA to the PoU**

For cache maintenance instructions that operate by VA to the PoU, Table D4-6 shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

**Table D4-6 PEs affected by cache maintenance instructions to the PoU**

<table>
<thead>
<tr>
<th>Shareability</th>
<th>PEs affected</th>
<th>Effective to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-shareable</td>
<td>The PE executing the instruction</td>
<td>The PoU of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction</td>
</tr>
<tr>
<td>Inner Shareable or Outer Shareable</td>
<td>All PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
<td>The PoU of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain as the PE executing the instruction</td>
</tr>
</tbody>
</table>
Note
The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the instruction.

Effects of All and set/way maintenance instructions
The IC IALLU and DC set/way instructions apply only to the caches of the PE that performs the instruction.

The IC IALLUIS instruction can affect the caches of all PEs in the same Inner Shareable shareability domain as the PE that performs the instruction. This instruction has an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain.

Note
The possible presence of system caches, as described in System level caches on page D4-2364, means architecture does not guarantee that all levels of the cache can be maintained using set/way instructions.

Effects of virtualization and Security state on the cache maintenance instructions
Each Security state has its own physical address (PA) space, therefore cache entries are associated with PA space.

Table D4-7 shows the effects of virtualization and security on the cache maintenance instructions. In the table, the Specified entries are entries that the architecture requires the instruction to affect. The rules described in General behavior of the caches on page D4-2341 mean that an instruction might also affect other entries.

</tbody>
</table>
For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in The interaction of cache lockdown with cache maintenance instructions on page D4-2363 applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, invalidate by set/way instructions can, instead, perform a clean and invalidate by set/way.

- As described in The data cache maintenance instruction (DC) on page D4-2353, the AArch64 Data cache invalidate instructions, DC_1VAC and DC_1SW, when executed at EL1 and EL0, and the AArch32 Data cache invalidate instructions DC1vAC and DC1SW, when executed at EL1, can be configured to perform a cache clean as well as a cache invalidation.

- TLB and instruction cache invalidate instructions executed at EL1 are broadcast across the Inner Shareable domain when all of the following is true:
  - When the value of HCR_EL2.FB is 1.
  - EL3 is not implemented, or EL3 is implemented and either SCR_EL3.NS == 1 or SCR_EL3.EEL2 == 1.

When EL1 is using AArch64, this applies to the IC_IALU instruction. This means the instruction performs the invalidation that would be performed by the corresponding Inner Shareable instruction IC_IALUIS.

For more information about the cache maintenance instructions, see About cache maintenance in AArch64 state on page D4-2348, A64 Cache maintenance instructions on page D4-2352, and Chapter D5 The AArch64 Virtual Memory System Architecture.
Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For VA-based cache maintenance instructions, the instruction operates on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
  - Is Normal memory or Device memory.
  - Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

Ordering and completion of data and instruction cache instructions

All data cache instructions, other than DC ZVA, that specify an address:

- Execute in program order relative to loads or stores which:
  - Access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
  - Use an address with the same cacheability attributes as the address passed to the data cache instruction.

- Can execute in any order relative to loads or stores which:
  - Access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
  - Use an address with different cacheability attributes as the address passed to the data cache instruction.
  - Do not have a DMB or DSB executed between the load or store instruction and the data cache instruction.

- Can execute in any order relative to loads or stores that access any address with the Device memory attribute, or with Normal memory with Inner Non-cacheable attribute unless a DMB or DSB is executed between the instructions.

- Execute in program order relative to other data cache instructions, other than DC ZVA, that specify an address within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.

- Can execute in any order relative to loads or stores that access an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to other data cache instructions, other than DC ZVA, that specify an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a DMB or DSB is executed between the instructions.

- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.

--- Note ---

Despite its mnemonic, the DC ZVA, Data Cache Zero by VA instruction is not a data cache maintenance instruction.

---

- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.
**Note**

- Data cache ordering rules by address are consistent with physically indexed physically tagged caches. See Data and unified caches on page D5-2521.
- Data cache zero instruction on page D4-2362 describes the ordering and completion rules for Data Cache Zero.

All data cache maintenance instructions that do not specify an address:

- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DS B is executed between the instructions.
- Can execute in any order relative to data cache maintenance instructions that specify an address, other than Data Cache Zero, unless a DMB or DS B is executed between the instructions.
- Can execute in any order relative to loads or stores unless a DMB or DS B is executed between the instructions.
- Can execute in any order relative to instruction cache maintenance instructions unless a DS B is executed between the instructions.

All instruction cache maintenance instructions can execute in any order relative to other instruction cache instructions, data cache instructions, loads, and stores unless a DS B is executed between the instructions.

A cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DS B instruction executed by the PE that executed the cache maintenance instruction. See also the requirements for cache maintenance instructions in Completion and endpoint ordering on page B2-102.

In all cases, where the text in this section refers to a DMB or a DS B, this means a DMB or DS B whose required access type is both loads and stores.

**Note**

These ordering requirements are extended from the requirements in AArch32 state given in:

- Ordering of cache and branch predictor maintenance instructions on page G4-5451.
- AArch32 instruction cache maintenance instructions (IC*) on page G4-5444.

**Performing cache maintenance instructions**

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the CTR_EL0.DMinLine value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the CTR_EL0.IMinLine value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

**Example code for cache maintenance instructions**

The cache maintenance instructions by set/way can clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

**Note**

Since the set/way instructions are performed only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Since any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the line is not affected by set/way based cache maintenance. Therefore, ARM strongly discourages the use of set/way
instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if this is required by the implementation.

The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and ARM advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

System level caches on page D4-2364 refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency. It assumes that the current Cache Size Identification Register is in 32-bit format. For more information, see Possible formats of the Cache Size Identification Register, CCSIDR_EL1 on page D4-2343.

```
MRS     X0, CLIDR_EL1
AND     W3, W0, #0x07000000     // Get 2 x Level of Coherence
LSR     W3, W3, #23              // W0 = 2 x cache level
CBZ     W3, Finished             // W0 = constant 0b1
MOV     W10, #0                  // W10 = 2 x cache level
MOV     W8, #1                   // W8 = constant 0b1
Loop1:  ADD     W2, W10, W10, LSR #1   // Calculate 3 x cache level
        LSR     W1, W0, W2           // extract 3-bit cache type for this level
        AND     W1, W1, #0x7        // W1 = 3-bit cache type
        CMP     W1, #2              // No data or unified cache at this level
        B.LT    Skip                // No data or unified cache at this level
        MSR     CSSELR_EL1, X10     // Select this cache level
        ISB                             // Synchronize change of CSSELR
        MRS     X1, CCSIDR_EL1       // Read CCSIDR
        AND     W2, W1, #7           // W2 = log2(linelen)-4
        ADD     W2, W2, #4           // W2 = log2(linelen)
        UBFX    W4, W1, #3, #10      // W4 = max way number, right aligned
        CLZ     W5, W4                // W5 = 32-log2(ways), bit position of way in DC operand
        LSL     W9, W4, W5            // W9 = max way number, aligned to position in DC operand
        LSL     W16, W8, W5           // W16 = amount to decrement way number per iteration
        Loop2: UBFX    W7, W1, #13, #15 // W7 = max set number, right aligned
                LSL     W7, W7, W2          // W7 = max set number, aligned to position in DC operand
                LSL     W17, W8, W2        // W17 = amount to decrement set number per iteration
        Loop3: ORR     W11, W10, W9     // W11 = combine way number and cache number ...
                ORR     W11, W11, W7     // ... and set number for DC operand
                DC      CSW, X11          // Do data cache clean by set and way
                SUBS    W7, W7, W17      // Decrement set number
                B.GE    Loop3            // Decrement way number
                SUBS    X9, X9, X16      // Decrement way number
                B.GE    Loop2            // Decrement way number
        Skip:  ADD     W10, W10, #2        // Increment 2 x cache level
                CMP     W3, W10           // Ensure completion of previous cache maintenance instruction
                DSB                             // Ensure completion of previous cache maintenance instruction
                B.GT    Loop1
Finished:
```

Similar approaches can be used for all cache maintenance instructions.
D4.4.9 Data cache zero instruction

The Data Cache Zero by Address instruction, DC ZVA, writes $0x0$ to each byte of a block of $N$ bytes, aligned in memory to $N$ bytes in size, where:

- The block in memory is identified by the address supplied as an argument to the DC ZVA instruction. There are no alignment restrictions on this address.

  **Note**

  This means that each byte of the block of memory that includes the supplied address is set to zero.

- The DCZID_EL0 register indicates the block size, $N$ bytes, that is written with byte values of zero.

Software can restrict access to this instruction. See Configurable instruction enables and disables, and trap controls on page D1-2196 and the description of the DC ZVA instruction.

The DC ZVA instruction behaves as a set of stores to the location being accessed, and:

- Generates a Permission fault if the translation regime being used when the instruction is executed does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instruction.

In addition:

- When the instruction is executed, it can generate memory faults or watchpoints that are prioritized in the same way as other memory related faults or watchpoints. Where a synchronous Data Abort fault or a watchpoint is generated, the CM bit in the syndrome field is not set to 1, which would be the case for all other cache maintenance instructions. See ISS encoding for an exception from a Data Abort on page D12-2781 for more information about the encoding of the associated ESR_ELx.ISS field.
- If the memory region being zeroed is any type of Device memory, then DC ZVA generates an Alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

  **Note**

  The architecture makes no statements about whether or not a DC ZVA instruction causes allocation to any particular level of the cache, for addresses that have a cacheable attribute for those levels of cache.

  Despite its mnemonic, the DC ZVA instruction is not a data cache maintenance instruction.

D4.4.10 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.
The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, \texttt{DC CSW}.
  - Cache invalidate by set/way, \texttt{DC ISW}.
  - Cache clean and invalidate by set/way, \texttt{DC CISW}.
  - Instruction cache invalidate all, \texttt{IC IALLU} and \texttt{IC IALLUIS}.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the DFSC value defined for this purpose, see \textit{ISS encoding for an exception from a Data Abort} on page D12-2781.

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:
- Cache clean by virtual address, \texttt{DC CVAC}, \texttt{DC CVAP}, and \texttt{DC CVAU}.
- Cache invalidate by virtual address, \texttt{DC IVAC}.
- Cache clean and invalidate by virtual address, \texttt{DC CIVAC}.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the DFSC value defined for this purpose. See \textit{ESR\_ELx} on page K13-7394.

In an implementation that includes EL2 enabled in the current Security state, if HCR\_EL2.TIDCP is set to 1, any exception relating to lockdown of an entry is routed to EL2.

\begin{note}
An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:
- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.
\end{note}

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.
### Additional cache functions for the implementation of lockdown

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED spaces reserved for Cache Lockdown, see Reserved encodings for IMPLEMENTATION DEFINED registers on page D11-2659.

### D4.4.11 System level caches

The ARM Architecture defines a system cache as a cache that is not described in the PE Cache Identification registers, CCSIDR_EL1 and CLIDR_EL1, and for which the set/way cache maintenance instructions do not apply.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by any cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the ARM architecture is explicitly prohibited.

2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by set/way instructions. Where maintenance of the entirety of such a cache must be performed, as in the case for power management, it must be performed using non-architectural mechanisms.

3. System caches which lie beyond the point of coherency and so are invisible to the software. The management of such caches is outside the scope of the architecture.

### D4.4.12 Branch prediction

ARMv8 does not define any branch predictor maintenance instructions for AArch64 state.

If branch prediction is architecturally visible, cache maintenance must also apply to branch prediction.
D4.5 External aborts

The ARM architecture defines External aborts as errors that occur in the memory system, other than those that are detected by the MMU or debug logic. An External abort might signal a data corruption to the PE. For example, a memory location might have been corrupted, and this corruption is detected by hardware using a parity or error correction code (ECC). The error might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

An External abort is one of the following:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see Exception terminology on page D1-2135.

The RAS Extension provides a more granular taxonomy of aborts. When the RAS Extension is not implemented, the ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous External aborts.

It is IMPLEMENTATION DEFINED which External aborts, if any, are supported.

VMSAv8-64 permits External aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous.

A synchronous External abort on an instruction fetch, including a translation table walk on an instruction fetch, is taken precisely using the Instruction Abort exception.

A synchronous External abort on a data read or write, including a translation table walk on a data read or write, is taken precisely using the Data Abort exception.

See Synchronous exception types, routing and priorities on page D1-2178.

When ARMv8.4-DFE is implemented, all External abort exceptions on instruction fetches must be synchronous.

An asynchronous External abort is taken using the SError interrupt exception. See Asynchronous exception types, routing, masking and priorities on page D1-2186.

The effect of a failed memory access is described in Effect of Data Aborts on page D1-2183.

Normally, External aborts are rare. An imprecise asynchronous External abort is likely to be fatal to the process that is running, ARM recommends that implementations make External aborts precise wherever possible.

The following subsections give more information about possible External aborts:

- Provision for the classification of External aborts.
- Parity or ECC error reporting, RAS Extension not implemented on page D4-2366.

D4.5.1 Provision for the classification of External aborts

In AArch64 state, an implementation can use ESR_ELx.EA, ISS[9], to provide more information about synchronous External aborts. For all synchronous aborts other than synchronous External aborts, ESR_ELx.EA, ISS[9], returns a value of 0.

If the RAS Extension is implemented:

- The ESR_ELx.SET field provides information about the state of the PE following a synchronous External abort.
- The ESR_ELx.AET field might contain more information following an asynchronous abort taken as an SError interrupt.
- The implementation might define error record registers.

For more information, see:

- ISS encoding for an exception from an Instruction Abort on page D12-2779.
• ISS encoding for an exception from a Data Abort on page D12-2781.
• ISS encoding for an SError interrupt on page D12-2825.
• ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

### D4.5.2 Parity or ECC error reporting, RAS Extension not implemented

The ARM architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache system. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see Use of the ESR_EL1, ESR_EL2, and ESR_EL3 on page D1-2160. However, when parity or ECC error reporting is implemented, it is implementation defined whether a parity or ECC error is reported using the assigned fault code or using another appropriate encoding.

For all purposes other than the Fault status encoding, parity or ECC errors are treated as External aborts.
D4.6 Memory barrier instructions

Memory barriers on page B2-103 describes the memory barrier instructions. This section describes the system level controls of those instructions.

D4.6.1 EL2 control of the shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 enabled in the current Security state and supports shareability limitations on the data barrier instructions, the HCR_EL2.BSU field can modify the required shareability of an instruction that is executed at EL0 or EL1. Table D4-8 shows the encoding of this field.

**Table D4-8 EL2 control of shareability of barrier instructions executed at EL0 or EL1**

<table>
<thead>
<tr>
<th>HCR_EL2.BSU</th>
<th>Minimum shareability of barrier instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect, shareability is as specified by the instruction</td>
</tr>
<tr>
<td>01</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Full system</td>
</tr>
</tbody>
</table>

For an instruction executed at EL0 or EL1, Table D4-9 shows how the HCR_EL2.BSU is combined with the shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction.

**Table D4-9 Effect of HCR_EL2.BSU on barrier instructions executed at EL1 or EL0**

<table>
<thead>
<tr>
<th>Shareability specified by the DMB or DSB argument</th>
<th>HCR_EL2.BSU</th>
<th>Resultant shareability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full system</td>
<td>Any</td>
<td>Full system</td>
</tr>
<tr>
<td>Outer Shareable</td>
<td>00, 01, or 10</td>
<td>Outer Shareable</td>
</tr>
<tr>

</table>
D4.7 Pseudocode description of general memory System instructions

This section lists the pseudocode describing general memory operations:

- Memory data type definitions.
- Basic memory access.
- Aligned memory access on page D4-2369.
- Unaligned memory access on page D4-2369.
- Exclusives monitors operations on page D4-2369.
- Access permission checking on page D4-2370.
- Abort exceptions on page D4-2370.
- Memory barriers on page D4-2370.

D4.7.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the AddressDescriptor type.
- Full address, defined by the FullAddress type.
- Memory attributes, defined by the MemoryAttributes type.
- Memory type, defined by the MemType enumeration.
- Device memory type, defined by the DeviceType enumeration.
- Normal memory attributes, defined by the MemAttrHints type.
- Cacheability attributes, defined by the MemAttr_NC, MemAttr_WT, and MemAttr_WB constants.
- Allocation hints, defined by the MemHint_No, MemHint_WA, MemHint_RA, and MemHint_RWA constants.
- Access permissions, defined by the Permissions type.

These types are defined in Chapter J1 ARMv8 Pseudocode.

D4.7.2 Basic memory access

The two forms of the _Mem[] accessor, non-assignment (memory read) _Mem[] and assignment (memory write) _Mem[], are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

The functions address the array using desc.paddress, that supplies:

- The physical address.
- An NS bit that selects between the Secure and Non-secure parts of the array.

The attributes in desc.memattrs are used by the memory system to determine caching and ordering behaviors as described in Memory types and attributes on page B2-122, Ordering and observability on page B2-98, and Atomicity in the Arm architecture on page B2-92.

An additional parameter to the _Mem[] accessor defines the access type, for example normal, exclusive, ordered, or streaming, and whether the access is made as part of a translation table walk.

The actual implemented array of physical memory might be smaller than the maximum size permitted by the architecture. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to External aborts or a System Error.

--- Note ---

The permitted physical memory size is:

- \(2^{52}\) bytes in an implementation that includes ARMv8.2-LPA. However, only \(2^{48}\) bytes are accessible using the 4KB or 16KB translation granule.
- \(2^{48}\) bytes otherwise.
PAMax() returns the IMPLEMENTATION DEFINED size of the physical address.

**D4.7.3 Aligned memory access**

The two MemSingle[] accessors, non-assignment (memory read) AArch64.MemSingle[] and assignment (memory write) AArch64.MemSingle[], make atomic, little-endian accesses of size bytes. These functions are defined in Chapter J1 ARMv8 Pseudocode.

**D4.7.4 Unaligned memory access**

The two Mem[] accessors, Non-assignment (memory read) Mem[] and Assignment (memory write) Mem[], make accesses of the required type. If an access is not architecturally defined to be atomic, Mem[] synthesizes accesses from multiple calls to AArch64.MemSingle[]. It also reverses the byte order if the access is big-endian.

The AArch64.CheckAlignment() function checks the alignment of memory accesses.

**D4.7.5 Exclusives monitors operations**

The AArch64.SetExclusiveMonitors() function sets the Exclusives monitors for a block of bytes, the size of which is determined by size, at the virtual address defined by address.

The AArch64.ExclusiveMonitorsPass() function checks whether the Exclusives monitors are set to include the location of a number of bytes specified by size, at the virtual address defined by address. The atomic write that follows after the Exclusives monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to AArch64.SetExclusiveMonitors().

The ExclusiveMonitorsStatus() function returns 0 if the previous atomic write was to the same physical memory locations selected by AArch64.ExclusiveMonitorsPass() and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The MarkExclusiveGlobal() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure records that the PE processorid has requested exclusive access covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONstrained UNpredictable whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The MarkExclusiveLocal() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure records in a local record that PE processorid has requested exclusive access to an address covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a MarkExclusiveGlobal() using the same parameters.

The IsExclusiveGlobal() function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked in a global record an address range as exclusive access requested that covers at least size bytes from address paddress. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, IsExclusiveGlobal() returns FALSE.

The IsExclusiveLocal() function takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked an address range as exclusive access requested that covers at least size bytes from address paddress. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of size bytes from address paddress. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of IsExclusiveGlobal() with the same parameters.

The ClearExclusiveByAddress() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure clears the global records of all PEs, other than processorid, for which an address region including any of size bytes starting from paddress has had a request for an exclusive access. It is
IMPLEMENTATION DEFINED whether the equivalent global record of the PE processorid is also cleared if any of size bytes starting from paddress has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The ClearExclusiveLocal() procedure takes as arguments the PE identifier processorid. The procedure clears the local record of PE processorid for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE processorid that an address has had a request for an exclusive access.

These functions are defined in Chapter J1 ARMv8 Pseudocode.

D4.7.6 Access permission checking

The function AArch64.CheckPermission() is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors. It returns the result of the call to AArch64.NoFault().

These functions are defined in Chapter J1 ARMv8 Pseudocode.

The interpretation of access permission is shown in Memory access control on page D5-2444.

D4.7.7 Abort exceptions

The function AArch64.Abort() generates either a Data Abort or an Instruction Abort exception by calling AArch64.DataAbort() or AArch64.InstructionAbort(). It also can generate a debug exception for debug related faults, see Chapter D2 AArch64 Self-hosted Debug.

The function AArch64.DataAbort() generates a Data Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, ESR_ELx. See ISS encoding for an exception from a Data Abort on page D12-2781. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, AArch64.DataAbort() also sets the FAR to the VA of the abort.

The function AArch64.InstructionAbort() generates an Instruction Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, ESR_ELx, see ISS encoding for an exception from an Instruction Abort on page D12-2779. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, AArch64.InstructionAbort() also sets the FAR to the VA of the abort.

The FaultRecord type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. Pseudocode description of the MMU faults on page D5-2496 provides a number of wrappers to generate FaultRecords.

The function AArch64.NoFault() returns a null record that indicates no fault. The IsFault() function tests whether a FaultRecord contains a fault.

D4.7.8 Memory barriers

The definition for the memory barrier functions is given by the enumerations MBReqDomain and MBReqTypes.

These enumerations define the required shareability domains and required access types used as arguments for DMB and DSB instructions.

The procedures DataMemoryBarrier, DataSynchronizationBarrier, and InstructionSynchronizationBarrier perform the memory barriers.*
Chapter D5
The AArch64 Virtual Memory System Architecture

This chapter provides a system level view of the AArch64 Virtual Memory System Architecture (VMSAv8-64), the memory system architecture of an ARMv8 implementation that is executing in AArch64 state. It contains the following sections:

- About the Virtual Memory System Architecture (VMSA) on page D5-2372.
- The VMSAv8-64 address translation system on page D5-2380.
- VMSAv8-64 translation table format descriptors on page D5-2432.
- Memory access control on page D5-2444.
- Memory region attributes on page D5-2464.
- Virtualization Host Extensions on page D5-2474.
- VMSAv8-64 memory aborts on page D5-2487.
- Nested virtualization on page D5-2480.
- Translation Lookaside Buffers (TLBs) on page D5-2497.
- TLB maintenance requirements and the TLB maintenance instructions on page D5-2503.
- Caches in a VMSAv8-64 implementation on page D5-2521.
D5.1 About the Virtual Memory System Architecture (VMSA)

This chapter describes the ARMv8 Virtual Memory System Architecture (VMSA), and in particular how it applies to a PE that is executing in AArch64 state. In this state the PE is using VMSAv8-64, as defined in ARMv8 VMSA naming. See The ARMv8 VMSA when some Exception levels are using AArch32 for information about the VMSA in other contexts.

A VMSA provides a Memory Management Unit (MMU), that controls address translation, access permissions, and memory attribute determination and checking, for memory accesses made by the PE. The process of address translation maps the virtual addresses (VAs) used by the PE onto the physical addresses (PAs) of the physical memory system. The mapping of a VA to a PA requires either a single stage of translation, or two sequential stages of translation.

The translations are defined independently for different Exception levels and Security states, as described in The VMSAv8-64 address translation system on page D5-2380.

VMSAv8-64 supports tagging of VAs, as described in Address tagging in AArch64 state on page D5-2374. As that section describes, this address tagging has no effect on the address translation process.

The remainder of this chapter gives a full description of VMSAv8-64 for an implementation that includes all of the Exception levels. The implemented Exception levels and the resulting translation stages and regimes on page D5-2384 describes the differences in the VMSA if some Exception levels are not implemented.

The following sections give more information about the VMSA:

• ARMv8 VMSA naming.
• The ARMv8 VMSA when some Exception levels are using AArch32.
• VMSA address types and address spaces on page D5-2373.
