In addition to an output address, a translation table entry that refers to page or region of memory includes fields that define properties of the target memory region. Information returned by a translation table lookup describes the classification of those fields as address map control, access control, and memory attribute fields. The access control fields, described in this section, determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access, then an MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

- About access permissions.
- About the PAN bit on page G5-5513.
- Access permissions for instruction execution on page G5-5514.
- Domains, Short-descriptor format only on page G5-5518.
- The Access flag on page G5-5518.
- Hyp mode control of Non-secure access permissions on page G5-5519.

G5.6.1 About access permissions

The translation table descriptors include fields that define access permissions for data accesses and for instruction fetches. This section introduces those fields. In addition:

- System register controls can prevent execution from writable locations, see Preventing execution from writable locations on page G5-5517.
- In ARMv8.1, the PSTATE.PAN can affect the access permissions for privileged data accesses, see About the PAN bit on page G5-5513.

Note

This section gives a general description of memory access permissions. Software executing at PL1 in Non-secure state can see only the access permissions defined by the Non-secure PL1&0 stage 1 translations. However, software executing at EL2 can modify these permissions, as described in Hyp mode control of Non-secure access permissions on page G5-5519. This modification is invisible to Non-secure software executing at EL1 or EL0.

Access permission bits in a translation table descriptor control access to the corresponding memory region. The details of this control depend on the translation table format, as follows:

Short-descriptor format

This format supports two options for defining the access permissions:

- Three bits, AP[2:0], define the access permissions.
- Two bits, AP[2:1], define the access permissions, and AP[0] can be used as an Access flag.

SCTLR.AFE selects the access permissions option. Setting this bit to 1, to enable the Access flag, also selects use of AP[2:1] to define access permissions.

ARM deprecates any use of the AP[2:0] scheme for defining access permissions.

Long-descriptor format

AP[2:1] to control the access permissions, and the descriptors provide an AF bit for use as an Access flag. This means VMSAv8-32 behaves as if the value of SCTLR.AFE is 1, regardless of the value that software has written to this bit.

Note

When use of the Long-descriptor format is enabled, SCTLR.AFE is UNK/SBOP.

The Access flag on page G5-5518 describes the Access flag, for both translation table formats.

The XN and PXN bits provide additional access controls for instruction fetches, see Access permissions for instruction execution on page G5-5514.
An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation. However, when using the Short-descriptor translation table format, it generates the fault only if the access is to memory in the Client domain, see Domains, Short-descriptor format only on page G5-5518.

Note

For the Non-secure PL1&0 translation regime, memory accesses are subject to two stages of translation. Each stage of translation has its own, independent, fault checking. Fault handling is different for the two stages, see Exception reporting in a VMSAv8-32 implementation on page G5-5566.

The following sections describe the two access permissions models:

• AP[2:1] access permissions model.
• AP[2:0] access permissions control, Short-descriptor format only on page G5-5512. This section includes some information on access permission control in earlier versions of the ARM VMSA.

AP[2:1] access permissions model

Note

ARM recommends that this model is always used, even where the AP[2:0] model is permitted. Some documentation describes the AP[2:1] model as the simplified access permissions model.

This access permissions model is used if the translation is either:

• Using the Long-descriptor translation table format.
• Using Short-descriptor translation table format, and the SCTLR.AFE bit is set to 1.

In this model:

• One bit, AP[2], selects between read-only and read/write access.
• A second bit, AP[1], selects between Application level (EL0) and System level (PL1) control.

For the Non-secure EL2 stage 1 translations, AP[1] is SBO.

This provides four access combinations:

• Read-only at all privilege levels.
• Read/write at all privilege levels.
• Read-only at PL1, no access by software executing at EL0.
• Read/write at PL1, no access by software executing at EL0.

Table G5-7 shows this access control model.

Table G5-7 VMSAv8-32 AP[2:1] access permissions model

<table>
<thead>
<tr>
<th>AP[2], disable write access</th>
<th>AP[1], enable unprivileged access</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0a</td>
<td>Read/write, only at PL1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Read/write, at any privilege level</td>
</tr>
<tr>
<td>1</td>
<td>0a</td>
<td>Read-only, only at PL1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Read-only, at any privilege level</td>
</tr>
</tbody>
</table>

a. Not valid for Non-secure EL2 stage 1 translation tables. AP[1] is SBO in these tables.
Hierarchical control of access permissions, Long-descriptor format

The Long-descriptor translation table format introduces a mechanism that entries at one level of translation table lookup can use to set limits on the permitted entries at subsequent levels of lookup. This applies to the access permissions, and also to the restrictions on instruction fetching described in Hierarchical control of instruction fetching, Long-descriptor format on page G5-5516.

The restrictions apply only to subsequent levels of lookup at the same stage of translation. The APTable[1:0] field restricts the access permissions, as Table G5-8 shows.

However, in an implementation that includes ARMv8.2-AA32HPD, when hierarchical control of data access permissions is disabled for a translation regime, the information in this subsection does not apply. See Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5494.

As stated in the table footnote, for the Non-secure EL2 stage 1 translation tables, APTable[0] is reserved, SBZ.

<table>
<thead>
<tr>
<th>APTable[1:0]</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No effect on permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>01&lt;sup&gt;a&lt;/sup&gt;</td>
<td>Access at EL0 not permitted, regardless of permissions in subsequent levels of lookup.</td>
</tr>
<tr>
<td>10</td>
<td>Write access not permitted, at any Exception level, regardless of permissions in subsequent levels of lookup.</td>
</tr>
</tbody>
</table>
| 11<sup>a</sup> | Regardless of permissions in subsequent levels of lookup:  
|               | • Write access not permitted, at any Exception level.  
|               | • Read access not permitted at EL0. |

<sup>a</sup> Not valid for the Non-secure EL2 stage 1 translation tables. In those tables, APTable[0] is SBZ.

Note

The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The Long-descriptor format provides APTable[1:0] control only for the stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

The effect of APTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to APTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

AP[2:0] access permissions control, Short-descriptor format only

This access permissions model applies when using the Short-descriptor translation tables format, and the SCTLR.AFE bit is set to 0. ARM deprecates any use of this access permissions model.

When SCTLR.AFE is set to 0, ensuring that the AP[0] bit is always set to 1 effectively changes the access model to the simpler model described in AP[2:1] access permissions model on page G5-5511.
Table G5-9 shows the full AP[2:0] access permissions model:

<table>
<thead>
<tr>
<th>AP[2]</th>
<th>AP[1:0]</th>
<th>PL1 access</th>
<th>Unprivileged access</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>00</td>
<td>No access</td>
<td>No access</td>
<td>All accesses generate Permission faults</td>
</tr>
<tr>
<td></td>
<td>01</td>
<td>Read/write</td>
<td>No access</td>
<td>Access only at PL1</td>
</tr>
<tr>
<td></td>
<td>10</td>
<td>Read/write</td>
<td>Read-only</td>
<td>Writes at EL0 generate Permission faults</td>
</tr>
<tr>
<td></td>
<td>11</td>
<td>Read/write</td>
<td>Read/write</td>
<td>Full access</td>
</tr>
<tr>
<td>1</td>
<td>00</td>
<td>-</td>
<td>-</td>
<td>Reserved</td>
</tr>
<tr>
<td></td>
<td>01</td>
<td>Read-only</td>
<td>No access</td>
<td>Read-only, only at PL1</td>
</tr>
<tr>
<td></td>
<td>10</td>
<td>Read-only</td>
<td>Read-only</td>
<td>Read-only at any Exception level, deprecated^a</td>
</tr>
<tr>
<td></td>
<td>11</td>
<td>Read-only</td>
<td>Read-only</td>
<td>Read-only at any Exception level^b</td>
</tr>
</tbody>
</table>

^a. From VMSAv7, ARM strongly recommends use of the 0b11 encoding for Read-only at any Exception level.
^b. This mapping was introduced in VMSAv7, and is reserved in earlier versions of the VMSA.

---

**Note**

- VMSAv8-32 supports the full set of access permissions shown in Table G5-9 only when SCTLR.AFE is set to 0. When SCTLR.AFE is set to 1, the only supported access permissions are those described in AP[2:1] access permissions model on page G5-5511.

### G5.6.2 About the PAN bit

When the value of PSTATE.PAN is 1, any privileged data access from PL1 or EL2 to a virtual memory address that is accessible at EL0 generates a Permission fault.

When the value of PSTATE.PAN is 0, the translation system is the same as in ARMv8.0.

A corresponding PAN bit is added to CPSR and SPSR for exception returns, and DSPSR for entry to and exit from Debug state.

A new SPAN bit is added to SCTLR that controls whether the PAN state bit is set on taking an exception to EL1 from either Secure or Non-secure state, or to EL3 from Secure state when EL3 is using AArch32.

CPSR.PAN bit can be written using an MSR instruction at PL1 or higher. Data writes to CPSR.PAN using an MSR instruction at EL0 are ignored. The value that is returned for an MSR instruction of CPSR from EL0 is UNKNOWN. In keeping with all other writes to the CPSR, other than for instruction fetches, the effect of the PAN state bit does not need to be explicitly synchronized.

The PAN state bit has no effect on:
- Data Cache instructions.
- Address translation instructions, other than ATS1CPRP and ATS1CPWP when ARMv8.2-ATS1E1 is implemented.
- Unprivileged instructions, LDRBT, LDRHT, LDRT, LDRSBT, LDRSHT, STRBT, STRHT, STRT, STRSBT, and STRSHT, unless HCR_EL2.{E2H, TGE} == {1, 0}.
- Instruction accesses.
- Manager domains.

If access is disabled, then the access will give rise to a stage 1 Permission fault.
On an exception taken from AArch32:
• CPSR.PAN is copied to SPSR_ELx.PAN, when the target Exception level is AArch64.
• CPSR.PAN is copied to SPSR.PAN, when the target Exception level is AArch32.

On an exception return from AArch32 to AArch32, SPSR.PAN is copied to CPSR.PAN.

On entry to Debug state, CPSR.PAN is copied to DSPSR.PAN.

On exit from Debug state, DSPSR.PAN is copied to CPSR.PAN.

The CPSR.PAN bit is not an Execution state bit.

Note
• In Non-debug state, in AArch32 state, software can use the SETPAN #imm instruction to modify PSTATE.PAN.
• In Debug state, in AArch32 state, a debugger can use the ERET instruction to perform a DRPS operation to modify PSTATE.PAN.

G5.6.3 Access permissions for instruction execution

Execute-never controls provide an additional level of control on memory accesses permitted by the access permissions settings. These controls are:

XN, Execute-never
Descriptor bit[54], defined as XN for:
• Stage 1 of any translation regime.
• Stage 2 translations when ARMv8.2-TTS2UXN is not implemented.

Note
XN[1:0], Execute-never, stage 2 only describes the stage 2 control when ARMv8.2-TTS2UXN is implemented.

This field applies to execution at any Exception level to which the stage of translation applies. A value of 0 indicates that this control permits execution.

PXN, Privileged execute-never, stage 1 only
Descriptor bit[53], used only for stage 1 of any translation regime for which the stage 1 translation can support two VA ranges:
• For stage 1 of a translation regime for which the stage 1 translation supports only a single VA range the stage 1 descriptors define a PXN field that is RES0, meaning it is ignored by hardware.

This field applies only to execution at an Exception level higher than EL0. A value of 0 indicates that this control permits execution.

XN[1:0], Execute-never, stage 2 only
Descriptor bits[54:53], defined as XN[1:0] for:
• Stage 2 translations when ARMv8.2-TTS2UXN is implemented.
Table G5-10 shows the operation of this control.

<table>
<thead>
<tr>
<th>XN[1]</th>
<th>XN[0]</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>The stage 2 control permits execution at EL1 and EL0 if read access is permitted</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>The stage 2 control does not permit execution at EL1, but permits execution at EL0 if read access is permitted</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>The stage 2 control does not permit execution at EL1 or at EL0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The stage 2 control permits execution at EL1 if read access is permitted, but does not permit execution at EL0</td>
</tr>
</tbody>
</table>

Note

For stage 2 translations when ARMv8.2-TTS2UXN is not implemented, descriptor bit[53] is RES0, meaning it is ignored by hardware, and bit[54] is the XN control, see XN, Execute-never on page G5-5514.

Executing an instruction at ELx in a particular Security state generates a Permission fault unless all of the following are true for the instruction address:

- Any stage 1 execute-never control that applies to execution at ELx in the current Security state permits execution.
- If the translation regime that applies to ELx in the current Security state has two stages of translations, the stage 2 execute-never control that applies to execution at ELx permits execution.
- Read access is permitted.

However, if a stage 1 translation is using the Short-descriptor translation table format and the address is in a Managers domain the stage 1 access permissions are not checked, and therefore the access cannot cause a stage 1 Permission fault, see Domains, Short-descriptor format only on page G5-5518.

See also Hyp mode control of Non-secure access permissions on page G5-5519.

In addition, System register controls can enforce execute-never restrictions, regardless of the settings in the translation table XN and PXN fields, see:

- Restriction on Secure instruction fetch on page G5-5517.
- Preventing execution from writable locations on page G5-5517.

The execute-never controls apply also to speculative instruction fetching. This means a speculative instruction fetch from a memory region that is execute-never at the current level of privilege is prohibited.

The execute-never controls means that, when the stage of address translation is enabled, the PE can fetch, or speculatively fetch, an instruction from a memory location only if all of the following apply:

- If using the Short-descriptor translation table format, the translation table descriptor for the location does not indicate that it is in a No access domain.
- If using the Long-descriptor translation table format, or using the Short descriptor format and the descriptor indicates that the location is in a Client domain, in the descriptor for the location the following apply:
  - The stage 1 execute-never control for the Exception level at which the instruction is executed permits execution.
  - For a translation regime with two stages of address translation, the stage 2 execute-never control that applies to the Exception level at which the instruction is executed permits execution.
  - The access permissions permit a read access from the current PE mode.
- No other Prefetch Abort condition exists.
Note

The PXN control applies to the PE privilege when it attempts to execute the instruction. In an implementation that fetches instructions speculatively, this might not be the privilege when the instruction was prefetched. Therefore, the architecture does not require the PXN control to prevent instruction fetching.

Although the XN control applies to speculative fetching, on a speculative instruction fetch from an XN location, no Permission fault is generated unless the PE attempts to execute the instruction that would have been fetched from that location. This means that, if a speculative fetch from an XN location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.

The software that defines a translation table must mark any region of memory that is read-sensitive as XN, to avoid the possibility of a speculative fetch accessing the memory region. This means it must mark any memory region that corresponds to a read-sensitive peripheral as XN. Hardware does not prevent speculative accesses to a region of any Device memory type unless that region is also marked as execute-never for all Exception levels from which it can be accessed.

When using the Short-descriptor translation table format, the XN attribute is not checked for domains marked as Manager. Therefore, the system must not include read-sensitive memory in domains marked as Manager, because the XN field does not prevent speculative fetches from a Manager domain.

When no stage of address translation for the translation regime is enabled, memory regions cannot have XN or PXN attributes assigned. Behavior of instruction fetches when all associated address translations are disabled on page G5-5474 describes how disabling all MMUs affects instruction fetching.

Hierarchical control of instruction fetching, Long-descriptor format

The Long-descriptor translation table format introduces a mechanism that means entries at one level of translation tables lookup can set limits on the permitted entries at subsequent levels of lookup. This applies to the restrictions on instruction fetching, and also to the access permissions described in Hierarchical control of access permissions, Long-descriptor format on page G5-5512.

Note

Similar hierarchical controls apply to data accesses, see Hierarchical control of access permissions, Long-descriptor format on page G5-5512.

However, in an implementation that includes ARMv8.2-HPD, when hierarchical control of instruction fetching is disabled for a translation regime, the information in this subsection does not apply. See Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5494.

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

- **XNTable** restricts the XN control:
  - When XNTable is set to 1, the XN field is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the field.
  - When XNTable is set to 0 it has no effect.

- **PXNTable** restricts the PXN control:
  - When PXNTable is set to 1, the PXN field is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the field.
  - When PXNTable is set to 0 it has no effect.

Note

The XNTable and PXNTable settings are combined with the XN and PXN fields in the translation table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The XNTable and PXNTable controls are provided only in the Long-descriptor translation table format, and only for stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.
The effect of XNTable or PXNTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to XNTable or PXNTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

### Preventing execution from writable locations

ARMv8 provides control bits that, when the corresponding stage 1 address translation is enabled, force writable memory to be treated as XN or PXN, regardless of the value of the XN or PXN field. When the translation stages are controlled by an Exception level that is using AArch32:

- For PL1&0 stage 1 translations, when SCTLR.WXN is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN.
- For PL1&0 stage 1 translations, when SCTLR.UWXN is set to 1, an instruction fetch is treated as accessing a PXN region if it accesses a region that software executing at EL0 can write to.
- For Non-secure EL2 stage 1 translations, when HSCTLR.WXN is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN.

#### Note

- The SCTLR.WXN controls are intended to be used in systems with very high security requirements.
- Setting a WXN or UXN bit to 1 changes the interpretation of the translation table entry, overriding a zero value of an XN or PXN field. It does not cause any change to the translation table entry.

For any given virtual machine, ARM expects WXN and UXN to remain static in normal operation. In particular, it is IMPLEMENTATION DEFINED whether TLB entries associated with a particular VMID reflect the effect of the values of these fields. A generic sequence to ensure synchronization of a change to these fields, when that change is made without a corresponding change of VMID, is:

```
Change the WXN or UXN bit
ISB                      ; This ensures synchronization of the change
Invalidate entire TLB of associated entries
DSB                      ; This completes the TLB Invalidation
ISB                      ; This ensures instruction synchronization
```

As with all Permission fault checking, if the stage 1 translation is using the Short-descriptor translation table format, the permission checks are performed only for Client domains. For more information, see [About access permissions](#) on page G5-5510.

For more information about address translation, see [About address translation for VMSAv8-32](#) on page G5-5467.

### Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, SCR.SIF. When this bit is to 1, any attempt in Secure state to execute an instruction fetched from Non-secure physical memory causes a Permission fault. As with all Permission fault checking, when using the Short-descriptor format translation tables the check applies only to Client domains, see [About access permissions](#) on page G5-5510.

ARM expects SCR.SIF to be static during normal operation. In particular, whether the TLB holds the effect of the SIF bit is IMPLEMENTATION DEFINED. The generic sequence to ensure visibility of a change to the SIF bit is:

```
Change the SCR.SIF bit
ISB                      ; This ensures synchronization of the change
Invalidate entire TLB
DSB                      ; This completes the TLB Invalidation
ISB                      ; This ensures instruction synchronization
```
G5.6.4 Domains, Short-descriptor format only

A domain is a collection of memory regions. The Short-descriptor translation table format supports 16 domains, and requires the software that defines a translation table to assign each VMSAv8-32 memory region to a domain. When using the Short-descriptor format:

- Level 1 translation table entries for translation tables and Sections include a domain field.
- Translation table entries for Supersections do not include a domain field. The Short-descriptor format defines Supersections as being in domain 0.
- Level 2 translation table entries inherit a domain setting from the parent level 1 translation table descriptor.
- Each TLB entry includes a domain field.

The domain field specifies which of the 16 domains the entry is in, and a two-bit field in the DACR defines the permitted access for each domain. The possible settings for each domain are:

- **No access** Any access using the translation table descriptor generates a Domain fault.
- **Clients** On an access using the translation table descriptor, the access permission attributes are checked. Therefore, the access might generate a Permission fault.
- **Managers** On an access using the translation table descriptor, the access permission attributes are not checked. Therefore, the access cannot generate a Permission fault.

See *The MMU fault-checking sequence* on page G5-5558 for more information about how, when using the Short-descriptor translation table format, the Domain attribute affects the checking of the other attributes in the translation table descriptor.

--- Note ---

A single program might:

- Be a Client of some domains.
- Be a Manager of some other domains.
- Have no access to the remaining domains.

---

The Long-descriptor translation table format does not support domains. When a stage of translation is using this format, all memory is treated as being in a Client domain, and the settings in the DACR are ignored.

G5.6.5 The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding translation table descriptor was set to 0:

- If address translation is using the Short-descriptor translation table format, it must set SCTLR.AFE to 1 to enable use of the Access flag. Setting this bit to 1 redefines the AP[0] bit in the translation table descriptors as an Access flag, and limits the access permissions information in the translation table descriptors to AP[2:1], as described in *AP[2:1] access permissions model* on page G5-5511.
- The Long-descriptor format always supports an Access flag bit in the translation table descriptors, and address translation using this format behaves as if SCTLR.AFE is set to 1, regardless of the value of that bit.

In ARMv8.0, the Access flag is managed by software as described in *Software management of the Access flag* on page G5-5519.

--- Note ---

Previous version of the ARM architecture optionally supported hardware management of the Access flag. ARMv8.0 obsoletes this option. However, ARMv8.1-TTHM provides a new mechanism for hardware management of the Access flag, that is supported only for the VMSAv8-64 translation regimes.
Software management of the Access flag

ARMv8.0 requires that software manages the Access flag. This means an Access flag fault is generated whenever an attempt is made to read into the TLB a translation table descriptor entry for which the value of the Access flag is 0.

--- Note ---
When using the Short-descriptor translation table format, Access flag faults are generated only if SCTLR.AFE is set to 1, to enable use of a translation table descriptor bit as an Access flag.

--- Note ---
The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

--- Note ---
If a system incorporates components that can autonomously update translation table entries that are shared with the ARM PE, then the software must be aware of the possibility that such components can update the access flag autonomously.

In such a system, system software should perform any changes of translation table entries with an Access flag of 0, other than changes to the Access flag value, by using an Load-Exclusive/Store-Exclusive loop, to allow for the possibility of simultaneous updates.

G5.6.6 Hyp mode control of Non-secure access permissions

When EL2 is using AArch32, Non-secure software executing in Hyp mode controls two sets of translation tables, both of which use the Long-descriptor translation table format:

- The translation tables that control the Non-secure EL2 stage 1 translations. These map VAs to PAs, for memory accesses made when executing in Non-secure state in Hyp mode, and are indicated and controlled by the HTTBR and HTCR.
  
  These translations have similar access controls to other Non-secure stage 1 translations using the Long-descriptor translation table format, as described in:
  - Access permissions for instruction execution on page G5-5514.

  The differences from the Non-secure stage 1 translations are that:
  - The APTable[0], PXNTable, and PXN bits are reserved, SBZ.
  - AP[1] is reserved, SBO.

- The translation tables that control the Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, for memory accesses made when executing in Non-secure state at PL1 or EL0, and are indicated and controlled by the VTTBR and VTCR.
  
  The descriptors in the virtualization translation tables define stage 2 access permissions, that are combined with the permissions defined in the stage 1 translation. This section describes this combining of access permissions.

--- Note ---
The level 2 access permissions mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:

- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.
The stage 2 access controls defined from Hyp mode:

- Affect only the Non-secure stage 1 access permissions settings.
- Take no account of whether the accesses are from a Non-secure PL1 mode or a Non-secure EL0 mode.
- Permit software executing in Hyp mode to assign a write-only attribute to a memory region.

The S2AP field in the stage 2 descriptors define the stage 2 access permissions, as Table G5-11 shows:

<table>
<thead>
<tr>
<th>S2AP</th>
<th>Access permission</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No access permitted</td>
</tr>
<tr>
<td>01</td>
<td>Read-only. Writes to the region are not permitted, regardless of the stage 1 permissions.</td>
</tr>
<tr>
<td>10</td>
<td>Write-only. Reads from the region are not permitted, regardless of the stage 1 permissions.</td>
</tr>
<tr>
<td>11</td>
<td>Read/write. The stage 1 permissions determine the access permissions for the region.</td>
</tr>
</tbody>
</table>

For more information about the S2AP field, see Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors on page G5-5497.

If the stage 2 permissions cause a Permission fault, this is a stage 2 MMU fault. Stage 2 MMU faults are taken to Hyp mode, and reported in the HSR using an EC code of 0x20 or 0x24. For more information, see Use of the HSR on page G5-5580.

--- Note ---
In the HSR, the combination of the EC code and the DFSC or IFSC value in the ISS indicate that the fault is a stage 2 MMU fault.

The stage 2 permissions include an XN attribute. If this identifies the region as execute-never, execution from the region is not permitted, regardless of the value of the XN or UXN attribute in the stage 1 translation. If a Permission fault is generated because the stage 2 XN field identifies the region as execute-never, this is reported as a stage 2 MMU fault.

--- Note ---
The stage 2 XN attribute:
- Is a single bit if ARMv8.2-TTS2UXN is not implemented, see XN, Execute-never on page G5-5514.
- Is a 2-bit field if ARMv8.2-TTS2UXN is implemented, see XN[1:0], Execute-never, stage 2 only on page G5-5514.

AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-5563 describes the abort prioritization if both stages of a translation generate a fault.
G5.7 Memory region attributes

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of that target memory region. Information returned by a translation table lookup on page G5-5477 describes the classification of those fields as address map control, access control, and memory attribute fields. The memory region attribute fields control the memory type, Cacheability, and Shareability of the region.

The following sections describe the assignment of memory region attributes for stage 1 translations:

- **Overview of memory region attributes for stage 1 translations.**
- **Short-descriptor format memory region attributes, without TEX remap** on page G5-5522.
- **Short-descriptor format memory region attributes, with TEX remap** on page G5-5524.
- **VMSAv8-32 Long-descriptor format memory region attributes** on page G5-5527.

For an implementation that is operating in Secure state, or in Hyp mode, these assignments define the memory attributes of the accessed region.

For an implementation that is operating in a Non-secure PL1 or EL0 mode, the Non-secure PL1&0 stage 2 translation can modify the memory attributes assigned by the stage 1 translation. **EL2 control of Non-secure memory region attributes** on page G5-5529 describes these stage 2 assignments.

G5.7.1 Overview of memory region attributes for stage 1 translations

The description of the memory region attributes in a translation descriptor divides into:

**Memory type and attributes**

These are described either:

- Directly, by bits in the translation table descriptor.
- Indirectly, by registers referenced by bits in the table descriptor. This is described as **remapping** the memory type and attribute description.

The Short-descriptor translation table format can use either of these approaches, selected by the SCTLR.TRE bit:

**TRE == 0** Remap disabled. The TEX[2:0], C, and B bits in the translation table descriptor define the memory region attributes. **Short-descriptor format memory region attributes, without TEX remap** on page G5-5522 describes this encoding.

--- Note ---

With the Short-descriptor format, remapping is called **TEX remap**, and the SCTLR.TRE bit is the **TEX remap enabled** bit.

The description of the TRE == 0 encoding includes information about the encoding in previous versions of the architecture.

**TRE == 1** Remap enabled. The TEX[0], C, and B bits in the translation table descriptor are index bits to the remap registers, that define the memory region attributes:

- The Primary Region Remap Register, PRRR.
- The Normal Memory Remap Register, NMRR.

**Short-descriptor format memory region attributes, with TEX remap** on page G5-5524 describes this encoding scheme.

This scheme reassigns translation table descriptor bits TEX[2:1] for use as bits managed by the operating system.

The Long-descriptor translation table format always uses remapping. This means that when the value of TTBCR.EAE is 1, enabling use of the Long-descriptor translation table format, SCTLR.TRE is RES1.

**VMSAv8-32 Long-descriptor format memory region attributes** on page G5-5527 describes this encoding.
Shareability  In the Short-descriptor translation table format, the S bit in the translation table descriptor is used in
determining the Shareability of the region. How the S bit is interpreted depends on whether TEX
remap is enabled, see:
- Shareability and the S bit, without TEX remap on page G5-5523.
- Determining the Shareability, with TEX remap on page G5-5525.

In the Long-descriptor translation table format, the SH[1:0] field in the translation table descriptor
encodes the Shareability of the region, see Shareability, Long-descriptor format on page G5-5527.

--- Note ---
Shareability is one of Non-shareable, Inner Shareable, and Outer Shareable. However, when using
the Short-descriptor translation table format without TEX remap, VMSA8-32 does not support any
distinction between Inner Shareable and Outer Shareable memory, and a memory region is either
Non-shareable or Outer Shareable.

### G5.7.2 Short-descriptor format memory region attributes, without TEX remap

When using the Short-descriptor translation table formats, TEX remap is disabled when the value of SCTLR.TRE
is 0.

--- Note ---
- The Short-descriptor format scheme without TEX remap is the scheme used in VMSA6.
- The B (Bufferable), C (Cacheable), and TEX (Type extension) bit names are inherited from earlier versions
of the architecture. These names no longer adequately describe the function of the B, C, and TEX bits.

Table G5-12 shows the C, B, and TEX[2:0] encodings when TEX remap is disabled. In the Page Shareability
column, an entry of S bit indicates that the S bit in the translation table descriptor determines the Shareability, see
Shareability and the S bit, without TEX remap on page G5-5523.

Cacheability attributes, without TEX remap

When the value of TEX[2] is 0, the same Cacheability attribute applies to Inner Cacheable and Outer Cacheable memory regions, and the \{TEX[1:0], C, B\} values identify this attribute, as Table G5-12 on page G5-5522 shows.

When the value of TEX[2] is 1, the memory described by the translation table entry is cacheable, and the rest of the encoding defines the Inner Cacheability and Outer Cacheability attributes:

- TEX[1:0] Define the Outer Cacheability attribute.
- C, B Define the Inner Cacheability attribute.

The translation table entries use the same encoding for the Outer and Inner Cacheability attributes, as Table G5-13 shows.

Shareability and the S bit, without TEX remap

The Short-descriptor format translation table entries include an S bit. This bit:

- Is ignored if the entry refers to any type of Device memory, or to Normal memory that is Inner Non-cacheable, Outer Non-cacheable.
- For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, determines whether the memory region is Outer Shareable or Non-shareable:
  - S == 0 Normal memory region is Non-shareable.
  - S == 1 Normal memory region is Outer Shareable.

Without TEX remapping there is no distinction between Inner Shareable and Outer Shareable memory, meaning the S bit determines whether the region is Non-shareable or Outer Shareable.
### G5.7.3 Short-descriptor format memory region attributes, with TEX remap

When using the Short-descriptor translation table formats, TEX remap is enabled when the value of SCTLR.TRE is 1. In this configuration:

- The software that defines the translation tables must program the PRRR and NMRR to define seven possible memory region attributes.
- The TEX[0], C, and B bits of the translation table descriptors define the memory region attributes, by indexing PRRR and NMRR.
- Hardware makes no use of TEX[2:1], see *The OS managed translation table bits* on page G5-5526.

When TEX remap is enabled:

- For seven of the eight possible combinations of the TEX[0], C, and B bits, fields in the PRRR and NMRR define the region attributes, as described in this section.
- The meaning of the eighth combination for the TEX[0], C and B bits is IMPLEMENTATION DEFINED.
- If the TEX[0], C and B bits determine that the region is a Device memory type, or is Normal Inner Non-cacheable, Outer Non-cacheable, then the region is Outer Shareable. Otherwise, the Shareability is determined by the combination of:
  - The S bit from the translation table descriptor.
  - The value of the PRRR.NS0 or PRRR.NS1 bit.
  - The value of the appropriate PRRR.NOSn bit, as shown in Table G5-14.

For more information, see *Determining the Shareability, with TEX remap* on page G5-5525.

For each of the possible encodings of the TEX[0], C, and B bits in a translation table entry, Table G5-14 shows which fields of the PRRR and NMRR registers describe the memory region attributes.

<table>

</tr>
</tbody>
</table>

- **Memory type**: For details of the Memory type encodings see the description of the PRRR. For details of the Outer Shareable encodings see the description of the NMRR.
- **Cache attributes**: Applies only if the memory type for the region is mapped as Normal memory.
- **Outer Shareable attribute**: Applies only if both of the following apply:
  - The memory type for the region is mapped as Normal memory that is not Inner Non-cacheable and Outer Non-cacheable.
  - The region is not Non-shareable.

See *Determining the Shareability, with TEX remap* on page G5-5525.
As Table G5-14 on page G5-5524 shows, when TEX remap is enabled, for a given set of \{TEX[0], C, B\} bits from a translation table descriptor:

1. The primary mapping, to memory type, is given by the PRRR.TRn field as shown in the Memory type column.
2. For any region that the PRRR.TRn maps as Normal memory, NMRR.IRn determines the Inner cacheability attribute, and NMRR.ORn determines the Outer cacheability attribute.
3. For a region that PRRR.TRn maps as Normal memory, if NMRR.{IRn, ORn} do not map the region as Inner Non-cacheable, Outer Non-cacheable, PRRR.{NS0, NS1} and PRRR.NOSn are used to determine the Shareability of the region, see Determining the Shareability, with TEX remap.

The TEX remap registers and the SCTLR.TRE bit are banked between the Secure and Non-secure Security states. For more information, see The effect of EL3 on TEX remap on page G5-5527.

The TEX remap registers must be static during normal operation. In particular, when the remap registers are changed:

- It is IMPLEMENTATION DEFINED when the changes take effect.
- It is CONSTRAINED UNPREDICTABLE whether the TLB caches the effect of the TEX remap on translation tables, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7195.

The software sequence to ensure the synchronization of changes to the TEX remap registers is:

1. Execute a DSB instruction. This ensures any memory accesses using the old mapping have completed.
2. Write the TEX remap registers or SCTLR.TRE bit.
3. Execute an ISB instruction. This ensures synchronization of the register updates.
4. Invalidate the entire TLB.
5. Execute a DSB instruction. This ensures completion of the entire TLB operation.
6. Clean and invalidate all caches. This removes any cached information associated with the old mapping.
7. Execute a DSB instruction. This ensures completion of the cache maintenance.
8. Execute an ISB instruction. This ensures instruction synchronization.

This extends the standard rules for the synchronization of changes to System registers described in Synchronization of changes to AArch32 System registers on page G8-5640, and provides implementation freedom as to whether or not the effect of the TEX remap is cached.

**Determining the Shareability, with TEX remap**

The memory type of a region, as indicated in the Memory type column of Table G5-14 on page G5-5524, provides the first level of control of the Shareability of the region:

- If the memory is any type of Device memory, then the region is Outer Shareable, and any Shareability attributes in the translation table descriptor and PRRR for that region are ignored.
  This applies also to a Normal memory region that the NMRR attributes identify as Inner Non-cacheable and Outer Non-cacheable,
- If using the Short descriptor translation table format then the Shareability of the region is determined using the value of the S bit in the translation table descriptor to index one of the PRRR.{NS1, NS0} bits, as described in this section.

Table G5-15 shows how the translation table S bit indexes into the PRRR:

**Table G5-15 Determining the Shareability attribute, with TEX remap**

<table>
<thead>
<tr>
<th>Memory type</th>
<th>Remapping when S == 0</th>
<th>Remapping when S == 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device or Normal Inner Non-cacheable, Outer Non-cacheable</td>
<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Normal, not Inner Non-cacheable, Outer Non-cacheable</td>
<td>PRRR.NS0</td>
<td>PRRR.NS1</td>
</tr>
</tbody>
</table>
For a Normal memory region that is not Inner Non-cacheable, Outer Non-cacheable, the appropriate bit of the
PRRR indicates whether the region is Non-shareable, as follows:

\[
\text{PRRR.NS}_n = 0 \quad \text{Non-shareable.}
\]
\[
\text{PRRR.}\{\text{NOS7\text{:}NOS0}\} \text{ are ignored.}
\]

\[
\text{PRRR.NS}_n = 1
\]

The appropriate PRRR.NOS\text{m} field, as shown in Table G5-14 on page G5-5524, indicates whether the region is Inner Shareable or Outer Shareable:

\[
\text{PRRR.NOS}_m = 0 \quad \text{Region is Outer Shareable.}
\]

\[
\text{PRRR.NOS}_m = 1 \quad \text{Region is Inner Shareable.}
\]

Note

This means that TEX remapping can map a translation table entry with \(S=0\) as shareable memory.

SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers

When TEX remap is disabled, because the value of the SCTLR.TRE bit is 0:

- The effect of the PRRR and NMRR registers can be IMPLEMENTATION DEFINED.
- The interpretation of the fields of the PRRR and NMRR registers can differ from the description given earlier in this section. One implication of this is that the implementation can provide an IMPLEMENTATION DEFINED mechanism to interpret the PRRR.\{NOS7\text{:}NOS0\} fields.

VMSAv8-32 requires that the effect of these registers is limited to remapping the attributes of memory locations. These registers must not change whether any cache hardware or stages of address translation are enabled. The mechanism by which the TEX remap registers have an effect when the value of the SCTLR.TRE bit is 0 is IMPLEMENTATION DEFINED. The AArch32 architecture requires that from reset, if the IMPLEMENTATION DEFINED mechanism has not been invoked:

- If the PL1&0 stage 1 address translation is enabled and is using the Short-descriptor format translation tables, the architecturally-defined behavior of the TEX[2:0], C, and B bits must apply, without reference to the TEX remap functionality. In other words, memory attribute assignment must comply with the scheme described in Short-descriptor format memory region attributes, without TEX remap on page G5-5522.
- If the PL1&0 stage 1 address translation is disabled, then the architecturally-defined behavior of VMSAv8-32 with address translation disabled must apply, without reference to the TEX remap functionality. See The effects of disabling address translation stages on VMSAv8-32 behavior on page G5-5472.

Possible mechanisms for enabling the IMPLEMENTATION DEFINED effect of the TEX remap registers when the value of SCTLR.TRE is 0 include:

- A control bit in the ACTLR, or in an IMPLEMENTATION DEFINED System register.
- Changing the behavior when the PRRR and NMRR registers are changed from their IMPLEMENTATION DEFINED reset values.

In addition, if the stage of address translation is disabled and the value of the SCTLR.TRE bit is 1, the architecturally-defined behavior of the VMSAv8-32 with the stage of address translation disabled must apply without reference to the TEX remap functionality.

In an implementation that includes EL3, the IMPLEMENTATION DEFINED effect of these registers must only take effect in the Security state of the registers. See also The effect of EL3 on TEX remap on page G5-5527.

The OS managed translation table bits

When TEX remap is enabled, the TEX[2:1] bits in the translation table descriptors are available as two bits that can be managed by the operating system. In VMSAv8-32, as long as the SCTLR.TRE bit is set to 1, the values of the TEX[2:1] bits are IGNORED by the PE. Software can write any value to these bits in the translation tables.
The effect of EL3 on TEX remap

In an implementation that includes EL3, when EL3 is using AArch32, the TEX remap registers are banked between the Secure and Non-secure Security states. When EL3 is using AArch32, write accesses to the Secure register for the current security state apply to all PL1&0 stage 1 translation table lookups in that state. The SCTLR.TRE bit is banked in the Secure and Non-secure copies of the register, and the appropriate version of this bit determines whether TEX remap is applied to translation table lookups in the current security state.

Write accesses to the Secure copies of the TEX remap registers are disabled when the CP15SDISABLE input is asserted HIGH, meaning the MCR operations to access these registers are UNDEFINED. For more information, see The CP15SDISABLE input signal on page G5-5598.

G5.7.4 VMSAv8-32 Long-descriptor format memory region attributes

When a PE is using the VMSAv8-32 Long-descriptor translation table format, the AttrIndx[2:0] field in a block or page translation table descriptor for a stage 1 translation indicates the 8-bit field, in the appropriate MAIR register, that specifies the attributes for the corresponding memory region, as follows:

- AttrIndx[2] indicates the MAIR register to be used:
  - AttrIndx[2] == 0 Use MAIR0.

- AttrIndx[2:0] indicates the required Attr field, Attr, where \( n = \text{AttrIndx}[2:0] \).

Each AttrIndx field defines, for the corresponding memory region:

- The memory type, Normal or a type of Device memory.
- For Normal memory:
  - The Inner cacheability and Outer cacheability attributes, each of which is one of Non-cacheable, Write-Through Cacheable, or Write-Back Cacheable.
  - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is Allocate or No allocate.

For more information about the AttrIndx[2:0] descriptor field, see Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors on page G5-5495.

Shareability, Long-descriptor format

When a PE is using the Long-descriptor translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region, if the MAIR entry for that region identifies it as Normal memory that is not both Inner Non-cacheable and Outer Non-cacheable. Table G5-16 shows the encoding of this field.

<table>
<thead>
<tr>
<th>SH[1:0]</th>
<th>Normal memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Non-shareable</td>
</tr>
<tr>
<td>01</td>
<td>Reserved, CONSTRAINED UNPREDICTABLE, see Reserved values in System and memory-mapped registers and translation table entries on page K1-7212 for the permitted behavior.</td>
</tr>
<tr>
<td>10</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Shareable</td>
</tr>
</tbody>
</table>

See Combining the Shareability attribute on page G5-5532 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.
For any type of Device memory, and for Normal Inner Non-cacheable, Outer Non-cacheable memory, the value of the SH[1:0] field of the translation table descriptor is ignored.

Other fields in the Long-descriptor translation table format descriptors

The following subsections describe the other fields in the translation table block and page descriptors when a PE is using the Long-descriptor translation table format:

- **Contiguous bit**
- **IGNORED fields**
- **Field reserved for software use on page G5-5529**

**Contiguous bit**

The Long-descriptor translation table format descriptors contain a Contiguous bit. Setting this bit to 1 indicates that 16 adjacent translation table entries point to a contiguous output address range. These 16 entries must be aligned in the translation table so that the top five bits of their input addresses, that index their position in the translation table, are the same. For example, to use this bit for a block of 16 entries in the level 3 translation table, bits[20:16] of the input addresses for the 16 entries must be the same.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

Use of this bit means that the TLB can cache a single entry to cover the 16 translation table entries.

This bit acts as a hint. The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of this bit.

**Note**

The use of the contiguous bit is similar to the approach used, in the Short-descriptor translation table format, for optimized caching of Large Pages and Supersections in the TLB. However, an important difference in the contiguous bit capability is that TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues. That is, any use of the contiguous bit has no effect on the minimum size of entry that must be invalidated from the TLB.

**IGNORED fields**

In the VMSA8-32 translation table long-descriptor format, the following fields are defined as IGNORED, meaning the architecture guarantees that a PE makes no use of these fields:

- In the stage 1 and stage 2 Table descriptors, bits[58:52] and bits[11:2].
- In the stage 1 and stage 2 Block and Page descriptors, bit[63] and bits[58:55].
- In the stage 1 and stage 2 Block and Page descriptors in an implementation that does not include ARMv8.2-TTPBHA, bits[62:59].

Of these fields:

- In the stage 1 and stage 2 block and page descriptors, bits[58:55] are reserved for software use, see Field reserved for software use on page G5-5529.
- In the stage 2 block and page descriptors:
  - Bit[63] is reserved for use by a System MMU.
  - In an implementation that does not include ARMv8.2-TTPBHA, bits[62:59] are reserved for use by a System MMU.
Field reserved for software use

The architecture reserves a 4-bit IGNORED field in the Block and translation table descriptors, bits[58:55], for software use. In considering migration from using the Short-descriptor format to the Long-descriptor format, this field is an extension of the Short-descriptor field described in The OS managed translation table bits on page G5-5526.

--- Note ---
The definition of IGNORED means there is no need to invalidate the TLB if these bits are changed.

G5.7.5 EL2 control of Non-secure memory region attributes

Software executing at EL2 controls two sets of translation tables, both of which use the Long-descriptor translation table format. These are:

- The translation tables that control Non-secure EL2 stage 1 translations. These map VAs to PAs, and when EL2 is using AArch32 they are indicated and controlled by the HTTBR and HTCR.
  These translations have exactly the same memory region attribute controls as any other stage 1 translations, as described in VMSAv8-32 Long-descriptor format memory region attributes on page G5-5527.

- The translation tables that control Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, and are indicated and when EL2 is using AArch32 they are controlled by the VTTBR and VTCR.
  The descriptors in the virtualization translation tables define level 2 memory region attributes, that are combined with the attributes defined in the stage 1 translation. This section describes this combining of attributes.

VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5491 describes the format of the entries in these tables.

--- Note ---
In a virtualization implementation, a hypervisor might usefully:
- Reduce the permitted Cacheability of a region.
- Increase the required Shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

---

In the stage 2 translation table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- The definition of the stage 2 SH[1:0] field is identical to the same field for a stage 1 translation, see Shareability, Long-descriptor format on page G5-5527.

- MemAttr[3:2] give a top-level definition of the memory type, and of the cacheability of a Normal memory region, as Table G5-17 shows:

<table>
<thead>
<tr>
<th>MemAttr[3:2]</th>
<th>Memory type</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Device, of type determined by MemAttr[1:0]</td>
<td>Not applicable</td>
</tr>
<tr>
<td>01</td>
<td>Normal, Inner cacheability determined by MemAttr[1:0]</td>
<td>Outer Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td>Outer Write-Through Cacheable</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>Outer Write-Back Cacheable</td>
<td></td>
</tr>
</tbody>
</table>
The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

— When MemAttr[3:2] == 0b00, indicating a type of Device memory, Table G5-18 shows the encoding of MemAttr[1:0]:

Table G5-18 MemAttr[1:0] encoding for the types of Device memory

<table>
<thead>
<tr>
<th>MemAttr[1:0]</th>
<th>Meaning when MemAttr[3:2] == 0b00</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Region is Device-n GnRnE memory</td>
</tr>
<tr>
<td>01</td>
<td>Region is Device-n GnRE memory</td>
</tr>
<tr>
<td>10</td>
<td>Region is Device-n GRE memory</td>
</tr>
<tr>
<td>11</td>
<td>Region is Device-GRE memory</td>
</tr>
</tbody>
</table>

— When MemAttr[3:2] != 0b00, indicating Normal memory, Table G5-19 shows the encoding of MemAttr[1:0]:

Table G5-19 MemAttr[1:0] encoding for Normal memory

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Reserved, CONSTRAINED UNPREDICTABLE, See Reserved values in System and memory-mapped registers and translation table entries on page K1-7212 for the permitted behavior.</td>
</tr>
<tr>
<td>01</td>
<td>Inner Non-cacheable</td>
</tr>
<tr>
<td>10</td>
<td>Inner Write-Through Cacheable</td>
</tr>
<tr>
<td>11</td>
<td>Inner Write-Back Cacheable</td>
</tr>
</tbody>
</table>

Note
The stage 2 translation does not assign any allocation hints.

The following sections describe how the memory type attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

• Combining the memory type attribute on page G5-5531.
• Combining the Cacheability attribute on page G5-5531.
• Combining the Shareability attribute on page G5-5532.

Note
• The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:
  — MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.

• In addition to the attribute combinations described in this section, Access permissions for instruction execution on page G5-5514 describes how the stage 1 and stage 2 execute-never permission fields are combined, so that a region is execute-never if it is defined as execute-never in at least one stage of translation.
Combining the memory type attribute

Table G5-20 shows how the stage 1 and stage 2 memory type assignments are combined:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device-nGnRnE</td>
<td>Any</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td>Device-nGnRE</td>
<td>Device-nGnRnE</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td></td>
<td>Not Device-nGnRnE</td>
<td>Device-nGnRE</td>
</tr>
<tr>
<td>Device-nGRE</td>
<td>Device-nGnRnE</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td></td>
<td>Device-nGnRE</td>
<td>Device-nGnRE</td>
</tr>
<tr>
<td></td>
<td>Not (Device-nGnRnE or Device-nGnRE)</td>
<td>Device-nGRE</td>
</tr>
<tr>
<td>Device-GRE</td>
<td>Device-nGnRnE</td>
<td>Device-nGnRnE</td>
</tr>
<tr>
<td></td>
<td>Device-nGnRE</td>
<td>Device-nGnRE</td>
</tr>
<tr>
<td></td>
<td>Device-nGRE</td>
<td>Device-nGRE</td>
</tr>
<tr>
<td></td>
<td>Device-GRE or Normal</td>
<td>Device-GRE</td>
</tr>
<tr>
<td>Normal</td>
<td>Any type of Device</td>
<td>Device type assigned at stage 2</td>
</tr>
<tr>
<td></td>
<td>Normal</td>
<td>Normal</td>
</tr>
</tbody>
</table>

See Combining the Shareability attribute on page G5-5532 for information about the Shareability of:

- A region for which the resultant type is any Device type.
- A region with a resultant type of Normal for which the resultant cacheability, described in Combining the Cacheability attribute, is Inner Non-cacheable, Outer Non-cacheable.

The combining of the memory type attribute means a translation table walk for a stage 1 translation can be made to a type of Device memory. If this occurs, then:

- If the value of HCR.PTW is 0, then the translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be done speculatively.
- If the value of HCR.PTW is 1, then the memory access generates a stage 2 Permission fault.

Combining the Cacheability attribute

For a Normal memory region, Table G5-21 shows how the stage 1 and stage 2 Cacheability assignments are combined. This combination applies, independently, for the Inner Cacheability and Outer Cacheability attributes:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-cacheable</td>
<td>Any</td>
<td>Non-cacheable</td>
</tr>
<tr>
<td>Any</td>
<td>Non-cacheable</td>
<td>Non-cacheable</td>
</tr>
</tbody>
</table>
Only Normal memory has a Cacheability attribute.

Combining the Shareability attribute

In the following cases, a memory region is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation:

- The resultant memory type attribute, described in Combining the memory type attribute on page G5-5531, is any type of Device memory.
- The resultant memory type attribute is Normal memory, and the resultant Cacheability, described in Combining the Cacheability attribute on page G5-5531, is Inner Non-cacheable Outer Non-cacheable.

For a memory region with a resultant memory type attribute of Normal that is not Inner Non-cacheable Outer Non-cacheable, Table G5-22 shows how the stage 1 and stage 2 shareability assignments are combined:

<table>
<thead>
<tr>
<th>Assignment in stage 1</th>
<th>Assignment in stage 2</th>
<th>Resultant Shareability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Outer Shareable</td>
<td>Any</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Inner Shareable</td>
<td>Non-shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Outer Shareable</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Inner Shareable</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Non-shareable</td>
<td>Non-shareable</td>
<td>Non-shareable</td>
</tr>
</tbody>
</table>
G5.8 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement to perform a translation table walk in memory for every memory access. The ARM architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.
- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.
- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.
- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Domain fault or a Permission fault might be held in the TLB.
- When address translation is enabled, any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not from a translation regime for an Exception level that is lower than the current Exception level can be allocated to a TLB at any time. The only translation table entries guaranteed not to be held in the TLB are those that generate a Translation fault, an Address size fault, or an Access flag fault.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>An TLB can hold translation table entries that do not generate a Translation fault but point to subsequent tables in the translation table walk. This can be referred to as intermediate caching of TLB entries.</td>
</tr>
</tbody>
</table>

The following sections give more information about TLB implementation:

- **Global and process-specific translation table entries.**
- **TLB matching** on page G5-5534.
- **TLB behavior at reset** on page G5-5534.
- **TLB lockdown** on page G5-5535.
- **TLB conflict aborts** on page G5-5535.

See also **TLB maintenance requirements** on page G5-5537.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>In addition to the functions described in this section, the TLB might cache information from control registers that are described as being “permitted to be cached in a TLB”, even when any or all of the stages of translation are disabled. This caching of information gives rise to the maintenance requirements described in General TLB maintenance requirements on page G5-5537.</td>
</tr>
</tbody>
</table>

### G5.8.1 Global and process-specific translation table entries

For VMSA v8-32, system software can divide a virtual memory map used by memory accesses at PL1 and EL0 into global and non-global regions, indicated by the nG bit in the translation table descriptors:

\[ \text{nG} = 0 \quad \text{The translation is global, meaning the region is available for all processes.} \]
The translation is non-global, or process-specific, meaning it relates to the current ASID, as defined by:

- TTBR0.ASID or TTBR1.ASID, if using the Long-descriptor translation table format. In this case, TTBCR.A1 selects which ASID is current.
- CONTEXTIDR.ASID, if using the Short-descriptor translation table format.

Each non-global region has an associated ASID. These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

For a symmetric multiprocessor cluster where a single operating system is running on the set of PEs, the architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all PEs in the system.

In AArch32 state, the translation regime used for accesses made at EL2 never supports ASIDs, and all pages are treated as global.

When a PE is using the Long-descriptor translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information see Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G5-5498.

G5.8.2 TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance instructions described in TLB maintenance requirements on page G5-5537 can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular ASID and VMID are changed without suitable invalidation of the TLB. This can occur only if the architecturally-required break-before-make sequence described in Using break-before-make when updating translation table entries on page G5-5538 is not used. If the break-before make sequence is not used, the TLB can hold two mappings for the same address, and this:

- Might generate an exception that is reported using the TLB Conflict fault code, see TLB conflict aborts on page G5-5535.
- Might lead to CONSTRAINED UNPREDICTABLE behavior. In this case, behavior will be consistent with one of the mappings held in the TLB, or with some amalgamation of the values held in the TLB, but cannot give access to regions of memory with permissions or attributes that could not be assigned by valid translation table entries in the translation regime being used for the access. See CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7195.

G5.8.3 TLB behavior at reset

The ARM architecture does not require a reset to invalidate the TLBs, and recognizes that an implementation might require caches, including TLBs, to maintain context over a system reset. Possible reasons for doing so include power management and debug requirements.

Therefore, for ARMv8:

- All TLBs reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
- All TLBs are disabled from reset. All stages of address translation that are used from the PE state entered on coming out of reset are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information see Enabling stages of address translation on page G5-5474.
• An implementation can require the use of a specific TLB invalidation routine, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device. ARM recommends that if an invalidation routine is required for this purpose, and the PE resets into AArch32 state, the routine is based on the AArch32 TLB maintenance instructions described in The scope of TLB maintenance instructions on page G5-5546.

Similar rules apply:
• To cache behavior, see Behavior of caches at reset on page G4-5439.
• To branch predictor behavior, see Behavior of the branch predictors at reset on page G4-5447.

G5.8.4 TLB lockdown

The ARM architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

• The architecture does not require TLB lockdown support.
• If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that:
• The TLB Type Register, TLBTR, does not define the lockdown scheme in use.
• In AArch32 state, a region of the \{coproc==0b1111, CRn==c10\} encodings is reserved for IMPLEMENTATION DEFINED TLB functions, such as TLB lockdown functions. The reserved encodings are those with:
  — \(<CRm>=\{c0, c1, c4, c8\}\).
  — All values of \(<opc2>\) and \(<opc1>\).

An implementation might use some of the \{coproc==0b1111, CRn==c10\} encodings that are reserved for IMPLEMENTATION DEFINED TLB functions to implement additional TLB control functions. These functions might include:
• Unlock all locked TLB entries.
• Preload into a specific level of TLB. This is beyond the scope of the PL1 and PL2 hint instructions.

The inclusion of EL2 in an implementation does not affect the TLB lockdown requirements. However, in an implementation that includes EL2, exceptions generated as a result of TLB lockdown when executing in a Non-secure PL1 mode or in Non-secure User mode can be routed to either:
• Non-secure Abort mode, using the Non-secure Data Abort exception vector.
• Hyp mode, using the Hyp Trap exception vector.

For more information, see Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-5337.

G5.8.5 TLB conflict aborts

If an address matches multiple entries in the TLB, it is IMPLEMENTATION DEFINED whether a TLB conflict abort is generated.

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses. A TLB conflict abort is classified as an MMU fault, see Types of MMU faults on page G5-5555. This means:
• A TLB conflict abort on an instruction fetch is reported as a Prefetch Abort exception,
• A TLB conflict abort on a data access is reported as a Data Abort exception,

Fault status codes for TLB conflict aborts are defined for both the Short-descriptor and Long-descriptor translation table formats, see:
• PL1 fault reporting with the Short-descriptor translation table format on page G5-5571
• PL1 fault reporting with the Long-descriptor translation table format on page G5-5573.
On a TLB conflict abort, the fault address register returns the address that generated the fault. That is, it returns the address that was being looked up in the TLB.

It is IMPLEMENTATION DEFINED whether a TLB conflict abort is a stage 1 abort or a stage 2 abort.

--- Note ---

- An address can hit multiple entries in the TLB if the TLB has been invalidated inappropriately, for example if TLB invalidation required by this manual has not been performed.

- A stage 2 abort cannot be generated if the Non-secure PL1&0 stage 2 address translation is disabled.

---

The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of any TLB that can generate the abort. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

If an address matches multiple entries in the TLB and no TLB conflict abort not generated, the resulting behavior is CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7195. The CONSTRAINED UNPREDICTABLE behavior must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Privilege level.
G5.9 TLB maintenance requirements

Translation Lookaside Buffers (TLBs) on page G5-5533 describes the ARM architectural provision for TLBs. Although the ARM architecture does not specify the form of any TLB structures, it does define the mechanisms by which TLBs can be maintained. The following sections describe the VMSAv8-32 TLB maintenance instructions:

- General TLB maintenance requirements.
- Maintenance requirements on changing System register values on page G5-5542.
- Atomicity of register changes on changing virtual machine on page G5-5543.
- Synchronization of changes of ASID and TTBR on page G5-5543.
- The scope of TLB maintenance instructions on page G5-5546.

G5.9.1 General TLB maintenance requirements

TLB maintenance instructions provide a mechanism to invalidate entries from a TLB. As Translation Lookaside Buffers (TLBs) on page G5-5533 describes, when address translation is enabled translation table entries can be allocated to a TLB at any time. This means that software must perform TLB maintenance between updating translation table entries that apply in a particular context and accessing memory locations whose translation is determined by those entries in that context.

Note

This requirement applies to any translation table entry at any level of the translation tables, including an entry that points to further levels of the tables, provided that the entry in that level of the tables does not cause a Translation fault, an Address size fault, or an Access flag fault.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information see Cache maintenance requirement created by changing translation table attributes on page G5-5553.

Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag fault to one that does not fault, does not require any TLB or branch predictor invalidation. However, a Context synchronization event is required to ensure that instruction fetches are affected by a completed change to translation table entries that, before the change, generated a Translation, Address size, or Access flag fault.

Special considerations apply to translation table updates that change the memory type, cacheability, or output address of an entry, see Using break-before-make when updating translation table entries on page G5-5538.

In addition, software must perform TLB maintenance after updating the System registers if the update means that the TLB might hold information that applies to a current translation context, but is no longer valid for that context. Maintenance requirements on changing System register values on page G5-5542 gives more information about this maintenance requirement.

Each of the translation regimes defined in Figure G5-1 on page G5-5466 is a different context, and:

- For the Non-secure PL1&0 regime, a change in the VMID or ASID value changes the context.
- For the Secure PL1&0 regime, a change in the ASID value changes the context.

For operation in Non-secure PL1 or EL0 modes, a change of HCR.VM, unless made at the same time as a change of VMID, requires the invalidation of all TLB entries for the Non-secure PL1&0 translation regime that apply to the current VMID. Otherwise, there is no guarantee that the effect of the change of HCR.VM is visible to software executing in the Non-secure PL1 and EL0 modes.

Any TLB maintenance instruction can affect any other TLB entries that are not locked down.

AArch32 state defines \{coproc==0b1111, Crn==c8\} System instructions for TLB maintenance instructions, and supports the following operations:

- Invalidate all unlocked entries in the TLB.
- Invalidate a single TLB entry, by VA, or VA and ASID for a non-global entry.
- Invalidate all TLB entries that match a specified ASID.
- Invalidate all TLB entries that match a specified VA, regardless of the ASID.
Operations that apply across multiprocessors in the same Inner Shareable domain.

--- Note ---

An address-based TLB maintenance instruction that applies to the Inner Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the instruction.

A TLB maintenance instruction that specifies a VA that would generate any MMU fault, including a VA that is not in the range of VAs that can be translated, does not generate an abort.

EL2 provides additional TLB maintenance instructions for use in AArch32 state at EL2, and has some implications for the effect of the other TLB maintenance instructions, see The scope of TLB maintenance instructions on page G5-5546.

In an implementation that includes EL3, the TLB maintenance instructions take account of the current Security state, as part of the address translation required for the TLB maintenance instruction.

Some TLB maintenance instructions are defined as operating only on instruction TLBs, or only on data TLBs. ARMv8 AArch32 state includes these instructions for backwards compatibility. However, more recent TLB maintenance instructions do not support this distinction. From the introduction of ARMv7, ARM deprecates any use of Instruction TLB maintenance instructions, or of Data TLB maintenance instructions, and developers must not rely on this distinction being maintained in future revisions of the ARM architecture.

The ARM architecture does not dictate the form in which the TLB stores translation table entries. However, for TLB invalidate instructions, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

The scope of TLB maintenance instructions on page G5-5546 describes the TLB maintenance instructions. The following subsections give more information about the general requirements for TLB maintenance:

- Using break-before-make when updating translation table entries.
- The interaction of TLB lockdown with TLB maintenance instructions on page G5-5539.
- Ordering and completion of TLB maintenance instructions on page G5-5540.
- Use of ASIDs and VMIDs to reduce TLB maintenance requirements on page G5-5541.

**Using break-before-make when updating translation table entries**

To avoid possibly creating multiple TLB entries for the same address, and to avoid the effects of TLB caching possibly breaking coherency, ordering guarantees or uniprocessor semantics, or possibly failing to clear the Exclusives monitors, the architecture requires the use of a break-before-make sequence when changing translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation table entries involves any of:

- A change of the memory type.
- A change of the cacheability attributes.
- A change of the output address (OA), if the OA of at least one of the old translation table entries and the new translation table entry is writable.
- A change to the size of block used by the translation system. This applies both:
  - When changing from a smaller size to a larger size, for example by replacing a table mapping with a block mapping in a stage 2 translation table.
  - When changing from a larger size to a smaller size, for example by replacing a block mapping with a table mapping in a stage 2 translation table.
- Creating a global entry when there might be non-global entries in a TLB that overlap with that global entry.

A break-before-make sequence on changing from an old translation table entry to a new translation table entry requires the following steps:

1. Replace the old translation table entry with an invalid entry, and execute a DSB instruction.
2. Invalidate the translation table entry with a broadcast TLB invalidation instruction, and execute a DSB instruction to ensure the completion of that invalidation.

3. Write the new translation table entry, and execute a DSB instruction to ensure that the new entry is visible.

This sequence ensures that at no time are both the old and new entries simultaneously visible to different threads of execution, and therefore the problems described at the start of this subsection cannot arise.

### The interaction of TLB lockdown with TLB maintenance instructions

The precise interaction of TLB lockdown with the TLB maintenance instructions is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance instructions must comply with these rules:

- The effect on locked entry of a TLB invalidate all unlocked entries instruction or a TLB invalidate by VA all ASID instruction that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
  - The instructions have no effect on entries that are locked down.
  - The instructions generate an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down. For an invalidate instruction performed in AArch32 state, the \{coproc==b1111, CRn==c5\} fault status register definitions include a Fault status code for cache and TLB lockdown faults, see Table G5-26 on page G5-5571 for the codes used with the Short-descriptor translation table formats, or Table G5-27 on page G5-5573 for the codes used with the Long-descriptor translation table formats.

  In an implementation that includes EL2, if EL2 is using AArch32 and the value of HCR.TIDCP is 1, any such exceptions taken from a Non-secure PL1 mode are routed to Hyp mode, see *Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations* on page G1-5337.

  This permits a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.

- The effect on a locked TLB entry of a TLB invalidate by VA instruction or a TLB invalidate by ASID match instruction that would invalidate that entry if the entry was not locked must be one of the following, and it is IMPLEMENTATION DEFINED which behavior applies:
  - A locked entry is invalidated in the TLB.
  - The instruction has no effect on a locked entry in the TLB. In the case of the Invalidate single entry by VA, this means the PE treats the instruction as a NOP.
  - The instruction generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down. For an invalidate instruction performed in AArch32 state, the \{coproc==b1111, CRn==c5\} fault status register definitions include a Fault status code for cache and TLB lockdown faults, see Table G5-26 on page G5-5571 and Table G5-27 on page G5-5573.

#### Note

Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required invalidation on entries that are not locked down.

- Implement one of the other specified alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined maintenance instructions. This minimizes the number of customized maintenance operations required.

In addition, an implementation that uses an abort mechanism for handling TLB maintenance instructions on entries that can be locked down but are not actually locked down must also must provide a mechanism that ensures that no TLB entries are locked.
Similar rules apply to cache lockdown, see The interaction of cache lockdown with cache maintenance instructions on page G4-5454.

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side-effect of a TLB maintenance instruction, any unlocked entry in the TLB might be invalidated.

**Ordering and completion of TLB maintenance instructions**

The following rules describe the relations between the memory order model and the TLB maintenance instructions:

- A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated are complete.
  
  After the TLB invalidate instruction is complete, no new memory accesses using the invalidated TLB entries will be architecturally performed by any observer that is affected by the TLB invalidation.

  **Note**
  
  This requirement does not mean that speculative memory accesses cannot be performed using those entries if it is impossible for software running on any observer to tell that those memory accesses have been performed.

- A TLB maintenance instruction is only guaranteed to be complete after the execution of a DSB instruction.

- An ISB instruction, or a return from an exception, causes the effect of all completed TLB maintenance instructions that appear in program order before the ISB or return from exception to be visible to all subsequent instructions, including the instruction fetches for those instructions.

- An exception causes all completed TLB maintenance instructions, that appear in the instruction stream before the point where the exception is taken, to be visible to all subsequent instructions, including the instruction fetches for those instructions.

- All TLB maintenance instructions are executed in program order relative to each other.

- The execution of a Data or Unified TLB maintenance instruction is only guaranteed to be visible to a subsequent explicit load or store instruction after both:
  
  | — The execution of a DSB instruction to ensure the completion of the TLB maintenance instruction. |
  | — Execution of a subsequent Context synchronization event. |

- The execution of an Instruction or Unified TLB maintenance instruction is only guaranteed to be visible to a subsequent instruction fetch after both:
  
  | — The execution of a DSB instruction to ensure the completion of the TLB maintenance instruction. |
  | — Execution of a subsequent Context synchronization event. |

In all cases in this section where a DMB or DSB is referred to, it refers to a DMB or DSB whose required access type is both loads and stores. A DSB NSH is sufficient to ensure completion of TLB maintenance instructions that apply to a single PE. A DSB ISH is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Inner Shareable domain.

The following rules apply when writing translation table entries. They ensure that the updated entries are visible to subsequent accesses and cache maintenance instructions.

For TLB maintenance, the translation table walk is treated as a separate observer. This means:

- A write to the translation tables is only guaranteed to be seen by a translation table walk caused by an explicit load or store after the execution of both a DSB and an ISB.

  However, the architecture guarantees that any writes to the translation tables are not seen by any explicit memory access that occurs in program order before the write to the translation tables.

- A write to the translation tables is only guaranteed to be seen by a translation table walk caused by the instruction fetch of an instruction that follows the write to the translation tables after both a DSB and an ISB.
Therefore, in a uniprocessor system, an example instruction sequence for writing a translation table entry, covering changes to the instruction or data mappings is:

```
STR rx, [Translation table entry]          ; write new entry to the translation table
DSB            ; ensures visibility of the new entry
Invalidate TLB entry by VA (and ASID if non-global) [page address]
Invalidate BTC
DSB            ; ensure completion of the Invalidate TLB instruction
ISB            ; ensure table changes visible to instruction fetch
```

**Use of ASIDs and VMIDs to reduce TLB maintenance requirements**

To reduce the need for TLB maintenance on context switches, the lookups from some translation regimes can be associated with an ASID, or with an ASID and a VMID.

--- Note ---

The use of ASIDs and VMIDs in VMSA8-32 is generally similar to their use in VMSA8-64, see *Use of ASIDs and VMIDs to reduce TLB maintenance requirements* on page D5-2497.

---

For more information about the use of ASIDs in VMSA8-32 see *Global and process-specific translation table entries* on page G5-5533.

**Common not private translations in VMSA8-32**

In an implementation that includes ARMv8.2-TTCNP, multiple PEs in the same Inner Shareable domain can use the same translation table entries for a given stage of address translation in a particular translation regime. This sharing is enabled by the TTBR.CnP field for the stage of address translation.

When the value of a TTBR.CnP field is 1, translation table entries pointed to by that TTBR are shared with all other PEs in the Inner Shareable domain for which the following conditions are met:

- The corresponding TTBR.CnP field has the value 1.
- That TTBR is using the Long-descriptor translation table format.
- If an ASID applies to the stage of translation corresponding to that TTBR then the current ASID value must be the same for all of the PEs that are sharing entries.
- If a VMID applies to the stage of translation corresponding to that TTBR then the current VMID value must be the same for all of the PEs that are sharing entries.

--- Note ---

In an implementation that includes EL3, the Secure instances of TTBR0 and TTBR1 relate to the Secure PL1&0 translation regime, and the Non-secure instances of TTBR0 and TTBR1 relate to the Non-secure PL1&0 translation regime.

---

Where a TLB combines information from stage 1 and stage 2 translation table entries into a single entry, this entry can be shared between different PEs only if the value of the TTBR.CnP bit is 1 for both stage 1 and stage 2 of the translation table walk.

The TTBR.CnP bit can be cached in a TLB.

For a given TTBR, if the value of TTBR.CnP is 1 on multiple PEs in the same Inner Shareable domain, and those PEs meet the other conditions for sharing translation table entries as defined in this section, but those TTBRs do not point to the same translation table entries, then the system is misconfigured, and performing an address translation using that TTBR:

- Might generate multiple hits in the TLB, and as a result generate an exception that is reported using the TLB conflict fault code, see *TLB conflict aborts* on page G5-5535.
- Otherwise, has a CONSTRAINED UNPREDICTABLE result, as described in *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-7195.
### G5.9.2 Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of System registers. This means the TLB entries associated with a translation regime affected by these control bits must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the VMID or ASID, if appropriate depending on the translation regime, that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:

```plaintext
; Change control bits in System registers
ISB ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits
```

The System register changes that this applies to are:

- Any change to the NMRR, PRRR, MAIR0, MAIR1, HMAIR0 or HMAIR1 registers.
- Any change to the SCTL.R.AFE bit, see Changing the Access flag enable.
- Any change to any of the SCTL.R.{TRE, WXN, UWXN} bits.
- Any change to the Translation table base 0 address in TTBR0.
- Any change to the Translation table base 1 address in TTBR1.
- Any change to HTTBR.BADDR.
- Any change to VTTBR.BADDR.
- Changing TTBCR.EAE, see Changing the current Translation table format on page G5-5543.
- In an implementation that includes EL3, any change to the SCR.SIF bit.
- In an implementation that includes EL2:
  - Any change to the HCR.VM bit.
  - Any change to HCR.PTW bit, see Changing HCR.PTW.
- When using the Short-descriptor translation table format:
  - Any change to the RGN, IRGN, S, or NOS fields in TTBR0 or TTBR1.
  - Any change to the N, EAE, PD0 or PD1 fields in TTBCR
- When using the Long-descriptor translation table format:
  - Any change to the EAE, TnSZ, ORGNn, IRGNn, SHn, or EPDn fields in the TTBCR, where n is 0 or 1.
  - Any change to the TTBCR2.
  - Any change to the T0SZ, ORGN0, IRGN0, or SH0 fields in the HTC.R.
  - Any change to the T0SZ, ORGN0, IRGN0, or SH0 fields in the VTC.R.

#### Changing the Access flag enable

In a PE that is using the Short-descriptor translation table format, it is CONstrained UNpredictable whether the TLB caches the effect of the SCTL.R.AFE bit on translation tables. This means that, after changing the SCTL.R.AFE bit software must invalidate the TLB before it relies on the effect of the new value of the SCTL.R.AFE bit, otherwise behavior is CONstrained UNpredictable, see CONstrained UNpredictable behaviors due to caching of control or data values on page K1-7195.

---

**Note**

There is no enable bit for use of the Access flag when using the Long-descriptor translation table format.

---

#### Changing HCR.PTW

When EL2 is using AArch32 and the value of the Protected table walk bit, HCR.PTW, is 1, a stage 1 translation table access in the Non-secure PL1&0 translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular VMID might hold entries that depend on the effect of HCR.PTW. Therefore, if the value of HCR.PTW is changed without a change to the VMID value, all TLB entries associated with the current VMID must be invalidated before executing software in a Non-secure PL1 or EL0 mode. If this is not done, behavior is CONstrained UNpredictable, see CONstrained UNpredictable behaviors due to caching of control or data values on page K1-7195.
Changing the current Translation table format

The effect of changing TTBCR.EAE when executing in the translation regime affected by TTBCR.EAE with any stage of address translation for that translation regime enabled is CONSTRAINED UNPREDICTABLE. This means that, when TTBCR.EAE is changed for a given context, the TLB must be invalidated before resuming execution in that context, otherwise the effect is CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7195.

G5.9.3 Atomicity of register changes on changing virtual machine

From the viewpoint of software executing in a Non-secure PL1 or EL0 mode, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for:

- Non-secure PL1&0 stage 1 address translations. This means that all of the following registers must change atomically:
  - PRRR and NMRR, if using the Short-descriptor translation table format.
  - MAIR0 and MAIR1, if using the Long-descriptor translation table format.
  - TTBR0, TTBR1, TTBCR, TTBCR2, DACR, and CONTEXTIDR.
  - The SCTLR.
- Non-secure PL1&0 stage 2 address translations. When EL2 is using AArch32, this means that all of the following registers and register fields must change atomically:
  - VTTBR and VTCR.
  - HMAIR0 and HMAIR1.
  - The HSCTLR.

Note

Only some bits of SCTLR affect the stage 1 translation, and only some bits of HSCTLR affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution in Non-secure PL1&0 modes. However, when updated as part of a switch of virtual machines they are updated by software executing in Hyp mode. This means the registers are out of context when they are updated, and no synchronization precautions are required.

Note

By contrast, a translation table change associated with a change of ASID, made by software executing at PL1, can require changes to registers that are in context. Synchronization of changes of ASID and TTBR describes appropriate precautions for such a change.

Software executing in Hyp mode, or in Secure state, must not use the registers associated with the Non-secure PL1&0 translation regime for speculative memory accesses.

G5.9.4 Synchronization of changes of ASID and TTBR

A common virtual memory management requirement is to change the ASID and TTBR together to associate the new ASID with different translation tables, without any change to the current translation regime. When using the Short-descriptor translation table format, different registers hold the ASID and the translation table base address, meaning these two values cannot be updated atomically. Since a PE can perform a speculative memory access at any time, this lack of atomicity is a problem that software must address. Such a change is complicated by:

- The depth of speculative fetch being IMPLEMENTATION DEFINED.
- The use of branch prediction.
When using the Short-descriptor translation table format, the virtual memory management operations must ensure the synchronization of changes of the ContextID and the translation table registers. For example, some or all of the TLBs, branch predictors, and other caching of ASID and translation information might become corrupt with invalid translations. Synchronization is required to avoid either:

- The old ASID being associated with translation table walks from the new translation tables.
- The new ASID being associated with translation table walks from the old translation tables.

There are a number of possible solutions to this problem, and the most appropriate approach depends on the system. Example G5-3, Example G5-4, and Example G5-5 on page G5-5545 describe three possible approaches.

---

**Note**

Another instance of the synchronization problem occurs if a branch is encountered between changing the ASID and performing the synchronization. In this case the value in the branch predictor might be associated with the incorrect ASID. Software can address this possibility using any of these approaches, but instead software might be written in a way that avoids such branches.

---

**Example G5-3 Using a reserved ASID to synchronize ASID and TTBR changes**

In this approach, a particular ASID value is reserved for use by the operating system, and is used only for the synchronization of the ASID and TTBR. This example uses the value of 0 for this purpose, but any value could be used.

This approach can be used only when the size of the mapping for any given VA is the same in the old and new translation tables.

The maintenance software uses the following sequence, that must be executed from memory marked as global:

- Change ASID to 0
- ISB
- Change TTBR
- ISB
- Change ASID to new value

This approach ensures that any non-global pages fetched at a time when it is uncertain whether the old or new translation tables are being accessed are associated with the unused ASID value of 0. Since the ASID value of 0 is not used for any normal operations these entries cannot cause corruption of execution.

---

**Example G5-4 Using translation tables containing only global mappings when changing the ASID**

A second approach involves switching the translation tables to a set of translation tables that only contain global mappings while switching the ASID.

The maintenance software uses the following sequence, that must be executed from memory marked as global:

- Change TTBR to the global-only mappings
- ISB
- Change ASID to new value
- ISB
- Change TTBR to new value

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.
This approach works without the need for TLB invalidations in systems that have caching of intermediate levels of translation tables, as described in General TLB maintenance requirements on page G5-5537, provided that the translation tables containing only global mappings have only level 1 translation table entries of the following kinds:

- Entries that are global.
- Pointers to level 2 tables that hold only global entries, and that are the same level 2 tables that are used for accessing global entries by both:
  - The set of translation tables that were used under the old ASID value.
  - The set of translation tables that will be used with the new ASID value.
- Invalid level 1 entries.

In addition, all sets of translation tables in this example should have the same Shareability and Cacheability attributes, as held in the TTBR0.{ORGN, IRGN} or TTBR1.{ORGN, IRGN} fields.

If these rules are not followed, then the implementation might cache level 1 translation table entries that require explicit invalidation.

Example G5-5 Disabling non-global mappings when changing the ASID

In systems where only the translation tables indexed by TTBR0 hold non-global mappings, maintenance software can use the TTBCR.PD0 field to disable use of TTBR0 during the change of ASID. This means the system does not require a set of global-only mappings.

The maintenance software uses the following sequence, that must be executed from a memory region with a translation that is accessed using the base address in the TTBR1 register, and is marked as global:

Set TTBCR.PD0 = 1
ISB
Change ASID to new value
Change TTBR to new value
ISB
Set TTBCR.PD0 = 0

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.

When using the Long-descriptor translation table format, TTBCR.A1 holds the number, 0 or 1, of the TTBR that holds the current ASID. This means the current TTBR can also hold the current ASID, and the current translation table base address and ASID can be updated atomically when:

- TTBR0 is the only TTBR being used. TTBCR.A1 must be set to 0.
- TTBR0 points to the only translation tables that hold non-global entries, and TTBCR.A1 is set to 0.
- TTBR1 points to the only translation tables that hold non-global entries, and TTBCR.A1 is set to 1.

In these cases, software can update the current translation table base address and ASID atomically, by updating the appropriate TTBR, and does not require a specific routine to ensure synchronization of the change of ASID and base address.

However, in all other cases using the Long-descriptor format, the synchronization requirements are identical to those when using the Short-descriptor formats, and the examples in this section indicate how synchronization might be achieved.

Note

When using the Long-descriptor translation table format, CONTEXTIDR.ASID has no significance for address translation, and is only an extension of the Context ID value.
G5.9.5   The scope of TLB maintenance instructions

TLB maintenance instructions provide a mechanism for invalidating entries from TLB caching structures, to ensure that changes to the translation tables are reflected correctly in the TLB caching structures. To support TLB maintenance in multiprocessor systems, there are maintenance operations that apply to the TLBs of all PEs in the same Inner Shareable domain.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault and that does not, itself, cause a Translation Fault, an Address size fault, or an Access Flag fault. This means the TLB:

• Cannot hold an entry that, when used for a translation table lookup, causes a Translation fault, an Address size fault, or an Access Flag fault.

• Can hold an entry for a translation table lookup for a translation that causes a Translation Fault, an Address size fault, or an Access Flag fault at a subsequent level of translation table lookup. For example, it can hold an entry for the level 1 lookup of a translation that causes a Translation fault, an Address size fault, or an Access Flag fault at level 2 or level 3 of lookup.

This means that entries cached in the TLB can include:

• Translation table entries that point to a subsequent table to be used in the current stage of translation.

• In an implementation that includes EL2:
  — Stage 2 translation table entries that are used as part of a stage 1 translation table walk.
  — Stage 2 translation table entries for translating the output address of a stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are distinct from the data caches, in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction on the form of these intermediate TLB caching structures.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries. In particular for translation regimes that involve two stages of translation, it recognizes that such caching structures might contain:

• At any level of the translation table walk, entries containing information from stage 1 translation table entries.

• In an implementation that includes EL2:
  — At any level of the translation table walk, entries containing information from stage 2 translation table entries.
  — At any level of the translation table walk, entries combining information from both stage 1 and stage 2 translation table entries.

Note
For the purpose of TLB maintenance, the term TLB entry denotes any structure, including temporary working registers in translation table walk hardware, that holds a translation table entry.

For the TLB maintenance instructions:

• If a TLB maintenance instruction is required to apply to stage 1 entries then it must apply to any cached entry in the caching structures that includes any stage 1 information that would be used to translate the address being invalidated, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Note
— Where stage 1 information has been cached in multiple TLB entries, as could occur from splintering a page when caching in the TLB, then the invalidation must apply to each cached entry containing stage 1 information from the page that is used to translate the address being invalidated, regardless of whether or not that cached entry would be used to translate the address being invalidated.
— As stated in Global and process-specific translation table entries on page G5-5533, translation table entries from levels of translation other than the final level are treated as being non-global. ARM expects that, in at least some implementations, cached copies of levels of the translation table walk
other than the last level are tagged with their ASID, regardless of whether the final level is global. This means that TLB invalidations that involve the ASID require the ASID to match such entries to perform the required invalidation.

- If a TLB maintenance instruction is required to apply to stage 2 entries only, then:
  - It is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
  - It must apply to caching structures that contain information only from stage 2 translation table entries.

- If a TLB maintenance instruction is required to apply to both stage 1 and stage 2 entries, then it must apply to any entry in the caching structures that includes information from either a stage 1 translation table entry or a stage 2 translation table entry, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Table G5-23 on page G5-5548 summarizes the required effect of the AArch32 TLB maintenance instructions, that operate only on TLBs on the PE that executes the instruction. Additional TLB maintenance instructions that:

- Apply across all PEs in the same Inner Shareable domain. Each instruction shown in the table has an Inner Shareable equivalent, identified by an IS suffix. For example, the Inner Shareable equivalent of TLBIALL is TLBIALLIS. See also \textit{EL2 forced broadcasting of TLB maintenance instructions} on page G5-5549.

- Can apply to separate Instruction or Data TLBs. These instructions are indicated by a footnote to the table. ARM deprecates any use of these instructions.

\textbf{Note}

- The architecture permits a TLB invalidation instruction to affect any unlocked entry in the TLB. Table G5-23 on page G5-5548 defines only the entries that each instruction must invalidate.

- All TLB instructions, including those that operate on a VA match, operate as described regardless of the value of SCTLR.M.

When interpreting the table:

\textbf{Related operations} Each instruction description applies also to any equivalent instruction that either:

- Applies to all PEs in the same Inner Shareable domain.
- Applies only to a data TLB, or only to an instruction TLB.

So, for example, the TLBIALL instruction description applies also to TLBIALLIS, ITLBIALL, and DTLBIALL.

Textit{TLB maintenance system instructions} on page K13-7438 lists all of the TLB maintenance instructions.

\textbf{Matches the VA} Means the VA argument for the instruction must match the VA value in the TLB entry.

\textbf{Matches the ASID} Means the ASID argument for the instruction must match the ASID in use when the TLB entry was assigned.

\textbf{Matches the current VMID} Means the current VMID must match the VMID in use when the TLB entry was assigned. The dependency on the VMID applies even when the value of HCR.VM is 0, including situations where there is no use of virtualization. However, VTTBR.VMID resets to zero, meaning there is a valid VMID from reset.

\textbf{Execution at EL2} Descriptions of operations at EL2 apply only to implementations that include EL2.
For the definitions of the translation regimes referred to in the table see *About VMSAv8-32* on page G5-5464.

### EL2 forced broadcasting of TLB maintenance instructions

In an implementation that includes EL2, when the value of HCR.FB is 1, the TLB maintenance instructions that are not broadcast across the Inner Shareable domain are forced to operate across the Inner Shareable domain when executed in a Non-secure PL1 mode. For example, when the value of HCR.FB is 1, a TLBIMVA instruction executed in a Non-secure PL1 mode performs the same invalidation as the invalidation performed by a TLBIMVAIS instruction.

---

  - Matches the current VMID. |
|             | Non-secure Hyp | Any entry for stage 2 of the PL1 translation regime that is from the last level of the translation table walk and both:  
  - Matches the IPA argument.  
  - Matches the current VMID. |

---

a. When a TLB maintenance instruction is executed at Secure EL1 in AArch32 state when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

b. The architecture defines variants of these instructions that apply only to instruction TLBs, and only to data TLBs. ARM deprecates any use of these variants. For more information, see the referenced description of the operation.

c. Available only in an implementation that includes EL2. See also **EL2 forced broadcasting of TLB maintenance instructions**.

d. This instruction is **CONSTRAINED UNPREDICTABLE** if executed in any AArch32 Secure privileged mode, see **Hyp mode TLB maintenance instructions** on page K1-7211.

e. This instruction executes as a NOP when SCR.NS == 0.
TLB maintenance with different translation granule sizes

If a TLB maintenance instruction specifying a VA affecting the EL2 translation regime is broadcast from a PE using AArch32 to a PE using AArch64 using a translation granule size that is different from the AArch32 translation granule size for that same translation regime, the TLB maintenance instruction is not required to perform any invalidation on the recipient PE.

If a TLB maintenance instruction specifying a VA affecting the PL1 translation regime is broadcast from a PE using AArch32 using one translation granule size for that translation regime for a particular ASID, VMID (if applicable), and Security state, to a PE using AArch64 where EL1 for the same ASID, VMID (if applicable), and Security state, is using a translation granule size that is different from the AArch32 translation granule size, the TLB maintenance instruction is not required to perform any invalidation on the recipient PE.
G5.10 Caches in VMSAv8-32

The ARM architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

Maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

• Summarizes the architectural requirements for the interaction between caches and memory translation.
• Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

• Data and unified caches.
• Instruction caches.

In addition Cache maintenance requirement created by changing translation table attributes on page G5-5553 describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see:

• AArch32 cache and branch predictor support on page G4-5433. This section describes the ARM cache maintenance instructions.
• Cache maintenance system instructions on page K13-7437. This section summarizes the System register encodings used for these operations when executing in AArch32 state.

G5.10.1 Data and unified caches

For data and unified caches, the use of memory address translation is entirely transparent to any data access other than as described inMismatched memory attributes on page E2-3602.

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

• Two writes to the same PA occur in program order.
• A read of a PA returns the value of the last successful write to that PA.
• A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance instructions.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses asPhysically-indexed, physically-tagged (PIPT) caches.

G5.10.2 Instruction caches

In the ARM architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The ARM architecture permits different behaviors for instruction caches. These are identified by descriptions of the associated expected implementation. The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of memory address translation transparent to the instruction cache:

• PIP (Physically-indexed, physically-tagged) instruction caches on page G5-5552.
• VPIPT (VMID-aware PIP) instruction caches on page G5-5552.
• VIPT (Virtually-indexed, physically-tagged) instruction caches on page G5-5552.
• The IVIPT architecture Extension on page G5-5553.

In AArch32 state, the CTR.L1Ip field identifies the form of the instruction caches.

——— Note ————
For software to be portable between implementations that might use any of PIPT instruction caches, VPIPT instruction caches, or VIPT instruction caches, software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

PIPT (Physically-indexed, physically-tagged) instruction caches

For a PIPT instruction cache:

• The use of memory address translation is entirely transparent to all instruction fetches other than as described in Mismatched memory attributes on page E2-3602.

• If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see The IVIPT architecture Extension on page G5-5553.

VPIPT (VMID-aware PIPT) instruction caches

An ARMv8.2 implementation can implement VPIPT instruction caches. If it does so then it is described as implementing ARMv8.2-VPIPT.

The CTR.L1Ip field identifies the implemented cache type, meaning it identifies whether ARMv8.2-VPIPT is implemented.

For a VPIPT instruction cache:

• Instruction fetches from Non-secure EL1 and Non-secure EL0 are only permitted to hit in the cache if the instruction fetch is made using the VMID that was used when the entry in the instruction cache was fetched.

• An instruction cache maintenance instruction executed at Non-secure EL0 or at Non-secure EL1 is required to have an effect on entries in the instruction cache only if those entries were fetched using the VMID that is current when the cache maintenance instruction is executed.

All other requirements for the use of cache maintenance instructions are the same as for PIPT (Physically-indexed, physically-tagged) instruction caches.

An implementation that provides VPIPT instruction caches implements the IVIPT Extension, see The IVIPT architecture Extension on page G5-5553.

VIPT (Virtually-indexed, physically-tagged) instruction caches

For a VIPT instruction cache:

• The use of memory address translation is transparent to all instruction fetches other than for the effect of memory address translation on instruction cache invalidate by address operations or as described in Mismatched memory attributes on page E2-3602.

——— Note ————
Cache invalidation is the only cache maintenance instruction that can be performed on an instruction cache.

• If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the VA supplied with the operation. The effect of the invalidation might not be visible to any other VA aliases of that physical memory location.
The only architecturally-guaranteed way to invalidate all aliases of a PA from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see The IVIPT architecture Extension.

The IVIPT architecture Extension

In ARMv8, any permitted instruction cache implementation can be described as implementing the IVIPT Extension to the ARM architecture.

The formal definition of the ARM IVIPT Extension is that it reduces the instruction cache maintenance requirement to the following condition:

- Instruction cache maintenance is required only after writing new data to a PA that holds an instruction.

Note

Previous versions of the ARM architecture have permitted an instruction cache option that does not implement the ARM IVIPT Extension.

G5.10.3   Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in General TLB maintenance requirements on page G5-5537. If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

- Write-Back to Write-Through.
- Write-Back to Non-cacheable.
- Write-Through to Non-cacheable.
- Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the Shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from them cache.
3. Change the Shareability attributes to the required new values.
G5.11 VMSAv8-32 memory aborts

In a VMSAv8-32 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

- **Debug exception**  
  An exception caused by the debug configuration, see Chapter G2 AArch32 Self-hosted Debug.

- **Alignment fault**  
  An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information see Unaligned data access on page E2-3586 and Alignment faults on page G5-5562.

- **MMU fault**  
  An MMU fault is a fault generated by the fault checking sequence for the current translation regime. See Types of MMU faults on page G5-5555.

- **External abort**  
  Any memory system fault other than a Debug exception, an Alignment fault, or an MMU fault.

Collectively, these mechanisms are called aborts. Chapter G2 AArch32 Self-hosted Debug and Chapter H3 Halting Debug Events describe Debug exceptions, and the remainder of this section describes Alignment faults, MMU faults, and External aborts.

An access that causes an abort is said to be aborted, and uses the Fault Address Registers (FARs) and Fault Status Registers (FSRs) or Exception Syndrome Registers (ESRs) to record context information.

The exception generated on a synchronous memory abort:
- On an instruction fetch is called the Prefetch Abort exception.
- On a data access is called the Data Abort exception.

--- Note ---

The Prefetch Abort exception applies to any synchronous memory abort on an instruction fetch. It is not restricted to speculative instruction fetches.

--- Note ---

The Exception level and PE mode that a VMSAv8-32 memory abort is taken to depends on the translation regime and stage that generate the abort. The fault context is dependent on whether:
- The abort is reported as a Prefetch Abort or as a Data Abort.
- The exception is taken from the same or a lower Exception level.

--- Note ---

A memory access from AArch32 state may be subject to one or more VMSAv8-64 translation stages. For example, a Non-secure EL0 access when EL1 is using AArch64 is subject to both stages of the VMSAv8-64 Non-secure EL1&0 translation regime. A memory abort generated on a VMSAv8-64 translation stage is handled as described in VMSAv8-64 memory aborts on page D5-2487.

--- Note ---

For more information, see Routing of aborts taken to AArch32 state on page G1-5266.

External aborts can be reported synchronously or asynchronously. Asynchronous External aborts are reported using the SError interrupt. For more information, see External aborts on page G4-5457.

In AArch32 state, asynchronous memory aborts are a type of External abort, and are treated as a type of Data Abort exception.

The following sections describe the abort mechanisms:
- Types of MMU faults on page G5-5555.
- VMSAv8-32 MMU fault terminology on page G5-5557.
- The MMU fault-checking sequence on page G5-5558.
- Alignment faults on page G5-5562.
- External abort on a translation table walk on page G5-5562.
• **AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-5563.**

An access that causes an abort is said to be aborted. On an abort, System registers are used to record context information. For more information see *Exception reporting in a VMSAv8-32 implementation on page G5-5566.*

### G5.11 Types of MMU faults

This section describes the faults that might be detected during one of the fault-checking sequences described in *The MMU fault-checking sequence on page G5-5558.* Unless indicated otherwise, information in this section applies to the fault checking sequences for both the Short-descriptor translation table format and the Long-descriptor translation table format.

MMU faults are always synchronous.

When an MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as any type of Device memory.

The MMU faults that might be detected during a fault checking sequence are:

- Permission fault.
- Translation fault.
- Address size fault.
- Access flag fault.
- Domain fault, short-descriptor translation tables only.
- TLB conflict abort.

See also *External abort on a translation table walk on page G5-5562.*

---

**Note**

- Although the TLB conflict abort is classified as an MMU fault, it is described in the section *Translation Lookaside Buffers (TLBs) on page G5-5533.*

- In VMSAv8-64 an External abort on a translation table walk is classified as an MMU fault. However, in VMSAv8-32, for consistency with earlier versions of the architecture these aborts are not classified as MMU faults.

---

**Permission fault**

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See *About access permissions on page G5-5510* for information about conditions that cause a Permission fault.

---

**Note**

When using the Short-descriptor translation table format, the translation table descriptors are checked for Permission faults only for accesses to memory regions in Client domains.

---

A TLB might hold a translation table entry that cause a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in *Ordering and completion of TLB maintenance instructions on page G5-5540.*

In an implementation that includes EL2, this maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache or branch predictor maintenance operations cannot cause a Permission fault, except that a stage 1 translation table walk performed as part of a cache or branch predictor maintenance operation can generate a stage 2 Permission fault as described in *Stage 2 fault on a stage 1 translation table walk.*
Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a translation table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information see:

- VMSAv8-32 Short-descriptor translation table format descriptors on page G5-5482.
- VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5491.

In addition, a Translation fault is generated if the input address for a translation either does not map onto an address range of a TTBR, or the TTBR range that it maps onto is disabled. In these cases the fault is reported as a level 1 Translation fault on the translation stage at which the mapping to a region described by a TTBR failed.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

A data or unified cache maintenance by VA instruction can generate a Translation fault. However:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by VA to the Point of Coherency instruction can generate a Translation fault.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Translation fault.

It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate a Translation fault.

It is IMPLEMENTATION DEFINED whether a branch predictor maintenance operation can generate a Translation fault.

Address size fault

An Address size fault can be generated at any level of lookup, and the reported fault code identifies the lookup level.

An Address size fault is generated if the translation table entries or the TTBR for the stage of translation have nonzero address bits above the most significant bit of the maximum output address size. Because VMSAv8-32 supports a maximum PA and IPA size of 40 bits, this means any case where a translation table entry or the TTBR holds an address for which A[47:40] is nonzero generates an Address size fault.

A data or unified cache maintenance by VA instruction can generate an Address size fault. However:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by VA instruction can generate an Address size fault.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate an Address size fault.

It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate an Address size fault.

It is IMPLEMENTATION DEFINED whether a branch predictor maintenance operation can generate an Address size fault.

The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

Access flag fault

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if all of the following apply:

- The translation tables support an Access flag bit:
  - The Short-descriptor format supports an Access flag only when SCTLR.AFE is set to 1.
  - The Long-descriptor format always supports an Access flag.
• A translation table descriptor with the Access flag bit set to 0 is loaded.

For more information about the Access flag bit see:
• VMSAv8-32 Short-descriptor translation table format descriptors on page G5-5482
• VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5491.

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

Whether any cache maintenance instruction by VA can generate Access flag faults is IMPLEMENTATION DEFINED.

Whether branch predictor invalidate by VA operations can generate Access flag faults is IMPLEMENTATION DEFINED.

For more information, see The Access flag on page G5-5518.

**Domain fault, Short-descriptor format translation tables only**

When using the Short-descriptor translation table format, a Domain fault can be generated at level 1 or level 2 of lookup. The reported fault code identifies the lookup level. The conditions for generating a Domain fault are:

**Level 1** When a level 1 descriptor fetch returns a valid Section level 1 descriptor, the domain field of that descriptor is checked against the DACR. A level 1 Domain fault is generated if this check fails.

**Level 2** When a level 2 descriptor fetch returns a valid level 2 descriptor, the domain field of the level 1 descriptor that required the level 2 fetch is checked against the DACR, and a level 2 Domain fault is generated if this check fails.

For more information, see Domains, Short-descriptor format only on page G5-5518.

Domain faults cannot occur on cache or branch predictor maintenance operations.

A TLB might hold a translation table entry that cause a Domain fault. Therefore, if the handling of a Domain fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in Ordering and completion of TLB maintenance instructions on page G5-5540.

Any change to the DACR must be synchronized by a Context synchronization event. For more information see Synchronization of changes to AArch32 System registers on page G8-5640.

**G5.11.2 VMSAv8-32 MMU fault terminology**

The ARMv7 Large Physical Address Extension introduced new terminology for faults on a stage of address translation, to provide consistent terminology across all implementations. Table G5-24 shows the terminology used in this manual for an MMU faults, compared with older ARM documentation. The current terms are the same for faults that occur with the Short-descriptor translation table format and with the Long-descriptor format, and also apply to faults in a level 3 lookup when using the Long-descriptor translation table format.

<table>
<thead>
<tr>
<th>Current term</th>
<th>Old term</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Level 1 Translation fault</td>
<td>Section Translation fault</td>
<td>-</td>
</tr>
<tr>
<td>Level 2 Translation fault</td>
<td>Page Translation fault</td>
<td>-</td>
</tr>
<tr>
<td>Level 3 Translation fault</td>
<td>-</td>
<td>Long-descriptor translation table format only.</td>

<tr>
<td>Level 1 Access flag fault</td>
<td>Section Access flag fault</td>
<td>-</td>
</tr>
<tr>
<td>Level 2 Access flag fault</td>
<td>Page Access flag fault</td>
<td>-</td>
</tr>
<tr>
<td>Level 3 Access flag fault</td>
<td>-</td>
<td>Long-descriptor translation table format only.</td>
</tr>
</tbody>
</table>
In an implementation that includes EL2, MMU faults are also classified by the translation stage at which the fault is generated. This means that a memory access from a Non-secure PL1 or EL0 mode can generate:

• A stage 1 MMU fault, for example, a stage 1 Translation fault.
• A stage 2 MMU fault, for example, a stage 2 Translation fault.

The MMU fault-checking sequence is largely independent of the translation table format, as the figures in this section show. The differences are:

When using the Short-descriptor format
- There are one or two levels of lookup.
- Lookup always starts at level 1.
- The final level of lookup checks the Domain field of the descriptor and:
  — Faults if there is no access to the Domain.
  — Checks the access permissions only for Client domains.

When using the Long-descriptor format
- There are one, two, or three levels of lookup.
- Lookup starts at either level 1 or level 2.
- Domains are not supported. All accesses are treated as Client domain accesses.

<table>
<thead>
<tr>
<th>Current term</th>
<th>Old term</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Level 1 Domain fault</td>

<tr>
<td>Level 3 Permission fault</td>
<td>-</td>
<td>Long-descriptor translation table format only.</td>
</tr>
</tbody>
</table>
The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see About address translation for VMSAv8-32 on page G5-5467.

--- Note ---

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in TLB conflict aborts on page G5-5535.

Types of MMU faults on page G5-5555 describes the faults that an MMU fault-checking sequence can report.

Figure G5-15 shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, in an implementation that includes EL2, if the translation is stage 1 of the Non-secure PL1&0 translation regime, then the descriptor address is in the IPA address map, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.

--- Note ---

Figure G5-15 and Figure G5-16 on page G5-5560 give an overview of the fault checking performed by the MMU. See AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-5563 for the complete set of possible faults and their prioritization.

--- Diagram ---

Figure G5-15 Fetching the descriptor in a VMSAv8-32 translation table walk

Figure G5-16 on page G5-5560 shows the full VMSAv8-32 fault checking sequence, including the alignment check on the initial access.
Figure G5-16 VMSAv8-32 fault checking sequence
Stage 2 fault on a stage 1 translation table walk

When an implementation that includes EL2 is operating in a Non-secure PL1 or EL0 mode, any memory access goes through two stages of translation:

- Stage 1, from VA to IPA.
- Stage 2, from IPA to PA.

Note

In a virtualized system that is using AArch32, typically, a Guest OS operating in a Non-secure PL1 mode defines the translation tables and translation table register entries controlling the Non-secure PL1&0 stage 1 translations. A Guest OS has no awareness of the stage 2 address translation, and therefore believes it is specifying translation table addresses in the PA map. However, it actually specifies these addresses in its IPA map. Therefore, to support virtualization, translation table addresses for the Non-secure PL1&0 stage 1 translations are always defined in the IPA address map.

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

- A Translation fault, Access flag fault, or Permission fault.
- A synchronous External abort on the memory access.

If SCR.EA is set to 1, a synchronous External abort is taken to EL3, and if EL3 is using AArch32 it is taken to Secure Monitor mode. Otherwise, these faults are reported as stage 2 memory aborts. When EL2 is using AArch32, HSR.ISS[7] is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information see Use of the HSR on page G5-5580.

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the Device memory attribute assigned on the stage 2 translation of the address accessed. When the value of the HCR.PTW bit is 1, such an access generates a stage 2 Permission fault.

Note

- On most systems, such a mapping to a Device memory type on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

A TLB might hold entries that depend on the effect of HCR.PTW. Therefore, if HCR.PTW is changed without changing the current VMID, the TLBs must be invalidated before executing in a Non-secure PL1 or EL0 mode. For more information see Changing HCR.PTW on page G5-5542.

A cache maintenance instruction executed at Non-secure PL1 can cause a stage 1 translation table walk that might generate a stage 2 Permission fault, as described in this section. However:

- If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a cache maintenance by VA instruction can generate a Permission fault in this way.
- If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Permission fault in this way.

Note

This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault.
The level associated with MMU faults

When an MMU fault is from a stage of translation that is using Long-descriptor translation table format, Table G5-25 shows how the LL bits in the STATUS field of DFSR, IFSR, and HSR encode the lookup level associated with the fault.

Table G5-25 Use of LL bits to encode the lookup level at which the fault occurred

<table>
<thead>
<tr>
<th>LL bits</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Level 0 of translation or translation table base register.</td>
</tr>
<tr>
<td>01</td>
<td>Level 1.</td>
</tr>
<tr>
<td>10</td>
<td>Level 2.</td>
</tr>
<tr>
<td>11</td>
<td>Level 3. When xFSR.STATUS indicates a Domain fault, this value is reserved.</td>
</tr>
</tbody>
</table>

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Also see Synchronous External abort errors from address translation caching structures on page G5-5565.

G5.11.4 Alignment faults

The ARM memory architecture requires support for strict alignment checking. This checking is controlled by:

- SCTLR.A, for accesses made from any PE mode other than Hyp mode.
- HSCTLR.A, for accesses made from Hyp mode.

In addition, some instructions do not support unaligned accesses, regardless of the value of SCTLR.A or HSCTLR.A.

Unaligned data access on page E2-3586:

- Defines when Alignment faults are generated, for both values of SCTLR.A or HSCTLR.A.
- Describes the possible generation of Alignment faults on accesses to Device memory by AArch32 Load Multiple or Store Multiple instructions when ARMv8.2-LSMAOC is implemented.

An Alignment fault can occur on an access for which the stage of address translation is disabled.

Any unaligned access to memory region with any Device memory type attribute generates an Alignment fault.

Routing of aborts taken to AArch32 state on page G1-5266 defines the mode to which an Alignment fault is taken.

The prioritization of Alignment faults depends on whether the fault was generated because of an access to a Device memory type, or for another reason. For more information see AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G5-5563.

G5.11.5 External abort on a translation table walk

An External abort on a translation table walk can be either synchronous or asynchronous. For more information on External aborts, see External aborts on page G4-5457.
An External abort on a translation table walk is reported:

• If the External abort is synchronous, using:
  — A synchronous Prefetch Abort exception if the translation table walk is for an instruction fetch.
  — A synchronous Data Abort exception if the translation table walk is for a data access.

• If the External abort is asynchronous, using an SError interrupt, which is taken as an asynchronous Data Abort exception.

If an implementation reports the error in the translation table walk asynchronously from executing the instruction whose instruction fetch or memory access caused the translation table walk, these aborts behave essentially as interrupts. The aborts are masked when PSTATE.A is set to 1, otherwise they are reported using the Data Abort exception.

**Behavior of External aborts on a translation table walk caused by address translation instructions**

The address translation instructions summarized in *Address translation system instructions on page K13-7437* require translation table walks. An External abort can occur in the translation table walk. The abort generates a Data Abort exception, and can be synchronous or asynchronous. For more information, see *Handling of faults and aborts during an address translation instruction on page G5-5589.*

**G5.11.6 AArch32 state prioritization of synchronous aborts from a single stage of address translation**

*Exception prioritization for exceptions taken to AArch32 state on page G1-5250* describes the prioritization of exceptions taken from an Exception level that is using AArch32. This section gives additional information about the prioritization of MMU faults from VMSAv8-32 translation regimes.

If a single instruction generates aborts on more than one memory access, the architecture does not define any prioritization between those aborts.

In general, the ARM architecture does not define when asynchronous events are taken, and therefore the prioritization of asynchronous events is IMPLEMENTATION DEFINED.

---  **Note**  ---

The priority numbering in this list only shows the relative priorities of aborts from a single stage of address translation in a VMSAv8-32 translation regime. This numbering has no global significance and, for example, does not correlate with the equivalent AArch64 list in *AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D5-2494.*

For a single stage of translation in a VMSAv8-32 translation regime, the following numbered list shows the priority of the possible memory management faults on a memory access. In this list:

• For memory accesses that undergo two stages of translation, the *italic entries show where the faults from the stage 2 translation can occur.* A stage 2 fault within a stage 1 translation table walk follows the same prioritization of faults.

• For synchronous External aborts from translation table walks see also *Synchronous External abort errors from address translation caching structures on page G5-5565.*

The priority order, from highest priority to lowest priority, is:

1. **Alignment fault not caused by memory type.** This is possible for a stage 1 translation only.
2. **Translation fault due to the input address being out of the address range to be translated or requiring an AArch32 TTBR that is disabled.** This includes VTCR.SL0 being inconsistent with VTCR.T0SZ or programmed to a reserved value.
3. **Address size fault on an AArch32 TTBR caused by the PA being out of the range implemented.**
4. **Second stage abort on a level 1 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented.** This is second stage abort during a first stage translation table walk.
5. Synchronous parity or ECC error on a level 1 lookup of a translation table walk.

6. Synchronous External abort on a level 1 lookup level of a translation table walk.

7. Translation fault on a level 1 translation table entry.

8. Address size fault on a level 1 lookup translation table entry caused by the output address being out of the range implemented.

9. Second stage abort on a level 2 lookup of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.

10. Synchronous parity or ECC error on a level 2 lookup of a translation table walk.

11. Synchronous External abort on a level 2 lookup level of a translation table walk.

12. Translation fault on a level 2 translation table entry.

13. Address size fault on a level 2 lookup translation table entry caused by the output address being out of the range implemented.

14. Second stage abort on a level 3 lookup of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.

15. Synchronous parity or ECC error on a level 3 lookup of a translation table walk.

16. Synchronous External abort on a level 3 lookup level of a translation table walk.

17. Translation fault on a level 3 translation table entry.

18. Address size fault on a level 3 lookup translation table entry caused by the output address being out of the range implemented.

19. Access Flag fault.

20. Alignment fault caused by the memory type.

--- Note ---
Domain faults are possible only when using the VMSA v8-32 Short-descriptor translation table format, see Domain fault, Short-descriptor format translation tables only on page G5-5557.

--- Note ---
- The prioritization of TLB Conflict aborts is IMPLEMENTATION DEFINED, as the exact cause of these aborts depends on the form of TLBs implemented. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.
- The prioritization of IMPLEMENTATION DEFINED MMU faults for a Load-Exclusive or Store-Exclusive to an unsupported memory type is IMPLEMENTATION DEFINED.

See also The MMU fault-checking sequence on page G5-5558.
Synchronous External abort errors from address translation caching structures

A caching structure used for caching translation table walks might support:
• An arbitrary number of levels of translation table lookup.
• One or more stages of translation, that might not correspond to the stages of an address translation lookup.

This might mean that, on a synchronous External abort arising from the caching structure, such as from a parity or ECC error, the PE cannot precisely determine one or both of the translation stage and level of lookup at which the error occurred. In this case:

• If the PE cannot determine precisely the translation stage at which the error occurred, it is reported and prioritized as a stage 1 error.

• If the PE cannot determine precisely the lookup level at which the error occurred, the level is reported and prioritized as either:
  — The lowest-numbered level that could have given rise to the error.
  — Level 1 if it the PE cannot determine any information about the level.
G5.12 Exception reporting in a VMSAv8-32 implementation

This section describes exception reporting, in AArch32 state, in a VMSAv8-32 implementation. That is, it describes only the reporting of exceptions that are taken to an Exception level that is using AArch32. EL2 provides an enhanced reporting mechanism for exceptions taken to the Non-secure EL2 mode, Hyp mode. This means that, for VMSAv8-32, the exception reporting depends on the mode to which the exception is taken.

Note

The enhanced reporting mechanism for exceptions that are taken to Hyp mode is generally similar to the reporting of exceptions that are taken to an Exception level that is using AArch64.

About exception reporting introduces the general approach to exception reporting, and the following sections then describe exception reporting at different privilege levels:

• Reporting exceptions taken to PL1 modes on page G5-5567.
• Fault reporting in PL1 modes on page G5-5570.
• Summary of register updates on faults taken to PL1 modes on page G5-5575.
• Reporting exceptions taken to Hyp mode on page G5-5576.
• Use of the HSR on page G5-5580.
• Summary of register updates on exceptions taken to Hyp mode on page G5-5583.

Note

The registers used for exception reporting also report information about debug exceptions. For more information see:

• Data Abort exceptions, taken to a PL1 mode on page G5-5568.
• Prefetch Abort exceptions, taken to a PL1 mode on page G5-5570.
• Reporting exceptions taken to Hyp mode on page G5-5576.

G5.12.1 About exception reporting

In an implementation that includes EL2 and EL3, exceptions can be taken to:

• Monitor mode, if EL3 is using AArch32.
• Hyp mode, if EL2 is using AArch32.
• A Secure or Non-secure PL1 mode.

Monitor mode is a PL1 mode, but:

• It is accessible only when EL3 is using AArch32.
• It is present only in Secure state.
• When EL3 is using AArch32, System register controls route some exceptions from Non-secure state to Monitor mode. These are the only cases where taking an exception to an Exception level that is using AArch32 changes the Security state of the PE.

Exception reporting in Hyp mode differs significantly from that in the other modes, but in general, exception reporting returns:

• Information about the exception:
  — On taking an exception to Hyp mode, the Hyp Syndrome Register, HSR, returns syndrome information.
  — On taking an exception to any other mode, a Fault Status Register (FSR) returns status information.

• For synchronous exceptions, one or more addresses associated with the exceptions, returned in Fault Address Registers (FARs). For a permitted exception to this requirement see Fault address reporting on synchronous External aborts on page G5-5567.

In all modes, additional IMPLEMENTATION DEFINED registers can provide additional information about exceptions.
Note

• **PE mode for taking exceptions** on page G1-5257 describes how the mode to which an exception is taken is determined.

• **EL2 provides:**
  — Specific exception types, that can only be taken from Non-secure PL1 and EL0 modes, and are always taken to Hyp mode.
  — Routing controls that can route some exceptions from Non-secure PL1 and EL0 modes to Hyp mode.

These exceptions are reported using the same mechanism as the Hyp mode reporting of VMSAv8-32 memory aborts, as described in this section.

Memory system faults generate either a Data Abort exception or a Prefetch Abort exception, as summarized in:

• **Reporting exceptions taken to PL1 modes.**
• **Memory fault reporting in Hyp mode** on page G5-5578.

On an access that might have multiple aborts, the MMU fault checking sequence and the prioritization of aborts determine which abort occurs. For more information, see **The MMU fault-checking sequence** on page G5-5558 and **AArch32 state prioritization of synchronous aborts from a single stage of address translation** on page G5-5563.

### Fault address reporting on synchronous External aborts

The general architectural requirement is that, on a synchronous abort, the faulting address is recorded in a *Fault Address Register* (FAR). This requirement is relaxed for the case of a synchronous External abort that is not a synchronous External abort on a translation table walk. In this case only:

• It is **IMPLEMENTATION DEFINED** whether the faulting address is recorded in a FAR.
• A bit in a fault reporting register, the FnV bit, indicates whether a valid address is recorded.

For exceptions taken to an Exception level that is using AArch32, the details of this reporting depend on whether the exception is taken to:

• A PL1 mode, as described in **Reporting exceptions taken to PL1 modes.**
• Hyp mode, as described in **Reporting exceptions taken to Hyp mode** on page G5-5576.

#### G5.12.2 Reporting exceptions taken to PL1 modes

The following sections give general information about the reporting of exceptions when they are taken to a Secure or Non-secure PL1 mode:

• **Registers used for reporting exceptions taken to PL1 modes.**
• **Data Abort exceptions, taken to a PL1 mode** on page G5-5568.
• **Prefetch Abort exceptions, taken to a PL1 mode** on page G5-5570.

**Fault reporting in PL1 modes** on page G5-5570 then describes the fault reporting in these modes, including the encodings used for reporting the faults.

Note

*Security state, Exception levels, and AArch32 execution privilege* on page G1-5226 describes how the Secure and Non-secure PL1 modes map onto the Exception levels.

#### Registers used for reporting exceptions taken to PL1 modes

AArch32 state defines the following registers, and register encodings, for exceptions taken to PL1 modes:

• The **DFSR** holds information about a Data Abort exception.
• The **DFAR** holds the faulting address for some synchronous Data Abort exceptions.
• The **IFSR** holds information about a Prefetch Abort exception.
• The **IFAR** holds the faulting address for some synchronous Prefetch Abort exceptions.
In addition, if implemented, the optional ADFSR and AIFSR can provide additional fault information, see Auxiliary Fault Status Registers.

**Auxiliary Fault Status Registers**

AArch32 state defines the following Auxiliary Fault Status Registers:

- The Auxiliary Data Fault Status Register, ADFSR.
- The Auxiliary Instruction Fault Status Register, AIFSR.

The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED. An implementation can use these registers to return additional fault status information. An example use of these registers is to return more information for diagnosing parity or ECC errors.

An implementation that does not need to report additional fault information must implement these registers as RES0. This ensures that an attempt to access these registers from software executing at PL1 does not cause an Undefined Instruction exception.

**Data Abort exceptions, taken to a PL1 mode**

On taking a Data Abort exception to a PL1 mode:

- If the exception is on an instruction cache or branch predictor maintenance operation by VA, its reporting depends on the value of TTBCR.EAE. For more information about the registers used when reporting the exception, see Data Abort on an instruction cache or branch predictor maintenance instruction by VA on page G5-5569.

- Otherwise, the DFSR is updated with details of the fault, including the appropriate Fault status code. If the Data Abort exception is synchronous, DFSR.WnR is updated to indicate whether the faulted instruction was a read or a write. However, if the fault is on a cache maintenance instruction, or on an address translation instruction, WnR is set to 1, to indicate a fault on a write instruction, and the CM bit is set to 1.

  If the Data Abort is external, then DFSR provides fields for additional classification of the abort, see Provision for classification of External aborts on page G4-5457.

  If the RAS Extension is implemented, and the exception is a virtual SError interrupt exception, the classification reported in DFSR is taken from VDFSR or VSESR_EL2. For more information, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

  See the register description for more information about the returned fault information. See also Data Abort on a Watchpoint exception on page G5-5569.

  If the Data Abort exception is

  - Synchronous, the DFAR is updated with the VA that caused the exception, but see Fault address reporting on synchronous External aborts on page G5-5567 for a permitted exception to this requirement.
  - Asynchronous, the DFAR becomes UNKNOWN.

  DFSR.WnR and DFSR.CM are UNKNOWN on an asynchronous Data Abort exception.

For all Data Abort exceptions, if the implementation includes EL3, the Security state of the PE in the mode to which the Data Abort exception is taken determines whether the Secure or Non-secure DFSR and DFAR are updated.
Data Abort on an instruction cache or branch predictor maintenance instruction by VA

If an instruction cache invalidation by VA or branch predictor invalidation by VA operation generates a Data Abort exception that is taken to a PL1 mode, the DFAR is updated to hold the faulting VA. However, the reporting of the fault depends on the value of TTBCR.EAE:

TTBCR.EAE == 0

When the value of TTBCR.EAE is 0, it is IMPLEMENTATION DEFINED which of the following is used when reporting the fault:

- The DFSR indicates an Instruction cache maintenance instruction fault, and the IFSR is valid and indicates the cause of the fault, a Translation fault or Access flag fault.
- The DFSR indicates the cause of the fault, a Translation fault or Access flag fault. The IFSR is UNKNOWN.

In either case:
- DFSR.WnR is set to 1.
- DFSR.CM is set to 1, to indicate a fault on a cache maintenance instruction.

TTBCR.EAE == 1

When the value of TTBCR.EAE is 1:

- DFSR.CM is set to 1, to indicate a fault on a cache maintenance instruction.
- DFSR.STATUS indicates the cause of the fault, a Translation or Access flag fault.
- DFSR.WnR is set to 1.
- The IFSR is UNKNOWN.

Data Abort on a Watchpoint exception

On taking a Data Abort exception caused by a watchpoint:

- DFSR.FS is updated to indicate a debug exception.
- DFSR.{WnR, Domain} are UNKNOWN.
- DFAR is set to the address that generated the watchpoint

Note

- LR_abt indicates the address of the instruction that triggered the watchpoint.
- In some ARMv7 AArch32 implementations, the DBGWFAR is set to the address of the instruction that triggered the watchpoint. In ARMv8 this register is RES0.

A watchpointed address can be any byte-aligned address. The address reported in DFAR might not be the watchpointed address, and:

- For a watchpoint due to an operation other than a Data Cache maintenance instruction, can be any address between and including:
  - The lowest address accessed by the instruction that triggered the watchpoint.
  - The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated. The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.

Note

- In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.
- The IMPLEMENTATION DEFINED power-of-two size must be no larger than the block size of the AArch64 DC ZVA operation.

- For a watchpoint due to a Data Cache operation, the address is the address passed to the instruction. This might be an address that is above the watchpointed location.
Prefetch Abort exceptions, taken to a PL1 mode

For a Prefetch Abort exception generated by an instruction fetch, the Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

• If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
• If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction, no Prefetch Abort exception is generated.

In addition, Breakpoint Instruction, Breakpoint, and Vector Catch exceptions, generate a Prefetch Abort exception, see the following for more information:

• Exception syndrome information and preferred return address for a BKPT instruction on page G2-5372.
• Exception syndrome information and preferred return address for a Breakpoint exception on page G2-5397.
• Exception syndrome information and preferred return address for a Vector Catch exception on page G2-5418.

Note

Usually, the term exception syndrome is used only for exceptions taken to Hyp mode, or to AArch64 state. The referenced sections use the term more generally, to include exception information reported in the IFSR.

On taking a Prefetch Abort exception to a PL1 mode:

• The IFSR is updated with details of the fault, including the appropriate fault code. If appropriate, the fault code indicates that the exception was generated by a debug exception. See the register description for more information about the returned fault information.
• For a Prefetch Abort exception generated by an instruction fetch, the IFAR is updated with the VA that caused the exception, but see Fault address reporting on synchronous External aborts on page G5-5567 for a permitted exception to this requirement.
• For a Prefetch Abort exception generated by a debug exception, the IFAR is UNKNOWN.

If the implementation includes EL3, the security state of the PE in the mode to which it takes the Prefetch Abort exception determines whether the exception updates the Secure or Non-secure IFSR and IFAR.

G5.12.3 Fault reporting in PL1 modes

The FSRs provide fault information, including an indication of the fault that occurred. The following subsections describe fault reporting in PL1 modes for each of the translation table formats:

• PL1 fault reporting with the Short-descriptor translation table format on page G5-5571.
• PL1 fault reporting with the Long-descriptor translation table format on page G5-5573.

Reserved encoding in the IFSR and DFSR encodings tables on page G5-5574 gives some additional information about the encodings for both formats.

Summary of register updates on faults taken to PL1 modes on page G5-5575 shows which registers are updated on each of the reported faults.

Reporting of External aborts taken from Non-secure state to Monitor mode describes how the fault status register format is determined for those aborts. For all other aborts, the current translation table format determines the format of the fault status registers.

Reporting of External aborts taken from Non-secure state to Monitor mode

When an External abort is taken from Non-secure state to Monitor mode:

• For a Data Abort exception, the Secure DFSR and DFAR hold information about the abort.
• For a Prefetch Abort exception, the Secure IFSR and IFAR hold information about the abort.
• The abort does not affect the contents of the Non-secure copies of the fault reporting registers.

Normally, the current translation table format determines the format of the DFSR and IFSR. However, when SCR.EA is set to 1, to route External aborts to Monitor mode, and an External abort is taken from Non-secure state, this section defines the DFSR and IFSR format.

For an External abort taken from Non-secure state to Monitor mode, the DFSR or IFSR uses the format associated with the Long-descriptor translation table format, as described in PL1 fault reporting with the Long-descriptor translation table format on page G5-5573, if any of the following applies:
• The value of the Secure TTBCR.EAE field is 1.
• The External abort is synchronous and is taken from either:
  — Hyp mode.
  — A Non-secure PL1 or EL0 mode, and the value of the Non-secure TTBCR.EAE field is 1.

Otherwise:
• For a synchronous External abort from a stage 2 translation routed to Monitor mode when the value of the Secure TTBCR.EAE field is 0 it is IMPLEMENTATION DEFINED whether:
  — The format associated with the Long-descriptor translation table format is used, as described in PL1 fault reporting with the Long-descriptor translation table format on page G5-5573.
  — The format associated with the Short-descriptor translation table format is used, as described in PL1 fault reporting with the Short-descriptor translation table format. ARM deprecates using this format. When this format is used, the value of DFSR.FS[1] or IFSR.FS[1] is UNKNOWN when reporting a synchronous External abort, or a synchronous parity or ECC error, on the stage 2 translation.
• In all other cases the DFSR or IFSR uses the format associated with the Short-descriptor translation table format, as described in PL1 fault reporting with the Short-descriptor translation table format.

**PL1 fault reporting with the Short-descriptor translation table format**

This subsection describes the fault reporting for a fault taken to a PL1 when address translation is using the Short-descriptor translation table format.

On taking an exception, bit[9] of the FSR is RAZ, or set to 0, if the PE is using this FSR format.

An FSR encodes the fault in a 5-bit FS field, that comprises FSR[10, 3:0]. Table G5-26 shows the encoding of that field. Summary of register updates on faults taken to PL1 modes on page G5-5575 shows:
• Whether the corresponding FAR is updated on the fault. That is:
  — For a fault reported in the IFSR, whether the IFAR holds a valid address.
  — For a fault reported in the DFSR, whether the DFAR holds a valid address.
• For faults that update DFSR, whether DFSR.DFSR.Domain is valid

When reading Table G5-26:
• FS values not shown in the table are reserved.
• FS values shown as DFSR only are reserved for the IFSR.

<table>

<td>Synchronous External abort on translation table walk&lt;sup&gt;a, b&lt;/sup&gt;</td>
<td>Level 2</td>
</tr>
</tbody>
</table>
The level associated with MMU faults on a Short-descriptor translation table lookup

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, Permission fault, or Domain fault, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Supersection, Section, or Page descriptor.

Also see Synchronous External abort errors from address translation caching structures on page G5-5565.

The Domain field in the DFSR

The DFSR includes a Domain field. This is inherited from previous versions of the VMSA. The IFSR does not include a Domain field. Summary of register updates on faults taken to PL1 modes on page G5-5575 describes when DFSR Domain is valid.
ARM deprecates any use of the Domain field in the DFSR. The Long-descriptor translation table format does not support a Domain field, and future versions of the ARM architecture might not support a Domain field in the Short-descriptor translation table format. ARM strongly recommends that new software does not use this field.

For both Data Abort exceptions and Prefetch Abort exceptions, software can find the domain information by performing a translation table read for the faulting address and extracting the Domain field from the translation table entry.

**PL1 fault reporting with the Long-descriptor translation table format**

This subsection describes the fault reporting for a fault taken to a PL1 mode when address translation is using the Long-descriptor translation table format.

When the PE takes an exception, bit[9] of the FSR is set to 1 if the PE is using this FSR format.

The FSRs encode the fault in a 6-bit STATUS field, that comprises FSR[5:0]. Table G5-27 shows the encoding of that field. In addition:

- For a fault taken to a PL1 mode, *Summary of register updates on faults taken to PL1 modes on page G5-5575* shows whether the corresponding FAR is updated on the fault. That is:
  - For a fault reported in the IFSR, whether the IFAR holds a valid address.
  - For a fault reported in the DFSR, whether the DFAR holds a valid address.

- For a fault taken to the Hyp mode, *Summary of register updates on exceptions taken to Hyp mode on page G5-5583* shows what registers are updated on the fault.

</tbody>
</table>

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Also see Synchronous External abort errors from address translation caching structures on page G5-5565.

Reserved encoding in the IFSR and DFSR encodings tables

With both the Short-descriptor and the Long-descriptor FSR format, the fault encodings reserve a single encoding for Cache and TLB lockdown faults. The details of these faults and any associated subsidiary registers are IMPLEMENTATION DEFINED.
### Summary of register updates on faults taken to PL1 modes

For faults that generate exceptions that are taken to a PL1 mode, Table G5-29 shows the registers affected by each fault. In this table:
- **Yes** indicates that the register is updated.
- **UNK** indicates that the fault makes the register value **UNKNOWN**.
- A null entry, `--`, indicates that the fault does not affect the register.

For faults that update the DFSR using the Short-descriptor format FSR encodings, Table G5-30 on page G5-5576 shows whether DFSR.Domain is valid.

\(^a\) IMPLEMENTATION DEFINED. The IFSR.FnV or DFSR.FnV bit indicates whether the register holds a valid address. See [Fault address reporting on synchronous External aborts](#).

\(^b\) For faults that use the Short-descriptor format FSR encodings, Table G5-30 on page G5-5576 shows whether DFSR.Domain is valid.

\(^c\) For faults that update the DFSR using the Short-descriptor format FSR encodings, Table G5-30 on page G5-5576 shows whether DFSR.Domain is valid.

\(^d\) For faults that use the Short-descriptor format FSR encodings, Table G5-30 on page G5-5576 shows whether DFSR.Domain is valid.

\(^e\) For faults that use the Short-descriptor format FSR encodings, Table G5-30 on page G5-5576 shows whether DFSR.Domain is valid.
b. When using the Long-descriptor translation table format, there is not a specific fault code for a fault on an instruction cache maintenance instruction. For more information see Data Abort on an instruction cache or branch predictor maintenance instruction by VA on page G5-5569.

c. The two lines of this entry show the alternative ways of reporting the fault when using the Short-descriptor translation table format. It is IMPLEMENTATION DEFINED which methods is used, see Data Abort on an instruction cache or branch predictor maintenance instruction by VA on page G5-5569.

d. Generates a Prefetch Abort exception.

e. Generates a Data Abort exception.

For those faults for which Table G5-29 on page G5-5575 shows that the DFSR is updated, if the fault is reported using the Short-descriptor FSR encodings, Table G5-30 shows whether DFSR.Domain is valid. In this table, UNK indicates that the fault makes DFSR.Domain UNKNOWN.

Table G5-30 Validity of Domain field on faults that update the DFSR when using the Short-descriptor encodings

a. Previously, this encoding was a deprecated encoding for Alignment fault. The extensive changes in the memory model in VMSAv8-32 mean there should be no possibility of confusing the new use of this encoding with its previous use.
b. Including asynchronous External abort on a data access, a translation table walk, or an instruction fetch.

G5.12.5 Reporting exceptions taken to Hyp mode

Hyp mode is the Non-secure EL2 mode. It is entered by taking an exception to Hyp mode.
Note

Software executing in Monitor mode, or at EL3 when EL3 is using AArch64, can perform an exception return to Hyp mode. This means Hyp mode can be entered either by taking an exception, or by a permitted exception return.

When EL2 is using AArch32, the following exceptions are taken to Hyp mode:

- SError interrupt exceptions, IRQ exceptions, and FIQ exceptions, from Non-secure PL1 and EL0 modes, if not routed to Secure Monitor mode, and if configured by the AMO, FMO or IMO bits. For more information see Asynchronous exception routing controls on page G1-5276.
- When HCR.TGE is set to 1, all exceptions that would be routed to Non-secure PL1 modes. For more information, see Routing exceptions from Non-secure EL0 to EL2 on page G1-5262.
- When HDCR.TDE is set to 1, any debug exception that would otherwise be taken to a Non-secure PL1 mode, see Routing debug exceptions to EL2 using AArch32 on page G1-5264.
- The privilege rules for taking exceptions mean that any exception taken from Hyp mode, if not routed to EL3, must be taken to Hyp mode.
- An abort that Routing of aborts taken to AArch32 state on page G1-5266 identifies as taken to Hyp mode.
- Hypervisor Call exceptions, and Hyp Trap exceptions, are always taken to Hyp mode. These exceptions are supported only as part of EL2.

Synchronous exceptions taken to Hyp mode provide syndrome information in the HSR.

On an abort exception taken to Hyp mode, the syndrome information in the HSR includes the Fault status code otherwise provided by the fault status register, and extends the fault reporting compared to that available for an exception taken to a PL1 mode.

In addition, for a Debug exception taken to Hyp mode, DBGDSCRInt.MOE or DBGDSCRExt.MOE shows what caused the Debug exception. This field is valid regardless of whether the Debug exception was taken from Hyp mode or from another Non-secure mode.

For more information, see the following subsections:
- Registers used for reporting exceptions taken to Hyp mode.
- Memory fault reporting in Hyp mode on page G5-5578.
- Use of the HSR on page G5-5580

Registers used for reporting exceptions taken to Hyp mode

The following registers are used for reporting exceptions taken to Hyp mode:
- The HSR holds syndrome information for the exception.
- The HDFAR holds the VA associated with a Data Abort exception.
- The HIFAR holds the VA associated with a Prefetch Abort exception.
- The HPFAR holds bits[39:12] of the IPA associated with some aborts on stage 2 address translations.

In addition, if implemented, the optional HADFSR and HAIFSR can provide additional fault information, see Hyp Auxiliary Fault Syndrome Registers.

Hyp Auxiliary Fault Syndrome Registers

EL2 also defines encodings for the following Hyp Auxiliary Fault Syndrome Registers:
- The Hyp Auxiliary Data Fault Syndrome Register, HADFSR.
- The Hyp Auxiliary Instruction Fault Syndrome Register, HAIFSR.
An implementation can use these registers to return additional fault status information for aborts taken to Hyp mode. They are the Hyp mode equivalents of the registers described in Auxiliary Fault Status Registers on page G5-5568. An example use of these registers is to return more information for diagnosing parity or ECC errors.

The architectural requirements for the HADFSR and HAIFSR are:

- The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED.
- An implementation with no requirement for additional fault reporting can implement these registers as RES0, but the architecture does not require it to do so.

Memory fault reporting in Hyp mode

Prefetch Abort and Data Abort exceptions taken to Hyp mode report memory faults. For these aborts, the HSR contains the following fault status information:

- The HSR.EC field indicates the type of abort, as Table G5-31 shows.
- The HSR.ISS field holds more information about the abort. In particular:
  - Bits[5:0] of this field hold the STATUS field for the abort, using the encodings defined in PL1 fault reporting with the Long-descriptor translation table format on page G5-5573.
  - Other subfields of the ISS give more information about the exception, equivalent to the information returned in the FSR for a memory fault reported at PL1.

See the descriptions of the ISS fields for the memory faults, referenced from the Syndrome description column of Table G5-31, for information about the returned fault information.

<td>Data Abort taken from Hyp mode</td>
<td></td>
</tr>
</tbody>
</table>

For more information, see Use of the HSR on page G5-5580.

A Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction that would abort if the PE attempted to execute it, no Prefetch Abort exception is generated.

Register updates on exception reporting in Hyp mode

The use of the HSR, and of the other registers listed in Registers used for reporting exceptions taken to Hyp mode on page G5-5577, depends on the cause of the Abort. In reporting these faults, in general:

- If the fault generates a synchronous Data Abort exception, the HDFAR holds the associated VA, but see Fault address reporting on synchronous External aborts on page G5-5567 for a permitted exception to this requirement.
- If the fault generates a Prefetch Abort exception, the HIFAR holds the associated VA, but see Fault address reporting on synchronous External aborts on page G5-5567 for a permitted exception to this requirement.
In the following cases, the HPFAR holds the faulting IPA:
- A Translation or Access flag fault on a stage 2 translation.
- A Translation, Access flag, or Permission fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.
- A stage 2 Address size fault.
In all other cases, the HPFAR is UNKNOWN.

- On a Data Abort exception that is taken to Hyp mode, the HIFAR is UNKNOWN.
- On a Prefetch Abort exception that is taken to Hyp mode, the HDFAR is UNKNOWN.

In addition, the reporting of particular aborts is as follows:

Abort on the stage 1 translation for a memory access from Hyp mode
The HDFAR or HIFAR holds the VA that caused the fault. The STATUS subfield of HSR.ISS indicates the type of fault, Translation, Address size, Access flag, or Permission. The HPFAR is UNKNOWN.

Abort on the stage 2 translation for a memory access from a Non-secure PL1 or EL0 mode
This includes aborts on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation. The HDFAR or HIFAR holds the VA that caused the fault. The STATUS subfield of HSR.ISS indicates the type of fault, Translation, Address size, Access flag, or Permission.

For any Access flag fault or Translation fault, and also for any Permission fault on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation, the HPFAR holds the IPA that caused the fault. Otherwise, the HPFAR is UNKNOWN.

Abort caused by a synchronous External abort, or synchronous parity or ECC error, and taken to Hyp mode
The HDFAR or HIFAR holds the VA that caused the fault, but see Fault address reporting on synchronous External aborts on page G5-5567 for a permitted exception to this requirement. The HPFAR is UNKNOWN.

Data Abort caused by a Watchpoint exception and routed to Hyp mode because HDCR.TDE is set to 1
When HDCR.TDE is set to 1, a Watchpoint exception generated in a Non-secure PL1 or EL0 mode, that would otherwise generate a Data Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.
HDFAR is set to the address that generated the watchpoint.

Note
ELR_hyp indicates the address of the instruction that triggered the watchpoint.

A watchpointed address can be any byte-aligned address. The address reported in HDFAR might not be the watchpointed address, and, for a watchpoint due to an operation other than a Data Cache maintenance instruction, can be any address between and including:
- The lowest address accessed by the instruction that triggered the watchpoint.
- The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

Note
In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.

The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.
The IMPLEMENTATION DEFINED power-of-two size must be no larger than the block size of the AArch64 DC ZVA operation.

See also Watchpoint exceptions on page G2-5399.

In all cases, HPFAR is UNKNOWN.

Prefetch Abort caused by a Breakpoint Instruction exception and taken to Hyp mode

This abort is generated if a BKPT instruction is executed in Hyp mode. The abort leaves the HIFAR and HPFAR UNKNOWN.

See also Breakpoint Instruction exceptions on page G2-5371.

Prefetch Abort caused by a Breakpoint Instruction, Breakpoint, or Vector Catch exception, and routed to Hyp mode because HDCR.TDE is set to 1

When HDCR.TDE is set to 1, a debug exception, generated in a Non-secure PL1 or EL0 mode, that would otherwise generate a Prefetch Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

The abort leaves the HIFAR and HPFAR UNKNOWN. This is identical to the reporting of a Prefetch Abort exception caused by a Debug exception on a BKPT instruction that is executed in Hyp mode.

The difference between these two cases is:

• The Debug exception on a BKPT instruction executed in Hyp mode generates a Prefetch Abort exception, taken to Hyp mode, and reported in the HSR using EC value 0x21.

• Aborts generated because HDCR.TDE is set to 1 generate a Hyp Trap exception, and are reported in the HSR using EC value 0x20.

Use of the HSR

The HSR holds syndrome information for any synchronous exception taken to Hyp mode. Compared with the reporting of exceptions taken to PL1 modes, the HSR:

• Always provides details of the fault. The DFSR and IFSR are not used.

• Provides more extensive information, for a wider range of exceptions.

The HSR register, to show how it encodes exception syndrome information, see the register description for more information. The register comprises:

• A 6-bit Exception class field, EC, that indicates the cause of the exception.

• An instruction length bit, IL. When an exception is caused by trapping an instruction to Hyp mode, this bit indicates the length of the trapped instruction, as follows:

  0  16-bit instruction trapped.

  1  32-bit instruction trapped.

In other cases the IL field is not valid and is RES1.

• An instruction specific syndrome field, ISS. Architecturally, this field could be defined independently for each defined Exception class (EC), but in practice several ISS formats are common to more than one EC.
The format of the HSR depends on the value of the EC field, as follows:

\[ 0b000000 \leq EC \leq 0b001110 \]

The ISS part of the returned value includes the CV and COND fields described in *Encoding of ISS[24:20] when 0b000000 < EC \leq 0b001110*. Figure G5-17 shows the HSR format in this case.

![Figure G5-17 HSR format when the ISS includes CV and COND fields](image)

**EC==0b000000 or EC<0b001110** There are no generic fields within the ISS. Figure G5-18 shows the HSR format in this case.

![Figure G5-18 HSR format when the ISS does not include a COND field](image)

*Encoding of ISS[24:20] when 0b000000 < EC \leq 0b001110*

For EC values that are nonzero and less than or equal to 0b001110, ISS[24:20] provides the Condition code field for the trapped instruction, together with a valid flag for this field. The encoding of this part of the ISS field is:

CV, ISS[24]
Condition code valid. Possible values of this bit are:
- 0 The COND field is not valid.
- 1 The COND field is valid

COND, ISS[23:20]
The Condition code for the trapped instruction. This field is valid only when CV is set to 1.

If CV is set to 0, this field is RES0

The full descriptions of the HSR.ISS formats give more information about the CV field.

--- Note ---

In some circumstances, it is IMPLEMENTATION DEFINED whether a conditional instruction that fails its Condition code check generates an Undefined Instruction exception, see *Conditional execution of undefined instructions on page G1-5284.*
HSR exception classes

Table G5-32 shows the encoding of the HSR exception class field, EC. Values of EC not shown in the table are reserved. For each EC value, the table references a subsection of the description of the HSR that describes the associated ISS format and gives information about the cause of the exception, for example the configuration required to enable the associated trap.

G5.12.6 Summary of register updates on exceptions taken to Hyp mode

For memory system faults that generate exceptions that are taken to Hyp mode, Table G5-33 shows the registers affected by each fault. In this table:

- Yes indicates that the register is updated.
- UNK indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.

--- Note ---

For a list of the MMU faults see Types of MMU faults on page G5-5555.

Classification of MMU faults taken to Hyp mode

This subsection gives more information about the MMU faults shown in Table G5-33 on page G5-5583.

Note

Unlike Table G5-29 on page G5-5575, the Hyp mode fault reporting table does not include an entry for a fault on an instruction cache maintenance instruction. That is because, when the fault is taken to Hyp mode, the reporting indicates the cause of the fault, for example a Translation fault, and ISS.CM is set to 1 to indicate that the fault was on a cache maintenance instruction, see ISS encoding for an exception from a Data Abort on page G8-5829.

Classification of MMU faults taken to Hyp mode

The table uses the following descriptions for MMU faults taken to Hyp mode:

MMU fault at stage 1

This is an MMU fault generated on a stage 1 translation performed in the Non-secure EL2 translation regime.

MMU fault at stage 2

This is an MMU fault generated on a stage 2 translation performed in the Non-secure PL1&0 translation regime.

As the table shows, for the faults in this group:

- Translation and Access flag faults update the HPFAR
- Permission faults leave the HPFAR UNKNOWN.

MMU stage 2 fault on a stage 1 translation

This is an MMU fault generated on the stage 2 translation of an address accessed in a stage 1 translation table walk performed in the Non-secure PL1&0 translation regime. For more information about these faults see Stage 2 fault on a stage 1 translation table walk on page G5-5561.

Figure G5-1 on page G5-5466 shows the different translation regimes and associated stages of translation.
G5.13 Address translation instructions

The System register encoding space includes encodings for instructions that either:

- Translate a virtual address (VA) to a physical address (PA).
- Translate a virtual address (VA) to an intermediate physical address (IPA).

Address translation system instructions on page K13-7437 summarizes these instructions.

When using the Short-descriptor translation table format, all translations performed by these instructions take account of TEX remap when this is enabled, see Short-descriptor format memory region attributes, with TEX remap on page G5-5524.

An address translation instruction that executes successfully returns the output address, a PA or an IPA, in the PAR. This is a 64-bit register, that can hold addresses of up to 40 bits.

It is IMPLEMENTATION DEFINED whether the address translation instructions return the values held in a TLB or the result of a translation table walk. Therefore, ARM recommends that these instructions are not used at a time when the TLB entries might be different from the underlying translation tables held in memory.

The following sections give more information about these instructions:

- Address translation instruction naming and operation summary.
- Encoding and availability of the address translation instructions on page G5-5587.
- Determining the PAR format on page G5-5589.
- Handling of faults and aborts during an address translation instruction on page G5-5589.

G5.13.1 Address translation instruction naming and operation summary

Some older documentation uses the original names for the address translation instructions that were included in the original ARMv7 documentation. Table G5-34 summarizes the instructions that are available in AArch32 state, and relates the old instruction names to the current names.

Table G5-34 Naming of address translation instructions

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

a. Instructions are added by ARMv8.2-ATS1E1 and do not have a previous name.
b. Instructions are part of EL2 and have no equivalent in the older descriptions.

In an implementation that does not include EL2, there is no distinction between stage 1 translations and stage 1 and 2 combined translations.

For the stage 1 current state and stages 1 and 2 Non-secure state only instructions, the meanings of the final letters of the names are:

- PR: PL1 mode, read operation.
- PRP: PL1 mode, read operation, taking account of PSTATE.PAN.
- PW: PL1 mode, write operation.
- PWP: PL1 mode, write operation, taking account of PSTATE.PAN.
- UR: User mode, read operation.
- UW: User mode, write operation.
User mode can be described as the unprivileged mode. It is the only EL0 mode.

For the stage 1 Hyp mode instructions, the last letter of the instruction name is R for the read operation and W for the write operation.

See also Encoding and availability of the address translation instructions on page G5-5587.

ATS1C**, Address translation stage 1, current security state

Any VMSAv8-32 implementation supports the ATS1C** instructions. They can be executed by any software executing at PL1 or higher, in either Security state.

The ATS1C** instructions are ATS1CPR, ATS1CPW, ATS1CUR, and ATS1CUW and, when ARMv8.2-ATS1E1 is implemented, ATS1CPRP and ATS1CPWP. These instructions perform the address translations of the PL1&0 translation regime.

In an implementation that includes EL2, when executed in Non-secure state, these instructions return the IPA that is the output address of the stage 1 translation. Figure G5-1 on page G5-5466 shows the different translation regimes.

The Non-secure PL1 and EL0 modes have no visibility of the stage 2 address translations, that can be defined only at EL2, and translate IPAs to be PAs.

See Determining the PAR format on page G5-5589 for the format used when returning the result of these instructions.

ATS12NSO**, Address translation stages 1 and 2, Non-secure state only

A VMSAv8-32 implementation supports the ATS12NSO** instructions only if it includes EL2. In an implementation that includes EL2, in AArch32 state, they can be executed:

- By software executing in Non-secure state at EL2. This means by software executing in Hyp mode.
- If the implementation includes EL3, when EL3 is using AArch32, by software executing in Secure state at PL1.

The ATS12NSO** instructions are ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, and ATS12NSOUW.

In an implementation that includes EL3, when EL3 is using AArch64 and EL1 is using AArch32, any execution of an ATS12NSO** instruction at Secure EL1 is trapped as an exception that is taken to EL3.

In an implementation that does not include EL2, but includes EL3, when EL3 is using AArch32 these instructions are not UNDEFINED but each instruction behaves in the same way as the equivalent ATS1C** instruction.

If an implementation does not include EL2 and does not include EL3 then these instructions are CONSTRAINED UNPREDICTABLE, with the permitted behavior that the instructions are UNDEFINED, see Unallocated System register access instructions on page K1-7193.

ARM deprecates use of these instructions from any Secure PL1 mode other than Monitor mode.

In Secure state and in Non-secure Hyp mode these instructions perform the translations made by the Non-secure PL1&0 translation regime.

These instructions always return the PA and final attributes generated by the translation. That is, for an implementation that includes EL2, they return:

- The result of the two stages of address translation for the specified Non-secure input address.
- The memory attributes obtained by the combination of the stage 1 and stage 2 attributes.
Note
From Hyp mode, the ATS1C** and ATS12NSO** instructions both return the results of address translations that would be performed in the Non-secure modes other than Hyp mode. The difference is:

- The ATS1C** instructions return the Non-secure PL1 view of the associated address translation. That is, they return the IPA output address corresponding to the VA input address.
- The ATS12NSO** instructions return the EL2, or Hyp mode, view of the associated address translation. That is, they return the PA output address corresponding to the VA input address, generated by two stages of translation.

See Determining the PAR format on page G5-5589 for the format used when returning the result of these instructions.

ATS1H*, Address translation stage 1, Hyp mode

A VMSAv8-32 implementation supports the ATS1H* instructions only if it includes EL2. They can be executed by:

- Software executing in Non-secure state at EL2. This means by software executing in Hyp mode.
- Software executing in Secure state in Monitor mode.

The ATS1H* instructions are ATS1HR and ATS1HW. In an implementation that includes EL3, these instructions are CONSTRAINED UNPREDICTABLE if executed in a Secure PL1 mode other than Monitor mode, see Hyp mode VA to PA address translation instructions on page K1-7211.

If an implementation does not include EL2 then these instructions are CONSTRAINED UNPREDICTABLE, with the permitted behavior that the instructions are UNDEFINED, see Unallocated System register access instructions on page K1-7193.

These instructions perform the translations made by the Non-secure EL2 translation regime. The instruction takes a VA input address and returns a PA output address.

These instructions always return a result in a 64-bit format PAR.

G5.13.2 Encoding and availability of the address translation instructions

Software executing at EL0 never has any visibility of the address translation instructions, but software executing at PL1 or higher can use the unprivileged address translation instructions to find the address translations used for memory accesses by software executing at PL1 and EL0.

Note
For information about translations when the stage of address translation is disabled see The effects of disabling address translation stages on VMSAv8-32 behavior on page G5-5472.

Table G5-35 shows the encodings for the address translation instructions, and their availability in different implementations in different PE modes and states.

<table>
<thead>
<tr>
<th>opc1</th>
<th>CRm</th>
<th>opc2</th>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>

<td>All VMSAv8-32 implementations, in all modes, at PL1 or higher, see ATS1C**, Address translation stage 1, current security state on page G5-5586</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The result of an instruction is always returned in the PAR. The PAR is a RW register and:

- In all implementations, the 32-bit format PAR is accessed using an MCR or MRC instruction with CRn set to c7, CRm set to c4, and opc1 and opc2 both set to 0.
- The 64-bit format PAR is accessed using an MCRR or MRRC instruction with CRm set to c7, and opc1 set to 0.

Address translation instructions that are not available in a particular implementation are reserved and CONSTRAINED UNPREDICTABLE. For example:

- In an implementation that does not include EL2, the encodings with an opc1 value of 4 are reserved and CONSTRAINED UNPREDICTABLE. These are the ATS1H* instructions.
- In an implementation that does not include either EL2 or EL3, the encodings with opc2 values of 4-7 are reserved and CONSTRAINED UNPREDICTABLE. These are the ATS12NSO** instructions.

The CONSTRAINED UNPREDICTABLE behavior of these encodings is that they are UNDEFINED, see Unallocated System register access instructions on page K1-7193.

a. Instruction only supported when ARMv8.2-ATS1E1 is implemented.

The result of an instruction is always returned in the PAR. The PAR is a RW register and:

- In all implementations, the 32-bit format PAR is accessed using an MCR or MRC instruction with CRn set to c7, CRm set to c4, and opc1 and opc2 both set to 0.
- The 64-bit format PAR is accessed using an MCRR or MRRC instruction with CRm set to c7, and opc1 set to 0.

Address translation instructions that are not available in a particular implementation are reserved and CONSTRAINED UNPREDICTABLE. For example:

- In an implementation that does not include EL2, the encodings with an opc1 value of 4 are reserved and CONSTRAINED UNPREDICTABLE. These are the ATS1H* instructions.
- In an implementation that does not include either EL2 or EL3, the encodings with opc2 values of 4-7 are reserved and CONSTRAINED UNPREDICTABLE. These are the ATS12NSO** instructions.

The CONSTRAINED UNPREDICTABLE behavior of these encodings is that they are UNDEFINED, see Unallocated System register access instructions on page K1-7193.
G5.13.3 Determining the PAR format

The PAR is a 64-bit register, that supports both 32-bit and 64-bit PAR formats. This section describes how the PAR format is determined, for returning a result from each of the groups of address translation instructions. The returned result might be the translated address, or might indicate a fault on the translation, see *Handling of faults and aborts during an address translation instruction*.

**ATS1C** instructions

Address translations for the current state. From modes other than Hyp mode:
- TTBCR.EAE determines whether the result is returned using the 32-bit or the 64-bit PAR format.
- If the implementation includes EL3, the translation performed is for the current security state and, depending on that state:
  - The Secure or Non-secure TTBCR.EAE determines the PAR format.
  - The result is returned to the Secure or Non-secure instance of the PAR

Instructions executed in Hyp mode always return a result to the Non-secure PAR, using the 64-bit format.

**ATS12NSO** instructions

Address translations for the Non-secure PL1 and EL0 modes. These instructions return a result using the 64-bit PAR format if at least one of the following is true:
- The Non-secure TTBCR.EAE bit is set to 1.
- The implementation includes EL2, and the value of HCR.VM is 1.

Otherwise, the instruction returns a result using the 32-bit PAR format.

Instructions executed in a Secure PL1 mode return a result to the Secure PAR. Instructions executed in Hyp mode return a result to the Non-secure PAR.

**ATS1H** instructions

Address translations from Hyp mode. These instructions always return a result using the 64-bit PAR format.

Instructions executed in Secure Monitor mode return a result to the Secure PAR. Instructions executed in Non-secure Hyp mode return a result to the Non-secure PAR.

G5.13.4 Handling of faults and aborts during an address translation instruction

When a stage of address translation is enabled, any corresponding address translation instruction requires a translation table lookup, and this might require a translation table walk. However, the input address for the translation might be a faulting address, either because:
- The translation table entries used for the translation indicate a fault.
- A stage 2 fault or an External abort occurs on the required translation table walk.

*VMSAv8-32 memory aborts on page G5-5554* describes the faults that might occur on a translation table walk in AArch32 state.

How the fault is handled, and whether it generates an exception, depends on the cause of the fault, as described in:
- *MMU fault on an address translation instruction*.
- *External abort during an address translation instruction on page G5-5590*.
- *Stage 2 fault on a current state address translation instruction on page G5-5590*.

**MMU fault on an address translation instruction**

In the following cases, an MMU fault on an address translation is reported in the PAR, and no abort is taken. This applies:
- For a faulting address translation instruction executed in Hyp mode, or in a Secure PL1 mode.
• For a faulting address translation instruction executed in a Non-secure PL1 mode, for cases where the fault would generate a stage 1 abort if it occurred on the equivalent load or store operation.

*Using the PAR to report a fault on an address translation instruction* gives more information about how these faults are reported.

--- Note ---

• The Domain fault encodings shown in Table G5-27 on page G5-5573 are used only for reporting a fault on an address translation instruction that uses the 64-bit PAR format. That is, they are used only in an implementation that includes EL2, and are used for reporting a Domain fault on either:
  — An ATS1C** instruction executed in Hyp mode.
  — An ATS12NSO** instruction executed when the value of HCR.VM is 1.

These encodings are never used for fault reporting in the DFSR, IFSR, or HSR.

• For an address translation instruction executed in a Non-secure PL1 mode, for a fault that would generate a stage 2 abort if it occurred on the equivalent load or store operation, the stage 2 abort is generated as described in *Stage 2 fault on a current state address translation instruction*.

---

*Using the PAR to report a fault on an address translation instruction*

For a fault on an address translation instruction for which no abort is taken, the PAR is updated with the following information, to indicate the fault:

• The fault code, that would normally be written to the Fault status register. The code used depends on the current translation table format, as described in either:
  — PL1 fault reporting with the Short-descriptor translation table format on page G5-5571.
  — PL1 fault reporting with the Long-descriptor translation table format on page G5-5573.

See also the Note at the start of *Determining the PAR format* on page G5-5589 about the Domain fault encodings shown in Table G5-27 on page G5-5573.

• A status bit, that indicates that the translation operation failed.

The fault does not update any Fault Address Register.

**External abort during an address translation instruction**

As stated in *External abort on a translation table walk* on page G5-5562, an External abort on a translation table walk generates a Data Abort exception. The abort can be synchronous or asynchronous, and behaves as follows:

**Synchronous External abort on a translation table walk**

The fault status and fault address registers of the Security state to which the abort is taken are updated. The fault status register indicates the appropriate External abort on a Translation fault, and the fault address register indicates the input address for the translation.

The PAR is UNKNOWN.

**Asynchronous External abort on a translation table walk**

The fault status register of the Security state to which the abort is taken is updated, to indicate the asynchronous External abort. No fault address registers are updated.

The PAR is UNKNOWN.

**Stage 2 fault on a current state address translation instruction**

If the PE is in a Non-secure PL1 mode and executes one of the ATS1C** instructions, then a fault in the stage 2 translation of an address accessed in a stage 1 translation table lookup generates an exception. This is equivalent to the case described in *Stage 2 fault on a stage 1 translation table walk* on page G5-5561. When this fault occurs on an ATS1C** address translation instruction:

• A Hyp Trap exception is taken to Hyp mode.
• The **PAR** is **UNKNOWN**.
• The **HSR** indicates that:
  — The fault occurred on a translation table walk.
  — The operation that faulted was a cache maintenance instruction.
• The **HPFAR** holds the IPA that faulted.
• The **HDFAR** holds the VA that the executing software supplied to the address translation instruction.
G5.14 Pseudocode description of VMSAv8-32 memory system operations

This section contains a list of pseudocode functions describing VMSAv8-32 memory operations. The following subsections describe the pseudocode functions:

- Alignment fault.
- Address translation.
- Domain checking.
- TLB operations.
- Translation table walk.
- Reporting syndrome information on page G5-5593.
- Memory access decode when TEX remap is enabled on page G5-5593.

See also the descriptions of pseudocode for general memory system operations in Pseudocode description of general memory System instructions on page G4-5460.

G5.14.1 Alignment fault

The AArch32.AlignmentFault() pseudocode function describes the generation of an Alignment fault Data Abort exception.

See also Abort exceptions on page G4-5462.

G5.14.2 Address translation

The AArch32.TranslateAddress() and AArch32.FullTranslate() pseudocode functions describe a VMSAv8-32 address translation.

The AArch32.FullTranslate() function calls either:
- The function described in Address translation when the stage 1 address translation is disabled.
- One of the functions described in Translation table walk.

See also Stage 2 translation table walk on page G5-5593.

Address translation when the stage 1 address translation is disabled

The AArch32.TranslateAddressS1Off() pseudocode function describes the address translation performed when the stage 1 address translation is disabled.

G5.14.3 Domain checking

The AArch32.CheckDomain() pseudocode function describes domain checking.

G5.14.4 TLB operations

The TLBRecord type represents the contents of a TLB entry:

G5.14.5 Translation table walk

Because of the complexity of a translation table walk, the following sections describe the different cases:
- Translation table walk using the Short-descriptor translation table format for stage 1.
- Translation table walk using the Long-descriptor translation table format for stage 1 on page G5-5593.
- Stage 2 translation table walk on page G5-5593.

Translation table walk using the Short-descriptor translation table format for stage 1

The AArch32.TranslationTableWalkSD() pseudocode function describes the translation table walk when the stage 1 translation tables use the Short-descriptor format. It calls the function described in Stage 2 translation table walk on page G5-5593 if necessary.
The ShortConvertAttrsHints() pseudocode function converts the Normal memory cacheability attribute, from the TTBR or the translation table TEX field, into the separate cacheability attribute and cache allocation hint defined in a Long-descriptor translation table descriptor.

Translation table walk using the Long-descriptor translation table format for stage 1

The AArch32.TranslationTableWalkLD() pseudocode function describes the translation table walk when the stage 1 translation tables use the Long-descriptor format. It calls the function described in Stage 2 translation table walk if necessary.

AArch32.TranslationTableWalkLD() calls the ConvertAttrsHints() pseudocode function that is defined in Translation table walk using the Short-descriptor translation table format for stage 1 on page G5-5592.

The AArch32.S1AttrDecode() pseudocode function uses the MAIR0 and MAIR1 registers to decode the Attr[2:0] value from a stage 1 translation table descriptor.

The S2AttrDecode() pseudocode function decodes the Attr[3:0] value from a stage 2 translation table descriptor.

Stage 2 translation table walk

In the Non-secure EL1&0 translation regime, a descriptor address returned by stage 1 lookup is in the IPA address map, and must be mapped to a PA by a stage 2 translation. When EL2 is using AArch32, function AArch32.SecondStageWalk() performs this translation, by calling the AArch32.SecondStageTranslate() function.

When called from AArch32.SecondStageWalk(), the AArch32.SecondStageTranslate() function performs a second stage translation, from IPA to PA, of the supplied address, including checking that the access has read permission at the second stage. If the access does not have second stage read permission it generates a second stage Permission fault on the first stage translation table walk. The second stage translation might hit in a TLB, or might involve a translation table walk, which will use the algorithm described in this section. Stage 2 translations always use the Long-descriptor translation table format.

The AArch32.CheckPermission() pseudocode function checks the access permissions for the stage 1 translation.

The AArch32.CheckS2Permission() pseudocode function checks the access permissions for the stage 2 translation.

The CombineS1S2Desc() pseudocode function combines the stage 1 and stage 2 access descriptors:

G5.14.6   Reporting syndrome information

The AArch32.ReportHypEntry(), AArch32.ReportDataAbort(), and AArch32.ReportPrefetchAbort() pseudocode functions write syndrome value information to the appropriate registers for the current mode.

G5.14.7   Memory access decode when TEX remap is enabled

When using the Short-descriptor translation table format, the function AArch32.RemappedTEXDecode() decodes the texcb and S attributes derived from the translation tables when TEX remap is enabled. Short-descriptor format memory region attributes, with TEX remap on page G5-5524 shows the interpretation of the arguments.
About the System registers for VMSAv8-32

The System registers and System instructions that are accessible in AArch32 state are almost all in the encoding space described in The AArch32 System register interface on page G1-5313. This section gives general information about these registers, which comprise:

- Registers in the \( \text{coproc} = 0b1111 \) encoding space, that provide control and status information for the PE in Non-debug state.
- Registers in the \( \text{coproc} = 0b1110 \) encoding space, including:
  - Debug registers.
  - Trace registers.
  - Legacy execution environment registers.

VMSAv8-32 organization of registers in the \( \text{coproc} = 0b1110 \) encoding space on page G7-5615 summarizes the registers in the \( \text{coproc} = 0b1110 \) encoding space, and indicates where these registers are described, either in this manual or in other architecture specifications.

VMSAv8-32 organization of registers in the \( \text{coproc} = 0b1111 \) encoding space on page G7-5618 summarizes the registers in the \( \text{coproc} = 0b1111 \) encoding space, and indicates where in this manual these registers are described.

Note: Many implementations include other interfaces to some System registers, for example a memory-mapped interface to some debug System registers. These are described in the appropriate sections of this manual.

Classification of System registers

Features provided by EL3 and EL2 integrate with many features of the architecture. Therefore, the descriptions of the individual System registers include information about how these Exception levels affect the register. This section:

- Summarizes how EL3 and EL2 affect the implementation of the System registers, and the classification of those registers.
- Summarizes how EL3 controls access to the System registers.
- Describes an EL3 signal that can control access to some registers in the \( \text{coproc} = 0b1111 \) encoding space.

It contains the following subsections:

- Banked System registers.
- Restricted access System registers on page G5-5595.
- Configurable access System registers on page G5-5595.
- EL2-mode System registers on page G5-5596.
- Common System registers on page G5-5597.
- Access to registers from Monitor mode on page G5-5597.
- The CP15SDISABLE input signal on page G5-5598.

Note: EL3 defines the register classifications of Banked, Restricted access, Configurable, and Common. EL2 defines the EL2-mode classification.

It is IMPLEMENTATION DEFINED whether each IMPLEMENTATION DEFINED register is Banked, Restricted access, Configurable, EL2-mode, or Common.

Banked System registers

In an implementation that includes EL3 using AArch32, some System registers are banked. Banked System registers have two copies, one Secure and one Non-secure. The SCR.NS bit selects the Secure or Non-secure instance of the register.
A Banked System register can contain a mixture of:

- Fields that are banked.
- Fields that are read-only in Non-secure PL1 or EL2 modes but read/write in the Secure state.

The System Control Register SCTL R is an example of a register of that contains this mixture of fields.

The Secure copies of the Banked System registers are sometimes referred to as the Secure Banked System registers. The Non-secure copies of the Banked System registers are sometimes referred to as the Non-secure Banked System registers.

**Restricted access System registers**

In an implementation that includes EL3, some System registers are present only in Secure state. These are called Restricted access registers, and their read/write access permissions are:

- In Non-secure state, software cannot modify Restricted access registers.
- For the NSACR, in Non-secure state:
  - Software running at PL1 or higher can read the register.
  - Unprivileged software, meaning software running at EL0, cannot read the register.

This means that Non-secure software running at PL1 or higher can read the access permissions for System registers that have Configurable access.

If EL3 is using AArch64, then any read of the NSACR from Non-secure EL2 using AArch32, or Non-secure EL1 using AArch32, returns the value 0x00000C00.

- For all other Restricted access registers, Non-secure software cannot read the register.

In an implementation that does not include EL3:

- SDER is implemented only in Secure state.
- Any read of the NSACR returns the value 0x00000C00.
- All other accesses to Restricted access System registers are UNDEFINED.

**Configurable access System registers**

Secure software can configure the access to some System registers. These registers are called Configurable access registers, and the control can be:

- A bit in the control register determines whether the register is:
  - Accessible from Secure state only.
  - Accessible from both Secure and Non-secure states.
- A bit in the control register changes the accessibility of a register bit or field. For example, setting a bit in the control register might mean that an RW field behaves as RAZ/WI when accessed from Non-secure state.

Bits in the NSACR control access.

In an AArch32 implementation that includes EL3:

- There are no Configurable access System registers in the (coproc==0b1110) encoding space.
- The only required Configurable access register in the (coproc==0b1111) encoding space is the CPACR.
  - Floating-point Status and Control Register, FPSCR
  - Floating-point Exception register, FPEXC.
  - Floating-point System ID register, FPSID.
  - Media and VFP Feature Register 0, MVFR0.
  - Media and VFP Feature Register 1, MVFR1.
  - Media and VFP Feature Register 2, MVFR2.
### EL2-mode System registers

In an implementation that includes EL2, if EL2 can use AArch32, the implementation provides a number of registers for use in the EL2 mode, Hyp mode. As with other System register encodings, some of these register encodings provide write-only operations. When the implementation includes EL3 and EL3 is using AArch32, these registers are also accessible from Monitor mode when the value of SCR.NS is 1.

The following subsections describe the EL2-mode registers:

- **Hyp mode read/write registers in the (coproc==0b1111) encoding space.**
- **Hyp mode encodings for shared (coproc==0b1111) System registers.**
- **Hyp mode (coproc==0b1111) write-only System instructions** on page G5-5597.

There are no EL2-mode registers in the (coproc==0b1110) encoding space.

#### Hyp mode read/write registers in the (coproc==0b1111) encoding space

These registers are implemented only in Non-secure state, and in Non-secure state they are accessible only from Hyp mode.

Except for accesses to CNTVOFF in an implementation that includes EL3 but not EL2, the behavior of accesses to these registers is as follows:

- In Secure state, the registers can be accessed from EL3 when SCR.NS is set to 1, see *Access to registers from Monitor mode* on page G5-5597.
- The following accesses are UNDEFINED:
  - Accesses from Non-secure PL1 modes.
  - Accesses in Secure state when SCR.NS is set to 0.

In an implementation that includes EL3 but not EL2, the behavior of accesses to CNTVOFF is as follows:

- Any access from Secure Monitor mode is CONSTRAINED UNPREDICTABLE, regardless of the value of SCR.NS. The CONSTRAINED UNPREDICTABLE behavior is that the access is UNDEFINED, see *Unallocated System register access instructions* on page K1-7193.
- All other accesses are UNDEFINED.

**Note**

Except for CNTVOFF, the Hyp mode registers are part of EL2, meaning they are implemented only if the implementation includes EL2. However, conceptually, CNTVOFF is part of any implementation of the Generic Timer, see *Status of the CNTVOFF register* on page G6-5607. This means the behavior of CNTVOFF in an implementation that does not include EL2 is not covered by the general definition of the behavior of the Hyp mode (coproc==0b1111) read/write registers.

#### Hyp mode encodings for shared (coproc==0b1111) System registers

Some Hyp mode registers share the Secure instance of an existing banked register. In this case, the implementation includes an encoding for the register that is accessible only in Hyp mode, or in Monitor mode when SCR.NS is set to 1.

For these registers, the following accesses are UNDEFINED:

- Accesses from Non-secure PL1 modes.
- Accesses in Secure state when SCR.NS is set to 0.

In Monitor mode, the Secure copies of these registers can be accessed either:

- Using the DFAR or IFAR encoding with SCR.NS set to 0.
- Using the HDFAR or HIFAR encoding with SCR.NS set to 1.

However, between accessing a register using one alias and accessing the register using the other alias, a **Context synchronization event** is required to ensure the ordering of the accesses.
**Hyp mode (coproc==0b1111) write-only System instructions**

Architecturally, these encodings are an extension of the banked register encodings described in Banked System registers on page G5-5594, where:

- The implementation does not implement the operation in Secure state.
- In Non-secure state, the operation is accessible only at EL2, that is, only from Hyp mode.

In Secure state:

- These instructions can be accessed from Monitor mode regardless of the value of SCR.NS, see Access to registers from Monitor mode.
- Accesses to these instructions are CONSTRAINED UNPREDICTABLE if executed in a Secure mode other than Monitor mode, see Hyp mode TLB maintenance instructions on page K1-7211 and Hyp mode VA to PA address translation instructions on page K1-7211.

Accesses to these instructions are UNDEFINED if accessed from a Non-secure PL1 mode.

**Common System registers**

Some System registers and operations are common to the Secure and Non-secure Security states. These are described as the Common access registers, or simply as the Common registers. These registers include:

- Read-only registers that hold configuration information.
- Register encodings used for various memory system operations, rather than to access registers.
- The ISR.
- All System registers in the (coproc==0b1110) encoding space.

**Secure System registers for the (coproc==0b1111) encoding space**

The Secure System registers in the (coproc==0b1111) encoding space comprise:

- The Secure copies of the Banked System registers in the (coproc==0b1111) encoding space.
- The Restricted access System registers in the (coproc==0b1111) encoding space.
- The Configurable access System registers in the (coproc==0b1111) encoding space that are configured to be accessible only from Secure state.

In an implementation that includes EL3, the Non-secure System registers are the System registers other than the Secure System registers.

**Access to registers from Monitor mode**

When the PE is in Monitor mode, the PE is in Secure state regardless of the value of the SCR.NS bit. In Monitor mode, the SCR.NS bit determines whether, for System registers in the (coproc==0b1111) encoding space, valid uses of the MRC, MCR, MRRC, and MCRR instructions access the Secure Banked System registers or the Non-secure Banked System registers. That is, when:

\[ NS == 0 \]

Common, Restricted access, and Secure Banked System registers are accessed by MRC, MCR, MRRC, and MCRR instructions that target the (coproc==0b1111) encoding space.

If the implementation includes EL2, the registers listed in Hyp mode read/write registers in the (coproc==0b1111) encoding space on page G5-5596 and Hyp mode encodings for shared (coproc==0b1111) System registers on page G5-5596 are not accessible, and any attempt to access them generates an Undefined Instruction exception.

---

**Note**

The operations listed in Hyp mode (coproc==0b1111) write-only System instructions are accessible in Monitor mode regardless of the value of SCR.NS.
System instructions in the (coproc==0b1111) encoding space use the Security state to determine all resources used, that is, all operations performed by these instructions are performed in Secure state.

**Note**

Where the contents of a register select the value accessed by an MRC or MCR access to a different register, then the register that is used for selection is being used as control state. For example, CSSELR selects the current Cache Size Identification Register, and therefore CSSELR is used as control state. Therefore, in Monitor mode:

- SCR.NS determines whether the Secure or Non-secure CSSELR is accessible.
- Because the PE is in Secure state, the Secure CSSELR selects the current Cache Size Identification Register.

From ARMv8.3, it is possible to have multiple Cache Size Identification Registers. For more details, see *Possible formats of the Cache Size Identification Registers, CCSIDR and CCSIDR2* on page G4-5435.

### The CP15SDISABLE input signal

When EL3 is using AArch32, it provides an input signal, **CP15SDISABLE**, that disables write access to some of the Secure registers when asserted HIGH. The **CP15SDISABLE** signal has no effect on:

- Register accesses from AArch64 state.
- Register accesses from Secure EL1 when EL3 is using AArch64 and EL1 is using AArch32.

**Note**

When EL3 is using AArch32, the interaction between **CP15SDISABLE** and any IMPLEMENTATION DEFINED register is IMPLEMENTATION DEFINED.

On a reset by the external system that resets the PE into EL3 using AArch32, the **CP15SDISABLE** input signal must be taken LOW. This permits the Reset code to set up the configuration of EL3 features. When the input is asserted HIGH, any attempt to write to the Secure registers that are affected by **CP15SDISABLE** results in an Undefined Instruction exception.

The **CP15SDISABLE** input does not affect reading Secure registers, or reading or writing Non-secure registers. It is IMPLEMENTATION DEFINED how the input is changed and when changes to this input are reflected in the PE, and an implementation might not provide any mechanism for driving the **CP15SDISABLE** input HIGH. However, in an implementation in which the **CP15SDISABLE** input can be driven HIGH, changes in the state of **CP15SDISABLE** must be reflected as quickly as possible. Any change must occur before completion of an Instruction Synchronization Barrier operation, issued after the change, is visible to the PE with respect to instruction execution boundaries. Software must perform an Instruction Synchronization Barrier operation meeting the above conditions to ensure all subsequent instructions are affected by the change to **CP15SDISABLE**.

When EL3 is using AArch32, use of **CP15SDISABLE** means key Secure features that are accessible only at PL1 can be locked in a known state. This provides an additional level of overall system security. ARM expects control of **CP15SDISABLE** to reside in the system, in a block dedicated to security.
G5.16 Functional grouping of VMSA v8-32 System registers

This section describes how the System registers in an VMSA v8-32 implementation divide into functional groups. The functional groups of AArch32 registers are:

- Special-purpose registers.
- VMSA-specific registers.
- ID registers.
- Performance monitors registers.
- Activity monitors registers.
- Debug registers.
- RAS Extension registers.
- Generic timer registers.
- Cache maintenance System instructions.
- Address translation System instructions.
- TLB maintenance System instructions.
- Base system registers.
- Legacy feature registers and System instructions.

For a list of these functional groups and the registers in each group, see Functional index of AArch32 registers and System instructions on page K13-7432.

Chapter G8 AArch32 System Register Descriptions describes each of these registers.

Note

- Table G7-3 on page G7-5622 lists all of the VMSA v8-32 System registers in the (coproc==0b1111) encoding space, ordered by:
  1. The CRn primary register used when using a 32-bit access to the register.
     For 64-bit register accesses using an MRR or MRRC instruction, the instruction arguments that identify the target register are \{coproc, Rn, opc1\} The value of Rn determines where these registers appear in Table G7-3 on page G7-5622, so that these registers appear with the 32-bit registers accessed using that value for CRn. So, for example, the 64-bit access to TTBR0, that uses (CRn==c2), appears with the 32-bit access to TTBR0, that uses (CRn==c2).
  2. The opc1 value used when accessing the register.
  3. For 32-bit registers, the \{CRn, opc2\} values used when accessing the register.

- The functional groups defined in this section mainly consist of the VMSA v8-32 System registers, but include some additional System registers.
- Some registers belong to more than one functional group.

For other related information see:

- The AArch32 System register interface on page G1-5313 for general information about the access to the AArch32 System registers, including the main register access instructions MRC and MCR.
- About the System registers for VMSA v8-32 on page G5-5594.
- VMSA v8-32 organization of registers in the (coproc==0b1110) encoding space on page G7-5615.
- VMSA v8-32 organization of registers in the (coproc==0b1111) encoding space on page G7-5618.
- About the AArch32 System registers on page G8-5636.

The register descriptions in Chapter G8 AArch32 System Register Descriptions, assume you are familiar with these functional groups, and use conventions and other information from them without any explanation.
This chapter describes the implementation of the ARM Generic Timer as an extension to an ARMv8 implementation. It includes an overview of the AArch32 System register interface to an ARM Generic Timer.

It contains the following sections:

- About the Generic Timer in AArch32 state on page G6-5602.
- The AArch32 view of the Generic Timer on page G6-5606.

Chapter D10 The Generic Timer in AArch64 state describes the AArch64 view of the Generic Timer, including an additional timer that can be implemented in AArch64 state, and Chapter I2 System Level Implementation of the Generic Timer describes the system level implementation of the Generic Timer.
G6.1 About the Generic Timer in AArch32 state

Figure G6-1 shows an example system-on-chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The *ARM Generic Interrupt Controller Architecture Specification* defines a possible architecture for the interrupt controllers.
- Generic Timer functionality is distributed across multiple components.

The Generic Timer:

- Provides a system counter, that measures the passing of time in real-time.

--- Note ---

The Generic Timer can also provide other components at a system level, but Figure G6-1 does not show any such components.

- Supports virtual counters that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.
- Timers, that can trigger events after a period of time has passed. The timers:
  — Can be used as count-up or as count-down timers.
  — Can operate in real-time or in virtual-time.

This chapter describes an instance of the Generic Timer component that Figure G6-1 shows as Timer_0 or Timer_1 within the Multiprocessor A or Multiprocessor B block. This component can be accessed from AArch64 state or AArch32 state, and this chapter describes access from AArch32 state. Chapter D10 *The Generic Timer in AArch64 state* describes access to this component from AArch64 state.

--- Note ---

The reset requirements of Generic Timer registers are more strict when they are accessed from AArch32 state than when they are accessed from AArch64 state.
A Generic Timer implementation must also include a memory-mapped system component, see *The full set of Generic Timer components*.

### G6.1 The full set of Generic Timer components

Within a system that might include multiple PEs, a full set of Generic Timer components is as follows:

**The system counter**

This provides a uniform view of system time, see *The system counter* on page G6-5604. Because this must be implemented at the system level, it is accessed through *The system level memory-mapped implementation of the Generic Timer*. However, during initialization, a status register in each implemented timer in the system must be programmed with the frequency of the system counter, so that software can read this frequency.

**PE implementations of the Generic Timer**

Each PE implementation of the Generic Timer provides the following components:

- A physical counter, that gives access to the count value of the system counter.
- A virtual counter, that gives access to virtual time. In AArch32 state, the CNTVOFF register defines the offset between physical time, as defined by the value of the system counter, and virtual time.
- A number of timers. In an implementation where all Exception levels are implemented and can use AArch32 state, the timers that are accessible from AArch64 state are:
  - A Secure PL1 physical timer.
  - A Non-secure EL1 physical timer.
  - An EL2 physical timer.
  - A virtual timer.

**Note**

The Secure PL1 physical timer uses the Secure banked instances of the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL registers, and the Non-secure EL1 physical timer uses the Non-secure instances of the same registers.

*The AArch32 view of the Generic Timer* on page G6-5606 describes these components.

**The system level memory-mapped implementation of the Generic Timer**

The memory-mapped registers that control the components of the system level implementation of the Generic Timer are grouped into *frames*. The Generic Timer architecture defines the offset of each register within its frame, but the base address of each frame is IMPLEMENTATION DEFINED, and defined by the system.

Each system level component has one or two register frames. The possible system level components are:

**The memory-mapped counter module, required**

This module controls the system counter. It has two frames:

- A control frame, CNTRLcontrolBase.
- A status frame, CNTRLreadBase.

**The memory-mapped timer control module, required**

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, CNTRCBBase.

**Memory-mapped timers, optional**

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the CNTBaseN frame.
G6.1 About the Generic Timer in AArch32 state

Chapter 12 System Level Implementation of the Generic Timer describes these components.

G6.1.2 The system counter

The Generic Timer provides a system counter with the following specification:

- **Width**: At least 56 bits wide.
  The value returned by any 64-bit read of the counter is zero-extended to 64 bits.

- **Frequency**: Increments at a fixed frequency, typically in the range 1-50MHz.
  Can support one or more alternative operating modes in which it increments by larger amounts at a lower frequency, typically for power-saving.

- **Roll-over**: Roll-over time of not less than 40 years.

- **Accuracy**: ARM does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period.
  Use of lower-frequency modes must not affect the implemented accuracy.

- **Start-up**: Starts operating from zero.

The system counter, once configured and running, must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:

1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes, the counter can increment by larger amounts at a lower frequency. For example, a 10MHz system counter might either increment:

- By 1 at 10MHz.
- By 500 at 20kHz, when the system lowers the clock frequency, to reduce power consumption.

In this case, the counter must support transitions between high-frequency, high-precision operation, and lower-frequency, lower-precision operation, without any impact on the required accuracy of the counter.

The **CNTFRQ** register is intended to hold a copy of the current clock frequency to allow fast reference to this frequency by software running on the PE. For more information see Initializing and reading the system counter frequency.

The mechanism by which the count from the system counter is distributed to system components is IMPLEMENTATION DEFINED, but each PE with a System register interface to the system counter must have a counter input that can capture each increment of the counter.

---

**Note**

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. Gray-count scheme for timer distribution scheme on page K5-7270 gives more information about this possibility.

---

**Initializing and reading the system counter frequency**

The **CNTFRQ** register must be programmed to the clock frequency of the system counter. Typically, this is done only during the system boot process, by using the System register interface to write the system counter frequency to the **CNTFRQ** register. Only software executing at the highest implemented Exception level can write to CNTFRQ.
Note

The CNTFRQ register is **unknown** at reset, and therefore the counter frequency must be set as part of the system boot process.

Software can read the CNTFRQ register, to determine the current system counter frequency, in the following states and modes:
- Hyp mode.
- Secure PL1 modes and Non-secure EL1 modes.
- When CNTKCTL.PL0PCTEN is set to 1, Secure and Non-secure EL0 modes.

**Memory-mapped controls of the system counter**

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:
- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the update frequency and increment value.
- Enabling Halt-on-debug, that a debugger can then use to suspend counting.

For descriptions of these controls, see Chapter 12 *System Level Implementation of the Generic Timer*.
G6.2 The AArch32 view of the Generic Timer

The following sections describe the components and features of a PE implementation of the Generic Timer, as seen from AArch32 state:

- The physical counter.
- The virtual counter.
- Event streams on page G6-5607.
- Timers on page G6-5608.

G6.2.1 The physical counter

The PE includes a physical counter that contains the count value of the system counter. The CNTPCT register holds the current physical counter value.

Accessing the physical counter

Software with sufficient privilege can read CNTPCT using a 64-bit System register read.

CNTPCT:

- Is always accessible from Secure PL1 modes and from Non-secure Hyp mode.
- Is accessible from Non-secure EL1 modes when the value of CNTHCTL.PL1PCTEN is 1. When the value of CNTHCTL.PL1PCTEN is 0, any attempt to access CNTPCT from Non-secure EL1 modes is trapped to Hyp mode.
- Is accessible from Secure User mode when the value of CNTHCTL.PL0PCTEN is 1. When the value of CNTHCTL.PL0PCTEN is 0, any attempt to access CNTPCT generates an UNDEFINED exception.
- Is accessible from Non-secure User mode when the value of CNTHCTL.PL1PCTEN is 1 and the value of CNTHCTL.PL0PCTEN is 1. Otherwise:
  - When the value of CNTHCTL.PL0PCTEN is 0, any attempt to access CNTPCT from Non-secure User mode generates an UNDEFINED exception.
  - When the value of CNTHCTL.PL0PCTEN is 1 and the value of CNTHCTL.PL1PCTEN is 0, any attempt to access CNTPCT from Non-secure User mode is trapped to Hyp mode.

Reads of CNTPCT can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that CNTPCT must be read, an ISB is used to ensure that the read of CNTPCT occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop
  LDR R1, [R2]  ; polling for some communication to indicate a requirement to read the timer
  CMP R1, #1
  BNE loop
  ISB          ; without this, the CNTPCT could be read before the memory location in [R2] has had the value 1 written to it
  MRS R1, CNTPCT
```

G6.2.2 The virtual counter

An implementation of the Generic Timer always includes a virtual counter, that indicates virtual time.

The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing in a Non-secure EL1 or EL0 mode, the virtual offset value relates to the current virtual machine.

The CNTVOFF register contains the virtual offset. CNTVOFF is only accessible:

- From Hyp mode.
- From Monitor mode only when SCR.NS is set to 1.

For more information see Status of the CNTVOFF register on page G6-5607.
The CNTVCT register holds the current virtual counter value.

**Accessing the virtual counter**

Software with sufficient privilege can read CNTVCT using a 64-bit System register read.

CNTVCT is always accessible from Secure PL1 modes and from Non-secure EL1 and EL2 modes.

In addition, when CNTKCTL.PL0VCTEN is set to 1, CNTVCT is accessible from EL0.

When CNTKCTL.PL0VCTEN is set to 0, any attempt to access CNTVCT from EL0 is UNDEFINED.

Reads of CNTVCT can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that CNTVCT must be read, an ISB is used to ensure that the read of CNTVCT occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
    LDR R1, [R2]  
    CMP R1, #1    
    BNE loop     
    ISB             ; without this, the CNTVCT could be read before the memory location in [R2] 
    MRS R1, CNTVCT ; has had the value 1 written to it
```

**Status of the CNTVOFF register**

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the CNTVOFF register that defines the virtual offset between the physical count and the virtual count. CNTVOFF is only accessible at EL2 or above. If EL2 is not implemented, the virtual counter uses a fixed virtual offset of zero.

**G6.2.3 Event streams**

Any implementation of the Generic Timer can use the system counter to generate one or more event streams, to generate periodic wake-up events as part of the mechanism described in *Wait for Event mechanism and Send event* on page D1-2243.

**Note**

An event stream might be used:

- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

An event stream is configured by:

- Selecting which bit, from the bottom 16 bits of a counter, triggers the event. This determines the frequency of the events in the stream.
- Selecting whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

The CNTKCTL.{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the virtual counter.

In all implementations the CNTHCTL.{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the physical counter.

The operation of an event stream is as follows:

- The pseudocode variables PreviousCNTVCT and PreviousCNPCT are initialized as:

```plaintext
// Variables used for generation of the timer event stream.
```
bits(64) PreviousCNTVCT = bits(64) UNKNOWN;
bits(64) PreviousCNTPCT = bits(64) UNKNOWN;

• The pseudocode functions TestEventCNTV() and TestEventCNTP() are called on each cycle of the PE clock.

• The TestEventCNTx() pseudocode template defines the functions TestEventCNTV() and TestEventCNTP():

// TestEventCNTx()
//===============

// Template for the TestEventCNTV() and TestEventCNTP() functions
// Describes operation when all Exception Levels are using AArch32:
// CNTxCT is CNTVCT or CNTPCT 64-bit count value
// CNTx_CTL is CNTV_CTL or CNTP_CTL Control register
// PreviousCNTxCT is PreviousCNTVCT or PreviousCNTPCT

TestEventCNTx()
if CNTx_CTL.EVNTEN == '1' then
  n = UInt(CNTx_CTL.EVNTI);
  SampleBit = CNTxCT<n>;
  PreviousBit = PreviousCNTxCT<n>;

  if CNTx_CTL.EVNTDIR == '0' then
    if PreviousBit == '0' && SampleBit == '1' then EventRegisterSet();
    else
      if PreviousBit == '1' && SampleBit == '0' then EventRegisterSet();

  PreviousCNTxCT = CNTxCT;
return;

G6.2.4 Timers

In an implementation that includes EL3, in any implementation of the Generic Timer, the following timers are accessible from AArch32 state, provided the appropriate Exception level can use AArch32:

• A Non-secure EL1 physical timer. A Non-secure EL1 control determines whether this register is accessible from Non-secure EL0.

• A Secure PL1 physical timer. This timer:
  — Is accessible from Secure EL1 using AArch32 when EL3 is using AArch64.
  — Is accessible from Secure EL3 when EL3 is using AArch32.

A Secure PL1 control determines whether this register is accessible from Secure EL0.

• A Non-secure EL2 physical timer.

• A virtual timer.

The output of each implemented timer:

• Provides an output signal to the system.

• If the PE interfaces to a Generic Interrupt Controller (GIC), signals a Private Peripheral Interrupt (PPI) to that GIC. In a multiprocessor implementation, each PE must use the same interrupt number for each timer.

Each timer:

• Is based around a 64-bit CompareValue that provides a 64-bit unsigned upcounter.

• Provides an alternative view of the CompareValue, called the TimerValue, that appears to operate as a 32-bit downcounter.

• Has, in addition, a 32-bit Control register.
In all implementations, the AArch32 System registers for the EL1 (or PL1) physical timer are banked, to provide the Secure and Non-secure implementations of the timer. Table G6-1 shows the Timer registers.

<table>
<thead>
<tr>
<th>Timer register</th>
<th>Secure PL1 or Non-secure EL1 physical timer</th>
<th>EL2 physical timer</th>
<th>Virtual timer</th>
</tr>
</thead>
<tbody>
<tr>
<td>CompareValue register</td>
<td>CNTP_CVAL(^a)</td>
<td>CNTHP_CVAL</td>
<td>CNTV_CVAL</td>
</tr>
<tr>
<td>TimerValue register</td>
<td>CNTP_TVAL(^a)</td>
<td>CNTHP_TVAL</td>
<td>CNTV_TVAL</td>
</tr>
<tr>
<td>Control register</td>
<td>CNTP_CTL(^a)</td>
<td>CNTHP_CTL</td>
<td>CNTV_CTL</td>
</tr>
</tbody>
</table>

\(^a\) In AArch32 state, these registers are banked to provide the Non-secure EL1 physical timer and the Secure PL1 physical timer.

The following sections describe:

- **Accessing the timer registers**
- **Operation of the CompareValue views of the timers** on page G6-5610
- **Operation of the TimerValue views of the timers** on page G6-5610.

### Accessing the timer registers

For each timer, all timer registers have the same access permissions, as follows:

#### Secure PL1 and Non-secure EL1 physical timer

The Secure PL1 physical timer is accessible from Secure PL1 modes.

Non-secure software executing at EL2 controls access to the Non-secure EL1 physical timer from Non-secure EL1 modes. The Non-secure EL1 physical timer is accessible from Monitor mode when the value of SCR.NS is 1.

When access from PL1 or EL1 modes is permitted, CNTKCTL.PL0PTEN determines whether the registers are accessible from EL0. If an access is not permitted because CNTKCTL.PL0PTEN is set to 0, an attempted access from EL0 is UNDEFINED.

In all implementations:

- Except for accesses from Monitor mode, accesses are to the registers for the current Security state.
- For accesses from Monitor mode, the value of SCR.NS determines whether accesses are to the Secure or the Non-secure registers.

**Note**

Monitor mode is present only when EL3 is using AArch32.

- The Non-secure registers are accessible from Hyp mode.
- CNTHCTL.PL1PCEN determines whether the Non-secure registers are accessible from Non-secure EL1 modes. If this bit is set to 1, to enable access from Non-secure EL1 modes, CNTKCTL.PL0PTEN determines whether the registers are accessible from Non-secure EL0.

If an access is not permitted because CNTHCTL.PL1PCEN is set to 0, an attempted access from a Non-secure EL1 or EL0 mode generates a Hyp Trap exception. However, if CNTKCTL.PL0PTEN is set to 0, this control takes priority, and an attempted access from EL0 is UNDEFINED.

#### EL2 physical timer

Accessible from Hyp mode, and from Secure Monitor mode when SCR_EL3.NS is set to 1.

#### Virtual timer

Accessible from Secure PL1 modes and Non-secure EL1 modes, and from Hyp mode.
CNTKCTL.PL0VTEN determines whether the registers are accessible from EL0 modes. If an access is not permitted because CNTKCTL.PL0VTEN is set to 0, an attempted access from EL0 is UNDEFINED.

**Operation of the CompareValue views of the timers**

The CompareValue view of a timer operates as a 64-bit upcounter. The timer condition is met when the appropriate counter reaches the value programmed into its CompareValue register. When the timer condition is met an interrupt is generated if the interrupt is not masked in the corresponding timer control register, CNTP_CTL, CNTHP_CTL, or CNTV_CTL. For CNTP_CTL, the interrupt is the same as the interrupt asserted by the Non-secure instance of the AArch64 register CNTP_CTL_EL0.

The operation of this view of a timer is:

\[
\text{TimerConditionMet} = (((\text{Counter}[63:0] - \text{Offset}[63:0])[63:0] - \text{CompareValue}[63:0]) >= 0)
\]

Where:
- **TimerConditionMet** is TRUE if the timer condition for this counter is met, and FALSE otherwise.
- **Counter** is the physical counter value, that can be read from the CNTPCCT register.

---  **Note**  ---

The virtual counter value, that can be read from the CNTVCT register, is the value:

\[
(\text{Counter} - \text{Offset})
\]

- **Offset** is zero for a physical timer and is the virtual offset, held in the CNTVOFF register.
- **CompareValue** is the value of the appropriate CompareValue register, CNTP_CVAL, CNTHP_CVAL, or CNTV_CVAL.

In this view of a timer, Counter, Offset, and CompareValue are all 64-bit unsigned values.

--- **Note**  ---

This means that a timer with a CompareValue of, or close to, 0xFFFF_FFFF_FFFF_FFFF might never meet its timer condition. However, there is no practical requirement to use values close to the counter wrap value.

**Operation of the TimerValue views of the timers**

The TimerValue view of a timer appears to operate as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer condition is met when the value reaches zero. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, CNTP_CTL, CNTHP_CTL, or CNTV_CTL.

This view of a timer depends on the following behavior of accesses to TimerValue registers:

**Reads**

\[
\text{TimerValue} = (\text{CompareValue} - (\text{Counter} - \text{Offset}))[31:0]
\]

**Writes**

\[
\text{CompareValue} = ((\text{Counter} - \text{Offset})[63:0] + \text{SignExtend}(\text{TimerValue}))[63:0]
\]

Where the arguments other than TimerValue have the definitions used in **Operation of the CompareValue views of the timers**, and in addition:

- **TimerValue** is the value of a TimerValue register, CNTP_TVAL, CNTHP_TVAL, or CNTV_TVAL.

In this view of a timer, values are signed, in standard two’s complement form.

A read of a TimerValue register after the timer condition has been met indicates the time since the timer condition was met.
--- Note ---

• Operation of the CompareValue views of the timers on page G6-5610 gives a strict definition of TimerConditionMet. However, provided that the TimerValue is not expected to wrap as a 32-bit signed value when decremented from $0x80000000$, the TimerValue view can be used as giving an effect equivalent to:

  \[ \text{TimerConditionMet} = (\text{TimerValue} \leq 0) \]

• Programming TimerValue to a negative number with magnitude greater than (Counter–Offset) can lead to an arithmetic overflow that causes the CompareValue to be an extremely large positive value. This potentially delays meeting the timer condition for an extremely long period of time.

---
Chapter G7
AArch32 System Register Encoding

This chapter describes the AArch32 System register encoding space. It contains the following sections:

- *The AArch32 System register encoding space on page G7-5614.*
- *VMSAv8-32 organization of registers in the (coproc == 0b1110) encoding space on page G7-5615.*
- *VMSAv8-32 organization of registers in the (coproc == 0b1111) encoding space on page G7-5618.*
G7.1 The AArch32 System register encoding space

The T32 and A32 instruction sets includes instructions that access the System register encoding space. These instructions provide:

- Access to System registers, including the debug registers, that provide system control, and system status information.
- The cache, branch predictor, and TLB maintenance instructions, and address translation instructions.

The AArch32 System register interface on page G1-5313 describes the instructions that provide access to these registers and instructions. Chapter G8 AArch32 System Register Descriptions describes these registers and encodings.

When accessing 32-bit registers, or executing these instructions, entries in the encoding space are characterized by the parameter set \{coproc, CRn, opc1, CRm, opc2\}. In ARMv8 this encoding space is defined only for the coproc values 0b1110 and 0b1111.

Note
- When accessing 64-bit registers entries in the encoding space are characterized by the parameter set \{coproc, CRn, opc1\}, for the coproc values 0b1110 and 0b1111. A CRm value in this parameter set is equivalent to a CRn value in the parameter set for accessing 32-bit registers.
- Background to the System register interface on page G1-5314 gives more information about this encoding model.

The following describe this encoding space:

- VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space on page G7-5615.
- VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space on page G7-5618.
G7.2 VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space

The System registers in the (coproc==0b1110) encoding space provide a number of distinct control functions, covering:

- Debug.
- Trace.
- Execution environment control, for identification of the trivial Jazelle implementation.

Because these functions are distinct, the descriptions of these registers are distributed, as follows:

- In this manual, Debug registers on page G8-6103 describes the Debug registers.
- The Embedded Trace Macrocell Architecture Specification describes the Trace registers.

This section summarizes the allocation of the System registers in the (coproc==0b1110) encoding space between these different functions, and the register encodings in this space that are reserved.

The 32-bit System register encodings are classified by the \{opc1, CRn, opc2, CRm\} values required to access them using an MCR or an MRC instruction. The 64-bit System register encodings are classified by the \{opc1, CRm\} values required to access them using an MCRR or an MRRC instruction. For the registers in the (coproc==0b1110) encoding space, the opc1 value determines the primary allocation of these registers, as follows:

\begin{itemize}
  \item opc1==0 Debug registers.
  \item opc1==1 Trace registers.
  \item opc1==7 Jazelle registers. Jazelle registers are implemented as required for a trivial Jazelle implementation.
\end{itemize}

**Other opc1 values**

Reserved.

---

**Note**

Primary allocation of (coproc==0b1110) register function by opc1 value differs from the allocation of (coproc==0b1111) registers, where primary allocation is by CRn value for 32-bit register accesses, or CRm value for 64-bit register accesses.

---

For the Debug and Jazelle registers, Table G7-1 on page G7-5616 defines:

- The \{opc1, CRn, opc2, CRm\} values used for accessing the 32-bit registers using the MRC and MCR instructions.
- The \{opc1, CRm\} values used for accessing the 64-bit register using the MRRC instruction.

Some Debug registers can also be accessed using the LDC and STC instructions. Table G7-2 on page G7-5617 defines the CRn values used for accessing the registers using these instructions.

---

**Note**

The only permitted uses of the LDC and STC instructions are:

- An LDC access to load data from memory to DBGDTRTXint.
- An STC access to store data to memory from DBGDTRRXint.

In the LDC and STC syntax descriptions in this Manual, the required coproc value of p14 and CRn value of c5 are given explicitly.
### G7.2.1 Register access instruction arguments, \((\text{coproc}==0b1110)\) registers

Table G7-1 shows the MCR, MRC, and MRRC instruction arguments required for accesses to each register that can be visible in the System register interface in the \((\text{coproc}==0b1110)\) encoding.

- If EL1 cannot use AArch32, this register is OPTIONAL and deprecated. See the register description for details.
- Not implemented breakpoint and watchpoint register access instructions are unallocated. If EL2 is not implemented or breakpoint \(n\) is not context-aware, \(\text{DBGBXVR}<n>\) is unallocated. CRm encodes \(<n>\), the breakpoint or watchpoint number.
- Legacy register.

Table G7-2 shows the LDC and STC instruction arguments required for accesses to the Debug registers that can be accessed using these instructions.

Note

In the instruction syntax descriptions for the LDC and STC instructions, the required coproc and CRn values are given explicitly as coproc==p14, CRn==c5.
G7.3 VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space

For 32-bit accesses to the System registers in the (coproc==0b1111) encoding space, the ordered set of parameters \{CRn, opc1, CRm, opc2\} determine the register order. Within this ordering, the CRn value originally provided a functional grouping of these registers. As the number of System registers has increased this ordering has become less appropriate.

This document now:

- Groups the ARMv8.0 System registers in the (coproc==0b1111) encoding space by functional group, see Functional index of AArch32 registers and System instructions on page K13-7432.
- Describes all of the ARMv8.0 System registers for VMSAv8-32, in Chapter G8 AArch32 System Register Descriptions.
- Gives additional information about the organization of the VMSAv8-32 System registers in the (coproc==0b1111) encoding space, in the remainder of this section.

Note

Not all System registers introduced by architectural extensions to ARMv8.0 are described in Chapter G8 AArch32 System Register Descriptions. For information about the System registers introduced by architectural extensions to ARMv8.0, see ARMv8 architecture extensions on page A1-56.

This section presents information about the register ordering by \{CRn, opc1, CRm, opc2\}. It contains the following subsections:

- System register summary for (coproc==0b1111) encodings by CRn value.
- Full list of VMSAv8-32 System registers in the (coproc==0b1111) encoding space on page G7-5621.

Note

The ordered listing of (coproc==0b1111) registers by the \{CRn, opc1, CRm, opc2\} encoding of the 32-bit registers is most likely to be useful to those implementing AArch32 state, and to those validating such implementations. However, otherwise, the grouping of registers by function is more logical.

In addition, the indexes in Appendix K13 Registers Index include all of the System registers.

G7.3.1 System register summary for (coproc==0b1111) encodings by CRn value

Figure G7-1 on page G7-5619 summarizes the grouping of the System registers in the (coproc==0b1111) encoding space, for a VMSAv8-32 implementation, by the value of CRn used for a 32-bit access to the register.
**Note**

For the System registers in the (coproc==0b1111) encoding space, Figure G7-1 gives only an overview of the assigned encodings for 32-bit registers for each of the CRn values c0-c15. For more information, see:

- The full list of registers in the (coproc==0b1111) encoding space, in Full list of VMSAv8-32 System registers in the (coproc == 0b1111) encoding space on page G7-5621, for the definition of the assigned and unassigned encodings for that register.
- The register definitions in Chapter G8 AArch32 System Register Descriptions for any dependencies on the implemented Exception levels.

In general, System register accesses using an unallocated set of \{CRn, opc1, CRm, opc2\} values are UNDEFINED. Behavior of VMSAv8-32 32-bit System registers with (coproc==0b1111, CRn==c0) described the only exceptions to this rule.

The 32-bit System registers with (coproc==0b1111, CRn==c15), and the corresponding 64-bit System registers, are reserved for implementation defined registers. For more information see Reserved encodings in the VMSAv8-32 System register (coproc == 0b1111) space on page G7-5620.

**The HSTR.Tn trap on (coproc==0b1111) System registers**

As General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space on page G1-5345 describes, when the value of HSTR.Tn is 1, Non-secure PL1 accesses to System registers in the (coproc==0b1111) encoding space using a CRn or CRm value that corresponds to the value of Tn are trapped to EL2, even if the encoding is UNDEFINED when the value of HSTR.Tn is 0. This applies:

- For 32 bit register accesses when the value of Rn in the MCR or MRC instruction corresponds to Tn.
- For 64 bit register accesses when the value of Rn in the MCCR or MRRC instruction corresponds to Tn.

If there are matching System register encodings that are accessible from Non-secure EL0 then those accesses are also trapped to EL2 when the value of HSTR.Tn is 1.

**Behavior of VMSAv8-32 32-bit System registers with (coproc==0b1111, CRn==c0)**

In the (coproc==0b1111) encoding space, the 32-bit System registers with (CRn==c0) provide device and feature identification.
Table G7-3 on page G7-5622 shows all of the architecturally required System registers with \{coproc==0b1111, CRn==c9\}. The behavior of 32-bit System register encodings in this group that are not shown in the table, and encodings that are part of an unimplemented Exception level, depends on the value of opc1, and possibly on the value of CRn and opc2, as follows:

\[ \text{opc1} = 0 \]
- All write accesses to the encodings are UNDEFINED.
- For read accesses:
  - The following encodings return an UNKNOWN value:
    - CRn==3, opc2==\{0, 1, 2\}.
    - CRn==\{4, 6, 7\}, opc2==\{0, 1\}.
    - CRn==5, opc2==\{0, 1, 4, 5\}.
  - All other encodings are RES0.

\[ \text{opc1} > 0 \]
- All accesses to the encodings are UNDEFINED.

See also \textit{Accesses to unallocated encodings in the (coproc==0b111x) encoding space} on page G8-5638.

\begin{table}[h]
\end{table}

**Note**

Some of these registers were previously described as being part of the CPUID identification scheme, see \textit{The CPUID identification scheme} on page G8-5637.

### Reserved encodings in the VMSAv8-32 System register (coproc==0b1111) space

AArch32 state reserves a number of regions in the (coproc==0b1111) encoding space for IMPLEMENTATION DEFINED System registers. These reservations are defined in terms of the encoding of 32-bit accesses to the System register encoding space. That is, they are defined by the reserved 32-bit \{CRn, opc1, CRm, opc2\} encodings.

In ARMv8, reserved encodings that do not have an IMPLEMENTATION DEFINED function are UNDEFINED.

The following subsections give more information about these reserved encodings:

- **Reserved 32-bit encodings with \{coproc==0b1111, CRn==c9\}**
- **Reserved 32-bit encodings with \{coproc==0b1111, CRn==c10\}**
- **Reserved 32-bit encodings with \{coproc==0b1111, CRn==c11\}** on page G7-5621.
- **Reserved 32-bit encodings with \{coproc==0b1111, CRn==c15\}** on page G7-5621.

### Reserved 32-bit encodings with \{coproc==0b1111, CRn==c9\}

In the AArch32 encoding space, for 32-bit encodings with \{coproc==0b1111, CRn==c9\}, the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with \{coproc==0b1111, CRn==c9, opc1==\{0-7\}, opc2==\{0-7\}, CRm==\{c8-c2, c5-c8\}\} are reserved for IMPLEMENTATION DEFINED branch predictor, cache, and TCM operations.
- Encodings with \{coproc==0b1111, CRn==c9, opc1==\{0-7\}, opc2==\{0-7\}, CRm==c15\} are reserved for IMPLEMENTATION DEFINED performance monitors.

**Note**

These are distinct from the OPTIONAL ARM Performance Monitors Extension, the registers for which use the encoding space \{coproc==0b1111, CRn==c9, opc1==\{0-7\}, opc2==\{0-7\}, CRm==\{c12-c14\}\}.

### Reserved 32-bit encodings with \{coproc==0b1111, CRn==c10\}

In the AArch32 encoding space, for 32-bit encodings with \{coproc==0b1111, CRn==c10\}, the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with \{coproc==0b1111, CRn==c10, opc==\{0-7\}, CRm==\{c0, c1, c4, c8\}\} are reserved for IMPLEMENTATION DEFINED TLB lockdown operations.
Reserved 32-bit encodings with \{coproc==0b1111, CRn==c11\}

In the AArch32 encoding space, for 32-bit encodings with \{coproc==0b1111, CRn==c11\}, the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with \{coproc==0b1111, CRn==c11, opc=={0-7}, CRm=={c0-c8, c15}\} are reserved for IMPLEMENTATION DEFINED DMA operations for TCM access.

In ARMv8, the remainder of the AArch32 \{coproc==0b1111, CRn==c11\} encoding space is UNDEFINED.

Reserved 32-bit encodings with \{coproc==0b1111, CRn==c15\}

ARMv8 reserves the AArch32 System register encodings with \{coproc==0b1111, CRn==c15\} for IMPLEMENTATION DEFINED purposes, and does not impose any restrictions on the use of the these encodings. The documentation of the ARM implementation must describe fully any registers implemented in the \{coproc==0b1111, CRn==c15\} encoding space. Normally, for processor implementations by ARM, this information is included in the Technical Reference Manual for the processor.

Typically, an implementation uses the \{coproc==0b1111, CRn==c15\} encodings to provide test features, and any required configuration options that are not covered by this Manual.

This reservation means that the AArch32 64-bit encodings with \{coproc==0b1111, CRm==c15\} are also reserved for IMPLEMENTATION DEFINED purposes, without any restrictions on the use of the these encodings.

G7.3.2 Full list of VMSAv8-32 System registers in the (coproc==0b1111) encoding space

Table G7-3 on page G7-5622 shows the System registers in the \{coproc==0b1111\} encoding space in VMSAv8-32, in the order of the \{CRn, opc1, CRm, opc2\} parameter values used in MCR or MRC accesses to the 32-bit registers:

- For MCR or MRC accesses to the 32-bit registers, CRn is the primary identifier of the target System register for the access. This applies, also, to MCR or MRC instructions that provide 32-bit accesses to a single word of a 64-bit System register.

- For MCRR or MRRC accesses to the 64-bit registers, CRn is the primary identifier of the target System register for the access. Table G7-3 on page G7-5622 orders the 64-bit registers with the 32-bit registers accessed using the same primary register identifier. For example, the 64-bit encoding of TTBR0, that is accessed with (CRn==c2), is listed with the 32-bit registers that are accessed with (CRn==c2).

a. REVIDR is an optional register. If it is not implemented, the encoding with opc2 set to 2 is an alias of MIDR.
b. When ARMv8.3-CCIDX is implemented, CCSIDR2 is implemented.
c. Implemented only as part of EL2 when EL2 is using AArch32. Otherwise, encoding is unallocated and UNDEFINED.
d. Implemented only as part of EL3 when EL3 is using AArch32. Otherwise, encoding is unallocated and UNDEFINED.
e. GIC System register, see About the GIC System registers. As that subsection describes, each ICV_* register uses the same encoding as the corresponding ICC_* register.
f. This register is accessible only in Debug state.
g. RAS Extension System registers, see The Reliability, Availability, and Serviceability (RAS) Extension on page A1-74.
h. For performance reasons, ARM deprecates any use of these memory barrier operations.
i. Reserved for implementation defined branch predictor, cache, and TCM operations, see Reserved 32-bit encodings with {coproc==0b1111, CRn==c9} on page G7-5620.
j. Performance Monitors Extension System register, see Performance Monitors registers on page G8-6204.
k. Reserved for implementation defined performance monitors, see Reserved 32-bit encodings with {coproc==0b1111, CRn==c9} on page G7-5620.
l. Reserved for implementation defined TLB lockdown operations, see Reserved 32-bit encodings with {coproc==0b1111, CRn==c10} on page G7-5620.
m. When an implementation is using the Long descriptor translation table format, these encodings access the MAIR0 and MAIR1 registers. Otherwise, they use PRRR and NMRR.
n. Reserved for implementation defined DMA operations for TCM access, see Reserved 32-bit encodings with {coproc==0b1111, CRn==c11} on page G7-5621.
o. Only one of RMR and HRMR is implemented, corresponding to the highest implemented Exception level, and the register is implemented only if that Exception level is using AArch32.
p. Activity Monitors System register, see Activity Monitors registers on page G8-6264.
q. Generic Timer System register, see Generic Timer registers on page D12-3444.
r. Implemented as RW as part of the Generic Timer on an implementation that includes EL2 and when EL2 is using AArch32. For more information, see Status of the CNTVOFF register on page G6-5607.
s. Reserved for implementation defined purposes, see Reserved 32-bit encodings with {coproc==0b1111, CRn==c15} on page G7-5621.

About the GIC System registers

From version 3.0 of the GIC architecture specification, the specification defines three groups of System registers, identified by the prefix of the register name:

- **ICC_***: GIC physical CPU interface System registers.
- **ICH_***: GIC virtual interface control System registers.
- **ICV_***: GIC Virtual CPU interface System registers.

--- Note ---

These registers are in addition to the GIC memory-mapped register groups GICC_, GICD_, GICH_, GICR_, GICV_, and GITS_.

In VMSAv8-32, the GIC System registers are all in the (coproc==0b1111) encoding space with (CRn==c12). The ICV_* registers have the same \{CRn, opc1, CRm, opc2\} encodings as the corresponding ICC_* registers. For these encodings, GIC register configuration fields determine which register is accessed.
When implemented, the GIC System registers form part of an ARM processor implementation, and therefore these registers are included in the register summaries. However, the registers are defined only in the GIC Architecture Specification.

For more information see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* (ARM IHI 0069).
G7 AArch32 System Register Encoding

G7.3 VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space
Chapter G8
AArch32 System Register Descriptions

This chapter describes each of the AArch32 System registers.

It contains the following sections:
• About the AArch32 System registers on page G8-5636.
• General system control registers on page G8-5651.
• Debug registers on page G8-6103.
• Performance Monitors registers on page G8-6204.
• Activity Monitors registers on page G8-6264.
• RAS registers on page G8-6294.
• Generic Timer registers on page G8-6342.
G8.1 About the AArch32 System registers

For general information about the AArch32 System registers, see:

In Chapter G5:
- About the System registers for VMSAv8-32 on page G5-5594.
- Functional grouping of VMSAv8-32 System registers on page G5-5599.

In Chapter G7:
- VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space on page G7-5615.
- VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space on page G7-5618.

In this chapter:
- Fixed values in the System register descriptions.
- General behavior of System registers.
- Principles of the ID scheme for fields in ID registers on page G8-5646.
- About AArch32 System register accesses on page G8-5648.

The remainder of this chapter describes the AArch32 System registers, in the following sections:
- General system control registers on page G8-5651.
- Debug registers on page G8-6103.
- Performance Monitors registers on page G8-6204.
- Generic Timer registers on page G8-6342.

G8.1.1 Fixed values in the System register descriptions

See Fixed values in AArch32 instruction and System register descriptions on page F2-3667. This section defines how the glossary terms RAZ, RES0, RAO, and RES1 can be represented in the System register descriptions.

G8.1.2 General behavior of System registers

Except where indicated, System registers are 32-bits wide. As stated in About the System registers for VMSAv8-32 on page G5-5594, there are some 64-bit registers, and these include cases where software can access either a 32-bit view or a 64-bit view of a register. The register summaries, and the individual register descriptions, identify the 64-bit registers and how they can be accessed.

The following sections give information about the general behavior of these registers:
- Register names.
- Read-only bits in read/write registers on page G8-5637.
- The CPUID identification scheme on page G8-5637.
- IMPLEMENTATION DEFINED performance monitors on page G8-5637.
- UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses on page G8-5637.
- Read-only and write-only register encodings on page G8-5639.
- Reset behavior of AArch32 System registers on page G8-5640.
- Synchronization of changes to AArch32 System registers on page G8-5640.

Unless otherwise indicated, information in the listed sections applies to all AArch32 System registers

See also About AArch32 System register accesses on page G8-5648.

Register names

The ARM architecture guarantees not to define any register name prefixed with IMP_ as part of the standard ARM architecture.
Note

ARM strongly recommends that any register names created in the IMPLEMENTATION DEFINED register spaces be prefixed with IMP_, where appropriate.

Read-only bits in read/write registers

Some read/write registers include bits that are read-only. These bits ignore writes.

The CPUID identification scheme

The ID_* registers were originally called the CPUID identification scheme registers. However, functionally, there is no value in separating these registers from the slightly larger Identification registers functional group. See Table K13-20 on page K13-7433 for a list of the ID_* registers.

IMPLEMENTATION DEFINED performance monitors

VMSAv8-32 reserves some additional System register encodings in the (coproc==0b1111) encoding space for optional additional IMPLEMENTATION DEFINED performance monitors. Table G8-1 shows the allocation of these encodings:

<table>
<thead>
<tr>
<th>CRn</th>
<th>opc1</th>
<th>CRm</th>
<th>opc2</th>
<th>Name</th>
<th>Width</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>c9</td>
<td>0-7</td>
<td>c12-c14</td>
<td>0-7</td>
<td>Performance Monitors Extension registers, see Table K13-21 on page K13-7434</td>
<td>32-bit</td>
<td>RW or RO^a</td>
</tr>
<tr>
<td>c15</td>
<td>0-7</td>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
<td></td>
<td>32-bit</td>
<td>b</td>
</tr>
</tbody>
</table>

^a. The table referenced in the Name entry shows the type of each of the OPTIONAL Performance Monitors Extension registers.

^b. Access depends on the register or operation, and is IMPLEMENTATION DEFINED.

UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses

This section defines UNPREDICTABLE and UNDEFINED behaviors for accesses to System registers, including those cases where the ARMv8 behavior is CONSTRAINED UNPREDICTABLE.

In AArch32 state the following operations are UNDEFINED:

- All LDC and STC accesses, except for the LDC access to DBGDTRTInt and the STC access to DBGDTRRXInt specified in Table G7-2 on page G7-5617.
- All MCR and MRC operations to the (coproc==0b111x) encoding space, except for those explicitly defined as accessing 64-bit System registers specified in Table G7-1 on page G7-5616 and Table G7-3 on page G7-5622.

Unless otherwise indicated in the individual register descriptions:

- Reserved fields in registers are RES0.
- Assigning a reserved value to a field has a CONSTRAINED UNPREDICTABLE effect, see Reserved values in System and memory-mapped registers and translation table entries on page K1-7212.

The following subsections give more information about UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for accesses to the (coproc==0b111x) encoding space:

- Accesses to unallocated encodings in the (coproc==0b111x) encoding space on page G8-5638.
- Additional rules for MCR and MRC accesses to System registers on page G8-5638.
- Effects of EL3 and EL2 on System register accesses on page G8-5638.
Accesses to unallocated encodings in the \((\text{coproc}==\text{0b111x})\) encoding space

In ARMv8-A, accesses to unallocated register encodings in the \((\text{coproc}==\text{0b111x})\) encoding space are UNDEFINED.

Note

In ARMv7, except for 32-bit registers encoded with a \(\text{Cn}\) value of \text{c12}, accesses to unallocated 32-bit registers were UNPREDICTABLE. The ARMv8 CONSTRAINED UNPREDICTABLE behavior of these accesses is that they are UNDEFINED, see Unallocated System register access instructions on page K1-7193.

Additional rules for MCR and MRC accesses to System registers

The following operations are CONSTRAINED UNPREDICTABLE for all encodings in the \((\text{coproc}==\text{0b111x})\) encoding space:

- All MCR operations from the PC.
- All MRC operations to APSR\_nzcv, except for the \((\text{coproc}==\text{0b1110})\) MRC operation to APSR\_nzcv from DBGDSCR\_int.

The CONSTRAINED UNPREDICTABLE behavior of these operations is that they are UNDEFINED, see Unallocated System register access instructions on page K1-7193.

For registers and operations that are accessible from a particular Privilege level, any attempt to access those registers from a lower Privilege level is UNDEFINED.

Some individual registers can be made inaccessible by setting configuration bits, possibly including IMPLEMENTATION DEFINED configuration bits, to disable access to the register. The effects of the architecturally-defined configuration bits are defined individually in this manual. Unless explicitly stated otherwise in this manual, setting a configuration bit to disable access to a register results in the register becoming UNDEFINED for MRC and MCR accesses.

See also Read-only and write-only register encodings on page G8-5639.

Effects of EL3 and EL2 on System register accesses

EL2 and EL3 introduce classes of System registers, described in Classification of System registers on page G5-5594. Some of these classes of register are either:

- Accessible only from certain modes or states.
- Accessible from certain modes or states only when configuration settings permit the access.

Accesses to these registers that are not permitted are UNDEFINED, meaning execution of the register access instruction generates an Undefined Instruction exception.

Note

This section applies only to registers that are accessible from some modes and states. That is, it applies only to register access instructions using an encoding that, under some circumstances, would perform a valid register access.

The following register classes restrict access in this way:

Restricted access System registers

- This register class is defined in any implementation that includes EL3.
- Restricted access registers other than the NSACR are accessible only from Secure EL3 modes. All other accesses to these registers are UNDEFINED.
- The NSACR is a special case of a Restricted access register and:
  - The NSACR is:
    - Read/write accessible from Secure PL1 modes.
    - Is Read-only accessible from Non-secure PL2 and PL1 modes.
  - All other accesses to the NSACR are UNDEFINED.
For more information, including behavior when EL3 is using AArch64 or is not implemented, see Restricted access System registers on page G5-5595.

Configurable access System registers

This register class is defined in any implementation that includes EL3.
Most Configurable access registers are accessible from Non-secure state only if control bits in the NSACR permit Non-secure access to the register. Otherwise, a Non-secure access to the register is UNDEFINED.

For other Configurable access registers, control bits in the NSACR control the behavior of bits or fields in the register when it is accessed from Non-secure state. That is, Non-secure accesses to the register are permitted, but the NSACR controls how they behave. The only architecturally-defined register of this type is the CPACR.

For more information, see Configurable access System registers on page G5-5595.

EL2-mode System registers

This register class is defined only in an implementation that includes EL2.
EL2-mode registers are accessible only from:
- The Non-secure EL2 mode, Hyp mode.
- Secure Monitor mode when SCR.NS is set to 1.

All other accesses to these registers are UNDEFINED.

For more information, see Hyp mode read/write registers in the (coproc == 0b1111) encoding space on page G5-5596 and Hyp mode encodings for shared (coproc == 0b1111) System registers on page G5-5596.

EL2-mode write-only operations

This register class is defined only in an implementation that includes EL2.
EL2-mode write-only operations are accessible only from:
- The Non-secure EL2 mode, Hyp mode.
- Secure Monitor mode, regardless of the value of SCR.NS.

Write accesses to these operations are:
- CONSTRAINED UNPREDICTABLE in Secure EL3 modes other than Monitor mode.
- UNDEFINED in Non-secure modes other than Hyp mode.

For more information, see Hyp mode (coproc == 0b1111) write-only System instructions on page G5-5597.

In addition, in any implementation that includes EL3, when EL3 is using AArch32, if write access to a register is disabled by the CP15SDISABLE signal then any MCR access to that register is UNDEFINED.

Read-only and write-only register encodings

Some System registers are read-only (RO) or write-only (WO). For example:
- Most identification registers are read-only.
- Most encodings that perform an operation, such as a cache maintenance instruction, are write-only.

If a particular Privilege level defines a register to be:
- RO, then any attempt to write to that register, at that Privilege level, is UNDEFINED. This means that any access to that register with L == 0 is UNDEFINED.
- WO, then any attempt to read from that register, at that Privilege level, is UNDEFINED. This means that any access to that register with L == 1 is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED.
--- Note ---
This section applies only to registers that this manual defines as RO or WO. It does not apply to registers for which other access permissions are explicitly defined.

---

**Reset behavior of AArch32 System registers**

Reset values apply only to RW registers and fields, however:

- Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.
- Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.
- Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.
- WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that state might have a defined reset value.
- IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception level that is using AArch32, see:

- *PE state on reset into AArch32 state on page G1-5305.*
- The appropriate Trace architecture specification, for the Trace System registers.

When the PE resets into an Exception level that is using AArch64, PE state that relates to execution in AArch32 state, including the System register values, is UNKNOWN. The only exception to this is state that applies to execution in both AArch64 state and AArch32 state and that has a defined reset value on the reset into AArch64 state. An example of such PE state is the EDPRSR.SR bit.

For a PE reset into an Exception level that is using AArch32, the architecture defines which AArch32 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and *PE state on reset into AArch32 state on page G1-5305* summarizes these architectural requirements. Otherwise, RW registers reset to an architecturally unknown value.

--- Note ---
In an implementation that includes EL3, unless this manual explicitly states otherwise, only the Secure instance of a banked register is reset to the defined value. This means that software must program the Non-secure instance of the register with the required values. Typically, this programming is part of the PE boot sequence.

---

**Pseudocode description of resetting System registers**

The `AArch32.ResetControlRegisters()` pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and *PE state on reset into AArch32 state on page G1-5305.*

--- Note ---
For debug and trace System registers, this function resets registers as defined for the appropriate level of reset.

---

**Synchronization of changes to AArch32 System registers**

In this section, *this PE* means the PE on which accesses are being synchronized.
A **direct write** to a System register might become visible at any point after the change to the register, but without a **Context synchronization event** there is no guarantee that the change becomes visible.

Any direct write to a System register is guaranteed not to affect any instruction that appears, in program order, before the instruction that performed the direct write, and any direct write to a System register must be synchronized before any instruction that appears after the direct write, in program order, can rely on the effect of that write. The only exceptions to this are:

- All direct writes to the same register, using the same encoding, are guaranteed to occur in program order.
- All direct writes to a register are guaranteed to occur in program order relative to all direct reads of the same register using the same encoding.
- Any System register access that an ARM Architecture Specification or equivalent specification defines as not requiring synchronization.
- If an instruction that appears in program order before the direct write performs a memory access, such as a memory-mapped register access, that causes an indirect read or write to a register, that memory access is subject to the memory order model. In this case, if permitted by the memory order model, the instruction that appears in program order before the direct write can be affected by the direct write. For information about the memory order model, see *Definition of the ARMv8 memory model* on page E2-3568.

These rules mean that an instruction that writes to one of the address translation instructions described in *Address translation instructions* on page G5-5585 must be explicitly synchronized to guarantee that the result of the address translation instruction is visible in the PAR.

**Note**

In this case, the direct write to the encoding of the address translation instruction causes an **indirect write** to the PAR. Without a **Context synchronization event** after the direct write, there is no guarantee that the indirect write to the PAR is visible.

Conceptually, the explicit synchronization occurs as the first step of any **Context synchronization event**. This means that if the operation uses the state that had been changed but not synchronized before the operation occurred, the operation is guaranteed to use the state as if it had been synchronized.

**Note**

- This explicit synchronization is applied as the first step of the execution of any instruction that causes the synchronization operation. This means it does not synchronize any effect of changes to the System registers that might affect the fetch and decode of the instructions that cause the operation, such as breakpoints or changes to translation tables.
- For a synchronous exception, the control state in use at the time the exception is generated determines the exception syndrome information, and this syndrome information is not changed by this synchronization at the start of taking the exception.

Except for the register reads listed in *Registers with some architectural guarantee of ordering or observability* on page G8-5643, if no **Context synchronization event** is performed, direct reads of System registers can occur in any order.

Table G8-2 on page G8-5642 shows the synchronization requirement between two reads or writes that access the same System register. In the column headings, **First** and **Second** refer to:

- Program order, for any read or write caused by the execution of an instruction by this PE, other than a read or write caused by a memory access made by that instruction.
• The order of arrival of asynchronous reads or writes made by this PE relative to the execution of instructions by this PE.

In addition:

• For indirect reads or writes caused by an external agent, such as a debugger, the mechanism that determines the order of the reads or writes is defined by that external agent. The external agent can provide mechanisms that ensure that any read or write it makes arrives at the PE. These indirect reads and writes are asynchronous to software execution on the PE.

• For indirect reads or writes caused by memory-mapped reads or writes made by this PE, the ordering of the memory accesses is subject to the memory order model, including the effect of the memory type of the accessed memory address. This applies, for example, if this PE reads or writes one of its registers in a memory-mapped register interface.

The mechanism for ensuring completion of these memory accesses, including ensuring the arrival of the asynchronous read or write at the PE, is defined by the system.

— **Note**

Such accesses are likely to be given a Device memory attribute, but requiring this is outside the scope of the architecture.

• For indirect reads or writes caused by autonomous asynchronous events that are counted, for example events caused by the passage of time, the events are ordered so that:
  — Counts progress monotonically.
  — The events arrive at the PE in finite time and without undue delay.

</table>
a. Although no synchronization is required between a Direct write and a Direct read, or between a Direct read and an Indirect write, this does not imply that a Direct read causes synchronization of a previous Direct write. This means that the sequence Direct write followed by Direct read followed by Indirect read, with no intervening context synchronization, does not guarantee that the Indirect read observes the result of the Direct write.

If the indirect write is to a register that *Registers with some architectural guarantee of ordering or observability* shows as having some guarantee of the visibility of an indirect write, synchronization might not be required.

If a direct read or a direct write to a register is followed by an indirect write to that register that is caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the indirect write relative to the direct read or direct write.

If an indirect write caused by a direct write is followed by an indirect write caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the two indirect writes.

Where an indirect write occurs as a side-effect of an access, this happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect. For other information about indirect writes after a direct read or a direct write, see *Definitions of direct and indirect reads and writes and their side-effects* on page G8-5645

**Note**

Where a register has more than one encoding, a direct write to the register using a particular encoding is not an indirect write to the same register with a different encoding.

Where an indirect write is caused by the action of an external agent, such as a debugger, or by a memory-mapped read or write by the PE, then an indirect write by that agent to a register using a particular access mechanism, followed by an indirect read by that agent to the same register using the same access mechanism and address does not need synchronization.

Without explicit synchronization to guarantee the order of the accesses, where the same register is accessed by two or more of a System register access instruction, and external agent, and autonomous asynchronous event, or as a result of a memory-mapped access, the behavior must be as if the accesses occurred atomically and in any order. This applies even if the accesses occur simultaneously.

For information about the additional synchronization requirements for memory-mapped registers, see *Synchronization requirements for AArch64 System registers* on page D12-2663.

To guarantee the visibility of changes to some registers, additional operations might be required before the *Context synchronization event*. For such a register, the definition of the register identifies these additional requirements.

In this manual, unless the context indicates otherwise:

- **Accessing** a System register refers to a direct read or write of the register.
- **Using** a System register refers to an indirect read or write of the register.

*Registers with some architectural guarantee of ordering or observability*

For the registers for which Table G8-3 on page G8-5644 shows that the ordering of direct reads is guaranteed, multiple direct reads of a single register, using the same encoding, occur in program order without any explicit ordering.

For the registers for which Table G8-3 on page G8-5644 shows that some observability of indirect writes is guaranteed, an indirect write to the register caused by an external agent, an autonomous asynchronous event, or as a result of a memory-mapped write, is both:

- Observable to direct reads of the register, in finite time, without explicit synchronization.
- Observable to subsequent indirect reads of the register without explicit synchronization.
These two sets of registers are similar, as Table G8-3 shows:

</table>

In addition to the requirements shown in Table G8-3:

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:
  - **OSLAR_EL1.** OSLAR_EL1 is indirectly read to determine whether the subsequent access is permitted.
    
    **Note**

    OSLAR_EL1 maps to the AArch32 System register DBGOSLAR.

  - **EDLAR,** if implemented. EDLAR is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.
    
    **Note**

    This requirement is stricter than the general requirement for the observability of indirect writes.

- The requirement that an indirect write to the registers in Table G8-3 is observable to direct reads in finite time does not imply that all observers will observe the indirect write at the same time.
For example, an increment of the system counter is an autonomous asynchronous event that performs an indirect write to the counter. This asynchronous event might generate a timer interrupt request, resulting in a Context synchronization event. When a GIC is used, the timer interrupt might arrive at the GIC after the PE has taken an interrupt request from another source, but before software reads the current interrupt ID from the GIC. This means that the GIC might identify the timer interrupt as the current interrupt. Software must not assume that a subsequent direct read of the counter register is guaranteed to observe the updated value of that register.

Although this example uses the counter-timer registers, it applies equally to other registers that might be linked to interrupt requests, including the PMU and Statistical Profiling status registers.

- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See DCC and ITR access in Debug state on page H4-6498.

The possibility that direct reads can occur early, in the absence of context synchronization, described in Ordering of reads of System registers on page G8-5648, still applies to the registers listed in Table G8-3 on page G8-5644.

**Definitions of direct and indirect reads and writes and their side-effects**

Direct and indirect reads and writes are defined as follows:

**Direct read**  
Is a read of a register, using an MRC, MRRC, or STC instruction, that the architecture permits for the current PE state.

If a direct read of a register has a side-effect of changing the value of a register, the effect of a direct read on that register is defined to be an indirect write, and has the synchronization requirements of an indirect write. This means the indirect write is guaranteed to have occurred, and to be visible to subsequent direct or indirect reads and writes only if synchronization is performed after the direct read.

---

**Note**

The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases.

---

**Direct write**  
Is a write to a register, using an MCR, MCRR, or LDC instruction, that the architecture permits for the current PE state.

In the following cases, the side-effect of the direct write is defined to be an indirect write of the affected register, and has the synchronization requirements of an indirect write:

- If the direct write has a side-effect of changing the value of a register other than the register accessed by the direct write.
- If the direct write has a side-effect of changing the value of the register accessed by the direct write, so that the value in that register might not be the value that the direct write wrote to the register.

In both cases, this means that the indirect write is not guaranteed to be visible to subsequent direct or indirect reads and writes unless synchronization is performed after the direct write.

---

**Note**

- As an example of a direct write to a register having an effect that is an indirect write of that register, writing 1 to a PMCNTENCLR.Px bit is also an indirect write, because if the Px bit had the value 1 before the direct write, the side-effect of the write changes the value of that bit to 0.
- The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases. For example, writing 1 to a PMCNTENCLR.Px bit that is set to 1 also changes the corresponding PMCNTENSET.Px bit from 1 to 0. This means that the direct write to the PMCNTENCLR defines indirect writes to both itself and to the PMCNTENSET.
Indirect read  
Is a use of the register by an instruction to establish the operating conditions for the instruction. Examples of operating conditions that might be determined by an indirect read are the translation table base address, or whether memory accesses are forced to be Non-cacheable.

Indirect reads include situations where the value of one register determines what value is returned by a second register. This means that any read of the second register is an indirect read of the register that determines what value is returned.

Indirect reads also include:

- Reads of the System registers by external agents, such as debuggers, as described in Debug registers on page G8-6103.
- Memory-mapped reads of the System registers made by the PE on which the System registers are implemented.

Where an indirect read of a register has a side-effect of changing the value of a register, that change is defined to be an indirect write, and has the synchronization requirements of an indirect write.

Indirect write  
Is an update to the value of a register as a consequence of either:

- An exception, operation, or execution of an instruction that is not a direct write to that register.
- The asynchronous operation of an external agent.

This can include:

- The passage of time, as seen in counters or timers, including performance counters.
- The assertion of an interrupt.
- A write from an external agent, such as a debugger.

However, for some registers, the architecture gives some guarantee of visibility without any explicit synchronization, see Registers with some architectural guarantee of ordering or observability on page G8-5643.

Note  
Taking an exception is a context-synchronizing operation. Therefore, any indirect write performed as part of an exception entry does not require additional synchronization. This includes the indirect writes to the registers that report the exception, as described in Exception reporting in a VMSAv8-32 implementation on page G5-5566.

G8.1.3  Principles of the ID scheme for fields in ID registers

The ARM architecture specifies a number of ID registers that are characterized as comprising a set of 4-bit ID fields. Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. AArch32 ID registers to which this scheme applies on page G8-5647 identifies the set of ID registers that are accessible from AArch32 state.

A small number of ID fields do not follow the scheme described in this section. In these cases, the field description states that it does not follow this scheme.

Note  
The ID fields described here are distinct from register fields that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors, or the amount of memory.

ID fields that do not follow this scheme include the ID_AA64DFR0_EL1.PMUVer, ID_DFR0_EL1.PerfMon, ID_DFR0.PerfMon and EDDFR.PMUVer fields, see Alternative ID scheme used for the Performance Monitors Extension version on page G8-5648.

The presence of an ID field for a feature does not imply that the feature is optional.

To provide forward compatibility, software can rely on the features of these fields that are described in this section.
The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, if a value of \(0x1\) indicates the presence of some instructions, then the value \(0x2\) will indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```c
if (value >= number) {    // do something that relies on the value of the feature}
```

For ID fields where the value \(0x0\) defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

- The field holds a signed value.
- The field value \(0xF\) indicates that the feature is not implemented.
- The field value \(0x0\) indicates that the feature is implemented.
- Software that depends on the feature can use the test:

  ```c
  if value >= 0 {    // Software features that depend on the presence of the hardware feature }
  ```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a *fractional* field that both:

- Is referred to in the definition of the original field.
- Applies only when the original field is at the lower value of the step.

In principle, a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. Example G8-1 shows the use of such a field.

#### Example G8-1 Example of the use of a fractional field

For a field describing some class of functionality:

- The value \(0x1\) was defined as indicating that item A is present.
- The value \(0x2\) was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value \(0x1\) when A and B only are present. This fractional field is valid only when the original ID field has the value \(0x1\).

This approach means that:

- Software that depends on the test if \((value >= 0x2)\) can rely on features A, B, and C being present,
- Software that depends on the test if \((value >= 0x2)\) can rely on feature A being present.
- If new software needs to check only that features A and B are present, then it can test:

  ```c
  if (value >= 0x2 || (value == 0x1 && fractional_value >= 0x1)) {    // Software features that depend on A and B only }
  ```

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Unused ID fields, and fractional fields that are not applicable, are \(RES0\) to allow their future use when features, or fractional implementation options, are added.

**AArch32 ID registers to which this scheme applies**

- The Auxiliary Feature register \(ID\_AFR0\).
- The Processor Feature registers \(ID\_PFR0\) and \(ID\_PFR1\).
- The Debug Feature register \(ID\_DFR0\).
• The Memory Model Feature registers ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, and ID_MMFR4.
• The Instruction Set Attribute registers ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.
• The Media and VFP Feature registers MVFR0, MVFR1, and MVFR2.

--- Note ---

Principles of the ID scheme for fields in ID registers on page D12-2668 includes information about the AArch64 System registers and the memory-mapped registers to which this scheme applies.

Alternative ID scheme used for the Performance Monitors Extension version

The ID_AA64DFR0_EL1.PMUVer, ID_DFR0_EL1.PerfMon, ID_DFR0.PerfMon, and EDDFR.PMUVer fields, which identify the version of the Performance Monitors Extension, do not follow the standard ID scheme. Software must treat these fields as follows:

• The value 0xF indicates that the ARM-architected Performance Monitors Extension is not implemented.
• If the field value is not 0xF the field is treated as an unsigned value, as described for the standard ID scheme.

This means that software that depends on the implementation of a particular version of the ARM Performance Monitors Extension must be written in the form:

if (value != 0xF and value >= number) { // do something that relies on version 'number' of the feature }

For these fields, ARM deprecates use of the value 0xF in new implementations.

G8.1.4 About AArch32 System register accesses

The following subsections give more information about accesses to the AArch32 System registers:

• Ordering of reads of System registers.
• Accessing 32-bit System registers on page G8-5649.
• Accessing 64-bit System registers on page G8-5650.

Ordering of reads of System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that both:

• Any data dependencies between the instructions, as specified in Synchronization of changes to AArch32 System registers on page G8-5640, including read-after-read dependencies, are respected.

• The reads to the register do not occur earlier than the most recent Context synchronization event to its architectural position in the instruction stream.

--- Note ---

In particular, the values read from System registers that hold self-incrementing counts, such as the Performance Monitors counters or the Generic Timer counter or timers, could be accessed from any time after the previous Context synchronization event. For example, where a memory access is used to communicate a read of such a counter, an ISB must be inserted between the read of the memory location that is known to have returned its data, either as a result of a condition on that data or of the read having completed, and the read of the counter, if it is necessary that the counter returns a count value after the memory communication.
Accessing 32-bit System registers

Software accesses most 32-bit System registers using the generic MCR and MRC System register access instructions, specifying some or all of the parameters \( \{ \text{coproc}, \text{CRn}, \text{opc1}, \text{CRm}, \text{opc2} \} \), where:

- \( \text{coproc} \): Identifies the primary region of the System register encoding space. Takes one of the values:
  - \( \text{p14} \): Encoded as \( 0b1110 \).
  - \( \text{p15} \): Encoded as \( 0b1111 \).

- \( \text{CRn} \): Takes a value in the range \( c0-c15 \), encoded the corresponding 4-bit binary value, \( 0b0000 - 0b1111 \).
  - In the \( \text{coproc} = 0b1110 \) encoding space, the \( \text{opc1} \) value identifies the System register functional group, and \( \text{CRn} \) is the most significant identifier for the required register within that group.
  - In the \( \text{coproc} = 0b1111 \) encoding space, \( \text{CRn} \) is the most significant identifier for the required register.

- \( \text{opc1} \): Takes a value in the range \( 0-7 \), encoded as its 3-bit binary value.
  - In the \( \text{coproc} = 0b1110 \) encoding space, the \( \text{opc1} \) value identifies the System register functional group, and can take the following values:
    - \( 0 \): Debug System registers.
    - \( 1 \): Trace System registers.
    - \( 7 \): Legacy Jazelle System registers.
  - In the \( \text{coproc} = 0b1111 \) encoding space, \( \text{opc1} \) can take any value in the range \( 0-7 \).

- \( \text{CRm} \): Takes a value in the range \( c0-c15 \), encoded the corresponding 4-bit binary value, \( 0b0000 - 0b1111 \).

- \( \text{opc2} \): Takes a value in the range \( 0-7 \), encoded as its 3-bit binary value.
  - \( \text{opc2} \) is optional in the MCR and MRC instruction syntax, and if no value is specified the encoding defaults to \( 0b000 \).

- \( \text{Rt} \): A general-purpose register to hold a 32-bit value to transfer to or from the System register. Takes a value in the range \( R0-R14 \), encoded as the corresponding 4-bit binary value, \( 0b0000 - 0b1110 \).

This means an MCR or MRC access to a specific 32-bit System register uses:
- A unique combination of \( \text{coproc}, \text{CRn}, \text{opc1}, \text{CRm}, \text{opc2} \), to specify the required System register.
- A general-purpose register, \( \text{Rt} \), for the transferred 32-bit value.

See also:
- \( MCR \) on page F5-4079.
- \( MRC \) on page F5-4102.

A small number of AArch32 debug System registers are accessed using LDC or STC instructions. In these cases, the register to be accessed is identified in the instruction syntax by the use of \( \text{p14, c5} \) where:

- \( \text{p14} \): Identifies that the access is to the \( \text{coproc} = 0b1110 \) encoding space.
- \( \text{c5} \): Identifies the target debug System register.

See the instruction descriptions:
- \( LDC \ (\text{immediate}) \) on page F5-3968.
- \( LDC \ (\text{literal}) \) on page F5-3970.
- \( STC \) on page F5-4317.

The only uses of LDC and STC permitted in ARMv8-A are:
- An LDC access to load data from memory to DBGDTRTXint, see \( LDC \ (\text{immediate}) \) on page F5-3968 and \( LDC \ (\text{literal}) \) on page F5-3970.
- An STC access to store data to memory from DBGDTRRXint, see \( STC \) on page F5-4317.

A small number of AArch32 System registers are accessed using MSR, MSR, VMRS, or VMR instructions, see the appropriate register and instruction description for more information, see:
- \( MRS \) on page F5-4106.
- \( MSR \ (\text{immediate}) \) on page F5-4116.
- \( MSR \ (\text{register}) \) on page F5-4118.
- \( VMRS \) on page F6-4902.
• **VMSR** on page F6-4905.

——— **Note** ————

• For example:
  — The APSR, CPSR, and SPSR are accessed using **MRS** or **MSR** instructions.
  — The MVFR0, MVFR1, and MVFR2 are accessed using **VMRS** or **VMSR** instructions.

• In addition, the banked register forms of the **MRS** and **MSR** instructions can be used to access some System registers associated with PE modes other than the mode in which the PE is currently executing, see **MRS (Banked register)** on page F5-4108 and **MSR (Banked register)** on page F5-4112.

### Accessing 64-bit System registers

Software accesses a 64-bit System register using the generic **MCRR** and **MRRC** System register access instructions, specifying the parameters \{coproc, \texttt{Crn}, opc1\}, where:

- **coproc**
  Identifies the primary region of the System register encoding space. Takes one of the values:
  - p14 Encoded as \(0b1110\).
  - p15 Encoded as \(0b1111\).

- **\texttt{Crn}**
  Takes a value in the range 0-15, encoded as its 4-bit binary value, \(0b0000-0b1111\).

  In the \((\text{coproc}==0b1110)\) encoding space, the opc1 value identifies the System register functional group, and \texttt{Crn} is the most significant identifier for the required register within that group.

  In the \((\text{coproc}==0b1111)\) encoding space, \texttt{Crn} is the most significant identifier for the required register.

- **opc1**
  Takes a value in the range 0-15, encoded as its 3-bit binary value.

  In the \((\text{coproc}==0b1110)\) encoding space, the opc1 value identifies the System register functional group, and can take the following values:
  - 0 Debug System registers.
  - 1 Trace System registers.

  In the \((\text{coproc}==0b1111)\) encoding space, opc1 can take any value in the range 0-15.

- **\texttt{Rt}**
  A general-purpose register to hold bits[31:0] of the value to transfer to or from the System register.

  Takes a value in the range 0-14, encoded as the corresponding 4-bit binary value, \(0b0000-0b1110\).

- **\texttt{Rt2}**
  A general-purpose register to hold bits[63:32] of the value to transfer to or from the System register.

  Takes a value in the range 0-14, encoded as the corresponding 4-bit binary value, \(0b0000-0b1110\).

This means an **MCRR** or **MRRC** access to a specific 64-bit System register uses:

• A unique combination of **coproc**, \texttt{Crn} and opc1, to specify the required 64-bit System register.

• Two general-purpose registers, each holding 32 bits of the value to transfer.

This means a PE can access a 64-bit System register using:

• An **MCRR** instruction to write to a System register, see **MCRR** on page F5-4081.

• An **MRRC** instruction to read a System register, see **MCRR** on page F5-4081.

When using an **MCRR** or **MRRC** instruction the System register access is 64-bit atomic.

Some 64-bit registers also have an **MCR** and **MRC** encoding. The **MCR** and **MRC** encodings for these registers access the least significant 32 bits of the register. For example, to access the PAR, software can:

• Use the following instructions to access all 64 bits of the register:
  - **MRRC** p15, 0, <\texttt{Rt}>, <\texttt{Rt2}>, c7 ; Read 64-bit PAR into Rt (low word) and Rt2 (high word)
  - **MCRR** p15, 0, <\texttt{Rt}>, <\texttt{Rt2}>, c7 ; Write Rt (low word) and Rt2 (high word) to 64-bit PAR

• Use the following instructions to access the least-significant 32 bits of the register:
  - **MRC** p15, 0, <\texttt{Rt}>, c7, c4, 0 ; Read PAR[31:0] into Rt
  - **MCR** p15, 0, <\texttt{Rt}>, c7, c4, 0 ; Write Rt to PAR[31:0]
G8.2 General system control registers

This section lists the System registers in AArch32 state that are not part of one of the other listed groups.
G8.2.1  **ACTLR, Auxiliary Control Register**

The ACTLR characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

**Configurations**

AArch32 System register ACTLR[31:0] is architecturally mapped to AArch64 System register ACTLR_EL1[31:0].

Some bits might define global configuration settings, and be common to the Secure and Non-secure instances of the register.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ACTLR is a 32-bit register.

**Field descriptions**

The ACTLR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED, bits [31:0]</td>
<td>IMPLEMENTATION DEFINED. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the ACTLR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRC<coproc>, <Rt>, <CRn>, <CRm>, (#<opc1>), (#<opc2>) \]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>0b000</td>
<td>0b0001</td>
<td>0b0000</td>
<td>0b001</td>
</tr>
</tbody>
</table>

```
if PSTATE.EL == EL0 then

G8.2.2 ACTLR2, Auxiliary Control Register 2

The ACTLR2 characteristics are:

**Purpose**

Provides additional space to the ACTLR register to hold IMPLEMENTATION DEFINED trap functionality for execution at EL1 and EL0.

**Configurations**

AArch32 System register ACTLR2[31:0] is architecturally mapped to AArch64 System register ACTLR_EL1[63:32].

In Armv8.0 and Armv8.1, it is IMPLEMENTATION DEFINED whether this register is implemented, or whether it causes UNDEFINED exceptions when accessed. The implementation of this register can be detected by examining ID-MMFR4.AC2.

From Armv8.2 this register must be implemented.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ACTLR2 is a 32-bit register.

**Field descriptions**

The ACTLR2 bit assignments are:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Bit Assignment</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td>[31:0]</td>
<td>IMPLEMENTATION DEFINED</td>
<td>This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the ACTLR2**

Accesses to this register use the following encodings in the System instruction encoding space:

```
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

```
if PSTATE.EL == EL0 then

G8.2.3 ADFSR, Auxiliary Data Fault Status Register

The ADFSR characteristics are:

**Purpose**

Provides additional IMPLEMENTATION DEFINED fault status information for Data Abort exceptions taken to EL1 modes, and EL3 modes when EL3 is implemented and is using AArch32.

**Configurations**

AArch32 System register ADFSR[31:0] is architecturally mapped to AArch64 System register AFSR0_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ADFSR is a 32-bit register.

**Field descriptions**

The ADFSR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td>IMPLEMENTATION DEFINED, bits [31:0]</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Accessing the ADFSR**

Accesses to this register use the following encodings in the System instruction encoding space:

G8.2.6 AMAIR0, Auxiliary Memory Attribute Indirection Register 0

The AMAIR0 characteristics are:

**Purpose**

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR0.

**Configurations**

AArch32 System register AMAIR0[31:0] is architecturally mapped to AArch64 System register AMAIR_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMAIR0 is a 32-bit register.

**Field descriptions**

The AMAIR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>IMPLEMENTATION DEFINED</strong></td>
<td></td>
</tr>
</tbody>
</table>

This register is RES0 in the following cases:

- When an implementation does not provide any IMPLEMENTATION DEFINED memory attributes.
- When the Long-descriptor translation table format is not used.

If EL3 is implemented and is using AArch32:

- AMAIR0(S) gives the value for memory accesses from Secure state.
- AMAIR0(NS) gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

**IMPLEMENTATION DEFINED, bits [31:0]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**Accessing the AMAIR0**

G8.2.7 AMAIR1, Auxiliary Memory Attribute Indirection Register 1

The AMAIR1 characteristics are:

**Purpose**

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR1.

**Configurations**

AArch32 System register AMAIR1[31:0] is architecturally mapped to AArch64 System register AMAIR_EL1[63:32].

When EL3 is using AArch32, write access to AMAIR1(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMAIR1 is a 32-bit register.

**Field descriptions**

The AMAIR1 bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>
```

This register is RES0 in the following cases:

- When an implementation does not provide any IMPLEMENTATION DEFINED memory attributes.
- When the Long-descriptor translation table format is not used.

If EL3 is implemented and is using AArch32:

- AMAIR1(S) gives the value for memory accesses from Secure state.
- AMAIR1(NS) gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

**IMPLEMENTATION DEFINED, bits [31:0]**

G8.2.8 APSR, Application Program Status Register

The APSR characteristics are:

Purpose

Hold program status and control information.

Configurations

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

APSR is a 32-bit register.

Field descriptions

The APSR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Z</td>
<td>C</td>
<td>V</td>
<td>Q</td>
<td>RES0</td>
<td>GE</td>
<td>RES0</td>
<td>RES0</td>
<td>RES0</td>
<td>RES1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

N, bit [31]

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then N is set to 1 if the result was negative, and N is set to 0 if the result was positive or zero.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

Bits [26:20]

Reserved, RES0.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

Bits [15:5]

Reserved, RES0.

Bit [4]

Reserved, RES1.
Bits [3:0]

Reserved, RES0.

It is permitted that, on a read of APSR:

- Bit[22] returns the value of PSTATE.PAN
- Bit[9] returns the value of PSTATE.E.
- Bit[4:0] returns the value of PSTATE.M[4:0]

--- Note ---

This is an exception to the general rule that an UNKNOWN field must not return information that cannot be obtained, at the current Privilege level, by an architected mechanism.

---

For more information see *The Application Program Status Register, APSR* on page E1-3543.
G8.2.9  ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read

The ATS12NSOPR characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for PL1 and the Non-secure state, with permissions as if reading from the given virtual address.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ATS12NSOPR is a 32-bit System instruction.

**Field descriptions**

The ATS12NSOPR input value bit assignments are:

```
31 0

Input address for translation
```

**Bits [31:0]**

Input address for translation. The resulting address can be read from the PAR.

This System instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

**Executing the ATS12NSOPR instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

```
MCR<|c>|<q> <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2}>
```

<table>

G8.2.10   ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write

The ATS12NSOPW characteristics are:

**Purpose**

Performs stage 1 and 2 address translations as defined for PL1 and the Non-secure state, with permissions as if writing to the given virtual address.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ATS12NSOPW is a 32-bit System instruction.

**Field descriptions**

The ATS12NSOPW input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 0</td>
<td>Input address for translation</td>
</tr>
</tbody>
</table>

Input address for translation. The resulting address can be read from the PAR.

This System instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

**Executing the ATS12NSOPW instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

```

\end{align*} \]
ATS1HR(R[t]);
elsif PSTATE.EL == EL3 then
  ATS1HR(R[t]);
G8.2.20   ATS1HW, Address Translate Stage 1 Hyp mode Write

The ATS1HW characteristics are:

**Purpose**

Performs stage 1 address translation as defined for PL2 and the Non-secure state, with permissions as if writing to the given virtual address.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ATS1HW is a 32-bit System instruction.

**Field descriptions**

The ATS1HW input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Input address for translation</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0</td>
</tr>
</tbody>
</table>

**Input address for translation**

Input address for translation. The resulting address can be read from the PAR.

This System instruction takes a VA as input. The resulting address is the PA that is the output address of the translation.

**Executing the ATS1HW instruction**

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Accesses to this register use the following encodings in the System instruction encoding space:

```
MCR(<c>){<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

<table>

G8.2.21 BPIALL, Branch Predictor Invalidate All

The BPIALL characteristics are:

**Purpose**

Invalidate all entries from branch predictors.

**Configurations**

In an implementation where the branch predictors are architecturally invisible, this instruction can execute as a NOP.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

BPIALL is a 32-bit System instruction.

**Field descriptions**

BPIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the BPIALL instruction**

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a BPIALLIS.

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MCR{<c>}{<q>}{<coproc>}, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>} \]

<table>
<thead>

G8.2.24 CCSIDR, Current Cache Size ID Register

The CCSIDR characteristics are:

**Purpose**

Provides information about the architecture of the currently selected cache.
When ARMv8.3-CCIDX is implemented, this register is used in conjunction with CCSIDR2.

**Configurations**

AArch32 System register CCSIDR[31:0] is architecturally mapped to AArch64 System register CCSIDR_EL1[31:0].
The implementation includes one CCSIDR for each cache that it can access. CSSELR and the Security state select which Cache Size ID Register is accessible.
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CCSIDR is a 32-bit register.

**Field descriptions**

The CCSIDR bit assignments are:

*When ARMv8.3-CCIDX is implemented:*

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>3</th>
<th>2</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Associativity</td>
<td>LineSize</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note**

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

**Bits [31:24]**

Reserved, RES0.

**Associativity, bits [23:3]**

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity
does not have to be a power of 2.

**LineSize, bits [2:0]**

(Log2(Number of bytes in cache line)) - 4. For example:
For a line length of 16 bytes: Log2(16) = 4, LineSize entry = 0. This is the minimum line length.
For a line length of 32 bytes: Log2(32) = 5, LineSize entry = 1.

**Otherwise:**

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>13</th>
<th>12</th>
<th>3</th>
<th>2</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNKNOWN</td>
<td>NumSets</td>
<td>Associativity</td>
<td>LineSize</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Note

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

UNKNOWN, bits [31:28]
Reserved, UNKNOWN.

NumSets, bits [27:13]
(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Associativity, bits [12:3]
(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]
(Log2(Number of bytes in cache line)) - 4. For example:
For a line length of 16 bytes: Log2(16) = 4, LineSize entry = 0. This is the minimum line length.
For a line length of 32 bytes: Log2(32) = 5, LineSize entry = 1.

Accessing the CCSIDR

If CSSEL.R.Level is programmed to a cache level that is not implemented, then on a read of the CCSIDR the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:
• The CCSIDR read is treated as NOP.
• The CCSIDR read is UNDEFINED.
• The CCSIDR read returns an UNKNOWN value.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MRC{<c>}{<q>} \, <coproc>, \{#<opc1>, \, <Rt>, \, <CRn>, \, <CRm>{, \{#<opc2>}}
\]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>0b001</td>
<td>0b0000</td>
<td>0b0000</td>
<td>0b000</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && !ELUsingAArch32(EL2) && HSTR_EL2.T0 == '1' then

    return CCSIDR;
endif
G8.2.25 CCSIDR2, Current Cache Size ID Register 2

The CCSIDR2 characteristics are:

**Purpose**

When ARMv8.3-CCIDX is implemented, in conjunction with CCSIDR, provides information about the architecture of the currently selected cache.

When ARMv8.3-CCIDX is not implemented, this register is not implemented.

**Configurations**

AArch32 System register CCSIDR2[31:0] is architecturally mapped to AArch64 System register CCSIDR2_EL1[31:0].

This register is present only when ARMv8.3-CCIDX is implemented. Otherwise, direct accesses to CCSIDR2 are UNDEFINED.

The implementation includes one CCSIDR2 for each cache that it can access. CSSEL R and the Security state select which Cache Size ID Register is accessible.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CCSIDR2 is a 32-bit register.

**Field descriptions**

The CCSIDR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>24-23</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td>NumSets</td>
</tr>
</tbody>
</table>

**Bits [31:24]**

Reserved, RES0.

**NumSets, bits [23:0]**

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

**Accessing the CCSIDR2**

If CSSEL R.Level is programmed to a cache level that is not implemented, then on a read of the CCSIDR2 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR2 read is treated as NOP.
- The CCSIDR2 read is UNDEFINED.
- The CCSIDR2 read returns an UNKNOWN value.

Accesses to this register use the following encodings in the System instruction encoding space:
### MRC(<c>)<q> <coproc>, (#)<opc1>, <Rt>, <CRn>, <CRm>{, (#)<opc2>}

<table>
<thead>
<tr>

  endif
elsif PSTATE.EL == EL2 then
  return CCSIDR2;
elsif PSTATE.EL == EL3 then
  return CCSIDR2;
G8.2.26 CLIDR, Cache Level ID Register

The CLIDR characteristics are:

**Purpose**

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architected cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

**Configurations**

AArch32 System register CLIDR[31:0] is architecturally mapped to AArch64 System register CLIDR_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CLIDR is a 32-bit register.

**Field descriptions**

The CLIDR bit assignments are:

<table>
<thead>
<tr>
<th>ICB</th>
<th>LoUU</th>
<th>LoC</th>
<th>LoUIS</th>
<th>Ctype7</th>
<th>Ctype6</th>
<th>Ctype5</th>
<th>Ctype4</th>
<th>Ctype3</th>
<th>Ctype2</th>
<th>Ctype1</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>30</td>
<td>29</td>
<td>28</td>
<td>27</td>
<td>26</td>
<td>25</td>
<td>24</td>
<td>23</td>
<td>22</td>
<td>21</td>
</tr>
<tr>
<td>ICB, bits [31:30]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.

The possible values are:

0b00  Not disclosed by this mechanism.
0b01  L1 cache is the highest Inner Cacheable level.
0b10  L2 cache is the highest Inner Cacheable level.
0b11  L3 cache is the highest Inner Cacheable level.

LoUU, bits [29:27]  
Level of Unification Uniprocessor for the cache hierarchy.

LoC, bits [26:24]  
Level of Coherence for the cache hierarchy.

LoUIS, bits [23:21]  
Level of Unification Inner Shareable for the cache hierarchy.

Ctype<n>, bits [3(n-1)+2:3(n-1)], for n = 1 to 7

Cache Type fields. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

0b000  No cache.
0b001  Instruction cache only.
0b010  Data cache only.
0b011  Separate instruction and data caches.
0b100  Unified cache.
All other values are reserved.
If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 000, no
 caches that can be managed using the architected cache maintenance instructions that operate by
 set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type
 field with a value of 000, the values of Ctype4 to Ctype7 must be ignored.

Accessing the CLIDR

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MRC\{c\}\{q\} <coproc>, \{\#\}<opc1>, <Rt>, <CRn>, <CRm>\{, \{\#\}<opc2>\}
\]

<table>

G8.2.27 CONTEXTIDR, Context ID Register

The CONTEXTIDR characteristics are:

**Purpose**

Identifies the current Process Identifier and, when using the Short-descriptor translation table format, the Address Space Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

**Configurations**

AArch32 System register CONTEXTIDR[31:0] is architecturally mapped to AArch64 System register CONTEXTIDR_EL1[31:0].

The register format depends on whether address translation is using the Long-descriptor or the Short-descriptor translation table format.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CONTEXTIDR is a 32-bit register.

**Field descriptions**

The CONTEXTIDR bit assignments are:

*When TTBCR.EAE == 0:

<table>
<thead>
<tr>
<th>Field</th>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

G8.2.31 CPACR, Architectural Feature Access Control Register

The CPACR characteristics are:

**Purpose**

Controls access to trace, and to Advanced SIMD and floating-point functionality from EL0, EL1, and EL3.

In an implementation that includes EL2, the CPACR has no effect on instructions executed at EL2.

**Configurations**

AArch32 System register CPACR[31:0] is architecturally mapped to AArch64 System register CPACR_EL1[31:0].

Bits in the NSACR control Non-secure access to the CPACR fields. See the field descriptions for more information.

---

**Note**

In the register field descriptions, controls are described as applying at specified Privilege levels. This is because, in Secure state, a PL1 control:

- Applies to execution in a Secure EL3 mode when EL3 is using AArch32.
- Applies to execution in a Secure EL1 mode when EL3 is using AArch64.

See Security state, Exception levels, and AArch32 execution privilege on page G1-5226.

---

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CPACR is a 32-bit register.

**Field descriptions**

The CPACR bit assignments are:

![CPACR Bit Assignment Diagram](image)

**ASEDIS, bit [31]**

Disables PL0 and PL1 execution of Advanced SIMD instructions.

- 0: This control permits execution of Advanced SIMD instructions at PL0 and PL1.
- 1: All instruction encodings that are Advanced SIMD instruction encodings, but are not also floating-point instruction encodings, are UNDEFINED at PL0 and PL1.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSASEDIS is 1, this field behaves as RAO/WI in Non-secure state, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.
For the list of instructions affected by this field, see Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-3554.

See the description of CPACR.cp10 for a list of other controls that can disable or trap execution of Advanced SIMD instructions in AArch32 state.

This field resets to 0.

**Bits [30:29]**

Reserved, RES0.

**TRCDIS, bit [28]**

Traps PL0 and PL1 System register accesses to all implemented trace registers to Undefined mode.

0b0 This control has no effect on PL0 and PL1 System register accesses to trace registers.

0b1 PL0 and PL1 System register accesses to all implemented trace registers are trapped to Undefined mode.

If the implementation does not include a PE trace unit, or does not include a System register interface to the PE trace unit registers, this field is RES0. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSTRCDIS is 1, this field behaves as RAO/WI in Non-secure state, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

--- Note ---

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the implementation includes an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- The architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

This field resets to an architecturally UNKNOWN value.

**Bits [27:24]**

Reserved, RES0.

**cp11, bits [23:22]**

The value of this field is ignored. If this field is programmed with a different value to the cp10 field then this field is UNKNOWN on a direct read of the CPACR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

In Non-secure state, if EL3 is implemented and is using AArch32, when the value of NSACR.cp10 is 0, this field behaves as RAZ/WI, regardless of its actual value.

This field resets to 0.

**cp10, bits [21:20]**

Defines the access rights for the floating-point and Advanced SIMD functionality. Possible values of the field are:

0b00 PL0 and PL1 accesses to floating-point and Advanced SIMD registers or instructions are UNDEFINED.

0b01 PL0 accesses to floating-point and Advanced SIMD registers or instructions are UNDEFINED.
0b10  Reserved. The effect of programming this field to this value is CONSTRAINED UNPREDICTABLE. See Reserved values in System and memory-mapped registers and translation table entries on page K1-7212.

0b11  This control permits full access to the floating-point and Advanced SIMD functionality from PL0 and PL1.

The floating-point and Advanced SIMD features controlled by these fields are:
- Execution of any floating-point or Advanced SIMD instruction.
- Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- Any access to the FPSCR, FPSID, MVFR0, MVFR1, MVFR2, or FPEXC System registers.

Note

The CPACR has no effect on floating-point and Advanced SIMD accesses from PL2. These can be disabled by the HCPTR.TCP10 field.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

In Non-secure state, if EL3 is implemented and is using AArch32, when the value of NSACR.cp10 is 0, this field behaves as RAZ/WI, regardless of its actual value.

Execution of floating-point and Advanced SIMD instructions in AArch32 state can be disabled or trapped by the following controls:
- CPACR.cp10, or, if executing at EL0, CPACR_EL1.FPEN.
- FPEXC.EN.
- If executing in Non-secure state:
  - HCPTR.TCP10, or if EL2 is using AArch64, CPTR_EL2.TFP.
  - NSACR.cp10, or if EL3 is using AArch64, CPTR_EL3.TFP.
- For Advanced SIMD instructions only:
  - CPACR.ASEDIS.
  - If executing in Non-secure state, HCPTR.TASE and NSACR.NSTRCDIS.

See the descriptions of the controls for more information.
This field resets to 0.

Bits [19:0]

Reserved, RES0.

Accessing the CPACR

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MRC}\{c\}\{q\}\ <\text{coproc},\ (#)<\text{opc1},\ <\text{Rt},\ <\text{CRn},\ <\text{CRm}\{,\ (#)<\text{opc2}\} \]

### G8.2.32 CPSR, Current Program Status Register

The CPSR characteristics are:

**Purpose**
Holds PE status and control information.

**Configurations**
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
CPSR is a 32-bit register.

**Field descriptions**
The CPSR bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| N  | Z  | C  | V  | Q  | RES0| GE | RES0| E  | A  | I  | F  | M  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

#### N, bit [31]
Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then N is set to 1 if the result was negative, and N is set to 0 if the result was positive or zero.

#### Z, bit [30]
Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

#### C, bit [29]
Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

#### V, bit [28]
Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

#### Q, bit [27]
Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

#### Bits [26:23]
Reserved, RES0.

#### PAN, bit [22]

*When ARMv8.1-PAN is implemented:*
Privileged Access Never.

0b0 The translation system is the same as Armv8.0.
0b1        Disables privileged read and write accesses to addresses accessible at EL0.
The value of this bit is usually preserved on taking an exception, except in the following situations:

- When the target of the exception is EL1, and the value of the SCTLR.SPAN bit for the current
  Security state is 0, this bit is set to 1.
- When the target of the exception is EL3, from Secure state, and the value of the Secure
  SCTLR.SPAN is 0, this bit is set to 1.
- When the target of the exception is EL3, from Non-secure state, this bit is set to 0 regardless
  of the value of the Secure SCTLR.SPAN bit.

Otherwise:
Reserved, RES0.

DIT, bit [21]

When ARMv8.4-DIT is implemented:

Data Independent Timing.

0b0        The architecture makes no statement about the timing properties of any instructions.

0b1        The architecture requires that:

- The timing of every load and store instruction is insensitive to the value of the data being loaded or stored.
- For certain data processing instructions, the instruction takes a time which is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- For certain data processing instructions, the response of the instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

The data processing instructions affected by this bit are:

- All cryptographic instructions. These instructions are:
  - AESD, Aese, AESIMC, AESMC, SHA1C, SHA1H, SHA1M, SHA1P, SHA1SUB, SHA1SU1, SHA256H,
    SHA256H2, SHA256SUB, and SHA256SU1.
- A subset of those instructions which use the general-purpose register file. For these instructions, the effects of CPSR.DIT apply only if they do not use R15 as either their source or destination and pass their condition execution check. The instructions are:
  - BFI, BFc, CLZ, CN, CMP, MLA, MLAS, MLS, MOV, MUL, MULS, NOP, PKHB, PKHTB, RBIT, REV, REV16,
    REVSH, RXX, SADD16, SADD8, SASX, SBFX, SADD16, SADD8, SHASX, SHASX, SHASX, SHASX, SHASX,
    SHASX, SHASX, SHASX, SHASX, SHASX, SHASX, SHASX, SHASX, SHASX, SHASX, SHASX, SHASX,
    SHASX, SHASX, SHASX, SHASX, SHASX, SHASX, SHASX, SHASX, SHASX, SHASX, SHASX, SHASX,

A subset of those instructions which use the general-purpose register file. For these instructions, the effects of CPSR.DIT apply only if they do not use R15 as either their source or destination. The effects of CPSR.DIT do not depend on these instructions passing their condition execution check. These instructions are:

- ADC (immediate), ADC (register), ADCS (register), ADD (immediate), ADD (register), ADDS (immediate), ADDS (register), AND (immediate), AND (register), ANDS (immediate), ANDS (register), ASR (immediate), ASR (register), ASRS (immediate), ASRS (register), BIC (immediate), BIC (register), BICS (immediate), BICS (register), EOR (immediate), EOR (register), EORS (immediate), EORS (register), LSL (immediate), LSL (register), LSLS (immediate), LSLS (register), LSR (immediate), LSR (register), LSRS (immediate), LSRS (register), MOV (immediate), MOV (register), MOVS (immediate), MOVS (register), MVN (immediate), MVN (register), MVNS (immediate), MVNS (register), ORR (immediate), ORR (register), ORRS (immediate), ORRS (register), ROR (immediate), ROR (register), RORS (immediate), RORS (register), RSB (immediate), RSB (register), RSBS (immediate), RSBS (register), RSC (immediate), RSC (register), RSCS (immediate), RSCS (register), SBC (immediate), SBC (register), SBCS (immediate), SBCS (register), SUB (immediate), SUB (register), SUBS (immediate), and SUBS (register).

A subset of those instructions which use the SIMD&FP register file. For these instructions, the effects of CPSR.DIT apply only if they pass their condition execution check. These instructions are:

- CRC32B, CRC32H, CRC32W, CRC32CW, VABA+, VABD+, VABS, VACEG, VACGT, VACLE, VACLT, VADD (integer), VADDH, VADDL, VADDX, VAND, VBAR, VBIF, VBIT, VBSL, VCEG, VCGT, VCLE, VCLS, VCLT, VCTL, VCPP, VCPM, VCNT, VDUP, VDOR, VEXT, VHADD, VHSUB, VMAX (integer), VMIN (integer), VMUL (integer), VMULT (integer and polynomial), VMMU, VNEG, VORN, VORR, VORR (integer), VPADD (integer), VPADDL, VPMAX (integer), VPMPN (integer), VRADDH, VREV+, VRHADD, VRSHL, VRSHR, VSHRN, VSRSA, VSWB, VSWL, VSWL, VSWL, VSWL, VSHL, VSHR, VSLT, VSRA, VRSA, VSUB (integer), VSUBH, VSUBL, VSUBL, VSWP, VTB, VTBX, VTRN, VTS, VUZP, and VZIP

This field resets to 0.

**Otherwise:**

Reserved, RES0.

**Bit [20]**

Reserved, RES0.

**GE, bits [19:16]**

Greater than or Equal flags, for parallel addition and subtraction.

**Bits [15:10]**

Reserved, RES0.

**E, bit [9]**

Endianness state bit. Controls the load and store endianness for data accesses:

- 0b0 Little-endian operation
- 0b1 Big-endian operation.

Instruction fetches ignore this bit.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.
When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

**A, bit [8]**

SError interrupt mask bit. The possible values of this bit are:

- 0b0 Exception not masked.
- 0b1 Exception masked.

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

- 0b0 Exception not masked.
- 0b1 Exception masked.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

- 0b0 Exception not masked.
- 0b1 Exception masked.

**Bit [5]**

Reserved, RES0.

**Bit [4]**

Reserved, RES1.

**M, bits [3:0]**

Current PE mode. Possible values are:

- 0b0000 User.
- 0b0001 FIQ.
- 0b0010 IRQ.
- 0b0011 Supervisor.
- 0b0110 Monitor.
- 0b0111 Abort.
- 0b1010 Hyp.
- 0b1011 Undefined.
- 0b1111 System.
G8.2.33 CSSELR, Cache Size Selection Register

The CSSELR characteristics are:

Purpose

Selects the current Cache Size ID Register, CCSIDR, by specifying the required cache level and the cache type, which is either instruction cache or data cache.

If ARMv8.3-CCIDX is implemented, CSSELR also selects the current CCSIDR2.

Configurations

AArch32 System register CSSELR[31:0] is architecturally mapped to AArch64 System register CSSELR_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CSSELR is a 32-bit register.

Field descriptions

The CSSELR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>4</th>
<th>3</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>Level</td>
<td>InD</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:4]

Reserved, RES0.

Level, bits [3:1]

Cache level of required cache. Permitted values are:

- 0b000 Level 1 cache.
- 0b001 Level 2 cache.
- 0b010 Level 3 cache.
- 0b011 Level 4 cache.
- 0b100 Level 5 cache.
- 0b101 Level 6 cache.
- 0b110 Level 7 cache.

All other values are reserved.

If CSSELR.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

InD, bit [0]

Instruction not Data bit. Permitted values are:

- 0b0 Data or unified cache.
- 0b1 Instruction cache.

If CSSELR.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

This field resets to an architecturally UNKNOWN value.
Accessing the CSSELR

Accesses to this register use the following encodings in the System instruction encoding space:

G8.2.34 CTR, Cache Type Register

The CTR characteristics are:

**Purpose**

Provides information about the architecture of the caches.

**Configurations**

AArch32 System register CTR[31:0] is architecturally mapped to AArch64 System register CTR_EL0[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CTR is a 32-bit register.

**Field descriptions**

The CTR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES1.</td>
</tr>
<tr>
<td>30</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
| 29  | DIC, bit [29] Instruction cache invalidation requirements for instruction to data coherence. The meaning of this bit is:
|     | 0b0 Instruction cache invalidation to the Point of Unification is required for instruction to data coherence. |
|     | 0b1 Instruction cache cleaning to the Point of Unification is not required for instruction to data coherence. |
| 28  | IDC, bit [28] Data cache clean requirements for instruction to data coherence. The meaning of this bit is:
|     | 0b0 Data cache clean to the Point of Unification is required for instruction to data coherence, unless CLIDR.LoC == 0b000 or (CLIDR.LoUIS == 0b000 && CLIDR.LoUU == 0b000). |
|     | 0b1 Data cache clean to the Point of Unification is not required for instruction to data coherence. |
| 27-24 | CWG, bits [27:24] Cache writeback granule. Log2 of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.
A value of 0b0000 indicates that this register does not provide Cache writeback granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache writeback granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than 0b1001 are reserved.

Arm recommends that an implementation that does not support cache write-back implements this field as 0b0001. This applies, for example, to an implementation that supports only write-through caches.

**ERG, bits [23:20]**

Exclusives reservation granule. Log2 of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

A value of 0b0000 indicates that this register does not provide Exclusives reservation granule information and the architectural maximum of 512 words (2KB) must be assumed.

Values greater than 0b1001 are reserved.

**DminLine, bits [19:16]**

Log2 of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

**L1Ip, bits [15:14]**

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

- 0b00: VMID aware Physical Index, Physical tag (VPIPT)
- 0b01: ASID-tagged Virtual Index, Virtual Tag (AIVIVT)
- 0b10: Virtual Index, Physical Tag (VIPT)
- 0b11: Physical Index, Physical Tag (PIPT)

The value 0b01 is reserved in Armv8.

The value 0b00 is permitted only in an implementation that includes ARMv8.2-VPIPT, otherwise the value is reserved.

**Bits [13:4]**

Reserved, RES0.

**IminLine, bits [3:0]**

Log2 of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

**Accessing the CTR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\langle c\rangle\langle q\rangle\langle \#\rangle\langle opc1\rangle\langle R\rangle\langle CRn\rangle\langle CRm\rangle\langle \#\rangle\langle opc2\rangle
\]

G8.2.35 DACR, Domain Access Control Register

The DACR characteristics are:

Purpose

Defines the access permission for each of the sixteen memory domains.

Configurations

AArch32 System register DACR[31:0] is architecturally mapped to AArch64 System register DACR32_EL2[31:0].

This register has no function when TTBCR.EAE is set to 1, to select the Long-descriptor translation table format.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DACR is a 32-bit register.

Field descriptions

The DACR bit assignments are:

\[
\begin{array}{cccccccccccccccc}
D_{15} & D_{14} & D_{13} & D_{12} & D_{11} & D_{10} & D_9 & D_8 & D_7 & D_6 & D_5 & D_4 & D_3 & D_2 & D_1 & D_0 \\
\end{array}
\]

D\<n\>, bits \(2n+1:2n\), for \(n = 0 \text{ to } 15\)

Domain \(n\) access permission, where \(n = 0 \text{ to } 15\). Permitted values are:

- 0b00: No access. Any access to the domain generates a Domain fault.
- 0b01: Client. Accesses are checked against the permission bits in the translation tables.
- 0b11: Manager. Accesses are not checked against the permission bits in the translation tables.
- 0b10: Reserved. The value 0b10 is reserved.

This field resets to an architecturally UNKNOWN value.

Accessing the DACR

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC\{<c>{<q}> <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}}
\]

\[
\begin{array}{cccccc}

```
DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC

The DCCIMVAC characteristics are:

**Purpose**

Clean and Invalidate data or unified cache line by virtual address to PoC.

**Configurations**

AArch32 System instruction DCCIMVAC performs the same function as AArch64 System instruction DCIVAC.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DCCIMVAC is a 32-bit System instruction.

**Field descriptions**

The DCCIMVAC input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 0</td>
<td></td>
</tr>
</tbody>
</table>

Virtual address to use. No alignment restrictions apply to this VA.

**Executing the DCCIMVAC instruction**

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see *AArch32 data cache maintenance instructions (DC*) on page G4-5445.

Accesses to this register use the following encodings in the System instruction encoding space:

```
MCR(<c>{<q>}) <coproc>, {$<opc1>}, <Rt>, <CRn>, <CRm>{, {$<opc2>}}
```

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>

G8.2.37 DCCISW, Data Cache line Clean and Invalidate by Set/Way

The DCCISW characteristics are:

**Purpose**
Clean and Invalidate data or unified cache line by set/way.

**Configurations**
AArch32 System instruction DCCISW performs the same function as AArch64 System instruction DC CISW.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
DCCISW is a 32-bit System instruction.

**Field descriptions**
The DCCISW input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>4</th>
<th>3</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SetWay</td>
<td>Level</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**SetWay, bits [31:4]**
Contains two fields:
- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.
Bits[L-1:4] are RES0.

A = Log2(ASSOCIATIVITY), L = Log2(LINELEN), B = (L + S), S = Log2(NSETS).
ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**
Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**
Reserved, RES0.

**Executing the DCCISW instruction**
If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.
Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MCR}\{<c>\}{<q}> \ <\text{coproc}, \ (#)<\text{opc1}>, \ <\text{Rt}>, \ <\text{CRn}>, \ <\text{CRm}>, \ (#)<\text{opc2}> \]

G8.2.43   DFAR, Data Fault Address Register

The DFAR characteristics are:

**Purpose**

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception.

**Configurations**

AArch32 System register DFAR[31:0] is architecturally mapped to AArch64 System register FAR_EL1[31:0].

AArch32 System register DFAR[31:0](S) is architecturally mapped to AArch32 System register HDFAR[31:0] when when HaveEL(EL2), HaveEL(EL3) and HighestELUsingAArch32().

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DFAR is a 32-bit register.

**Field descriptions**

The DFAR bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:0]</td>
<td>VA of faulting address of synchronous Data Abort exception</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Accessing the DFAR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}(<c>\{<q>\}, \{#\}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>} \\

G8.2.44 DFSR, Data Fault Status Register

The DFSR characteristics are:

**Purpose**

Holds status information about the last data fault.

**Configurations**

AArch32 System register DFSR[31:0] is architecturally mapped to AArch64 System register ESR_EL1[31:0]. The current translation table format determines which format of the register is used. RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DFSR is a 32-bit register.

**Field descriptions**

The DFSR bit assignments are:

*When TTBCR.EAE == 0:*

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-17</td>
<td>RES0</td>
</tr>
<tr>
<td>16</td>
<td>FnV, bit[16]</td>
</tr>
<tr>
<td>15-14</td>
<td>AET, bits[15:14]</td>
</tr>
<tr>
<td>13-8</td>
<td>Domain</td>
</tr>
<tr>
<td>7</td>
<td>FS[3:0]</td>
</tr>
<tr>
<td>4-0</td>
<td>LPAE, FS[4], WnR, ExT, CM</td>
</tr>
</tbody>
</table>

**Bits [31:17]**

Reserved, RES0.

**FnV, bit [16]**

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

- 0b0: DFAR is valid.
- 0b1: DFAR is not valid, and holds an UNKNOWN value.

This field is only valid for a synchronous External abort other than a synchronous External abort on a translation table walk. It is RES0 for all other Data Abort exceptions. This field resets to an architecturally UNKNOWN value.

**AET, bits [15:14]**

Asynchronous Error Type. When the RAS Extension is implemented, this field describes the state of the PE after taking an asynchronous Data Abort exception. Possible values are:

- 0b00: Uncontainable error (UC) or uncategorized.
- 0b01: Unrecoverable error (UEU).
- 0b10: Restartable error (UEO) or Corrected error (CE).
- 0b11: Recoverable error (UER).
When the RAS Extension is not implemented, or on a synchronous Data Abort, this field is RES0.

--- Note ---

Armv8.2 requires the implementation of the RAS Extension.

--- Note ---

In the event of multiple errors taken as a single SError interrupt exception, the overall state of the PE is reported.

--- Note ---

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

This field resets to an architecturally UNKNOWN value.

**CM, bit [13]**

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance instruction generated the fault. The possible values of this bit are:

- 0b0: Abort not caused by execution of a cache maintenance instruction.
- 0b1: Abort caused by execution of a cache maintenance instruction, or on an address translation.

On a synchronous Data Abort on a translation table walk, this bit is UNKNOWN.

On an asynchronous fault, this bit is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

**ExT, bit [12]**

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of External aborts.

In an implementation that does not provide any classification of External aborts, this bit is RES0.

For aborts other than External aborts this bit always returns 0.

This field resets to an architecturally UNKNOWN value.

**WnR, bit [11]**

Write not Read bit. Indicates whether the abort was caused by a write or a read instruction. The possible values of this bit are:

- 0b0: Abort caused by a read instruction.
- 0b1: Abort caused by a write instruction.

For faults on the cache maintenance and address translation System instructions in the (coproc==0b1111) encoding space this bit always returns a value of 1.

This field resets to an architecturally UNKNOWN value.

**FS[4], bit [10]**

This field is bit[4] of FS[4:0].

Fault status bits. Possible values of FS[4:0] are:

- 0b00001: Alignment fault
- 0b00010: Debug exception
- 0b00011: Access flag fault, level 1
- 0b00100: Fault on instruction cache maintenance
- 0b00101: Translation fault, level 1
- 0b00110: Access flag fault, level 2
- 0b00111: Translation fault, level 2
0b01000  Synchronous External abort, not on translation table walk
0b01001  Domain fault, level 1
0b01011  Domain fault, level 2
0b01100  Synchronous External abort, on translation table walk, level 1
0b01101  Permission fault, level 1
0b01110  Synchronous External abort, on translation table walk, level 2
0b01111  Permission fault, level 2
0b10000  TLB conflict abort
0b10100  IMPLEMENTATION DEFINED fault (Lockdown fault)
0b10101  IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
0b10110  SError interrupt
0b11000  SError interrupt, from a parity or ECC error on memory access
0b11001  Synchronous parity or ECC error on memory access, not on translation table walk
0b11100  Synchronous parity or ECC error on translation table walk, level 1
0b11110  Synchronous parity or ECC error on translation table walk, level 2

All other values are reserved.

When the RAS Extension is implemented, 0b11000, 0b11001, 0b11100, and 0b11110, are reserved.

For more information about the lookup level associated with a fault, see The level associated with MMU faults on a Short-descriptor translation table lookup on page G5-5572.

The FS field is split as follows:
- FS[4] is DFSR[10].
- FS[3:0] is DFSR[3:0].

This field resets to an architecturally UNKNOWN value.

**LPAE, bit [9]**

On taking a Data Abort exception, this bit is set as follows:
- 0b0 Using the Short-descriptor translation table formats.
- 0b1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

This field resets to an architecturally UNKNOWN value.

**Bit [8]**

Reserved, RES0.

**Domain, bits [7:4]**

The domain of the fault address.

Arm deprecates any use of this field, see The Domain field in the DFSR on page G5-5572.

This field is UNKNOWN for certain faults where the DFSR is updated and reported using the Short-descriptor FSR encodings, see Table G5-30 on page G5-5576.

This field resets to an architecturally UNKNOWN value.

**FS[3:0], bits [3:0]**

This field is bits[3:0] of FS[4:0].

When TTBCR.EAE == 1:

<table>
<thead>
<tr>
<th>31</th>
<th>17 16 15 14 13 12 11 10 9 8 6 5 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>AET</td>
</tr>
</tbody>
</table>

FnV, bit [16]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

- **0b0**: DFAR is valid.
- **0b1**: DFAR is not valid, and holds an UNKNOWN value.

This field is only valid for a synchronous External abort other than a synchronous External abort on a translation table walk. It is RES0 for all other Data Abort exceptions.

This field resets to an architecturally UNKNOWN value.

AET, bits [15:14]

Asynchronous Error Type. When the RAS Extension is implemented, this field describes the state of the PE after taking an asynchronous Data Abort exception. Possible values are:

- **0b00**: Uncontainable error (UC) or uncategorized.
- **0b01**: Unrecoverable error (UEU).
- **0b10**: Restartable error (UEO) or Corrected error (CE).
- **0b11**: Recoverable error (UER).

When the RAS Extension is not implemented, or on a synchronous Data Abort, this field is RES0.

--- Note ---

Armv8.2 requires the implementation of the RAS Extension.

--- Note ---

In the event of multiple errors taken as a single SError interrupt exception, the overall state of the PE is reported.

--- Note ---

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

This field resets to an architecturally UNKNOWN value.

CM, bit [13]

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance instruction generated the fault. The possible values of this bit are:

- **0b0**: Abort not caused by execution of a cache maintenance instruction.
- **0b1**: Abort caused by execution of a cache maintenance instruction.

On a synchronous Data Abort on a translation table walk, this bit is UNKNOWN.
On an asynchronous fault, this bit is **UNKNOWN**.
This field resets to an architecturally **UNKNOWN** value.

**ExT, bit [12]**
External abort type. This bit can be used to provide an **IMPLEMENTATION DEFINED** classification of External aborts.
In an implementation that does not provide any classification of External aborts, this bit is **RES0**.
For aborts other than External aborts this bit always returns **0**.
This field resets to an architecturally **UNKNOWN** value.

**WnR, bit [11]**
Write not Read bit. Indicates whether the abort was caused by a write or a read instruction. The possible values of this bit are:

- **0b0**: Abort caused by a read instruction.
- **0b1**: Abort caused by a write instruction.

For faults on the cache maintenance and address translation System instructions in the (coproc==**0b1111**) encoding space this bit always returns a value of **1**.
This field resets to an architecturally **UNKNOWN** value.

**Bit [10]**
Reserved, **RES0**.

**LPAE, bit [9]**
On taking a Data Abort exception, this bit is set as follows:

- **0b0**: Using the Short-descriptor translation table formats.
- **0b1**: Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.
This field resets to an architecturally **UNKNOWN** value.

**Bits [8:6]**
Reserved, **RES0**.

**STATUS, bits [5:0]**
Fault status bits. Possible values of this field are:

- **0b000000**: Address size fault in **TTBR0** or **TTBR1**.
- **0b000001**: Address size fault, level 1.
- **0b000010**: Address size fault, level 2.
- **0b000011**: Address size fault, level 3.
- **0b000100**: Translation fault, level 1.
- **0b000101**: Translation fault, level 2.
- **0b000110**: Translation fault, level 3.
- **0b000111**: Access flag fault, level 1.
- **0b001001**: Access flag fault, level 2.
- **0b001010**: Access flag fault, level 3.
- **0b001011**: Permission fault, level 1.
- **0b001100**: Permission fault, level 2.
- **0b001101**: Permission fault, level 3.
- **0b010000**: Synchronous External abort, not on translation table walk.
0b010001  SError interrupt.
0b010101  Synchronous External abort, on translation table walk, level 1.
0b010110  Synchronous External abort, on translation table walk, level 2.
0b011011  Synchronous External abort, on translation table walk, level 3.
0b011000  Synchronous parity or ECC error on memory access, not on translation table walk.
0b011101  SError interrupt, from a parity or ECC error on memory access.
0b011110  Synchronous parity or ECC error on memory access on translation table walk, level 1.
0b011111  Synchronous parity or ECC error on memory access on translation table walk, level 2.
0b011111  Synchronous parity or ECC error on memory access on translation table walk, level 3.
0b100001  Alignment fault.
0b100010  Debug exception.
0b110000  TLB conflict abort.
0b110100  IMPLEMENTATION DEFINED fault (Lockdown fault).
0b110101  IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault).
All other values are reserved.
When the RAS Extension is implemented, 0b011000, 0b011001, 0b011101, 0b011110, and 0b011111, are reserved.
For more information about the lookup level associated with a fault, see The level associated with MMU faults on a Long-descriptor translation table lookup on page G5-5574.
This field resets to an architecturally UNKNOWN value.

Accessing the DFSR

G8.2.45   DTLBIALL, Data TLB Invalidate All

The DTLBIALL characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from data TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at Secure EL1 when EL3 is using AArch64, all entries that would be required for the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at Non-secure EL1, all stage 1 translation table entries that would be required for the Non-secure PL1&0 translation regime and, if EL2 is implemented, they must match the current VMID.
- If executed at EL2, the stage 1 or stage 2 translation table entries that would be required for the Non-secure PL1&0 translation regime and matches the current VMID.

The invalidation only applies to the PE that executes this System instruction.

Arm deprecates the use of this System instruction. It is only provided for backwards compatibility with earlier versions of the Arm architecture.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DTLBIALL is a 32-bit System instruction.

**Field descriptions**

DTLBIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the DTLBIALL instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MCR<\langle c\rangle,<q\rangle,<coproc>,<opc1>,<Rt>,<CRn>,<CRm>,<opc2>\]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>0b000</td>
<td>0b1000</td>
<td>0b0110</td>
<td>0b000</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then
  if EL2Enabled() && ELUsingAArch32(EL2) && HSTR_EL2.T8 == '1' then
    AArch64.AArch32SystemAccessTrap(EL2, 0x03);
  elsif EL2Enabled() && ELUsingAArch32(EL2) && HSTR.T8 == '1' then
    AArch32.TakeHypTrapException(0x03);
  elsif EL2Enabled() && ELUsingAArch32(EL2) && HCR_EL2.TTLB == '1' then
    AArch64.AArch32SystemAccessTrap(EL2, 0x03);
  elsif EL2Enabled() && ELUsingAArch32(EL2) && HCR.TTLB == '1' then
    AArch32.TakeHypTrapException(0x03);
  else
    DTLBIALL();
  elsif PSTATE.EL == EL2 then
    DTLBIALL();

elsif PSTATE.EL == EL3 then
  DTLBIAALL();
G8.2.46 DTLBIASID, Data TLB Invalidate by ASID match

The DTLBIASID characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from data TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

Arm deprecates the use of this System instruction. It is only provided for backwards compatibility with earlier versions of the Arm architecture.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DTLBIASID is a 32-bit System instruction.

**Field descriptions**

The DTLBIASID input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>8</td>
<td>7</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this System instruction.

**Executing the DTLBIASID instruction**

Accesses to this register use the following encodings in the System instruction encoding space:
MCR{<c>}{<q>}, <coproc>, #<opc1>, <Rt>, <CRn>, <CRm>{, #<opc2>}

<table>
<thead>

G8.2.47 DTLBIMVA, Data TLB Invalidate by VA

The DTLBIMVA characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from data TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

Arm deprecates the use of this System instruction. It is only provided for backwards compatibility with earlier versions of the Arm architecture.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DTLBIMVA is a 32-bit System instruction.

**Field descriptions**

The DTLBIMVA input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

**Bits [11:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.
Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

**Executing the DTLBIMVA instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MCR\{<c>\}{<q>} \{\#\}<opc1>, <Rt>, <CRn>, <CRm\}{, \{\#\}<opc2>}
\]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>0b000</td>
<td>0b1000</td>
<td>0b0110</td>
<td>0b001</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then

    DTLBIMVA(R[t]);

endif
**G8.2.48 ELR_hyp, Exception Link Register (Hyp mode)**

The ELR_hyp characteristics are:

**Purpose**

When taking an exception to Hyp mode, holds the address to return to.

**Configurations**

AArch32 System register ELR_hyp[31:0] is architecturally mapped to AArch64 System register ELR_EL2[31:0].

On a reset into an Exception level that is using AArch32 ELR_hyp is UNKNOWN.

**Attributes**

ELR_hyp is a 32-bit register.

**Field descriptions**

The ELR_hyp bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return address</td>
<td>This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the ELR_hyp**

ELR_hyp is accessible only at Hyp mode and Monitor mode. For more details, see MRS (Banked register) and MSR (Banked register) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS<reg>{<c>{<q>}, ELR_hyp**

<table>
<thead>
<tr>
<th>R</th>
<th>M</th>
<th>M1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>0b1</td>
<td>0b1110</td>
</tr>
</tbody>
</table>

**MSR<reg>{<c>{<q>}, ELR_hyp, <Rn>**

<table>
<thead>
<tr>
<th>R</th>
<th>M</th>
<th>M1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>0b1</td>
<td>0b1110</td>
</tr>
</tbody>
</table>
FCSEIDR, FCSE Process ID register

The FCSEIDR characteristics are:

**Purpose**

Identifies whether the Fast Context Switch Extension (FCSE) is implemented.

In Armv8, the FCSE is not implemented, so this register is RAZ/WI. Software can access this register to determine that the implementation does not include the FCSE.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

FCSEIDR is a 32-bit register.

**Field descriptions**

The FCSEIDR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RAZ/WI</td>
</tr>
</tbody>
</table>

**Accessing the FCSEIDR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC} \{c\}\{q\} <\text{coproc}>, \{#\} <\text{opc}1>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>, \{#\} <\text{opc}2> 
\]

<table>

G8.2.50  FPEXC, Floating-Point Exception Control register

The FPEXC characteristics are:

**Purpose**

Provides a global enable for the implemented Advanced SIMD and floating-point functionality, and reports floating-point status information.

**Configurations**

AArch32 System register FPEXC[31:0] is architecturally mapped to AArch64 System register FPEXC32_EL2[31:0].

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

FPEXC is a 32-bit register.

**Field descriptions**

The FPEXC bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 11 | 10 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| EX | EN | DEX | FP2V | TFV | RES0 | VECITR | IOF | DZF | OFF | UFF | IXF | RES0 | IDF |

**EX, bit [31]**

Exception bit. In Armv8, this bit is RAZ/WI. This field resets to an architecturally UNKNOWN value.

**EN, bit [30]**

Enables access to the Advanced SIMD and floating-point functionality from all Exception levels, except that setting this field to 0 does not disable the following:

- VMSR accesses to the FPEXC or FPSID.
- VMRS accesses from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2.

0b0  Accesses to the FPSCR, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers, are UNDEFINED at all Exception levels.

0b1  This control permits access to the Advanced SIMD and floating-point functionality at all Exception levels.

Execution of floating-point and Advanced SIMD instructions in AArch32 state can be disabled or trapped by the following controls:

- CPACR.cp10, or, if executing at EL0, CPACR_EL1.FPEN.
• FPEXC.EN.
• If executing in Non-secure state:
  — HCPTR.TCP10, or if EL2 is using AArch64, CPTR_EL2.TFP.
  — NSACR.cp10, or if EL3 is using AArch64, CPTR_EL3.TFP.
• For Advanced SIMD instructions only:
  — CPACR.ASEDIS.
  — If executing in Non-secure state, HCPTR.TASE and NSACR.NSTRCDIS.

See the descriptions of the controls for more information.

**Note**

When executing at EL0 using AArch32:

• If EL1 is using AArch64 then behavior is as if the value of FPEXC.EN is 1.
• If EL2 is using AArch64 and enabled in the current Security state, and the value of HCR_EL2.{RW, TGE} is \{1, 1\}, then the behavior is as if the value of FPEXC.EN is 1.
• If EL2 is using AArch64 and enabled in the current Security state, and the value of HCR_EL2.{RW, TGE} is \{0, 1\}, then it is IMPLEMENTATION DEFINED whether the behavior is:
  — As if the value of FPEXC.EN is 1.
  — Determined by the value of FPEXC.EN, as described in this field description. However, Arm deprecates using the value of FPEXC.EN to determine behavior.

This field resets to 0.

**DEX, bit [29]**

Defined synchronous exception on floating-point execution.

This field identifies whether a synchronous exception generated by the attempted execution of an instruction was generated by an unallocated encoding. The instruction must be in the encoding space that is identified by the pseudocode function ExecutingCP10or11Instr() returning TRUE. This field also indicates whether the FPEXC.TFV field is valid.

The meaning of this bit is:

0b0  The exception was generated by the attempted execution of an unallocated instruction in the encoding space that is identified by the pseudocode function ExecutingCP10or11Instr(). If FPEXC.TFV is RW then it is invalid and UNKNOWN. If FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} are RW then they are invalid and UNKNOWN.

0b1  The exception was generated during the execution of an unallocated encoding. FPEXC.TFV is valid and indicates the cause of the exception.

On an exception that sets this bit to 1 the exception-handling routine must clear this bit to 0.

On an implementation that both does not support trapping of floating-point exceptions and implements the FPSCR.{Stride, Len} fields as RAZ, this bit is RES0.

This field resets to an architecturally UNKNOWN value.

**FP2V, bit [28]**

FPINST2 instruction valid bit. In Armv8, this bit is RES0.

This field resets to an architecturally UNKNOWN value.

**VV, bit [27]**

VECITR valid bit. In Armv8, this bit is RES0.

This field resets to an architecturally UNKNOWN value.
TFV, bit [26]
Trapped Fault Valid bit. Valid only when the value of FPEXC.DEX is 1. When valid, it indicates the cause of the exception and therefore whether the FPEXC. {IDF, IXF, UFF, OFF, DZF, IOF} bits are valid.

0b0 The exception was caused by the execution of a floating-point VABS, VADD, VDIV, VFMA, VFMS, VFNMA, VFNMS, VMLA, VMLS, VMOV, VMUL, VNMLA, VNMLS, VNMLD, VSQRT, or VSUB instruction when one or both of FPSCR. {Stride, Len} was non-zero. If the FPEXC. {IDF, IXF, UFF, OFF, DZF, IOF} bits are RW then they are invalid and UNKNOWN.

0b1 FPEXC. {IDF, IXF, UFF, OFF, DZF, IOF} indicate the presence of trapped floating-point exceptions that had occurred at the time of the exception. Bits are set for all trapped exceptions that had occurred at the time of the exception.

This bit returns a status value and ignores writes.
When the value of FPEXC.DEX is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
On an implementation that supports the trapping of floating-point exceptions and implements FPSCR. {Stride, Len} as RAZ, this bit is RAO/WI.
This field resets to an architecturally UNKNOWN value.

Bits [25:11]
Reserved, RES0.

VECITR, bits [10:8]
Vector iteration count. In Armv8, this field is RES1.
This field resets to an architecturally UNKNOWN value.

IDF, bit [7]
Input Denormal trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Input Denormal exception occurred while FPSCR.IDE was 1:

0b0 Input Denormal exception has not occurred.
0b1 Input Denormal exception has occurred.

Input Denormal exceptions can occur only when FPSCR.FZ is 1.

Note
A half-precision floating-point value that is flushed to zero because the value of FPSCR.FZ16 is 1 does not generate an Input Denormal exception.

This bit must be cleared to 0 by the exception-handling routine.
When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.
This field resets to an architecturally UNKNOWN value.

Bits [6:5]
Reserved, RES0.

IXF, bit [4]
Inexact trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Inexact exception occurred while FPSCR.IXE was 1:

0b0 Inexact exception has not occurred.
0b1 Inexact exception has occurred.
This bit must be cleared to 0 by the exception-handling routine. When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

This field resets to an architecturally UNKNOWN value.

**UFF, bit [3]**

Underflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

- 0b0: Underflow exception has not occurred.
- 0b1: Underflow exception has occurred.

Underflow trapped exceptions can occur:
- On half-precision data-processing instructions only when FPSCR.FZ16 is 0.
- Otherwise only when FPSCR.FZ is 0.

This bit must be cleared to 0 by the exception-handling routine. When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

This field resets to an architecturally UNKNOWN value.

**OFF, bit [2]**

Overflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

- 0b0: Overflow exception has not occurred.
- 0b1: Overflow exception has occurred.

This bit must be cleared to 0 by the exception-handling routine. When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

This field resets to an architecturally UNKNOWN value.

**DZF, bit [1]**

Divide by Zero trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether a Divide by Zero exception occurred while FPSCR.DZE was 1:

- 0b0: Divide by Zero exception has not occurred.
- 0b1: Divide by Zero exception has occurred.

This bit must be cleared to 0 by the exception-handling routine. When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

This field resets to an architecturally UNKNOWN value.

**IOF, bit [0]**

Invalid Operation trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

- 0b0: Invalid Operation exception has not occurred.
- 0b1: Invalid Operation exception has occurred.

This bit must be cleared to 0 by the exception-handling routine. When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.
On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

This field resets to an architecturally UNKNOWN value.

### Accessing the FPEXC

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{VMRS} \{<c>\} \{<q>\} \text{ <Rt>, <spec_reg>} 
\]

<table>
<thead>
<tr>

G8.2.51 FPSCR, Floating-Point Status and Control Register

The FPSCR characteristics are:

Purpose
Provides floating-point system status information and control.

Configurations
The named fields in this register map to the equivalent fields in the AArch64 FPCR and FPSR.
It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.
Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.
RW fields in this register reset to architecturally UNKNOWN values.

Attributes
FPSCR is a 32-bit register.

Field descriptions
The FPSCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>N</td>
<td>Negative condition flag. This is updated by floating-point comparison operations. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>30</td>
<td>Z</td>
<td>Zero condition flag. This is updated by floating-point comparison operations. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>29</td>
<td>C</td>
<td>Carry condition flag. This is updated by floating-point comparison operations. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>
V, bit [28]
Overflow condition flag. This is updated by floating-point comparison operations.
This field resets to an architecturally UNKNOWN value.

QC, bit [27]
Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.
This field resets to an architecturally UNKNOWN value.

AHP, bit [26]
Alternative half-precision control bit:
0b0 IEEE half-precision format selected.
0b1 Alternative half-precision format selected.
This bit is only used for conversions between half-precision floating-point and other floating-point formats.
The data-processing instructions added as part of the ARMv8.2-FP16 extension always use the IEEE half-precision format, and ignore the value of this bit.
This field resets to an architecturally UNKNOWN value.

DN, bit [25]
Default NaN mode control bit:
0b0 NaN operands propagate through to the output of a floating-point operation.
0b1 Any operation involving one or more NaNs returns the Default NaN.
The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Default NaN setting, regardless of the value of the DN bit.
This field resets to an architecturally UNKNOWN value.

FZ, bit [24]
Flush-to-zero mode control bit:
0b0 Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
0b1 Flush-to-zero mode enabled.
The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Flush-to-zero setting, regardless of the value of the FZ bit.
This bit has no effect on half-precision calculations.
This field resets to an architecturally UNKNOWN value.

RMode, bits [23:22]
Rounding Mode control field. The encoding of this field is:
0b00 Round to Nearest (RN) mode.
0b01 Round towards Plus Infinity (RP) mode.
0b10 Round towards Minus Infinity (RM) mode.
0b11 Round towards Zero (RZ) mode.
The specified rounding mode is used by almost all scalar floating-point instructions. Advanced SIMD arithmetic always uses the Round to Nearest setting, regardless of the value of the RMode bits.
This field resets to an architecturally UNKNOWN value.

Stride, bits [21:20]
It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.
If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions. Arm strongly recommends that software never sets this field to a value other than zero. The value of this field is ignored when processing Advanced SIMD instructions. This field resets to an architecturally UNKNOWN value.

FZ16, bit [19]

When ARMv8.2-FP16 is implemented:
Flush-to-zero mode control bit on half-precision data-processing instructions:

- 0b0  Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
- 0b1  Flush-to-zero mode enabled.

The value of this bit applies to both scalar and Advanced SIMD floating-point half-precision calculations. This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Len, bits [18:16]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions. Arm strongly recommends that software never sets this field to a value other than zero. The value of this field is ignored when processing Advanced SIMD instructions. This field resets to an architecturally UNKNOWN value.

IDE, bit [15]

Input Denormal floating-point exception trap enable. Possible values are:

- 0b0  Untrapped exception handling selected. If the floating-point exception occurs then the IDC bit is set to 1.
- 0b1  Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IDC bit. The trap handling software can decide whether to set the IDC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RAZ/WI.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state. This field resets to an architecturally UNKNOWN value.

Bits [14:13]

Reserved, RES0.

IXE, bit [12]

Inexact floating-point exception trap enable. Possible values are:

- 0b0  Untrapped exception handling selected. If the floating-point exception occurs then the IXC bit is set to 1.
- 0b1  Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IXC bit. The trap handling software can decide whether to set the IXC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RAZ/WI.
When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.
This field resets to an architecturally UNKNOWN value.

**UFE, bit [11]**
Underflow floating-point exception trap enable. Possible values are:
0b0 Untrapped exception handling selected. If the floating-point exception occurs then the UFC bit is set to 1.
0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the UFC bit. The trap handling software can decide whether to set the UFC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RAZ/WI.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.
This field resets to an architecturally UNKNOWN value.

**OFE, bit [10]**
Overflow floating-point exception trap enable. Possible values are:
0b0 Untrapped exception handling selected. If the floating-point exception occurs then the OFC bit is set to 1.
0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the OFC bit. The trap handling software can decide whether to set the OFC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RAZ/WI.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.
This field resets to an architecturally UNKNOWN value.

**DZE, bit [9]**
Divide by Zero floating-point exception trap enable. Possible values are:
0b0 Untrapped exception handling selected. If the floating-point exception occurs then the DZC bit is set to 1.
0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the DZC bit. The trap handling software can decide whether to set the DZC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RAZ/WI.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.
This field resets to an architecturally UNKNOWN value.

**IOE, bit [8]**
Invalid Operation floating-point exception trap enable. Possible values are:
0b0 Untrapped exception handling selected. If the floating-point exception occurs then the IOC bit is set to 1.
0b1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IOC bit. The trap handling software can decide whether to set the IOC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RAZ/WI.
When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

This field resets to an architecturally UNKNOWN value.

IDC, bit [7]

Input Denormal cumulative floating-point exception bit. This bit is set to 1 to indicate that the Input Denormal floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IDE bit.

Advanced SIMD instructions set this bit if the Input Denormal floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IDE bit.

This field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXC, bit [4]

Inexact cumulative floating-point exception bit. This bit is set to 1 to indicate that the Inexact floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IXE bit.

Advanced SIMD instructions set this bit if the Inexact floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IXE bit.

This field resets to an architecturally UNKNOWN value.

UFC, bit [3]

Underflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Underflow floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the UFE bit.

Advanced SIMD instructions set this bit if the Underflow floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the UFE bit.

This field resets to an architecturally UNKNOWN value.

OFC, bit [2]

Overflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Overflow floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the OFE bit.

Advanced SIMD instructions set this bit if the Overflow floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the OFE bit.

This field resets to an architecturally UNKNOWN value.

DZC, bit [1]

Divide by Zero cumulative floating-point exception bit. This bit is set to 1 to indicate that the Divide by Zero floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the DZE bit.

Advanced SIMD instructions set this bit if the Divide by Zero floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the DZE bit.

This field resets to an architecturally UNKNOWN value.
IOC, bit [0]

Invalid Operation cumulative floating-point exception bit. This bit is set to 1 to indicate that the Invalid Operation floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IOE bit.

Advanced SIMD instructions set this bit if the Invalid Operation floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IOE bit.

This field resets to an architecturally UNKNOWN value.

G8.2.52  FPSID, Floating-Point System ID register

The FPSID characteristics are:

Purpose
Provides top-level information about the floating-point implementation.
This register largely duplicates information held in the MIDR. Arm deprecates use of it.

Configurations
Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.
RW fields in this register reset to architecturally UNKNOWN values.

Attributes
FPSID is a 32-bit register.

Field descriptions
The FPSID bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24 23 22</th>
<th>16 15</th>
<th>8 7</th>
<th>4 3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implementer</td>
<td>Subarchitecture</td>
<td>PartNum</td>
<td>Variant</td>
<td>Revision</td>
<td>SW</td>
</tr>
</tbody>
</table>

Implementer, bits [31:24]
Implementer codes are the same as those used for the MIDR.
For an implementation by Arm this field is 0x41, the ASCII code for A.
This field resets to an architecturally UNKNOWN value.

SW, bit [23]
Software bit. Defined values are:

0b0  The implementation provides a hardware implementation of the floating-point instructions.

0b1  The implementation supports only software emulation of the floating-point instructions.
In Armv8-A the only permitted value is 0b0.
This field resets to an architecturally UNKNOWN value.

Subarchitecture, bits [22:16]
Subarchitecture version number. For an implementation by Arm, defined values are:

0b0000000  VFPv1 architecture with an IMPLEMENTATION DEFINED subarchitecture.
0b0000001  VFPv2 architecture with Common VFP subarchitecture v1.
0b0000010  VFPv3 architecture, or later, with Common VFP subarchitecture v2. The VFP architecture version is indicated by the MVFR0 and MVFR1 registers.
0b0000011  VFPv3 architecture, or later, with Null subarchitecture. The entire floating-point implementation is in hardware, and no software support code is required. The VFP architecture version is indicated by the MVFR0 and MVFR1 registers. This value can be used only by an implementation that does not support the trap enable bits in the FPSCR.
0b0000100  VFPv3 architecture, or later, with Common VFP subarchitecture v3, and support for trap enable bits in FPSCR. The VFP architecture version is indicated by the MVFR0 and MVFR1 registers.

For a subarchitecture designed by Arm the most significant bit of this field, register bit[22], is 0. Values with a most significant bit of 0 that are not listed here are reserved.

When the subarchitecture designer is not Arm, the most significant bit of this field, register bit[22], must be 1. Each implementer must maintain its own list of subarchitectures it has designed, starting at subarchitecture version number 0x40.

In Armv8-A the permitted values are 0b0000011 and 0b0000100.

This field resets to an architecturally UNKNOWN value.

PartNum, bits [15:8]
An IMPLEMENTATION DEFINED part number for the floating-point implementation, assigned by the implementer.

This field resets to an architecturally UNKNOWN value.

Variant, bits [7:4]
An IMPLEMENTATION DEFINED variant number. Typically, this field distinguishes between different production variants of a single product.

This field resets to an architecturally UNKNOWN value.

Revision, bits [3:0]
An IMPLEMENTATION DEFINED revision number for the floating-point implementation.

This field resets to an architecturally UNKNOWN value.

Accessing the FPSID
Accesses to this register use the following encodings in the System instruction encoding space:

G8.2.53 HACR, Hyp Auxiliary Configuration Register

The HACR characteristics are:

**Purpose**
Controls trapping to Hyp mode of IMPLEMENTATION DEFINED aspects of Non-secure EL1 or EL0 operation.

**Configurations**
AArch32 System register HACR[31:0] is architecturally mapped to AArch64 System register HACR_EL2[31:0].
If EL2 is not implemented, this register is RES0 from EL3.
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
HACR is a 32-bit register.

**Field descriptions**
The HACR bit assignments are:

G8.2.55 HACTLR2, Hyp Auxiliary Control Register 2

The HACTLR2 characteristics are:

**Purpose**

Provides additional space to the HACTLR register to hold IMPLEMENTATION DEFINED trap functionality.

**Configurations**

AArch32 System register HACTLR2[31:0] is architecturally mapped to AArch64 System register ACTLR_EL2[63:32].

In Armv8.0 and Armv8.1, it is IMPLEMENTATION DEFINED whether this register is implemented, or whether it causes UNDEFINED exceptions when accessed. The implementation of this register can be detected by examining ID_MMFR4.AC2.

From Armv8.2 this register must be implemented.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HACTLR2 is a 32-bit register.

**Field descriptions**

The HACTLR2 bit assignments are:

<table>
<thead>
<tr>
<th>Field assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED, bits [31:0]</td>
<td>IMPLEMENTATION DEFINED. This field resets to an architecturally UNKNOWN value.</td>

### G8.2.58 HAMAIR0, Hyp Auxiliary Memory Attribute Indirection Register 0

The HAMAIR0 characteristics are:

**Purpose**

Provides IMPLEMENTATIONDEFINED memory attributes for the memory attribute encodings defined by HMAIR0. These IMPLEMENTATIONDEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in HMAIR0.

**Configurations**

AArch32 System register HAMAIR0[31:0] is architecturally mapped to AArch64 System register AMAIR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HAMAIR0 is a 32-bit register.

**Field descriptions**

The HAMAIR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>

G8.2.60   HCPTR, Hyp Architectural Feature Trap Register

The HCPTR characteristics are:

Purpose

Controls:

• Trapping to Hyp mode of Non-secure access, at EL1 or EL0, to trace, and to Advanced SIMD and floating-point functionality.
• Hyp mode access to trace, and to Advanced SIMD and floating-point functionality.

Note

Accesses to this functionality:

• From Non-secure modes other than Hyp mode are also affected by settings in the CPACR and NSACR.
• From Hyp mode are also affected by settings in the NSACR.

Exceptions generated by the CPACR and NSACR controls are higher priority than those generated by the HCPTR controls.

Configurations

AArch32 System register HCPTR[31:0] is architecturally mapped to AArch64 System register CPTR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HCPTR is a 32-bit register.

Field descriptions

The HCPTR bit assignments are:

TCPAC, bit [31]

Traps Non-secure EL1 accesses to the CPACR to Hyp mode.

0b0  This control does not cause any instructions to be trapped.
0b1  Non-secure EL1 accesses to the CPACR are trapped to Hyp mode.

Note

The CPACR is not accessible at EL0.

In a system where the PE resets into EL2 or EL3, this field resets to 0.
TAM, bit [30]

When AMUv1 is implemented:

Trap Activity Monitor access. Traps Non-secure EL1 and EL0 accesses to all Activity Monitor registers to EL2.

0b0  Accesses from Non-secure EL1 and EL0 to Activity Monitor registers are not trapped.

0b1  Accesses from Non-secure EL1 and EL0 to Activity Monitor registers are trapped to Hyp mode.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

Otherwise:

Reserved, RES0.

Bits [29:21]

Reserved, RES0.

TTA, bit [20]

Traps Non-secure System register accesses to all implemented trace registers to Hyp mode.

0b0  This control does not cause any instructions to be trapped.

0b1  Any Non-secure System register access to an implemented trace register is trapped to Hyp mode, unless the access is trapped to EL1 by a CPACR or NSACR control, or the access is from Non-secure EL0 and the definition of the register in the appropriate trace architecture specification indicates that the register is not accessible from EL0. A trapped instruction generates:

- A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.
- An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode.

If the implementation does not include a PE trace unit, or does not include a System register interface to the PE trace unit registers, it is IMPLEMENTATION DEFINED whether this bit:

- Is RES0.
- Is RES1.
- Can be written from Hyp mode, and from Secure Monitor mode when SCR.NS is 1.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSTRCDIS is 1, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the implementation includes an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and a resulting Undefined Instruction exception is higher priority than a HCPR.TTA Hyp Trap exception.
- The architecture does not provide traps on trace register accesses through the optional memory-mapped debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

Bits [19:16]

Reserved, RES0.
TASE, bit [15]

Traps Non-secure execution of Advanced SIMD instructions to Hyp mode when the value of HCPTR.TCP10 is 0.

0b0 This control does not cause any instructions to be trapped.

0b1 When the value of HCPTR.TCP10 is 0, any attempt to execute an Advanced SIMD instruction in Non-secure state is trapped to Hyp mode, unless it is trapped to EL1 by a CPACR or NSACR control. A trapped instruction generates:

• A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.
• An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode.

When the value of HCPTR.TCP10 is 1, the value of this field is ignored.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, then it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSASEDIS is 1, in Non-secure state this field behaves as RAO/WI, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

For the list of instructions affected by this field, see Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-3554.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

Bit [14]

Reserved, RES0.

Bits [13:12]

Reserved, RES1.

TCP11, bit [11]

The value of this field is ignored. If this field is programmed with a different value to the TCP10 bit then this field is UNKNOWN on a direct read of the HCPTR.

TCP10, bit [10]

Trap Non-secure accesses to Advanced SIMD and floating-point functionality to Hyp mode:

0b0 This control does not cause any instructions to be trapped.

0b1 Any attempted access to Advanced SIMD and floating-point functionality from Non-secure state is trapped to Hyp mode, unless it is trapped to EL1 by a CPACR or NSACR control. A trapped instruction generates:

• A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.
• An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode.

The Advanced SIMD and floating-point features controlled by these fields are:

• Execution of any floating-point or Advanced SIMD instruction.
• Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
• Any access to the FPSCR, FPSID, MVFR0, MVFR1, MVFR2, or FPEXC System registers.
If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1.

If EL3 is implemented and is using AArch32, and the value of NSACR.cp10 is 0, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**Bits [9:0]**

Reserved, RES1.

**Accessing the HCPTR**

Accesses to this register use the following encodings in the System instruction encoding space:

G8.2.61  HCR, Hyp Configuration Register

The HCR characteristics are:

**Purpose**

Provides configuration controls for virtualization, including defining whether various Non-secure operations are trapped to Hyp mode.

**Configurations**

AArch32 System register HCR[31:0] is architecturally mapped to AArch64 System register HCR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HCR is a 32-bit register.

**Field descriptions**

The HCR bit assignments are:

- **Bit [31]**
  - Reserved, RES0.

- **TRVM, bit [30]**
  - Trap Reads of Virtual Memory controls. Traps Non-secure EL1 reads of the virtual memory control registers to EL2, when EL2 is enabled in the current Security state.

  The registers for which read accesses are trapped are as follows:
  - SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFS0, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

  **0x0** This control does not cause any instructions to be trapped.
Non-secure EL1 read accesses to the specified Virtual Memory controls are trapped to EL2.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**HCD, bit [29]**

HVC instruction disable. Disables Non-secure EL1 and EL2 execution of HVC instructions, when EL2 is enabled in the current Security state.

0b0 HVC instruction execution is enabled at EL2 and EL1.

0b1 HVC instructions are UNDEFINED at EL2 and Non-secure EL1.

The Undefined Instruction exception is taken to the Exception level at which the HVC instruction is executed.

--- Note ---

HVC instructions are always UNDEFINED at EL0.

---

This bit is only implemented if EL3 is not implemented. Otherwise, it is RES0.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**Bit [28]**

Reserved, RES0.

**TGE, bit [27]**

Trap General Exceptions, from Non-secure EL0.

0b0 This control has no effect on execution at EL0.

0b1 When EL2 is not enabled in the current Security state, this control has no effect on execution at EL0.

When EL2 is enabled in the current Security state, then:

- All exceptions that would be routed to EL1 are routed to EL2.
- The SCTLR.M bit is treated as being 0 for all purposes other than returning the result of a direct read of SCTLR.
- The HCR.{FMO, IMO, AMO} bits are treated as being 1 for all purposes other than returning the result of a direct read of HCR.
- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.
- An exception return to EL1 is treated as an illegal exception return.
- Monitor mode execution of an MSR or CPS instruction that changes CPSR.M to a Non-secure EL1 mode is an illegal change to PSTATE.M. For more information see *Illegal changes to PSTATE.M* on page G1-5243.

Also, when HCR.TGE is 1:

- If EL3 is using AArch32, an attempt to change from a Secure PL1 mode to a Non-secure EL1 mode by changing SCR.NS from 0 to 1 results in SCR.NS remaining as 0.
- The HDCR.{TDRA, TDOSA, TDA, TDE} bits are ignored and treated as being 1 other than for the purpose of a direct read of HDCR.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**TVM, bit [26]**

Trap Virtual Memory controls. Traps Non-secure EL1 writes to the virtual memory control registers to EL2, when EL2 is enabled in the current Security state.

The registers for which write accesses are trapped are as follows:
SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, DACR, DFSR, IFSR, DFAR, IFAR, ADIFSR, AIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

0b0  This control does not cause any instructions to be trapped.
0b1  Non-secure EL1 write accesses to the specified virtual memory control registers are trapped to EL2.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

TTLB, bit [25]

Trap TLB maintenance instructions. Traps Non-secure EL1 execution of a TLBI instruction to EL2, when EL2 is enabled in the current Security state.

This applies to the following instructions:
TLBIALLIS, TLBIMVAIS, TLBIALISDIS, TLBIMVAALIS, TLBIALISDIS, TLBIMVAALIS,
ITLBIALL, ITLBIMVA, ITLBIALIS, ITLBIMVAAL, ITLBIALL, ITLBIMVA, ITLBIALIS, ITLBIMVAAL

0b0  This control does not cause any instructions to be trapped.
0b1  Non-secure EL1 accesses to the specified TLB maintenance instructions are trapped to EL2.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

TPU, bit [24]

Trap cache maintenance instructions that operate to the Point of Unification. Traps Non-secure EL1 execution of those cache maintenance instructions to EL2, when EL2 is enabled in the current Security state.

This applies to the following instructions:
• ICIMVAU, ICIALLU, ICIALLUIS, DCCMV.

——— Note ————
An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

0b0  This control does not cause any instructions to be trapped.
0b1  Non-secure EL1 execution of the specified cache maintenance instructions is trapped to EL2.

If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean by VA to the Point of Unification instruction can be trapped when the value of this control is 1.

If the Point of Unification is before any level of instruction cache, it is IMPLEMENTATION DEFINED whether the execution of any instruction cache invalidate to the Point of Unification instruction can be trapped when the value of this control is 1.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

TPC, bit [23]

Trap data or unified cache maintenance instructions that operate to the Point of Coherency. Traps Non-secure EL1 execution of those cache maintenance instructions to EL2, when EL2 is enabled in the current Security state.

This applies to the following instructions:
• DCIMVC, DCCIMVC, DCCMV.

——— Note ————
An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

0b0  This control does not cause any instructions to be trapped.
0b1 Non-secure EL1 execution of the specified cache maintenance instructions is trapped to EL2.

If the Point of Coherency is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of any data or unified cache clean, invalidate, or clean and invalidate instruction that operates by VA to the point of coherency can be trapped when the value of this control is 1.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

TSW, bit [22]

Trap data or unified cache maintenance instructions that operate by Set/Way. Traps Non-secure EL1 execution of those cache maintenance instructions by set/way to EL2, when EL2 is enabled in the current Security state.

This applies to the following instructions:
- DCISW, DCCSW, DCCISW.

--- Note ---

An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

0b0 This control does not cause any instructions to be trapped.
0b1 Non-secure EL1 execution of the specified cache maintenance instructions is trapped to EL2.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

TAC, bit [21]

Trap Auxiliary Control Registers. Traps Non-secure EL1 accesses to the Auxiliary Control Registers to EL2, when EL2 is enabled in the current Security state, from both Execution states.

This applies to the following register accesses:
- ACTLR and, if implemented, ACTLR2.

0b0 This control does not cause any instructions to be trapped.
0b1 Non-secure EL1 accesses to the specified registers are trapped to EL2.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

TIDCP, bit [20]

Trap IMPLEMENTATION DEFINED functionality. Traps Non-secure EL1 accesses to the encodings for IMPLEMENTATION DEFINED System Registers to EL2, when EL2 is enabled in the current Security state.

MCR and MRC instructions accessing the following encodings:
- All coproc==p15, CRn==c9, Opcode1 = {0-7}, CRm == {c0-c2, c5-c8}, opcode2 == {0-7}.
- All coproc==p15, CRn==c10, Opcode1 == {0-7}, CRm == {c0, c1, c4, c8}, opcode2 == {0-7}.
- All coproc==p15, CRn==c11, Opcode1=={0-7}, CRm == {c0-c8, c15}, opcode2 == {0-7}.

When HCR.TIDCP is set to 1, it is IMPLEMENTATION DEFINED whether any of this functionality accessed from Non-secure EL0 is trapped to EL2. Otherwise, it is UNDEFINED and the PE takes an Undefined Instruction exception to Non-secure Undefined mode.

0b0 This control does not cause any instructions to be trapped.
0b1 Non-secure EL1 accesses to the specified System register encodings for IMPLEMENTATION DEFINED functionality are trapped to EL2.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

TSC, bit [19]

Trap SMC instructions. Traps Non-secure EL1 execution of SMC instructions to Hyp mode.

0b0 This control does not cause any instructions to be trapped.
Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to Hyp mode, regardless of the value of SCR.SCD.

The Armv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

--- Note ---
- This trap is only implemented if the implementation includes EL3.
- SMC instructions are always UNDEFINED at PL0.
- This bit traps execution of the SMC instruction. It is not a routing control for the SMC exception. Hyp Trap exceptions and SMC exceptions have different preferred return addresses.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**TID3, bit [18]**

Trap ID group 3. Traps Non-secure EL1 reads of the following registers to EL2, when EL2 is enabled in the current Security state:

- ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0, ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5, MVFR0, MVFR1, MVFR2, and ID_MMFR4, except that if ID_MMFR4 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether accesses to ID_MMFR4 are trapped.

Also, an MRC access to any of the following encodings:
- coproc==p15, opc1 == 0, CRn == c0, CRm == {c3-c7}, opc2 == {0,1}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c3, opc2 == 2.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c5, opc2 == {4,5}.

It is IMPLEMENTATION DEFINED whether this bit traps MRC accesses to the following encodings:
- coproc==p15, opc1 == 0, CRn == c0, CRm == c2, opc2 == 7.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c3, opc2 == {3-7}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == {c4, c6, c7}, opc2 == {2-7}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c5, opc2 == {2, 3, 6, 7}.

0b0 This control does not cause any instructions to be trapped.

0b1 The specified Non-secure EL1 read accesses to ID group 3 registers are trapped to EL2.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**TID2, bit [17]**

Trap ID group 2. Traps the following register accesses to EL2, when EL2 is enabled in the current Security state:

- Non-secure EL1 and EL0 reads of the CTR, CCSIDR, CCSIDR2, CLIDR, and CSSEL.R.
- Non-secure EL1 and EL0 writes to the CSSEL.R.

0b0 This control does not cause any instructions to be trapped.

0b1 The specified Non-secure EL1 and EL0 accesses to ID group 2 registers are trapped to EL2.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**TID1, bit [16]**

Trap ID group 1. Traps Non-secure EL1 reads of the following registers to EL2, when EL2 is enabled in the current Security state:

TCMTR, TLBTR, REVIDR, AIDR.

0b0 This control does not cause any instructions to be trapped.
The specified Non-secure EL1 read accesses to ID group 1 registers are trapped to EL2.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**TID0, bit [15]**

Trap ID group 0. Traps the following register accesses to EL2, when EL2 is enabled in the current Security state:

- Non-secure EL1 reads of the JIDR and FPSID.
- If the JIDR is RAZ from Non-secure EL0, Non-secure EL0 reads of the JIDR.

---

**Note**

- It is IMPLEMENTATION DEFINED whether the JIDR is RAZ or UNDEFINED at EL0. If it is UNDEFINED at EL0 then the Undefined Instruction exception takes precedence over this trap.
- The FPSID is not accessible at EL0.
- Writes to the FPSID are ignored, and not trapped by this control.

---

0b0  This control does not cause any instructions to be trapped.
0b1  The specified Non-secure EL1 read accesses to ID group 0 registers are trapped to EL2.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**TWE, bit [14]**

Traps Non-secure EL0 and EL1 execution of WFE instructions to EL2, when EL2 is enabled in the current Security state.

0b0  This control does not cause any instructions to be trapped.
0b1  Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWE.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

---

**Note**

Since a WFE can complete at any time, even without a Wakeup event, the traps on WFE are not guaranteed to be taken, even if the WFE is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**TWI, bit [13]**

Traps Non-secure EL0 and EL1 execution of WFI instructions to EL2, when EL2 is enabled in the current Security state.

0b0  This control does not cause any instructions to be trapped.
0b1  Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWI.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

---

**Note**

Since a WFI can complete at any time, even without a Wakeup event, the traps on WFI are not guaranteed to be taken, even if the WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

In a system where the PE resets into EL2 or EL3, this field resets to 0.
DC, bit [12]

Default Cacheability.

0b0  This control has no effect on the Non-secure EL1&0 translation regime.
0b1  In Non-secure state:

- The SCTLR.M field behaves as 0 for all purposes other than a direct read of the value of the field.
- The HCR.VM field behaves as 1 for all purposes other than a direct read of the value of the field.
- The memory type produced by the first stage of the EL1&0 translation regime is Normal Non-Shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate.

This field has no effect on the EL2 and EL3 translation regimes.

This field is permitted to be cached in a TLB.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

BSU, bits [11:10]

Barrier Shareability upgrade. This field determines the minimum shareability domain that is applied to any barrier instruction executed from Non-secure EL1 or Non-secure EL0:

0b00  No effect.
0b01  Inner Shareable.
0b10  Outer Shareable.
0b11  Full system.

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

FB, bit [9]

Force broadcast. Causes the following instructions to be broadcast within the Inner Shareable domain when executed from Non-secure EL1:

BPIALL, TLBIALL, TLBIMVA, TLBIASID, DTLBIALL, DTLBIMVA, DTLBIASID, ITLBIALL, ITLBIMVA, ITLBIASID, TLBIMVA, ICIALLU, TLBIMVAL, TLBIMVAAL.

0b0  This field has no effect on the operation of the specified instructions.
0b1  When one of the specified instruction is executed at Non-secure EL1, the instruction is broadcast within the Inner Shareable shareability domain.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

VA, bit [8]

Virtual SError interrupt exception.

0b0  This mechanism is not making a virtual SError interrupt pending.
0b1  A virtual SError interrupt is pending because of this mechanism.

The virtual SError interrupt is enabled only when the value of HCR.{TGE, AMO} is {0, 1}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

VI, bit [7]

Virtual IRQ exception.

0b0  This mechanism is not making a virtual IRQ pending.
0b1  A virtual IRQ is pending because of this mechanism.

The virtual IRQ is enabled only when the value of HCR.{TGE, IMO} is {0, 1}.
The Guest OS cannot distinguish the virtual exception from the corresponding physical exception. In a system where the PE resets into EL2 or EL3, this field resets to 0.

**VF, bit [6]**

Virtual FIQ exception.

- **0b0**: This mechanism is not making a virtual FIQ pending.
- **0b1**: A virtual FIQ is pending because of this mechanism.

The virtual FIQ is enabled only when the value of HCR.{TGE, FMO} is {0, 1}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception. In a system where the PE resets into EL2 or EL3, this field resets to 0.

**AMO, bit [5]**

SError interrupt Mask Override. When this bit is set to 1, it overrides the effect of CPSR.A, and enables virtual exception signaling by the VA bit.

If the value of HCR.TGE is 0, then virtual SError interrupts are enabled in Non-secure state.

If the value of HCR.TGE is 1, then in Non-secure state the HCR.AMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**IMO, bit [4]**

IRQ Mask Override. When this bit is set to 1, it overrides the effect of CPSR.I, and enables virtual exception signaling by the VI bit.

If the value of HCR.TGE is 0, then Virtual IRQ interrupts are enabled in the Non-secure state.

If the value of HCR.TGE is 1, then in Non-secure state the HCR.IMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**FMO, bit [3]**

FIQ Mask Override. When this bit is set to 1, it overrides the effect of CPSR.F, and enables virtual exception signaling by the VF bit.

If the value of HCR.TGE is 0, then Virtual FIQ interrupts are enabled in the Non-secure state.

If the value of HCR.TGE is 1, then in Non-secure state the HCR.FMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**PTW, bit [2]**

Protected Table Walk. In the Non-secure PL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two stages of translation means the access might be made to a type of Device memory. If this occurs then the value of this bit determines the behavior:

- **0b0**: The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.
- **0b1**: The memory access generates a stage 2 Permission fault.

This field is permitted to be cached in a TLB.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**SWIO, bit [1]**

Set/Way Invalidation Override. Causes Non-secure EL1 execution of the data cache invalidate by set/way instructions to perform a data cache clean and invalidate by set/way.

- **0b0**: This control has no effect on the operation of data cache invalidate by set/way instructions.
0b1

Data cache invalidate by set/way instructions perform a data cache clean and invalidate by set/way.

When this bit is set to 1, DCISW performs the same invalidation as a DCCISW instruction.

As a result of changes to the behavior of DCISW, this bit is redundant in Armv8. This bit can be implemented as RES1.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

VM, bit [0]

Virtualization enable. Enables stage 2 address translation for the Non-secure EL1&0 translation regime.

0b0 Non-secure EL1&0 stage 2 address translation disabled.

0b1 Non-secure EL1&0 stage 2 address translation enabled.

If the HCR.DC bit is set to 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with HCR.VM being 1, regardless of the actual value of HCR.VM, other than the value returned by an explicit read of HCR.VM.

When the value of this bit is 1, data cache invalidate instructions executed at Non-secure EL1 perform a data cache clean and invalidate. For the invalidate by set/way instruction this behavior applies regardless of the value of the HCR.SWIO bit.

This bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

Accessing the HCR

Accesses to this register use the following encodings in the System instruction encoding space:

\[

### HCR2, Hyp Configuration Register 2

The HCR2 characteristics are:

#### Purpose

Provides additional configuration controls for virtualization.

#### Configurations

AArch32 System register HCR2[31:0] is architecturally mapped to AArch64 System register HCR_EL2[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

#### Attributes

HCR2 is a 32-bit register.

#### Field descriptions

The HCR2 bit assignments are:

<table>
<thead>
<tr>

</tbody>
</table>

#### Bits [31:7]

Reserved, RES0.

#### MIOCNCE, bit [6]

Mismatched Inner/Outer Cacheable Non-Coherency Enable, for the Non-secure PL1&0 translation regime.

- **0b0**: For the Non-secure PL1&0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there must be no loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

- **0b1**: For the Non-secure PL1&0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there might be a loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

For more information see *Mismatched memory attributes on page E2-3602*. This field can be implemented as RAZ/WI.

In a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.
TEA, bit [5]
Route synchronous External abort exceptions from EL0 and EL1 to EL2. If the RAS Extension is implemented, the possible values of this bit are:

- **0b0**: Does not route synchronous External abort exceptions from Non-secure EL0 and EL1 to EL2.
- **0b1**: Route synchronous External abort exceptions from Non-secure EL0 and EL1 to EL2, if not routed to EL3.

When the RAS Extension is not implemented, this field is RES0.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

TERR, bit [4]

**When RAS is implemented:**

Error record accesses from EL1 to EL2. Trap accesses to the following registers from EL1 to EL2:
- ERRIDR, ERRSELR, ERXADDR, ERXADDR2, ERXCTLR, ERXCTLR2, ERXF, ERXF2, ERXMISC0, ERXMISC1, ERXMISC2, ERXMISC3, and ERXSTATUS. When ARMv8.4-RAS is implemented, ERXMISC4, ERXMISC5, ERXMISC6, and ERXMISC7.

- **0b0**: This control does not cause any instructions to be trapped.
- **0b1**: Accesses to the specified registers from EL1 generate a Trap exception to EL2.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**Otherwise:**
Reserved, RES0.

Bits [3:2]
Reserved, RES0.

ID, bit [1]
Stage 2 Instruction access cacheability disable. For the Non-secure PL1&0 translation regime, when HCR.VM==1, this control forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

- **0b0**: This control has no effect on stage 2 of the Non-secure PL1&0 translation regime.
- **0b1**: For the Non-secure PL1&0 translation regime, forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

This bit has no effect on the EL2 translation regime.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

CD, bit [0]
Stage 2 Data access cacheability disable. When HCR.VM==1, this forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the Non-secure PL1&0 translation regime.

- **0b0**: This control has no effect on stage 2 of the Non-secure PL1&0 translation regime for data accesses and translation table walks.
- **0b1**: For the Non-secure PL1&0 translation regime, forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

This bit has no effect on the EL2 translation regime.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**Accessing the HCR2**
Accesses to this register use the following encodings in the System instruction encoding space:
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

<table>
<thead>
<tr>

G8.2.63 HDFAR, Hyp Data Fault Address Register

The HDFAR characteristics are:

**Purpose**

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception that is taken to Hyp mode.

**Configurations**

AArch32 System register HDFAR[31:0] is architecturally mapped to AArch64 System register FAR_EL2[31:0].

AArch32 System register HDFAR[31:0] is architecturally mapped to AArch32 System register DFAR[31:0] (S) when when HaveEL(EL2), HaveEL(EL3) and HighestELUsingAArch32().

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HDFAR is a 32-bit register.

**Field descriptions**

The HDFAR bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [31:0]</td>
<td>VA of faulting address of synchronous Data Abort exception taken to Hyp mode.</td>
</tr>
</tbody>
</table>

On a Prefetch Abort exception, this register is UNKNOWN.

Any execution in a Non-secure EL1 or Non-secure EL0 mode makes this register UNKNOWN.

This field resets to an architecturally UNKNOWN value.

**Accessing the HDFAR**

Accesses to this register use the following encodings in the System instruction encoding space:

```
MRC{<c>{<q>}} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

<table>
<thead>
<tr>

G8.2.64  HIFAR, Hyp Instruction Fault Address Register

The HIFAR characteristics are:

**Purpose**

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception that is taken to Hyp mode.

**Configurations**

AArch32 System register HIFAR[31:0] is architecturally mapped to AArch64 System register FAR_EL2[63:32].

AArch32 System register HIFAR[31:0] is architecturally mapped to AArch32 System register IFAR[31:0] (S) when when HaveEL(EL2), HaveEL(EL3) and HighestELUsingAArch32().

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HIFAR is a 32-bit register.

**Field descriptions**

The HIFAR bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>

HMAIR0, Hyp Memory Attribute Indirection Register 0

The HMAIR0 characteristics are:

Purpose
Along with HMAIR1, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

AttrIndx[2] indicates the HMAIR register to be used:
- When AttrIndx[2] is 0, HMAIR0 is used.
- When AttrIndx[2] is 1, HMAIR1 is used.

Configurations
AArch32 System register HMAIR0[31:0] is architecturally mapped to AArch64 System register MAIR_EL2[31:0].
If EL2 is not implemented, this register is RES0 from EL3.
RW fields in this register reset to architecturally UNKNOWN values.

Attributes
HMAIR0 is a 32-bit register.

Field descriptions
The HMAIR0 bit assignments are:

When TTBCR.EAE == 1:

<table>
<thead>
<tr>
<th>31</th>
<th>24 23</th>
<th>16 15</th>
<th>8 7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr3</td>
<td>Attr2</td>
<td>Attr1</td>
<td>Attr0</td>
<td></td>
</tr>
</tbody>
</table>

Attr<n>, bits [8n+7:8n], for n = 0 to 3
The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:
- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>0b00RW, RW not 0b00</td>
<td>Normal memory, Outer Write-Through Transient.</td>
</tr>
<tr>
<td>0b0100</td>
<td>Normal memory, Outer Non-cacheable.</td>
</tr>
<tr>
<td>0b01RW, RW not 0b00</td>
<td>Normal memory, Outer Write-Back Transient.</td>
</tr>
<tr>
<td>0b10RW</td>
<td>Normal memory, Outer Write-Through Non-transient.</td>
</tr>
<tr>
<td>0b11RW</td>
<td>Normal memory, Outer Write-Back Non-transient.</td>
</tr>
</tbody>
</table>

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.
The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[3:0]</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is 0b0000</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is not 0b0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device-nGnRnE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>0b00RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Transient</td>
</tr>
<tr>
<td>0b0100</td>
<td>Device-nGnRE memory</td>
<td>Normal memory, Inner Non-cacheable</td>
</tr>
<tr>
<td>0b01RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Transient</td>
</tr>
<tr>
<td>0b1000</td>
<td>Device-nGRE memory</td>
<td>Normal memory, Inner Write-Through Non-transient (RW=0b00)</td>
</tr>
<tr>
<td>0b10RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Non-transient</td>
</tr>
<tr>
<td>0b1100</td>
<td>Device-GRE memory</td>
<td>Normal memory, Inner Write-Back Non-transient (RW=0b00)</td>
</tr>
<tr>
<td>0b11RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>0b1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

### Accessing the HMAIR0

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}{<q>}\text{<coproc>,}\{\#<opc1>,\text{<Rt>,}\text{<CRn>,}\text{<CRm>,}\{\#<opc2>\}}
\]

<table>
<thead>

### HMAIR1, Hyp Memory Attribute Indirection Register 1

The HMAIR1 characteristics are:

**Purpose**

Along with HMAIR0, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

AttrIndx[2] indicates the HMAIR register to be used:
- When AttrIndx[2] is 0, HMAIR0 is used.
- When AttrIndx[2] is 1, HMAIR1 is used.

**Configurations**

AArch32 System register HMAIR1[31:0] is architecturally mapped to AArch64 System register MAIR_EL2[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HMAIR1 is a 32-bit register.

**Field descriptions**

The HMAIR1 bit assignments are:

*When TTBCR.EAE == 1:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Attr7</td>
</tr>
<tr>
<td>24</td>
<td>Attr6</td>
</tr>
<tr>
<td>16</td>
<td>Attr5</td>
</tr>
<tr>
<td>8</td>
<td>Attr4</td>
</tr>
</tbody>
</table>

**Attr<n>, bits [8(n-4)+7:8(n-4)], for n = 4 to 7**

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:
- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>0b00RW, RW not 0b0</td>
<td>Normal memory, Outer Write-Through Transient.</td>
</tr>
<tr>
<td>0b0100</td>
<td>Normal memory, Outer Non-cacheable.</td>
</tr>
<tr>
<td>0b01RW, RW not 0b0</td>
<td>Normal memory, Outer Write-Back Transient.</td>
</tr>
<tr>
<td>0b10RW</td>
<td>Normal memory, Outer Write-Through Non-transient.</td>
</tr>
<tr>
<td>0b11RW</td>
<td>Normal memory, Outer Write-Back Non-transient.</td>
</tr>
</tbody>
</table>

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.
The meaning of bits [3:0] depends on the value of bits [7:4]:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[3:0]</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is 0b0000</th>
<th>Meaning when Attr&lt;n&gt;[7:4] is not 0b0000</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device-nGnRnE memory</td>
<td>UNPREDICTABLE</td>
</tr>
<tr>
<td>0b00RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Transient</td>
</tr>
<tr>
<td>0b0100</td>
<td>Device-nGnRE memory</td>
<td>Normal memory, Inner Non-cacheable</td>
</tr>
<tr>
<td>0b01RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Transient</td>
</tr>
<tr>
<td>0b1000</td>
<td>Device-nGRE memory</td>
<td>Normal memory, Inner Write-Through Non-transient (RW=0b00)</td>
</tr>
<tr>
<td>0b10RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Through Non-transient</td>
</tr>
<tr>
<td>0b1100</td>
<td>Device-GRE memory</td>
<td>Normal memory, Inner Write-Back Non-transient (RW=0b00)</td>
</tr>
<tr>
<td>0b11RW, RW not 0b00</td>
<td>UNPREDICTABLE</td>
<td>Normal memory, Inner Write-Back Non-transient</td>
</tr>
</tbody>
</table>

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

<table>
<thead>
<tr>
<th>R or W</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>No Allocate</td>
</tr>
<tr>
<td>0b1</td>
<td>Allocate</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

**Accessing the HMAIR1**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}{<q>}, \{\#<opc1>\}, <Rt>, <CRn>, <CRm>, \{\#<opc2>\}
\]

<table>

G8.2.68 HRMR, Hyp Reset Management Register

The HRMR characteristics are:

**Purpose**

If EL2 is the highest implemented Exception level and this register is implemented:
- A write to the register at EL2 can request a Warm reset.
- If EL2 can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

**Configurations**

AArch32 System register HRMR[31:0] is architecturally mapped to AArch64 System register RMR_EL2[31:0].

Only implemented if EL2 is the highest implemented Exception level. In this case:
- If EL2 can use AArch32 and AArch64 then this register must be implemented.
- If EL2 cannot use AArch64 then it is IMPLEMENTATION DEFINED whether the register is implemented.

See the field descriptions for the reset values. These apply whenever the register is implemented.

**Attributes**

HRMR is a 32-bit register.

**Field descriptions**

The HRMR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>30-2</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>RR</td>
</tr>
<tr>
<td>0</td>
<td>AA64</td>
</tr>
</tbody>
</table>

**Bits [31:2]**

Reserved, RES0.

**RR, bit [1]**

Reset Request. Setting this bit to 1 requests a Warm reset.

This field resets to 0.

**AA64, bit [0]**

When EL2 can use AArch64, determines which Execution state the PE boots into after a Warm reset:
- 0b0: AArch32.
- 0b1: AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL2 cannot use AArch64 this bit is RAZ/WI.

When implemented as a RW field, this field resets to 0 on a Cold reset.

**Accessing the HRMR**

Accesses to this register use the following encodings in the System instruction encoding space:
### MRC\{c\}\{q\} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

<table>
<thead>
<tr>

else
  UNDEFINED;
G8.2.69 HSCTLR, Hyp System Control Register

The HSCTLR characteristics are:

**Purpose**

Provides top level control of the system operation in Hyp mode.

**Configurations**

AArch32 System register HSCTLR[31:0] is architecturally mapped to AArch64 System register SCTLR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HSCTLR is a 32-bit register.

**Field descriptions**

The HSCTLR bit assignments are:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|  TE  |   |   |   | RES0 | I |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| RES0 | RES1 | RES0 | EE | RES0 | RES1 | RES0 | WXN | RES1 | RES0 | RES0 | RES1 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES0 | RES1 |
```

**Bit [31]**

Reserved, RES0.

**TE, bit [30]**

T32 Exception Enable. This bit controls whether exceptions to EL2 are taken to A32 or T32 state:

- 0b0 Exceptions, including reset, taken to A32 state.
- 0b1 Exceptions, including reset, taken to T32 state.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**Bits [29:28]**

Reserved, RES1.

**Bits [27:26]**

Reserved, RES0.
EE, bit [25]

The value of the PSTATE.E bit on entry to Hyp mode, the endianness of stage 1 translation table walks in the EL2 translation regime, and the endianness of stage 2 translation table walks in the PL1&0 translation regime.

The possible values of this bit are:

0b0  Little-endian. PSTATE.E is cleared to 0 on entry to Hyp mode. Stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the PL1&0 translation regime are little-endian.

0b1  Big-endian. PSTATE.E is set to 1 on entry to Hyp mode. Stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the PL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.

In a system where the PE resets into EL2, this field resets to an IMPLEMENTATION DEFINED value.

Bit [24]

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

Bits [21:20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL2 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

0b0  This control has no effect on memory access permissions.

0b1  Any region that is writable in the EL2 translation regime is forced to XN for accesses from software executing at EL2.

The WXN bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

Bit [18]

Reserved, RES1.

Bit [17]

Reserved, RES0.

Bit [16]

Reserved, RES1.

Bits [15:13]

Reserved, RES0.

I, bit [12]

Instruction access Cacheability control, for accesses at EL2:

0b0  All instruction access to Normal memory from EL2 are Non-cacheable for all levels of instruction and unified cache.

If the value of HSCTLR.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
All instruction access to Normal memory from EL2 can be cached at all levels of instruction and unified cache.
If the value of HSCTLR.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the PL1&0 translation regime.
In a system where the PE resets into EL2, this field resets to 0.

**Bit [11]**

Reserved, RES1.

**Bits [10:9]**

Reserved, RES0.

**SED, bit [8]**

SETEND instruction disable. Disables SETEND instructions at EL2.
- **0b0** SETEND instruction execution is enabled at EL2.
- **0b1** SETEND instructions are UNDEFINED at EL2.

If the implementation does not support mixed-endian operation at EL2, this bit is RES1.
In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

**ITD, bit [7]**

IT Disable. Disables some uses of IT instructions at EL2.
- **0b0** All IT instruction functionality is enabled at EL2.
- **0b1** Any attempt at EL2 to execute any of the following is UNDEFINED:
  - All encodings of the IT instruction with hw1[3:0]!=1000.
  - All encodings of the subsequent instruction with the following values for hw1:
    - 11xxxxxxxxxxx: All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
    - 1011xxxxxxxxxx: All instructions in Miscellaneous 16-bit instructions on page F3-3695.
    - 10100xxxxxxx: ADD Rd, PC, #imm
    - 01001xxxxxxx: LDR Rd, [PC, #imm]
    - 0100x1xxx1111xxx: ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.
    - 010001xx1xxxx111: ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers unpredictable cases with BLX Rn.

These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.
It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:
- A 16-bit instruction, that can only be followed by another 16-bit instruction.
- The first half of a 32-bit instruction.
This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.
An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is CONSTRAINED UNPREDICTABLE. For more information see Changes to an ITD control by an instruction in an IT block on page E1-3546

ITD is optional, but if it is implemented in the SCTLR then it must also be implemented in the HSCTLR. If it is not implemented then this bit is RAZ/WI.
In a system where the PE resets into EL2, this field resets to an architecturally **UNKNOWN** value.

**Bit [6]**

Reserved, **RES0**.

**CP15BEN, bit [5]**

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the \( \text{coproc}=\#b1111 \) encoding space from EL2:

\( \#b0 \)  

EL2 execution of the **CP15DMB**, **CP15DSB**, and **CP15ISB** instructions is **UNDEFINED**.

\( \#b1 \)  

EL2 execution of the **CP15DMB**, **CP15DSB**, and **CP15ISB** instructions is enabled.

CP15BEN is optional, but if it is implemented in the **SCTLR** then it must also be implemented in the **HSCTLR**. If it is not implemented then this bit is RAO/WI.

In a system where the PE resets into EL2, this field resets to an architecturally **UNKNOWN** value.

**LSMAOE, bit [4]**

**When ARMv8.2-LSMAOC is implemented:**

Load Multiple and Store Multiple Atomicity and Ordering Enable.

\( \#b0 \)

For all memory accesses at EL2, A32 and T32 Load Multiple and Store Multiple can have an interrupt taken during the sequence memory accesses, and the memory accesses are not required to be ordered.

\( \#b1 \)

The ordering and interrupt behavior of A32 and T32 Load Multiple and Store Multiple at EL2 is as defined for Armv8.0.

This bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to 1.

**Otherwise:**

Reserved, **RES1**.

**nTLSMD, bit [3]**

**When ARMv8.2-LSMAOC is implemented:**

No Trap Load Multiple and Store Multiple to Device-nGRE/Device-nGnRE/Device-nGnRnE memory.

\( \#b0 \)

All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL2 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are trapped and generate a stage 1 Alignment fault.

\( \#b1 \)

All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL2 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are not trapped.

This bit is permitted to be cached in a TLB.

In a system where the PE resets into EL2, this field resets to 1.

**Otherwise:**

Reserved, **RES1**.

**C, bit [2]**

Cacheability control, for data accesses at EL2:

\( \#b0 \)

All data access to Normal memory from EL2, and all accesses to the EL2 translation tables, are **Non-cacheable** for all levels of data and unified cache.

\( \#b1 \)

All data access to Normal memory from EL2, and all accesses to the EL2 translation tables, can be cached at all levels of data and unified cache.

This bit has no effect on the PL1&0 translation regime.

In a system where the PE resets into EL2, this field resets to 0.
A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL2:

0b0  Alignment fault checking disabled when executing at EL2.
Instructions that load or store one or more registers, other than load/store exclusive and
load-acquire/store-release, do not check that the address being accessed is aligned to the
size of the data element or data elements being accessed.

0b1  Alignment fault checking enabled when executing at EL2.
All instructions that load or store one or more registers have an alignment check that the
address being accessed is aligned to the size of the data element or data elements being
accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort
exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless
of the value of the A bit.

In a system where the PE resets into EL2, this field resets to an architecturally UNKNOWN value.

M, bit [0]

MMU enable for EL2 stage 1 address translation. Possible values of this bit are:

0b0  EL2 stage 1 address translation disabled.
See the HSCTLR.I field for the behavior of instruction accesses to Normal memory.

0b1  EL2 stage 1 address translation enabled.
In a system where the PE resets into EL2, this field resets to 0.

Accessing the HSCTLR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

<table>

  else
    HSCTLR = R[t];

G8.2.70   HSR, Hyp Syndrome Register

The HSR characteristics are:

**Purpose**

Holds syndrome information for an exception taken to Hyp mode.

**Configurations**

AArch32 System register HSR[31:0] is architecturally mapped to AArch64 System register ESR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HSR is a 32-bit register.

**Field descriptions**

The HSR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>26 25 24</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>EC</td>
<td>IL</td>
<td>ISS</td>
</tr>
</tbody>
</table>

Execution in any Non-secure PE mode other than Hyp mode makes this register UNKNOWN.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of HSR is UNKNOWN. The value written to HSR must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

**EC, bits [31:26]**

Exception Class. Indicates the reason for the exception that this register holds information about. Possible values of this field are:

- **EC == 0b000000**
  
  Unknown reason.
  
  See [ISS encoding for exceptions with an unknown reason on page G8-5816](#).

- **EC == 0b000001**
  
  Trapped WFI or WFE instruction execution.
  
  Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.
  
  See [ISS encoding for an exception from a WFI or WFE instruction on page G8-5818](#).

- **EC == 0b000011**
  
  Trapped MCR or MRC access with (coproc==0b1111) that is not reported using EC 0b000000.
  
  See [ISS encoding for an exception from an MCR or MRC access on page G8-5819](#).

- **EC == 0b000100**
  
  Trapped MCRR or MRRC access with (coproc==0b1111) that is not reported using EC 0b000000.
  
  See [ISS encoding for an exception from an MCRR or MRRC access on page G8-5821](#).

- **EC == 0b000101**
  
  Trapped MCR or MRC access with (coproc==0b1110).
  
  See [ISS encoding for an exception from an MCR or MRC access on page G8-5819](#).
EC == 0b000110
Trapped LDC or STC access.
The only architected uses of these instructions are:
• An STC to write data to memory from DBGDTRRXint.
• An LDC to read data from memory to DBGDTRTXint.
See ISS encoding for an exception from an LDC or STC instruction on page G8-5822.

EC == 0b000111
Access to Advanced SIMD or floating-point functionality trapped by a HCPTR. {TASE, TCP10} control.
Excludes exceptions generated because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.
See ISS encoding for an exception from an access to SIMD or floating-point functionality, resulting from HCPTR on page G8-5824.

EC == 0b001000
Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.
See ISS encoding for an exception from an MCR or MRC access on page G8-5819.

EC == 0b001100
Trapped MRRC access with (coproc==0b1110).
See ISS encoding for an exception from an MCRR or MRRC access on page G8-5821.

EC == 0b001110
Illegal exception return to AArch32 state.
See ISS encoding for an exception from an Illegal state or PC alignment fault on page G8-5829.

EC == 0b010001
Exception on SVC instruction execution in AArch32 state routed to EL2.
See ISS encoding for an exception from HVC or SVC instruction execution on page G8-5825.

EC == 0b010010
HVC instruction execution in AArch32 state, when HVC is not disabled.
See ISS encoding for an exception from HVC or SVC instruction execution on page G8-5825.

EC == 0b010011
Trapped execution of SMC instruction in AArch32 state.
See ISS encoding for an exception from SMC instruction execution on page G8-5826.

EC == 0b100000
Prefetch Abort from a lower Exception level.
See ISS encoding for an exception from a Prefetch Abort on page G8-5827.

EC == 0b100001
Prefetch Abort taken without a change in Exception level.
See ISS encoding for an exception from a Prefetch Abort on page G8-5827.

EC == 0b100010
PC alignment fault exception.
See ISS encoding for an exception from an Illegal state or PC alignment fault on page G8-5829.

EC == 0b100100
Data Abort from a lower Exception level.
See MRC{<c>|<q>}{coproc}, {#}<opc1>, <Rt>, <CRn>, {#}<opc2> on page G8-5841.
EC == 0b100101
Data Abort taken without a change in Exception level.
See ISS encoding for an exception from a Data Abort on page G8-5829.

All other EC values are reserved by Arm, and:
- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is constrained unpredictable, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7227.

This field resets to an architecturally UNKNOWN value.

IL, bit [25]
Instruction length bit. Indicates the size of the instruction that has been trapped to Hyp mode. When this bit is valid, possible values of this bit are:
- 0b0 16-bit instruction trapped.
- 0b1 32-bit instruction trapped.

This field is RES1 and not valid for the following cases:
- When the EC field is 0b000000, indicating an exception with an unknown reason.
- prefetch aborts.
- Data aborts for which the HSR.ISS.ISV field is 0.
- When the EC value is 0b001110, indicating an Illegal state exception.

--- Note ---
This is a change from the behavior in Armv7, where the IL field is UNK/SBZP for the corresponding cases.

---

The IL field is not valid and is UNKNOWN on an exception from a PC alignment fault.
This field resets to an architecturally UNKNOWN value.

ISS, bits [24:0]
Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

The following subsections describe each ISS format.

ISS encoding for exceptions with an unknown reason

24 0

RES0

Bits [24:0]
Reserved, RES0.
This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction in the current PE mode in the current Security state, including:
  - A read access using a System register encoding pattern that is not allocated for reads at the current Exception level and Security state.
  - A write access using a System register encoding pattern that is not allocated for writes at the current Exception level and Security state.
  - Instruction encodings for instructions not implemented in the implementation.

- A read access using a System register encoding pattern that is not allocated for reads at the current Exception level and Security state. A write access using a System register encoding pattern that is not allocated for writes at the current Exception level and Security state. Instruction encodings for instructions not implemented in the implementation.

- In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.

- In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.

- The attempted execution of a short vector floating-point instruction.

- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.

- An exception generated because of the value of one of the SCTLR.{ITD, SED, CP15BEN} control bits.

- Attempted execution of:
  - An HVC instruction when disabled by HCR.HCD, SCR.HCE, or SCR_EL3.HCE.
  - An SMC instruction when disabled by SCR.SCD or SCR_EL3.SMD.
  - An HLT instruction when disabled by EDSCR.HDE.

- An HVC instruction when disabled by HCR.HCD, SCR.HCE, or SCR_EL3.HCE. An SMC instruction when disabled by SCR.SCD or SCR_EL3.SMD. An HLT instruction when disabled by EDSCR.HDE.

- An exception generated because of the attempted execution of an MSR (Banked register) or MRS (Banked register) instruction that would access a Banked register that is not accessible from the Security state and PE mode at which the instruction was executed.

An exception is generated only if the CONSTRAINED UNPREDICTABLE behavior of the instruction is that it is **UNDEFINED**, see *MSR (banked register) and MRS (banked register)* on page K1-7212.

- Attempted execution, in Debug state, of:
  - A DCPS1 instruction in Non-secure state from EL0 when EL2 is using AArch32 and the value of HCR.TGE is 1.
  - A DCPS2 instruction at EL1 or EL0 when EL2 is not implemented, or when EL3 is using AArch32 and the value of SCR.NS is 0, or when EL3 is using AArch64 and the value of SCR_EL3.NS is 0.
  - A DCPS3 instruction when EL3 is not implemented, or when the value of EDSCR.SDD is 1.

- In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.

Untied Instruction exception, when the value of HCR.TGE is 1 on page G1-5263 describes the configuration settings for a trap that returns an HSR.EC value of 0b000000.
ISS encoding for an exception from a WFI or WFE instruction

CV, bit [24]
Condition code valid. Possible values of this bit are:
- 0b0: The COND field is not valid.
- 0b1: The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.
This field resets to an architecturally UNKNOWN value.

COND, bits [23:20]
The condition code for the trapped instruction.
When an A32 instruction is trapped, CV is set to 1 and:
- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:
- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.
This field resets to an architecturally UNKNOWN value.

Bits [19:1]
Reserved, RES0.

TI, bit [0]
Trapped instruction. Possible values of this bit are:
- 0b0: WFI trapped.
- 0b1: WFE trapped.
This field resets to an architecturally UNKNOWN value.

Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-5341 describes the configuration settings for this trap.

CV, bit [24]
Condition code valid. Possible values of this bit are:
- 00 The COND field is not valid.
- 01 The COND field is valid.
When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.
This field resets to an architecturally UNKNOWN value.

COND, bits [23:20]
The condition code for the trapped instruction.
When an A32 instruction is trapped, CV is set to 1 and:
- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.
A conditional A32 instruction that is known to pass its condition code check can be presented either:
- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.
This field resets to an architecturally UNKNOWN value.

Opc2, bits [19:17]
The Opc2 value from the issued instruction.
For a trapped VMRS access, holds the value 0b000.
This field resets to an architecturally UNKNOWN value.

Opc1, bits [16:14]
The Opc1 value from the issued instruction.
For a trapped VMRS access, holds the value 0b111.
This field resets to an architecturally UNKNOWN value.
CRn, bits [13:10]
The CRn value from the issued instruction.
For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.
This field resets to an architecturally UNKNOWN value.

Bit [9]
Reserved, RES0.

Rt, bits [8:5]
The Rt value from the issued instruction, the general-purpose register used for the transfer.
This field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]
The CRm value from the issued instruction.
For a trapped VMRS access, holds the value 0b0000.
This field resets to an architecturally UNKNOWN value.

Direction, bit [0]
Indicates the direction of the trapped instruction. The possible values of this bit are:
0b0    Write to System register space. MCR instruction.
0b1    Read from System register space. MRC or VMRS instruction.
This field resets to an architecturally UNKNOWN value.

The following sections describe configuration settings for traps that are reported using EC value 0b000011:

• Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the ID registers on page G1-5338.
• Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-5337.
• Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions on page G1-5336.
• Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions on page G1-5335.
• Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register on page G1-5336.
• Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page G1-5349.
• Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Activity Monitors registers on page G1-5341.
• Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the CPACR on page G1-5343.
• Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers on page G1-5334.
• General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc == 0b1111) encoding space on page G1-5345.

The following sections describe configuration settings for traps that are reported using EC value 0b000101:

• ID group 0, Primary device identification registers on page G1-5339.
• Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-5344.
• Trapping Non-secure System register accesses to Debug ROM registers on page G1-5347.
• Trapping Non-secure System register accesses to powerdown debug registers on page G1-5347.
• Trapping general Non-secure System register accesses to debug registers on page G1-5347.
The following sections describes configuration settings for traps that are reported using EC value 0b001000:

- **ID group 0, Primary device identification registers** on page G1-5339.
- **ID group 3, Detailed feature identification registers** on page G1-5340.

**ISS encoding for an exception from an MCRR or MRRC access**

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0b0 The COND field is not valid.
- 0b1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110 or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

This field resets to an architecturally UNKNOWN value.

Bits [15:14]

Reserved, RES0.
Rt2, bits [13:10]
The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.
This field resets to an architecturally UNKNOWN value.

Bit [9]
Reserved, RES0.

Rt, bits [8:5]
The Rt value from the issued instruction, the first general-purpose register used for the transfer.
This field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]
The CRm value from the issued instruction.
This field resets to an architecturally UNKNOWN value.

Direction, bit [0]
Indicates the direction of the trapped instruction. The possible values of this bit are:
0b0  Write to System register space. MCRR instruction.
0b1  Read from System register space. MRRC instruction.
This field resets to an architecturally UNKNOWN value.

The following sections describe configuration settings for traps that are reported using EC value 0b000100:

- Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers on page G1-5334.
- Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page G1-5349.
- Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Activity Monitors registers on page G1-5341.
- Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page G1-5348.
- General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space on page G1-5345.

The following sections describe configuration settings for traps that are reported using EC value 0b001100:

- Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-5344.
- Trapping Non-secure System register accesses to Debug ROM registers on page G1-5347.

**ISS encoding for an exception from an LDC or STC instruction**

| 24 23 20 19 12 11 9 8 5 4 3 1 0 |
|------------------------------|------------------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| COND imm8 RES0 Rn AM         |

CV, bit [24]
Condition code valid. Possible values of this bit are:
0b0  The COND field is not valid.
0b1  The COND field is valid.
When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

**imm8, bits [19:12]**

The immediate value from the issued instruction.

This field resets to an architecturally UNKNOWN value.

**Bits [11:9]**

Reserved, RES0.

**Rn, bits [8:5]**

The Rn value from the issued instruction. Valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction.

When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

**Offset, bit [4]**

Indicates whether the offset is added or subtracted:

- 0b0 Subtract offset.
- 0b1 Add offset.

This bit corresponds to the U bit in the instruction encoding.

This field resets to an architecturally UNKNOWN value.

**AM, bits [3:1]**

Addressing mode. The permitted values of this field are:

- 0b000 Immediate unindexed.
- 0b001 Immediate post-indexed.
- 0b010 Immediate offset.
- 0b011 Immediate pre-indexed.
G8.2 General system control registers

0b100  Literal unindexed.
LDC instruction in A32 instruction set only.
For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.

0b110  Literal offset.
LDC instruction only.
For a trapped STC instruction, this encoding is reserved.

The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7212.

Bit [2] in this subfield indicates the instruction form, immediate or literal.
Bits [1:0] in this subfield correspond to the bits \{P, W\} in the instruction encoding.
This field resets to an architecturally UNKNOWN value.

Direction, bit [0]
Indicates the direction of the trapped instruction. The possible values of this bit are:
0b0  Write to memory. STC instruction.
0b1  Read from memory. LDC instruction.
This field resets to an architecturally UNKNOWN value.

Trapping general Non-secure System register accesses to debug registers on page G1-5347 describes the configuration settings for the trap that is reported using EC value 0b000110.

ISS encoding for an exception from an access to SIMD or floating-point functionality, resulting from HCPTR

```
24 23 20 19  6  5  4  3  0
COND RES0 TA  coproc
CV
RES0
```

Excludes exceptions that occur because Advanced SIMD and floating-point functionality is not implemented, or because the value of HCR.TGE or HCR_EL2.TGE is 1. These are reported with EC value 0b000000.

CV, bit [24]
Condition code valid. Possible values of this bit are:
0b0  The COND field is not valid.
0b1  The COND field is valid.
When an A32 instruction is trapped, CV is set to 1.
When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.
This field resets to an architecturally UNKNOWN value.

COND, bits [23:20]
The condition code for the trapped instruction.
When an A32 instruction is trapped, CV is set to 1 and:
- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.
A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field resets to an architecturally UNKNOWN value.

**Bits [19:6]**

Reserved, RES0.

**TA, bit [5]**

Indicates trapped use of Advanced SIMD functionality. The possible values of this bit are:

- 0b0 Exception was not caused by trapped use of Advanced SIMD functionality.
- 0b1 Exception was caused by trapped use of Advanced SIMD functionality.

Any use of an Advanced SIMD instruction that is not also a floating-point instruction that is trapped to Hyp mode because of a trap configured in the HCPTR sets this bit to 1.

For a list of these instructions, see Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-3554.

This field resets to an architecturally UNKNOWN value.

**Bit [4]**

Reserved, RES0.

**coproc, bits [3:0]**

When the TA field returns the value 1, this field returns the value 1010, otherwise this field is RES0.

This field resets to an architecturally UNKNOWN value.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000111:

- General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-5342.
- Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality on page G1-5343.

**ISS encoding for an exception from HVC or SVC instruction execution**

```
<table>
<thead>
<tr>
<th>24</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td>imm16</td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [24:16]**

Reserved, RES0.

**imm16, bits [15:0]**

The value of the immediate field from the HVC or SVC instruction.
For an HVC instruction, this is the value of the imm16 field of the issued instruction.

For an SVC instruction:

- If the instruction is unconditional, then:
  - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- For the T32 instruction, this field is zero-extended from the imm8 field of the instruction. For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

The HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

*Supervisor Call exception, when the value of HCR.TGE is 1 on page G1-5263* describes the configuration settings for the trap reported with EC value 0b010001.

**ISS encoding for an exception from SMC instruction execution**

<table>
<thead>
<tr>
<th>CV</th>
<th>COND</th>
<th>RES0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>24 23</td>
<td>20 19 18</td>
</tr>
</tbody>
</table>

**CV, bit [24]**

Condition code valid. Possible values of this bit are:
- 0b0  The COND field is not valid.
- 0b1  The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

This field resets to an architecturally UNKNOWN value.

**COND, bits [23:20]**

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:
- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:
- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field is only valid if CCKOWNPASS is 1, otherwise it is RES0.

This field resets to an architecturally UNKNOWN value.

**CCKOWNPASS, bit [19]**

Indicates whether the instruction might have failed its condition code check.

0b0 The instruction was unconditional, or was conditional and passed its condition code check.

0b1 The instruction was conditional, and might have failed its condition code check.

This field resets to an architecturally UNKNOWN value.

**Bits [18:0]**

Reserved, RES0.

*Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-5338* describes the configuration settings for this trap, for instructions executed in Non-secure EL1.

**ISS encoding for an exception from a Prefetch Abort**

```

**Bits [24:11]**

Reserved, RES0.

**FnV, bit [10]**

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

0b0 HIFAR is valid.

0b1 HIFAR is not valid, and holds an UNKNOWN value.

This field is only valid if the IFSC code is 0b010000. It is RES0 for all other aborts.

This field resets to an architecturally UNKNOWN value.

**EA, bit [9]**

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

This field resets to an architecturally UNKNOWN value.
Bit [8]
Reserved, RES0.

S1PTW, bit [7]
For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:
0b0 Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.
For any abort other than a stage 2 fault this bit is RES0.
This field resets to an architecturally UNKNOWN value.

Bit [6]
Reserved, RES0.

IFSC, bits [5:0]
Instruction Fault Status Code. Possible values of this field are:
0b000000 Address size fault, translation table base register.
0b000001 Address size fault, level 1.
0b000010 Address size fault, level 2.
0b000011 Address size fault, level 3.
0b000101 Translation fault, level 1.
0b000110 Translation fault, level 2.
0b000111 Translation fault, level 3.
0b001001 Access flag fault, level 1.
0b001010 Access flag fault, level 2.
0b001011 Access flag fault, level 3.
0b001101 Permission fault, level 1.
0b001110 Permission fault, level 2.
0b001111 Permission fault, level 3.
0b010000 Synchronous External abort, not on translation table walk.
0b010101 Synchronous External abort, on translation table walk, level 1.
0b010110 Synchronous External abort, on translation table walk, level 2.
0b010111 Synchronous External abort, on translation table walk, level 3.
0b011000 Synchronous parity or ECC error on memory access, not on translation table walk.
0b011101 Synchronous parity or ECC error on memory access on translation table walk, level 1.
0b011110 Synchronous parity or ECC error on memory access on translation table walk, level 2.
0b011111 Synchronous parity or ECC error on memory access on translation table walk, level 3.
0b100010 Debug exception.
0b110000 TLB conflict abort.
All other values are reserved.

Note
Armv8.2 requires the implementation of the RAS Extension.

For more information about the lookup level associated with a fault, see The level associated with MMU faults on a Long-descriptor translation table lookup on page G5-5574.
If the S1PTW bit is set, then the level refers the level of the stage 2 translation that is translating a stage 1 translation walk.

This field resets to an architecturally UNKNOWN value.

The following sections describe cases where Prefetch Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0b100000:

- *Abort exceptions, when the value of HCR.TGE is 1 on page G1-5263.*
- *Routing debug exceptions to EL2 using AArch32 on page G1-5264.*

**ISS encoding for an exception from an Illegal state or PC alignment fault**

![ISS encoding diagram]

**Bits [24:0]**

Reserved, RES0.

For more information about the Illegal state exception, see:

- *Illegal changes to PSTATE.M on page G1-5243.*
- *Illegal return events from AArch32 state on page G1-5270.*
- *Legal returns that set PSTATE.IL to 1 on page G1-5272.*
- *The Illegal Execution state exception on page G1-5272.*

For more information about the PC alignment fault exception, see *Branching to an unaligned PC on page K1-7192.*

**ISS encoding for an exception from a Data Abort**

![ISS encoding diagram]

**ISV, bit [24]**

Instruction syndrome valid. Indicates whether the syndrome information in ISS[23:14] is valid.

- 0b0 : No valid instruction syndrome. ISS[23:14] are RES0.

This bit is 0 for all faults except Data Aborts generated by stage 2 address translations for which all the following apply to the instruction that generated the Data Abort exception:

- The instruction is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAB, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STRT, STR, STRT, STRH, STLB, STRB, STL, or STRBT instruction.
- The instruction is not performing register writeback.
The instruction is not using the PC as a source or destination register.

For these cases, ISV is UNKNOWN if the exception was generated in Debug state in memory access mode, as described in Data Aborts in Memory access mode on page H4-6488, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

--- Note

In the A32 instruction set, LDR*T and STR*T instructions always perform register writeback and therefore never return a valid instruction syndrome.

---

When the RAS Extension is implemented, ISV is 0 for any synchronous External abort.

ISV is set to 0 on a stage 2 abort on a stage 1 translation table walk.

When the RAS Extension is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

This field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]
Syndrome Access Size. When ISV is 1, indicates the size of the access attempted by the faulting operation.

- 0b00: Byte
- 0b01: Halfword
- 0b10: Word
- 0b11: Doubleword

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

This field resets to an architecturally UNKNOWN value.

SSE, bit [21]
Syndrome Sign Extend. When ISV is 1, for a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

- 0b0: Sign-extension not required.
- 0b1: Data item must be sign-extended.

For all other operations this bit is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

This field resets to an architecturally UNKNOWN value.

Bit [20]
Reserved, RES0.

SRT, bits [19:16]
Syndrome Register transfer. When ISV is 1, the register number of the Rt operand of the faulting instruction.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

This field resets to an architecturally UNKNOWN value.

Bit [15]
Reserved, RES0.
AR, bit [14]

Acquire/Release. When ISV is 1, the possible values of this bit are:

0b0  Instruction did not have acquire/release semantics.
0b1  Instruction did have acquire/release semantics.

This field is UNKNOWN when the value of ISV is UNKNOWN.
This field is RES0 when the value of ISV is 0.
This field resets to an architecturally UNKNOWN value.

Bits [13:12]

Reserved, RES0.

AET, bits [11:10]

Asynchronous Error Type.
When the RAS Extension is implemented and the value returned in the DFSC field is 0b010001, describes the state of the PE after taking the SError interrupt exception. The possible values of this field are:

0b00  Uncontainable error (UC) or uncategorized.
0b01  Unrecoverable error (UEU).
0b10  Restartable error (UEO) or Corrected error (CE).
0b11  Recoverable error (UER).

On a synchronous Data Abort, this field is RES0.
If multiple errors are taken as a single SError interrupt exception, the overall state of the PE is reported. For example, if both a Recoverable and Unrecoverable error occurred, the state is Unrecoverable.

Note
Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

When the RAS Extension is not implemented, or when DFSC is not 0b010001:
• Bit[11] is RES0.
• Bit[10] forms the FnV field.

Note
Armv8.2 requires the implementation of the RAS Extension.

This field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.
For any abort other than an External abort this bit returns a value of 0.
This field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. For a synchronous fault, identifies fault that comes from a cache maintenance or address translation instruction. For synchronous faults, the possible values of this bit are:

0b0  Fault not generated by a cache maintenance or address translation instruction.
0b1  Fault generated by a cache maintenance or address translation instruction.

For an asynchronous Data Abort exception, this bit is 0.
This field resets to an architecturally UNKNOWN value.

**SIPTW, bit [7]**

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- **0b0**: Fault not on a stage 2 translation for a stage 1 translation table walk.
- **0b1**: Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is **RES0**.

This field resets to an architecturally UNKNOWN value.

**WnR, bit [6]**

Write not Read. Indicates whether a synchronous abort was caused by a write instruction or a read instruction. The possible values of this bit are:

- **0b0**: Abort caused by a read instruction.
- **0b1**: Abort caused by a write instruction.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

On an asynchronous Data Abort:

- When the RAS Extension is not implemented, this bit is **UNKNOWN**.
- When the RAS Extension is implemented, this bit is **RES0**.

---

**Note**

Armv8.2 requires the implementation of the RAS Extension.

---

This field resets to an architecturally UNKNOWN value.

**DFSC, bits [5:0]**

Data Fault Status Code. Possible values of this field are:

- **0b000000**: Address size fault, translation table base register.
- **0b000001**: Address size fault, level 1.
- **0b000010**: Address size fault, level 2.
- **0b000011**: Address size fault, level 3.
- **0b000101**: Translation fault, level 1.
- **0b000110**: Translation fault, level 2.
- **0b000111**: Translation fault, level 3.
- **0b001001**: Access flag fault, level 1.
- **0b001010**: Access flag fault, level 2.
- **0b001011**: Access flag fault, level 3.
- **0b001101**: Permission fault, level 1.
- **0b001110**: Permission fault, level 2.
- **0b001111**: Permission fault, level 3.
- **0b010000**: Synchronous External abort, not on translation table walk.
- **0b010001**: SError interrupt.
- **0b010101**: Synchronous External abort, on translation table walk, level 1.
- **0b010110**: Synchronous External abort, on translation table walk, level 2.
- **0b010111**: Synchronous External abort, on translation table walk, level 3.
- **0b011000**: Synchronous parity or ECC error on memory access, not on translation table walk.
- **0b011001**: SError interrupt from a parity or ECC error on memory access.
0b011101  Synchronous parity or ECC error on memory access on translation table walk, level 1.
0b011110  Synchronous parity or ECC error on memory access on translation table walk, level 2.
0b011111  Synchronous parity or ECC error on memory access on translation table walk, level 3.
0b100000  Alignment fault.
0b100010  Debug exception.
0b110000  TLB conflict abort.
0b110100  IMPLEMENTATION DEFINED fault (Lockdown).
0b110101  IMPLEMENTATION DEFINED fault (Unsupported Exclusive access).

All other values are reserved.

When the RAS Extension is implemented, 0b011000, 0b011001, 0b011101, 0b011110, and 0b011111, are reserved.

For more information about the lookup level associated with a fault, see The level associated with MMU faults on a Long-descriptor translation table lookup on page G5-5574.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

This field resets to an architecturally UNKNOWN value.

The following describe cases where Data Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0b100100:

- Abort exceptions, when the value of HCR.TGE is 1 on page G1-5263.
- Routing debug exceptions to EL2 using AArch32 on page G1-5264.

The following describe cases that can cause a Data Abort exception that is taken to Hyp mode, and reported in the HSR with EC value of 0b100000 or 0b100100:

- Hyp mode control of Non-secure access permissions on page G5-5519.
- Memory fault reporting in Hyp mode on page G5-5578.

Accessing the HSR

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MRC}\{c\}\{q\} \text{ coproc, \{#\}opc1, \text{ CRn, CRm\{, \{#\}opc2\}} \]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>

</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then
  if EL2Enabled() && !ELUsingAArch32(EL2) && HSTR_EL2.T5 == '1' then
    AArch64.AArch32SystemAccessTrap(EL2, 0x03);
  elsif EL2Enabled() && ELUsingAArch32(EL2) && HSTR.T5 == '1' then
    AArch32.TakeHypTrapException(0x03);
  else
    UNDEFINED;
elsif PSTATE.EL == EL2 then
  HSR = R[t];
elsif PSTATE.EL == EL3 then
  if SCR.NS == '0' then
    UNDEFINED;
  else
    HSR = R[t];

**G8.2.71 HSTR, Hyp System Trap Register**

The HSTR characteristics are:

**Purpose**

Controls trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to System registers in the coproc == 0b1111 encoding space:

- By the CRn value used to access the register using MCR or MRC instruction.
- By the CRm value used to access the register using MCRR or MRRC instruction.

**Configurations**

AArch32 System register HSTR[31:0] is architecturally mapped to AArch64 System register HSTR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HSTR is a 32-bit register.

**Field descriptions**

The HSTR bit assignments are:

```
| 31 | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  |  9  |  8  |  7  |  6  |  5  |  4  |  3  |  2  |  1  |  0  |
|----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| RES0 |
```

**Bits [31:16]**

Reserved, RES0.

**T<n>, bit [n], for n = 0 to 15**

Fields T14 and T4 are RES0.

The remaining fields control whether Non-secure EL0 and EL1 accesses, using MCR, MRC, MCRR, and MRRC instructions, to the System registers in the coproc == 0b1111 encoding space are trapped to Hyp mode:

- **0b0** This control has no effect on Non-secure EL0 or EL1 accesses to System registers.
- **0b1** Any Non-secure EL1 MCR or MRC access with coproc == 0b1111 and CRn == <n> is trapped to Hyp mode. A Non-secure EL0 MCR or MRC access with these values is trapped to Hyp mode only if the access is not UNDEFINED when the value of this field is 0.

Any Non-secure EL1 MCRR or MRRC access with coproc == 0b1111 and CRm == <n> is trapped to Hyp mode. A Non-secure EL0 MCRR or MRRC access with these values is trapped to Hyp mode only if the access is not UNDEFINED when the value of this field is 0.
For example, when HSTR.T7 is 1, for instructions executed at Non-secure EL1:

- An MCR or MRC instruction with coproc set to 0b1111 and \(<CRn>\) set to c7 is trapped to Hyp mode.
- An MCRR or MRRC instruction with coproc set to 0b1111 and \(<CRm>\) set to c7 is trapped to Hyp mode.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

**Accessing the HSTR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MRC\{<c>\}{<q>\ <coproc>, \{#\<opc1\>, <Rt>, <CRn>, \<CRm>\}, \{#\<opc2\>}} \]

<table>
<thead>

G8.2.72 HTCR, Hyp Translation Control Register

The HTCR characteristics are:

**Purpose**

The control register for stage 1 of the EL2 translation regime.

--- **Note** ---

This stage of translation always uses the Long-descriptor translation table format.

**Configurations**

AArch32 System register HTCR[31:0] is architecturally mapped to AArch64 System register TCR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HTCR is a 32-bit register.

**Field descriptions**

The HTCR bit assignments are:

**Bit [31]**

Reserved, RES1.

**IMPLEMENTATION DEFINED, bit [30]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**Bit [29]**

Reserved, RES0.

**HWU62, bit [28]**

*When ARMv8.2-TTPBHA is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry.

*0b0* Bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1 Bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of HTCR.HPD is 1.

The Effective value of this field is 0 if the value of HTCR.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU61, bit [27]
When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry.

0b0 Bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 Bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of HTCR.HPD is 1.

The Effective value of this field is 0 if the value of HTCR.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU60, bit [26]
When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry.

0b0 Bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 Bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of HTCR.HPD is 1.

The Effective value of this field is 0 if the value of HTCR.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU59, bit [25]
When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry.

0b0 Bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 Bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of HTCR.HPD is 1.

The Effective value of this field is 0 if the value of HTCR.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.
HPD, bit [24]

When ARMv8.2-AA32HPD is implemented:
Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, XNTable, and PXNTable, in the PL2 translation regime.

- 0b0  Hierarchical permissions are enabled.
- 0b1  Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bit [23]
Reserved, RES1.

Bits [22:14]
Reserved, RES0.

SH0, bits [13:12]
Shareability attribute for memory associated with translation table walks using HTTBR.

- 0b00  Non-shareable.
- 0b10  Outer Shareable.
- 0b11  Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7212.
This field resets to an architecturally UNKNOWN value.

ORGN0, bits [11:10]
Outer cacheability attribute for memory associated with translation table walks using HTTBR.

- 0b00  Normal memory, Outer Non-cacheable.
- 0b01  Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10  Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11  Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IRGN0, bits [9:8]
Inner cacheability attribute for memory associated with translation table walks using HTTBR.

- 0b00  Normal memory, Inner Non-cacheable.
- 0b01  Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10  Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11  Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

Bits [7:3]
Reserved, RES0.

T0SZ, bits [2:0]
The size offset of the memory region addressed by HTTBR. The region size is $2^{(32-T0SZ)}$ bytes.
This field resets to an architecturally UNKNOWN value.
### Accessing the HTCR

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MRC{c}\{q\} <\text{coproc}>, \{\#\}<\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>, \{\#\}<\text{opc2}>
\]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>

G8.2.73 HTPIDR, Hyp Software Thread ID Register

The HTPIDR characteristics are:

**Purpose**

Provides a location where software running in Hyp mode can store thread identifying information that is not visible to Non-secure software executing at EL0 or EL1, for hypervisor management purposes.

The PE makes no use of this register.

**Configurations**

AArch32 System register HTPIDR[31:0] is architecturally mapped to AArch64 System register TPIDR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

**Note**

The PE never updates this register.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HTPIDR is a 32-bit register.

**Field descriptions**

The HTPIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Thread ID</strong></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Thread ID. Thread identifying information stored by software running at this Exception level. This field resets to an architecturally UNKNOWN value.

**Accessing the HTPIDR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MRC}\{c\}\{q\} \ <\text{coproc}\>, \{#\}<\text{opc1}\>, \ <Rt\>, \ <\text{CRn}\>, \ <\text{CRm}\>, \{#\}<\text{opc2}\> \]

G8.2.74   HTTBR, Hyp Translation Table Base Register

The HTTBR characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of an address translation in the EL2 translation regime, and other information for this translation regime.

Configurations

AArch32 System register HTTBR[47:1] is architecturally mapped to AArch64 System register TTBR0_EL2[47:1].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HTTBR is a 64-bit register.

Field descriptions

The HTTBR bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
</tr>
<tr>
<td>48</td>
</tr>
<tr>
<td>47</td>
</tr>
<tr>
<td>46</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

**RES0**

Reserved, RES0.

**BADDR**, bits [47:1]

Translation table base address, bits[47:x], Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are CONstrained Unpredictable, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of HTCR.T0SZ as follows:

- If HTCR.T0SZ is 0 or 1, x = 5 - HTCR.T0SZ.
- If HTCR.T0SZ is greater than 1, x = 14 - HTCR.T0SZ.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.

This field resets to an architecturally UNKNOWN value.

**CnP**, bit [0]

When ARMv8.2-TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by HTTBR is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of HTTBR.CnP is 1.

0b0  The translation table entries pointed to by HTTBR are permitted to differ from corresponding entries for HTTBR for other PEs in the Inner Shareable domain. This is not affected by the value of HTTBR.CnP on those other PEs.
The translation table entries pointed to by HTTBR are the same as the translation table entries pointed to by HTTBR on every other PE in the Inner Shareable domain for which the value of HTTBR.CnP is 1.

--- Note ---

If the value of the HTTBR.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those HTTBRs do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7195.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

### Accessing the HTTBR

### G8.2.75 HVBAR, Hyp Vector Base Address Register

The HVBAR characteristics are:

**Purpose**

Holds the vector base address for any exception that is taken to Hyp mode.

**Configurations**

AArch32 System register HVBAR[31:0] is architecturally mapped to AArch64 System register VBAR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HVBAR is a 32-bit register.

**Field descriptions**

The HVBAR bit assignments are:

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>

endif
G8.2.76   ICIALLU, Instruction Cache Invalidate All to PoU

The ICIALLU characteristics are:

Purpose

Invalidate all instruction caches to PoU. If branch predictors are architecturally visible, also flush branch predictors.

Configurations

AArch32 System instruction ICIALLU performs the same function as AArch64 System instruction IC IALLU.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ICIALLU is a 32-bit System instruction.

Field descriptions

ICIALLU ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the ICIALLU instruction

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

When HCR.FB is 1, at Non-secure EL1 this instruction executes as a ICIALLUIS.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MCR}\{<c>\}{<q>} <\text{coproc}>, \{#\}<\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>, \{#\}<\text{opc2}>

G8.2.77 ICIALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The ICIALLUIS characteristics are:

**Purpose**

Invalidate all instruction caches Inner Shareable to PoU. If branch predictors are architecturally visible, also flush branch predictors.

**Configurations**

AArch32 System instruction ICIALLUIS performs the same function as AArch64 System instruction IC IALLUIS.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ICIALLUIS is a 32-bit System instruction.

**Field descriptions**

ICIALLUIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the ICIALLUIS instruction**

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

Accesses to this register use the following encodings in the System instruction encoding space:

```
MCR{<c>}{<q>} <coproc>, {#<opc1>, <Rt>, <CRn>, <CRm>{, {#<opc2>}
```

<table>

```
G8.2.78  ICIMVAU, Instruction Cache line Invalidate by VA to PoU

The ICIMVAU characteristics are:

**Purpose**

Invalidate instruction cache line by virtual address to PoU.

**Configurations**

AArch32 System instruction ICIMVAU performs the same function as AArch64 System instruction IC IVAU.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ICIMVAU is a 32-bit System instruction.

**Field descriptions**

The ICIMVAU input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual address to use</td>
</tr>
</tbody>
</table>

Virtual address to use. No alignment restrictions apply to this VA.

**Executing the ICIMVAU instruction**

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see *AArch32 instruction cache maintenance instructions (IC*)* on page G4-5444.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MCR(<c>)(<q>) <coproc>, (#<opc1>, <Rt>, <CRn>, <CRm>, (#<opc2>)
\]

<table>

G8.2.80 ID_DFR0, Debug Feature Register 0

The ID_DFR0 characteristics are:

**Purpose**

Provides top level information about the debug system in AArch32 state.

Must be interpreted with the Main ID Register, MIDR.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-5646.

**Configurations**

AArch32 System register ID_DFR0[31:0] is architecturally mapped to AArch64 System register ID_DFR0_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_DFR0 is a 32-bit register.

**Field descriptions**

The ID_DFR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28 27</th>
<th>24 23</th>
<th>20 19</th>
<th>16 15</th>
<th>12 11</th>
<th>8 7</th>
<th>4 3</th>
<th>0</th>

</thead>
<tbody>
<tr>
<td>TraceFilt</td>
<td>PerfMon</td>
<td>MProfDbg</td>
<td>MMapTrc</td>
<td>CopTrc</td>
<td>MMapDbg</td>
<td>CopSDbg</td>
<td>CopDbg</td>
<td></td>
</tr>
</tbody>
</table>

**TraceFilt, bits [31:28]**

Armv8.4 Self-hosted Trace Extension version. Defined values are:

- **0b0000** Armv8.4 Self-hosted Trace Extension not implemented.
- **0b0001** Armv8.4 Self-hosted Trace Extension implemented.

All other values are reserved.

ARMv8.4-Trace implements the functionality added by the value 0b0001.

From Armv8.3, the permitted values are **0b0000** and **0b0001**.

**PerfMon, bits [27:24]**

Performance Monitors Extension version.

This field does not follow the standard ID scheme, but uses the alternative ID scheme described in *Alternative ID scheme used for the Performance Monitors Extension version* on page G8-5648.

Defined values are:

- **0b0000** Performance Monitors Extension not implemented.
- **0b0001** Performance Monitors Extension version 1 implemented, PMUv1.
- **0b0010** Performance Monitors Extension version 2 implemented, PMUv2.
- **0b0011** Performance Monitors Extension version 3 implemented, PMUv3.
- **0b0100** PMUv3 for Armv8.1. As 0b0111, and also includes support for:
  - Extended 16-bit PMEVTYPER<n>.evtCount field.
  - If EL2 is implemented, the HDCR.HPMD control bit.
- **0b0101** PMUv3 for Armv8.4. As 0b0100 and also includes support for the PMMIR register.
- **0b1111** IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported. Arm does not recommend this value in new implementations.
ARMv8.1-PMU implements the functionality added by the value 0b0100.
ARMv8.4-PMU implements the functionality added by the value 0b0101.

All other values are reserved.
In any Armv8 implementation, the values 0b0001 and 0b0010 are not permitted.
From Armv8.1, the value 0b0011 is not permitted.
From Armv8.4, the value 0b0100 is not permitted.

**Note**
In Armv7, the value 0b0000 can mean that PMUv1 is implemented. PMUv1 is not permitted in an Armv8 implementation.

MProfDbg, bits [23:20]
M Profile Debug. Support for memory-mapped debug model for M profile processors. Defined values are:
- 0b0000 Not supported.
- 0b0001 Support for M profile Debug architecture, with memory-mapped access.
All other values are reserved.
In Armv8-A, the only permitted value is 0b0000.

MMapTrc, bits [19:16]
Memory Mapped Trace. Support for memory-mapped trace model. Defined values are:
- 0b0000 Not supported.
- 0b0001 Support for Arm trace architecture, with memory-mapped access.
All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.
See the ETM Architecture Specification for more information.

CopTrc, bits [15:12]
Support for System registers-based trace model, using registers in the coproc == 0b1110 encoding space. Defined values are:
- 0b0000 Not supported.
- 0b0001 Support for Arm trace architecture, with System registers access.
All other values are reserved.
In Armv8-A, the permitted values are 0b0000 and 0b0001.
See the ETM Architecture Specification for more information.

MMapDbg, bits [11:8]
Memory Mapped Debug. Support for v7 memory-mapped debug model, for A and R profile processors.
In Armv8-A, this field is RES0.
The optional memory map defined by Armv8 is not compatible with Armv7.

CopSdbg, bits [7:4]
Support for a System registers-based Secure debug model, using registers in the coproc = 0b1110 encoding space, for an A profile processor that includes EL3.
If EL3 is not implemented and the implemented Security state is Non-secure state, this field is RES0.
Otherwise, this field reads the same as bits [3:0].
CopDbg, bits [3:0]

Support for System registers-based debug model, using registers in the coproc == 0b1110 encoding space, for A and R profile processors. Defined values are:

- 0b0000  Not supported.
- 0b0010  Support for Armv6, v6 Debug architecture, with System registers access.
- 0b0011  Support for Armv6, v6.1 Debug architecture, with System registers access.
- 0b0100  Support for Armv7, v7 Debug architecture, with System registers access.
- 0b0101  Support for Armv7, v7.1 Debug architecture, with System registers access.
- 0b0110  Support for Armv8 debug architecture, with System registers access.
- 0b0111  Support for Armv8 debug architecture, with System registers access, and Virtualization Host extensions.
- 0b1000  Support for Armv8.2 debug architecture.
- 0b1001  Support for Armv8.4 debug architecture.

All other values are reserved.

In any Armv8 implementation, the values 0b0000, 0b0010, 0b0011, 0b0100, and 0b0101 are not permitted.

If ARMv8.1-VHE is not implemented, the only permitted value is 0b0110.

In an Armv8.0 implementation, the value 0b1000 is not permitted.

Accessing the ID_DFR0

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MRC}\{<c>\}\{<q>\} \{coproc\}, \{#\}op1, \{Rt\}, \{CRn\}, \{CRm\}\{, \{#\}op2\} \]

<table>
<thead>

G8.2.81  ID_ISAR0, Instruction Set Attribute Register 0

The ID_ISAR0 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-5646.

**Configurations**

AArch32 System register ID_ISAR0[31:0] is architecturally mapped to AArch64 System register ID_ISAR0_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_ISAR0 is a 32-bit register.

**Field descriptions**

The ID_ISAR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>27-24</td>
<td>Debug</td>
</tr>
<tr>
<td>23-20</td>
<td>Coproc</td>
</tr>
<tr>
<td>19-16</td>
<td>CmpBranch</td>
</tr>
<tr>
<td>15-12</td>
<td>BitField</td>
</tr>
<tr>
<td>11-8</td>
<td>BitCount</td>
</tr>
<tr>
<td>7-4</td>
<td>Swap</td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**Divide, bits [27:24]**

Indicates the implemented Divide instructions. Defined values are:

- 0b0000  None implemented.
- 0b0001  Adds SDIV and UDIV in the T32 instruction set.
- 0b0010  As for 0b0001, and adds SDIV and UDIV in the A32 instruction set.

All other values are reserved.

In Armv8-A the only permitted value is 0b0010.

**Debug, bits [23:20]**

Indicates the implemented Debug instructions. Defined values are:

- 0b0000  None implemented.
- 0b0001  Adds BKPT.

All other values are reserved.

In Armv8-A the only permitted value is 0b0001.

**Coproc, bits [19:16]**

Indicates the implemented System register access instructions. Defined values are:

- 0b0000  None implemented, except for instructions separately attributed by the architecture to provide access to AArch32 System registers and System instructions.
- 0b0001  Adds generic CDP, LDC, MCR, MRC, and STC.
- 0b0010  As for 0b0001, and adds generic CDP2, LDC2, MCR2, MRC2, and STC2.
- 0b0011  As for 0b0010, and adds generic MCRR and MRRC.
0b0100  As for 0b011, and adds generic MCRR2 and MRRC2.  
All other values are reserved. 
In Armv8-A the only permitted value is 0b0000.

CmpBranch, bits [15:12] 
Indicates the implemented combined Compare and Branch instructions in the T32 instruction set. 
Defined values are:
  0b0000  None implemented. 
  0b0001  Adds CBNZ and CBZ. 
All other values are reserved. 
In Armv8-A the only permitted value is 0b0001.

BitField, bits [11:8] 
Indicates the implemented BitField instructions. Defined values are:
  0b0000  None implemented. 
  0b0001  Adds BFC, BFI, SBFX, and UBFX. 
All other values are reserved. 
In Armv8-A the only permitted value is 0b0001.

BitCount, bits [7:4] 
Indicates the implemented Bit Counting instructions. Defined values are:
  0b0000  None implemented. 
  0b0001  Adds CLZ. 
All other values are reserved. 
In Armv8-A the only permitted value is 0b0001.

Swap, bits [3:0] 
Indicates the implemented Swap instructions in the A32 instruction set. Defined values are:
  0b0000  None implemented. 
  0b0001  Adds SWP and SWPB. 
All other values are reserved. 
In Armv8-A the only permitted value is 0b0000.

Accessing the ID_ISAR0

ID_ISAR1, Instruction Set Attribute Register 1

The ID_ISAR1 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-5646.

**Configurations**

AArch32 System register ID_ISAR1[31:0] is architecturally mapped to AArch64 System register ID_ISAR1_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_ISAR1 is a 32-bit register.

**Field descriptions**

The ID_ISAR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jazelle</td>
<td>Interwork</td>
<td>Immediate</td>
<td>IfThen</td>
<td>Extend</td>
<td>Except_AR</td>
<td>Except</td>
<td>Endian</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Jazelle, bits [31:28]**

Indicates the implemented Jazelle extension instructions. Defined values are:

- 0b0000: No support for Jazelle.
- 0b0001: Adds the BXJ instruction, and the J bit in the PSR. This setting might indicate a trivial implementation of the Jazelle extension.

All other values are reserved.

In Armv8-A the only permitted value is 0b0001.

**Interwork, bits [27:24]**

Indicates the implemented Interworking instructions. Defined values are:

- 0b0000: None implemented.
- 0b0001: Adds the BX instruction, and the T bit in the PSR.
- 0b0010: As for 0b0001, and adds the BLX instruction. PC loads have BX-like behavior.
- 0b0011: As for 0b0010, and guarantees that data-processing instructions in the A32 instruction set with the PC as the destination and the S bit clear have BX-like behavior.

All other values are reserved.

In Armv8-A the only permitted value is 0b0011.

**Immediate, bits [23:20]**

Indicates the implemented data-processing instructions with long immediates. Defined values are:

- 0b0000: None implemented.
- 0b0001: Adds:
  - The MOVT instruction
  - The MOV instruction encodings with zero-extended 16-bit immediates.
The T32 ADD and SUB instruction encodings with zero-extended 12-bit immediates, and the other ADD, ADR, and SUB encodings cross-referenced by the pseudocode for those encodings.

All other values are reserved.
In Armv8-A the only permitted value is \(0b0001\).

**IfThen, bits [19:16]**
Indicates the implemented If-Then instructions in the T32 instruction set. Defined values are:
- \(0b0000\): None implemented.
- \(0b0001\): Adds the IT instructions, and the IT bits in the PSRs.

All other values are reserved.
In Armv8-A the only permitted value is \(0b0001\).

**Extend, bits [15:12]**
Indicates the implemented Extend instructions. Defined values are:
- \(0b0000\): No scalar sign-extend or zero-extend instructions are implemented, where scalar instructions means non-Advanced SIMD instructions.
- \(0b0001\): Adds the SXTB, SXTH, UXTB, and UXTH instructions.
- \(0b0010\): As for \(0b0001\), and adds the SXTB16, SXTAB, SXTAB16, SXTAH, UXTB16, UXTAB, UXTAB16, and UXTAH instructions.

All other values are reserved.
In Armv8-A the only permitted value is \(0b0010\).

**Except_AR, bits [11:8]**
Indicates the implemented A and R profile exception-handling instructions. Defined values are:
- \(0b0000\): None implemented.
- \(0b0001\): Adds the SRS and RFE instructions, and the A and R profile forms of the CPS instruction.

All other values are reserved.
In Armv8-A the only permitted value is \(0b0001\).

**Except, bits [7:4]**
Indicates the implemented exception-handling instructions in the A32 instruction set. Defined values are:
- \(0b0000\): Not implemented. This indicates that the User bank and Exception return forms of the LDM and STM instructions are not implemented.
- \(0b0001\): Adds the LDM (exception return), LDM (user registers), and STM (user registers) instruction versions.

All other values are reserved.
In Armv8-A the only permitted value is \(0b0001\).

**Endian, bits [3:0]**
Indicates the implemented Endian instructions. Defined values are:
- \(0b0000\): None implemented.
- \(0b0001\): Adds the SETEND instruction, and the E bit in the PSRs.

All other values are reserved.
In Armv8-A the permitted values are \(0b0000\) and \(0b0001\).

Accessing the ID_ISAR1

G8.2.83  ID_ISAR2, Instruction Set Attribute Register 2

The ID_ISAR2 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-5646.

**Configurations**

AArch32 System register ID_ISAR2[31:0] is architecturally mapped to AArch64 System register ID_ISAR2_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_ISAR2 is a 32-bit register.

**Field descriptions**

The ID_ISAR2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reversal</td>
<td>PSR_AR</td>
<td>MultU</td>
<td>MultS</td>
<td>Mult</td>
<td>MemHint</td>
<td>LoadStore</td>
<td>MultiAccessInt</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Reversal, bits [31:28]**

Indicates the implemented Reversal instructions. Defined values are:

| 0b0000 | None implemented. |
| 0b0001 | Adds the REV, REV16, and REVSH instructions. |
| 0b0010 | As for 0b0001, and adds the RBIT instruction. |

All other values are reserved.

In Armv8-A the only permitted value is 0b0010.

**PSR_AR, bits [27:24]**

Indicates the implemented A and R profile instructions to manipulate the PSR. Defined values are:

| 0b0000 | None implemented. |
| 0b0001 | Adds the MRS and MSR instructions, and the exception return forms of data-processing instructions. |

All other values are reserved.

In Armv8-A the only permitted value is 0b0001.

The exception return forms of the data-processing instructions are:

- In the A32 instruction set, data-processing instructions with the PC as the destination and the S bit set. These instructions might be affected by the WithShifts attribute.
- In the T32 instruction set, the SUBS PC,LR,#N instruction.

**MultU, bits [23:20]**

Indicates the implemented advanced unsigned Multiply instructions. Defined values are:

| 0b0000 | None implemented. |
0b0001  Adds the UMULL and UMLAL instructions.
0b0010  As for 0b0001, and adds the UMAAL instruction.
All other values are reserved.
In Armv8-A the only permitted value is 0b0010.

**MultS, bits [19:16]**
Indicates the implemented advanced signed Multiply instructions. Defined values are:
0b0000  None implemented.
0b0001  Adds the SMULL and SMLAL instructions.
0b0010  As for 0b0001, and adds the SMLABB, SMLABT, SMLALBB, SMLALBT,
        SMLALTB, SMLALTT, SMLATB, SMLATT, SMLAWB, SMLAWT, SMULBB,
        SMULBT, SMULTB, SMULTT, SMULWB, and SMULWT instructions. Also adds the
        Q bit in the PSRs.
0b0011  As for 0b0010, and adds the SMLAD, SMLADX, SMLALD, SMLALDX, SMLSD,
        SMLSDX, SMLSLD, SMLSLDX, SMLLA, SMLAR, SMMLS, SMMLSR,
        SMMUL, SMMLUR, SMUAD, SMUADX, SMUSD, and SMUSDX instructions.
All other values are reserved.
In Armv8-A the only permitted value is 0b0011.

**Mult, bits [15:12]**
Indicates the implemented additional Multiply instructions. Defined values are:
0b0000  No additional instructions implemented. This means only MUL is implemented.
0b0001  Adds the MLA instruction.
0b0010  As for 0b0001, and adds the MLS instruction.
All other values are reserved.
In Armv8-A the only permitted value is 0b0010.

**MultiAccessInt, bits [11:8]**
Indicates the support for interruptible multi-access instructions. Defined values are:
0b0000  No support. This means the LDM and STM instructions are not interruptible.
0b0001  LDM and STM instructions are restartable.
0b0010  LDM and STM instructions are continuable.
All other values are reserved.
In Armv8-A the only permitted value is 0b0000.

**MemHint, bits [7:4]**
Indicates the implemented Memory Hint instructions. Defined values are:
0b0000  None implemented.
0b0001  Adds the PLD instruction.
0b0010  Adds the PLD instruction. (0b0001 and 0b0010 have identical effects.)
0b0011  As for 0b0001 (or 0b0010), and adds the PLI instruction.
0b0100  As for 0b0011, and adds the PLDW instruction.
All other values are reserved.
In Armv8-A the only permitted value is 0b0000.

**LoadStore, bits [3:0]**
Indicates the implemented additional load/store instructions. Defined values are:
0b0000  No additional load/store instructions implemented.
0b0001  Adds the LDRD and STRD instructions.
0b0010  As for 0b0001, and adds the Load Acquire (LDAB, LDAH, LDA, LDAEXB, LDAEXH, LDAEX, LDAEXD) and Store Release (STLB, STLH, STL, STLEXB, STLEXH, STLEX, STLEXD) instructions.

All other values are reserved.
In Armv8-A the only permitted value is 0b0010.

Accessing the ID_ISAR2

Accesses to this register use the following encodings in the System instruction encoding space:

\[

G8.2.84  ID_ISAR3, Instruction Set Attribute Register 3

The ID_ISAR3 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state. Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR4, and ID_ISAR5. For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-5646.

**Configurations**

AArch32 System register ID_ISAR3[31:0] is architecturally mapped to AArch64 System register ID_ISAR3_EL1[31:0]. RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_ISAR3 is a 32-bit register.

**Field descriptions**

The ID_ISAR3 bit assignments are:

<table>

</tbody>
</table>

**T32EE, bits [31:28]**

Indicates the implemented T32EE instructions. Defined values are:

- **0b0000**: None implemented.
- **0b0001**: Adds the ENTERX and LEAVEX instructions, and modifies the load behavior to include null checking.

All other values are reserved.

In Armv8-A the only permitted value is 0b0000.

**TrueNOP, bits [27:24]**

Indicates the implemented true NOP instructions. Defined values are:

- **0b0000**: None implemented. This means there are no NOP instructions that do not have any register dependencies.
- **0b0001**: Adds true NOP instructions in both the T32 and A32 instruction sets. This also permits additional NOP-compatible hints.

All other values are reserved.

In Armv8-A the only permitted value is 0b0001.

**T32Copy, bits [23:20]**

Indicates the support for T32 non flag-setting MOV instructions. Defined values are:

- **0b0000**: Not supported. This means that in the T32 instruction set, encoding T1 of the MOV (register) instruction does not support a copy from a low register to a low register.
- **0b0001**: Adds support for T32 instruction set encoding T1 of the MOV (register) instruction, copying from a low register to a low register.

All other values are reserved.

In Armv8-A the only permitted value is 0b0001.
TabBranch, bits [19:16]
Indicates the implemented Table Branch instructions in the T32 instruction set. Defined values are:
- 0b0000  None implemented.
- 0b0001  Adds the TBB and TBH instructions.
All other values are reserved.
In Armv8-A the only permitted value is 0b0001.

SynchPrim, bits [15:12]
Used in conjunction with ID_ISAR4.SynchPrim_frac to indicate the implemented Synchronization Primitive instructions. Defined values are:
- 0b0000  If SynchPrim_frac == 0b000, no Synchronization Primitives implemented.
- 0b0001  If SynchPrim_frac == 0b000, adds the LDREX and STREX instructions.
  If SynchPrim_frac == 0b011, also adds the CLREX, LDREXB, STREXB, and STREXH instructions.
- 0b0010  If SynchPrim_frac == 0b000, as for [0b001, 0b011] and also adds the LDREXD and STREXD instructions.
All other combinations of SynchPrim and SynchPrim_frac are reserved.
In Armv8-A the only permitted value is 0b0010.

SVC, bits [11:8]
Indicates the implemented SVC instructions. Defined values are:
- 0b0000  Not implemented.
- 0b0001  Adds the SVC instruction.
All other values are reserved.
In Armv8-A the only permitted value is 0b0001.

SIMD, bits [7:4]
Indicates the implemented SIMD instructions. Defined values are:
- 0b0000  None implemented.
- 0b0001  Adds the SSAT and USAT instructions, and the Q bit in the PSRs.
- 0b0011  As for 0b0001, and adds the PKHBT, PKHTB, QADD16, QADD8, QASX, QSUB16, QSUB8, QSAX, SADD16, SADD8, SASX, SEL, SHADD16, SHADD8, SHASX, SHSUB16, SHSUB8, SHSAX, SSAT16, SSUB16, SSUB8, SSAX, SXTAB16, SXTB16, UADD16, UADD8, UASX, UHADD16, UHADD8, UHASX, UHSUB16, UHSUB8, UHAX, UQADD16, UQADD8, UQASX, UQSUB16, UQSUB8, UQSAX, USAD8, USADA8, USAT16, USUB16, USUB8, USAX, UXTAB16, and UXTB16 instructions. Also adds support for the GE[3:0] bits in the PSRs.
All other values are reserved.
In Armv8-A the only permitted value is 0b0011.

The SIMD field relates only to implemented instructions that perform SIMD operations on the general-purpose registers. In an implementation that supports floating-point and Advanced SIMD instructions, MVFR0, MVFR1, and MVFR2 give information about the implemented Advanced SIMD instructions.

Saturate, bits [3:0]
Indicates the implemented Saturate instructions. Defined values are:
- 0b0000  None implemented. This means no non-Advanced SIMD saturate instructions are implemented.
- 0b0001  Adds the QADD, QDADD, QDSUB, and QSUB instructions, and the Q bit in the PSRs.
All other values are reserved.
In Armv8-A the only permitted value is 0b0001.

**Accessing the ID_ISAR3**

Accesses to this register use the following encodings in the System instruction encoding space:

\[

G8.2.85 ID_ISAR4, Instruction Set Attribute Register 4

The ID_ISAR4 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, and ID_ISAR5.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-5646.

**Configurations**

AArch32 System register ID_ISAR4[31:0] is architecturally mapped to AArch64 System register ID_ISAR4_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_ISAR4 is a 32-bit register.

**Field descriptions**

The ID_ISAR4 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**SWP_frac, bits [31:28]**

Indicates support for the memory system locking the bus for SWP or SWPB instructions. Defined values are:

- 0b0000: SWP or SWPB instructions not implemented.
- 0b0001: SWP or SWPB implemented but only in a uniprocessor context. SWP and SWPB do not guarantee whether memory accesses from other masters can come between the load memory access and the store memory access of the SWP or SWPB.

All other values are reserved. This field is valid only if the ID_ISAR0.Swap_instrs field is 0b0000. In Armv8-A the only permitted value is 0b0000.

**PSR_M, bits [27:24]**

Indicates the implemented M profile instructions to modify the PSRs. Defined values are:

- 0b0000: None implemented.
- 0b0001: Adds the M profile forms of the CPS, MRS, and MSR instructions.

All other values are reserved. In Armv8-A the only permitted value is 0b0000.

**SynchPrim_frac, bits [23:20]**

Used in conjunction with ID_ISAR3.SynchPrim to indicate the implemented Synchronization Primitive instructions. Possible values are:

- 0b0000: If SynchPrim == 0b0000, no Synchronization Primitives implemented. If SynchPrim == 0b0001, adds the LDREX and STREX instructions. If SynchPrim == 0b0010, also adds the CLREX, LDREXB, LDREXH, STREXB, STREXH, LDREXD, and STREXD instructions.
If SynchPrim == 0b0001, adds the LDREX, STREX, CLREX, LDREXB, LDREXH, STREXB, and STREXH instructions.

All other combinations of SynchPrim and SynchPrim_frac are reserved.

In Armv8-A the only permitted value is 0b0000.

Barrier, bits [19:16]
Indicates the implemented Barrier instructions in the A32 and T32 instruction sets. Defined values are:
- 0b0000: None implemented. Barrier operations are provided only as System instructions in the (coproc==0b1111) encoding space.
- 0b0001: Adds the DMB, DSB, and ISB barrier instructions.

All other values are reserved.
In Armv8-A the only permitted value is 0b0001.

SMC, bits [15:12]
Indicates the implemented SMC instructions. Defined values are:
- 0b0000: None implemented.
- 0b0001: Adds the SMC instruction.

All other values are reserved.
In Armv8-A the only permitted value is 0b0001.

Writeback, bits [11:8]
Indicates the support for Writeback addressing modes. Defined values are:
- 0b0000: Basic support. Only the LDM, STM, PUSH, POP, SRS, and RFE instructions support writeback addressing modes. These instructions support all of their writeback addressing modes.
- 0b0001: Adds support for all of the writeback addressing modes.

All other values are reserved.
In Armv8-A the only permitted value is 0b0001.

WithShifts, bits [7:4]
Indicates the support for instructions with shifts. Defined values are:
- 0b0000: Nonzero shifts supported only in MOV and shift instructions.
- 0b0001: Adds support for shifts of loads and stores over the range LSL 0-3.
- 0b0011: As for 0b0001, and adds support for other constant shift options, both on load/store and other instructions.
- 0b0100: As for 0b0011, and adds support for register-controlled shift options.

All other values are reserved.
In Armv8-A the only permitted value is 0b0100.

Unpriv, bits [3:0]
Indicates the implemented unprivileged instructions. Defined values are:
- 0b0000: None implemented. No T variant instructions are implemented.
- 0b0001: Adds the LDRBT, LDRT, STRBT, and STRT instructions.
- 0b0010: As for 0b0001, and adds the LDRHT, LDRSBT, LDRSHT, and STRHT instructions.

All other values are reserved.
In Armv8-A the only permitted value is 0b0010.
Accessing the ID_ISAR4

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRC\{<c>\}{<q>} <coproc>, \{#\}<opc1>, <Rt>, <CRn>, <CRm>{, \{#\}<opc2>} \]

\[
\begin{array}{cccccc}
\text{coproc} & \text{opc1} & \text{CRn} & \text{CRm} & \text{opc2} \\
0b1111 & 0b000 & 0b0000 & 0b0010 & 0b100 \\
\end{array}
\]

If \( \text{PSTATE.EL} = \text{EL0} \) then

  - return ID_ISAR4;
ID_ISAR5, Instruction Set Attribute Register 5

The ID_ISAR5 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, and ID_ISAR4.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-5646.

**Configurations**

AArch32 System register ID_ISAR5[31:0] is architecturally mapped to AArch64 System register ID_ISAR5_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_ISAR5 is a 32-bit register.

**Field descriptions**

The ID_ISAR5 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>

<td>SHA1</td>
<td>AES</td>
<td>SEVL</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**VCMA, bits [31:28]**

*From ARMv8.3:*

Indicates AArch32 support for complex number addition and multiplication where numbers are stored in vectors. Defined values are:

- 0b0000: The VCMLA and VCADD instructions are not implemented in AArch32.
- 0b0001: The VCMLA and VCADD instructions are implemented in AArch32.

All other values are reserved.

In Armv8.0, Armv8.1 and Armv8.2 the only permitted value is 0b0000.

From Armv8.3 the only permitted value is 0b0001. This feature is identified as ARMv8.3-CompNum.

*Otherwise:*

Reserved, RES0.

**RDM, bits [27:24]**

*From ARMv8.1:*

Indicates whether the VQRDMLAH and VQRDMLSH instructions are implemented in AArch32 state. Defined values are:

- 0b0000: No VQRDMLAH and VQRDMLSH instructions implemented.
- 0b0001: VQRDMLAH and VQRDMLSH instructions implemented.

All other values are reserved.

ARMv8.1-RDMA implements the functionality identified by the value 0b0001.

From Armv8.1 the only permitted value is 0b0001.

*Otherwise:*

Reserved, RES0.
### Bits [23:20]
Reserved, RES0.

**CRC32, bits [19:16]**
Indicates whether the CRC32 instructions are implemented in AArch32 state.

- **0b0000**: No CRC32 instructions implemented.
- **0b0001**: CRC32B, CRC32H, CRC32W, CRC32CB, CRC32CH, and CRC32CW instructions implemented.

All other values are reserved.

In Armv8.0 the permitted values are 0b0000 and 0b0001.

From Armv8.1 the only permitted value is 0b0001.

**SHA2, bits [15:12]**
Indicates whether the SHA2 instructions are implemented in AArch32 state.

- **0b0000**: No SHA2 instructions implemented.
- **0b0001**: SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 implemented.

All other values are reserved.

In Armv8-A the permitted values are 0b0000 and 0b0001.

**SHA1, bits [11:8]**
Indicates whether the SHA1 instructions are implemented in AArch32 state.

- **0b0000**: No SHA1 instructions implemented.
- **0b0001**: SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 implemented.

All other values are reserved.

In Armv8-A the permitted values are 0b0000 and 0b0001.

**AES, bits [7:4]**
Indicates whether the AES instructions are implemented in AArch32 state.

- **0b0000**: No AES instructions implemented.
- **0b0001**: AESE, AESD, AESMC, and AESIMC implemented.
- **0b0010**: As for 0b0001, plus VMULL (polynomial) instructions operating on 64-bit data quantities.

All other values are reserved.

In Armv8-A the permitted values are 0b0000 and 0b0010.

**SEVL, bits [3:0]**
Indicates whether the SEVL instruction is implemented in AArch32 state.

- **0b0000**: SEVL is implemented as a NOP.
- **0b0001**: SEVL is implemented as Send Event Local.

All other values are reserved.

In Armv8-A the only permitted value is 0b0001.

### Accessing the ID_ISAR5
Accesses to this register use the following encodings in the System instruction encoding space:

G8.2.87   ID_ISAR6, Instruction Set Attribute Register 6

The ID_ISAR6 characteristics are:

**Purpose**

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4 and ID_ISAR5.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-5646.

**Configurations**

AArch32 System register ID_ISAR6[31:0] is architecturally mapped to AArch64 System register ID_ISAR6_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_ISAR6 is a 32-bit register.

**Field descriptions**

The ID_ISAR6 bit assignments are:

<p>| | | | | |</p>
<table>
<thead>
<tr>

</tbody>
</table>

**Bits [31:12]**

Reserved, RES0.

**FHM, bits [11:8]**

*From ARMv8.2:*

Indicates whether VFMAL and VFMSL instructions are implemented.

- **0b0000**: VFMAL and VMFSL instructions not implemented.
- **0b0001**: VFMAL and VMFSL instructions implemented.

**ARMv8.2-FHM** implements the functionality identified by the value **0b0001**.

*Otherwise:*

Reserved, RES0.

**DP, bits [7:4]**

*From ARMv8.2:*

Indicates the support for dot product instructions in AArch32 state.

- **0b0000**: No dot product instructions implemented.
- **0b0001**: VUDOT and VSDOT instructions implemented.

All other values are reserved.

**ARMv8.2-DotProd** implements the functionality identified by the value **0b0001**.

*Otherwise:*

Reserved, RES0.
JSCVT, bits [3:0]

*From ARMv8.3:*  
Indicates whether the Javascript conversion instruction is implemented in AArch32 state. Defined values are:
- 0b0000  The VJCVT instruction is not implemented.
- 0b0001  The VJCVT instruction is implemented.
All other values are reserved.

In Armv8.0, Armv8.1 and Armv8.2 the only permitted value is 0b0000.
From Armv8.3 the only permitted value is 0b0001. This feature is identified as ARMv8.3-JConv.

*Otherwise:*  
Reserved, RES0.

**Accessing the ID_ISR6**

Accesses to this register use the following encodings in the System instruction encoding space:

G8.2.88   **ID_MMFR0, Memory Model Feature Register 0**

The ID_MMFR0 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR1, ID_MMFR2, ID_MMFR3, and ID_MMFR4.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-5646.

**Configurations**

AArch32 System register ID_MMFR0[31:0] is architecturally mapped to AArch64 System register ID_MMFR0_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_MMFR0 is a 32-bit register.

**Field descriptions**

The ID_MMFR0 bit assignments are:

<table>
<thead>
<tr>
<th>InnerShr</th>
<th>FCSE</th>
<th>AuxReg</th>
<th>TCM</th>
<th>ShareLvl</th>
<th>OuterShr</th>
<th>PMSA</th>
<th>VMSA</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 28 27</td>
<td>24 23</td>
<td>20 19</td>
<td>16 15</td>
<td>12 11</td>
<td>8 7</td>
<td>4 3</td>
<td>0</td>
</tr>
</tbody>
</table>

**InnerShr, bits [31:28]**

Innermost Shareability. Indicates the innermost shareability domain implemented. Defined values are:

- **0b0000**  Implemented as Non-cacheable.
- **0b0001**  Implemented with hardware coherency support.
- **0b1111**  Shareability ignored.

All other values are reserved.

In Armv8 the permitted values are **0b0000**, **0b0001**, and **0b1111**.

This field is valid only if the implementation supports two levels of shareability, as indicated by ID_MMFR0.ShareLvl having the value **0b0001**.

When ID_MMFR0.ShareLvl is zero, this field is UNK.

**FCSE, bits [27:24]**

Indicates whether the implementation includes the FCSE. Defined values are:

- **0b0000**  Not supported.
- **0b0001**  Support for FCSE.

All other values are reserved.

In Armv8 the only permitted value is **0b0000**.

**AuxReg, bits [23:20]**

Auxiliary Registers. Indicates support for Auxiliary registers. Defined values are:

- **0b0000**  None supported.
- **0b0001**  Support for Auxiliary Control Register only.
Support for Auxiliary Fault Status Registers (AIFSR and ADFSR) and Auxiliary Control Register.

All other values are reserved.

In Armv8 the only permitted value is 0b0010.

Note

Accesses to unimplemented Auxiliary registers are UNDEFINED.

TCM, bits [19:16]
Indicates support for TCMs and associated DMAs. Defined values are:

- 0b0000  Not supported.
- 0b0001  Support is IMPLEMENTATION DEFINED. Armv7 requires this setting.
- 0b0010  Support for TCM only, Armv6 implementation.
- 0b0011  Support for TCM and DMA, Armv6 implementation.

All other values are reserved.

In Armv8-A the only permitted value is 0b0000.

ShareLvl, bits [15:12]
Shareability Levels. Indicates the number of shareability levels implemented. Defined values are:

- 0b0000  One level of shareability implemented.
- 0b0001  Two levels of shareability implemented.

All other values are reserved.

In Armv8 the only permitted value is 0b0001.

OuterShr, bits [11:8]
Outermost Shareability. Indicates the outermost shareability domain implemented. Defined values are:

- 0b0000  Implemented as Non-cacheable.
- 0b0001  Implemented with hardware coherency support.
- 0b1111  Shareability ignored.

All other values are reserved.

In Armv8 the permitted values are 0b0000, 0b0001, and 0b1111.

PMSA, bits [7:4]
Indicates support for a PMSA. Defined values are:

- 0b0000  Not supported.
- 0b0001  Support for IMPLEMENTATION DEFINED PMSA.
- 0b0010  Support for PMSAv6, with a Cache Type Register implemented.
- 0b0011  Support for PMSAv7, with support for memory subsections. Armv7-R profile.

All other values are reserved.

In Armv8-A the only permitted value is 0b0000.

VMSA, bits [3:0]
Indicates support for a VMSA. Defined values are:

- 0b0000  Not supported.
- 0b0001  Support for IMPLEMENTATION DEFINED VMSA.
- 0b0010  Support for VMSAv6, with Cache and TLB Type Registers implemented.
0b0011  Support for VMSAv7, with support for remapping and the Access flag. ARMv7-A profile.

0b0100  As for 0b0011, and adds support for the PXN bit in the Short-descriptor translation table format descriptors.

0b0101  As for 0b0100, and adds support for the Long-descriptor translation table format.

All other values are reserved.

In Armv8-A the only permitted value is 0b0101.

**Accessing the ID_MMFR0**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
 MRC\{c\}\{q\} \{coproc\}, \{#\}cr1, crn, \{CRm\}{, \{#\}opc2}\n\]

<table>
<thead>
<tr>
<th>coproc</th>

G8.2.89 ID_MMFR1, Memory Model Feature Register 1

The ID_MMFR1 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0, ID_MMFR2, ID_MMFR3, and ID_MMFR4.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-5646.

**Configurations**

AArch32 System register ID_MMFR1[31:0] is architecturally mapped to AArch64 System register ID_MMFR1_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_MMFR1 is a 32-bit register.

**Field descriptions**

The ID_MMFR1 bit assignments are:

**BPred, bits [31:28]**

Branch Predictor. Indicates branch predictor management requirements. Defined values are:

- **0b0000**: No branch predictor, or no MMU present. Implies a fixed MPU configuration.
- **0b0001**: Branch predictor requires flushing on:
  - Enabling or disabling a stage of address translation.
  - Writing new data to instruction locations.
  - Writing new mappings to the translation tables.
  - Changes to the TTBR0, TTBR1, or TTBCR registers.
  - Changes to the ContextID or ASID, or to the FCSE ProcessID if this is supported.
- **0b0010**: Branch predictor requires flushing on:
  - Enabling or disabling a stage of address translation.
  - Writing new data to instruction locations.
  - Writing new mappings to the translation tables.
  - Any change to the TTBR0, TTBR1, or TTBCR registers without a change to the corresponding ContextID or ASID, or FCSE ProcessID if this is supported.
- **0b0011**: Branch predictor requires flushing only on writing new data to instruction locations.
- **0b0100**: For execution correctness, branch predictor requires no flushing at any time.

All other values are reserved.

In Armv8-A the permitted values are 0b0010, 0b0011, or 0b0100. For values other than 0b0000 and 0b0100 the Arm Architecture Reference Manual, or the product documentation, might give more information about the required maintenance.
**L1TstCln, bits [27:24]**

Level 1 cache Test and Clean. Indicates the supported Level 1 data cache test and clean operations, for Harvard or unified cache implementations. Defined values are:

- **0b0000** None supported.
- **0b0001** Supported Level 1 data cache test and clean operations are:
  - Test and clean data cache.
- **0b0010** As for 0001, and adds:
  - Test, clean, and invalidate data cache.

All other values are reserved.

In Armv8-A the only permitted value is 0b0000.

**L1Uni, bits [23:20]**

Level 1 Unified cache. Indicates the supported entire Level 1 cache maintenance operations for a unified cache implementation. Defined values are:

- **0b0000** None supported.
- **0b0001** Supported entire Level 1 cache operations are:
  - Invalidate cache, including branch predictor if appropriate.
  - Invalidate branch predictor, if appropriate.
- **0b0010** As for 0001, and adds:
  - Clean cache, using a recursive model that uses the cache dirty status bit.
  - Clean and invalidate cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.

In Armv8-A the only permitted value is 0b0000.

**L1Hvd, bits [19:16]**

Level 1 Harvard cache. Indicates the supported entire Level 1 cache maintenance operations for a Harvard cache implementation. Defined values are:

- **0b0000** None supported.
- **0b0001** Supported entire Level 1 cache operations are:
  - Invalidate instruction cache, including branch predictor if appropriate.
  - Invalidate branch predictor, if appropriate.
- **0b0010** As for 0001, and adds:
  - Invalidate data cache.
  - Invalidate data cache and instruction cache, including branch predictor if appropriate.
- **0b0011** As for 0010, and adds:
  - Clean data cache, using a recursive model that uses the cache dirty status bit.
  - Clean and invalidate data cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.

In Armv8-A the only permitted value is 0b0000.

**L1UniSW, bits [15:12]**

Level 1 Unified cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a unified cache implementation. Defined values are:

- **0b0000** None supported.
0b0001  Supported Level 1 unified cache line maintenance operations by set/way are:
  •   Clean cache line by set/way.

0b0010  As for 0001, and adds:
  •   Clean and invalidate cache line by set/way.

0b0011  As for 0010, and adds:
  •   Invalidate cache line by set/way.

All other values are reserved.
In Armv8-A the only permitted value is 0b0000.

L1HvdSW, bits [11:8]
Level 1 Harvard cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a Harvard cache implementation. Defined values are:
0b0000  None supported.
0b0001  Supported Level 1 Harvard cache line maintenance operations by set/way are:
  •   Clean data cache line by set/way.
  •   Clean and invalidate data cache line by set/way.

0b0010  As for 0001, and adds:
  •   Invalidate data cache line by set/way.

0b0011  As for 0010, and adds:
  •   Invalidate instruction cache line by set/way

All other values are reserved.
In Armv8-A the only permitted value is 0b0000.

L1UniVA, bits [7:4]
Level 1 Unified cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a unified cache implementation. Defined values are:
0b0000  None supported.
0b0001  Supported Level 1 unified cache line maintenance operations by VA are:
  •   Clean cache line by VA.
  •   Invalidate cache line by VA.
  •   Clean and invalidate cache line by VA.

0b0010  As for 0001, and adds:
  •   Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.
In Armv8-A the only permitted value is 0b0000.

L1HvdVA, bits [3:0]
Level 1 Harvard cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a Harvard cache implementation. Defined values are:
0b0000  None supported.
0b0001  Supported Level 1 Harvard cache line maintenance operations by VA are:
  •   Clean data cache line by VA.
  •   Invalidate data cache line by VA.
  •   Clean and invalidate data cache line by VA.
  •   Clean instruction cache line by VA.

0b0010  As for 0001, and adds:
  •   Invalidate branch predictor by VA, if branch predictor is implemented.
All other values are reserved.
In Armv8-A the only permitted value is 0b0000.

**Accessing the ID_MMFR1**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}{<q>} <\text{coproc}>, \{#<\text{opc1}>\}, \langle\text{Rt}\rangle, \langle\text{CRn}\rangle, \langle\text{CRm}\rangle, \{#<\text{opc2}>\}

G8.2.90   ID_MMFR2, Memory Model Feature Register 2

The ID_MMFR2 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0, ID_MMFR1, ID_MMFR3, and ID_MMFR4.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-5646.

Configurations

AArch32 System register ID_MMFR2[31:0] is architecturally mapped to AArch64 System register ID_MMFR2_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ID_MMFR2 is a 32-bit register.

Field descriptions

The ID_MMFR2 bit assignments are:

<table>
<thead>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

HWAccFlg, bits [31:28]

Hardware Access Flag. In earlier versions of the Arm Architecture, this field indicates support for a Hardware Access flag, as part of the VMSA v7 implementation. Defined values are:

0b0000  Not supported.
0b0001  Support for VMSA v7 Access flag, updated in hardware.
All other values are reserved.

In Armv8 the only permitted value is 0b000.

WFIStall, bits [27:24]

Wait For Interrupt Stall. Indicates the support for Wait For Interrupt (WFI) stalling. Defined values are:

0b0000  Not supported.
0b0001  Support for WFI stalling.
All other values are reserved.

In Armv8 the permitted values are 0b000 and 0b001.

MemBarr, bits [23:20]

Memory Barrier. Indicates the supported memory barrier System instructions in the (coproc==1111) encoding space:

0b0000  None supported.
0b0001  Supported memory barrier System instructions are:
  • Data Synchronization Barrier (DSB).
0b0010  As for 0b001, and adds:
  • Instruction Synchronization Barrier (ISB).
• Data Memory Barrier (DMB).

All other values are reserved.

In Armv8 the only permitted value is 0b010.

Arm deprecates the use of these operations. ID_ISAR4.Barrier_intrs indicates the level of support for the preferred barrier instructions.

**UniTLB, bits [19:16]**

Unified TLB. Indicates the supported TLB maintenance operations, for a unified TLB implementation. Defined values are:

- **0b0000** Not supported.
- **0b0001** Supported unified TLB maintenance operations are:
  - Invalidate all entries in the TLB.
  - Invalidate TLB entry by VA.
- **0b0010** As for 0b001, and adds:
  - Invalidate TLB entries by ASID match.
- **0b0011** As for 0b010, and adds:
  - Invalidate instruction TLB and data TLB entries by VA All ASID. This is a shared unified TLB operation
- **0b0100** As for 0b011, and adds:
  - Invalidate Hyp mode unified TLB entry by VA.
  - Invalidate entire Non-secure PL1&0 unified TLB.
  - Invalidate entire Hyp mode unified TLB.
- **0b0101** As for 0b100, and adds the following operations: TLBIMVALIS, TLBIMVAALIS, TLBIMVALHIS, TLBIMVAL, TLBIMVAAL, TLBIMVALH.
- **0b0110** As for 0b101, and adds the following operations: TLBIIPAS2IS, TLBIIPAS2LIS, TLBIIPAS2, TLBIIPAS2L.

All other values are reserved.

In Armv8-A the only permitted value is 0b110.

**HvdTLB, bits [15:12]**

If the Unified TLB field (UniTLB, bits [19:16]) is not 0000, then the meaning of this field is IMPLEMENTATION DEFINED. Arm deprecates the use of this field by software.

**L1HvdRng, bits [11:8]**

Level 1 Harvard cache Range. Indicates the supported Level 1 cache maintenance range operations, for a Harvard cache implementation. Defined values are:

- **0b0000** Not supported.
- **0b0001** Supported Level 1 Harvard cache maintenance range operations are:
  - Invalidate data cache range by VA.
  - Invalidate instruction cache range by VA.
  - Clean data cache range by VA.
  - Clean and invalidate data cache range by VA.

All other values are reserved.

In Armv8 the only permitted value is 0b0000.
L1HvdBG, bits [7:4]
Level 1 Harvard cache Background fetch. Indicates the supported Level 1 cache background fetch operations, for a Harvard cache implementation. When supported, background fetch operations are non-blocking operations. Defined values are:

- 0b0000  Not supported.
- 0b0001  Supported Level 1 Harvard cache background fetch operations are:
  - Fetch instruction cache range by VA.
  - Fetch data cache range by VA.

All other values are reserved.

In Armv8 the only permitted value is 0b0000.

L1HvdFG, bits [3:0]
Level 1 Harvard cache Foreground fetch. Indicates the supported Level 1 cache foreground fetch operations, for a Harvard cache implementation. When supported, foreground fetch operations are blocking operations. Defined values are:

- 0b0000  Not supported.
- 0b0001  Supported Level 1 Harvard cache foreground fetch operations are:
  - Fetch instruction cache range by VA.
  - Fetch data cache range by VA.

All other values are reserved.

In Armv8 the only permitted value is 0b0000.

Accessing the ID_MMFR2
Accesses to this register use the following encodings in the System instruction encoding space:

G8.2.91   ID_MMFR3, Memory Model Feature Register 3

The ID_MMFR3 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0, ID_MMFR1, ID_MMFR2, and ID_MMFR4.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-5646.

**Configurations**

AArch32 System register ID_MMFR3[31:0] is architecturally mapped to AArch64 System register ID_MMFR3_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_MMFR3 is a 32-bit register.

**Field descriptions**

The ID_MMFR3 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Supersec, bits [31:28]**

Supersections. On a VMSA implementation, indicates whether Supersections are supported.

Defined values are:

- **0b0000** Supersections supported.
- **0b1111** Supersections not supported.

All other values are reserved.

In Armv8-A the permitted values are **0b0000** and **0b1111**.

**CMemSz, bits [27:24]**

Cached Memory Size. Indicates the physical memory size supported by the caches. Defined values are:

- **0b0000** 4GB, corresponding to a 32-bit physical address range.
- **0b0001** 64GB, corresponding to a 36-bit physical address range.
- **0b0010** 1TB or more, corresponding to a 40-bit or larger physical address range.

All other values are reserved.

In Armv8-A the permitted values are **0b0000**, **0b0001**, and **0b0010**.

**CohWalk, bits [23:20]**

Coherent Walk. Indicates whether Translation table updates require a clean to the Point of Unification. Defined values are:

- **0b0000** Updates to the translation tables require a clean to the Point of Unification to ensure visibility by subsequent translation table walks.
- **0b0001** Updates to the translation tables do not require a clean to the Point of Unification to ensure visibility by subsequent translation table walks.
All other values are reserved.
In Armv8-A the only permitted value is 0b0001.

**PAN, bits [19:16]**

*From ARMv8.1:*
Privileged Access Never. Indicates support for the PAN bit in CPSR, SPSR, and DSPSR in AArch32 state. Defined values are:
- 0b0000 PAN not supported.
- 0b0001 PAN supported.
- 0b0010 PAN supported and ATS1CPRP and ATS1CPWP instructions supported.
All other values are reserved.

**ARMv8.1-PAN** implements the functionality identified by the value 0b0001.

**ARMv8.2-ATS1E1** implements the functionality added by the value 0b0010.
In Armv8.1 the value 0b0000 is not permitted.
From Armv8.2, the only permitted value is 0b0010.

*Otherwise:*
Reserved, RES0.

**MaintBest, bits [15:12]**
Maintenance Broadcast. Indicates whether Cache, TLB, and branch predictor operations are broadcast. Defined values are:
- 0b0000 Cache, TLB, and branch predictor operations only affect local structures.
- 0b0001 Cache and branch predictor operations affect structures according to shareability and defined behavior of instructions. TLB operations only affect local structures.
- 0b0010 Cache, TLB, and branch predictor operations affect structures according to shareability and defined behavior of instructions.
All other values are reserved.
In Armv8-A the only permitted value is 0b0010.

**BPMaint, bits [11:8]**
Branch Predictor Maintenance. Indicates the supported branch predictor maintenance operations in an implementation with hierarchical cache maintenance operations. Defined values are:
- 0b0000 None supported.
- 0b0001 Supported branch predictor maintenance operations are:
  - Invalidate all branch predictors.
- 0b0010 As for 0001, and adds:
  - Invalidate branch predictors by VA.
All other values are reserved.
In Armv8-A the only permitted value is 0b0010.

**CMaintSW, bits [7:4]**
Cache Maintenance by Set/Way. Indicates the supported cache maintenance operations by set/way, in an implementation with hierarchical caches. Defined values are:
- 0b0000 None supported.
- 0b0001 Supported hierarchical cache maintenance instructions by set/way are:
  - Invalidate data cache by set/way.
  - Clean data cache by set/way.
  - Clean and invalidate data cache by set/way.
All other values are reserved.
In Armv8-A the only permitted value is 0b0001.

In a unified cache implementation, the data cache maintenance operations apply to the unified caches.

CMaintVA, bits [3:0]
Cache Maintenance by Virtual Address. Indicates the supported cache maintenance operations by VA, in an implementation with hierarchical caches. Defined values are:

- 0b0000 None supported.
- 0b0001 Supported hierarchical cache maintenance operations by VA are:
  - Invalidate data cache by VA.
  - Clean data cache by VA.
  - Clean and invalidate data cache by VA.
  - Invalidate instruction cache by VA.
  - Invalidate all instruction cache entries.

All other values are reserved.
In Armv8-A the only permitted value is 0b0001.
In a unified cache implementation, data cache maintenance operations apply to the unified caches, and the instruction cache maintenance instructions are not implemented.

Accessing the ID_MMFR3
Accesses to this register use the following encodings in the System instruction encoding space:

\[

G8.2.92   ID_MMFR4, Memory Model Feature Register 4

The ID_MMFR4 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0, ID_MMFR1, ID_MMFR2, and ID_MMFR3.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-5646.

**Configurations**

AArch32 System register ID_MMFR4[31:0] is architecturally mapped to AArch64 System register ID_MMFR4_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_MMFR4 is a 32-bit register.

**Field descriptions**

The ID_MMFR4 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>CCIDX</td>
<td>LSM</td>
<td>HPDS</td>
<td>CnP</td>
<td>XNX</td>
<td>AC2</td>
<td>SpecSEI</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**CCIDX, bits [27:24]**

From ARMv8.3:

Support for use of the revised CCSIDR format and the presence of the CCSIDR2 is indicated.

Defined values are:

- **0b0000**: 32-bit format implemented for all levels of the CCSIDR, and the CCSIDR2 register is not implemented.
- **0b0001**: 64-bit format implemented for all levels of the CCSIDR, and the CCSIDR2 register is implemented.

All other values are reserved.

From Armv8.3, the permitted values are **0b0000** and **0b0001**. This feature is identified as **ARMv8.3-CCIDX**.

Otherwise:

Reserved, RAZ.

**LSM, bits [23:20]**

From ARMv8.2:

Indicates support for LSMAOE and nTLSMD bits in HSCTLR and SCTLR. Defined values are:

- **0b0000**: LSMAOE and nTLSMD bits not supported.
- **0b0001**: LSMAOE and nTLSMD bits supported.

All other values are reserved.

**ARMv8.2-LSMAOC** implements the functionality identified by the value **0b0001**.
**Otherwise:**
Reserved, RAZ.

**HPDS, bits [19:16]**

*From ARMv8.2:*
Hierarchical permission disables bits in translation tables. Defined values are:
- **0b0000** Disabling of hierarchical controls not supported.
- **0b0001** Supports disabling of hierarchical controls using the **TTBCR2.HPD0, TTBCR2.HPD1, and HPCR.HPD** bits.
- **0b0010** As for value **0b0001**, and adds possible hardware allocation of bits[62:59] of the translation table descriptors from the final lookup level for IMPLEMENTATION DEFINED use.

All other values are reserved.
**ARMv8.2-AA32HPD** implements the functionality identified by the value **0b0001**.
**ARMv8.2-TTPBHA** implements the functionality added by the value **0b0010**.

--- **Note**
The value **0b0000** implies that the encoding for TTBCR2 is unallocated.

**Otherwise:**
Reserved, RAZ.

**CnP, bits [15:12]**

*From ARMv8.2:*
Common not Private translations. Defined values are:
- **0b0000** Common not Private translations not supported.
- **0b0001** Common not Private translations supported.

All other values are reserved.
**ARMv8.2-TTCNP** implements the functionality identified by the value **0b0001**.
From Armv8.2 the only permitted value is **0b0001**.

**Otherwise:**
Reserved, RAZ.

**XNX, bits [11:8]**

*From ARMv8.2:*
Support for execute-never control distinction by Exception level at stage 2. Defined values are:
- **0b0000** Distinction between EL0 and EL1 execute-never control at stage 2 not supported.
- **0b0001** Distinction between EL0 and EL1 execute-never control at stage 2 supported.

All other values are reserved.
**ARMv8.2-TTS2UXN** implements the functionality identified by the value **0b0001**.
When **ARMv8.2-TTS2UXN** is implemented:
- If all of the following conditions are true it is IMPLEMENTATION DEFINED whether the value of ID.MMFR4.XNX is **0b0000** or **0b0001**:
  - ID.AA64MMFR1_EL1.XNX ==1.
  - EL2 cannot use AArch32.
  - EL1 can use AArch32.
- If EL2 can use AArch32 then the only permitted value is **0b0001**.
**AC2, bits [7:4]**

Indicates the extension of the ACTLR and HACTLR registers using ACTLR2 and HACTLR2. Defined values are:

- **0b0000**: ACTLR2 and HACTLR2 are not implemented.
- **0b0001**: ACTLR2 and HACTLR2 are implemented.

All other values are reserved.

In Armv8.0 and Armv8.1 the permitted values are **0b0000** and **0b0001**. From Armv8.2, the only permitted value is **0b0001**.

**SpecSEI, bits [3:0]**

*When RAS is implemented:*

Describes whether the PE can generate SError interrupt exceptions from speculative reads of memory, including speculative instruction fetches. The defined values of this field are:

- **0b0000**: The PE never generates an SError interrupt due to an External abort on a speculative read.
- **0b0001**: The PE might generate an SError interrupt due to an External abort on a speculative read.

All other values are reserved.

*Otherwise:*

Reserved, RES0. This provides no information about whether the PE generates a speculative SError interrupt.

**Accessing the ID_MMFR4**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}{<q>} \text{ <coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm>{, \{#<opc2}\} }
\]

else
    return ID_MMFR4;
end if
```
G8.2.93   ID_PFR0, Processor Feature Register 0

The ID_PFR0 characteristics are:

Purpose

Gives top-level information about the instruction sets and other features supported by the PE in AArch32 state.

Must be interpreted with ID_PFR1.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-5646.

Configurations

AArch32 System register ID_PFR0[31:0] is architecturally mapped to AArch64 System register ID_PFR0_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ID_PFR0 is a 32-bit register.

Field descriptions

The ID_PFR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>

RAS, bits [31:28]

RAS Extension version.

- 0b0000  No RAS Extension.
- 0b0001  RAS Extension present.
- 0b0010  ARMv8.4-RAS present. As 0b0001, and adds support for additional ERXMISC<m>
  System registers.

  Error records accessed through System registers conform to RAS System Architecture v1.1, which includes simplifications to ERR<n>STATUS and support for the optional RAS Timestamp Extension.

  All other values are reserved.

  From Armv8.4, when ARMv8.4-DFE is not implemented, and ERRIDR.NUM is zero, the permitted values are IMPLEMENTATION DEFINED 0b0001 or 0b0010. Otherwise from Armv8.4 the only permitted value is 0b0010.

  ARMv8.4-RAS implements the functionality identified by the value 0b0010.

  In Armv8.2, the only permitted value is 0b0001.

  In Armv8.1 and Armv8.0, the permitted values are 0b0000 and 0b0010.

DIT, bits [27:24]

From ARMv8.4:

Data Independent Timing. Defined values are:

- 0b0000  AArch32 does not guarantee constant execution time of any instructions.
- 0b0001  AArch32 provides the CPSR.DIT mechanism to guarantee constant execution time of certain instructions.

All other values are reserved.
ARMv8.4-DIT implements the functionality identified by the value 0b0000. From Armv8.4, the only permitted value is 0b0001.

Otherwise:
Reserved, RES0.

AMU, bits [23:20]

From ARMv8.4:
Activity Monitors Extension. Defined values are:
- 0b0000  Activity Monitors Extension is not implemented.
- 0b0001  Activity Monitors Extension Version 1 is implemented.
All other values are reserved.

AMUv1 implements the functionality identified by the value 0b0001.
In Armv8.0, Armv8.1, Armv8.2, and Armv8.3, the only permitted value is 0b0000.
From Armv8.4, the permitted values are 0b0000 and 0b0001.

Otherwise:
Reserved, RES0.

Bits [19:16]
Reserved, RES0.

State3, bits [15:12]
T32EE instruction set support. Defined values are:
- 0b0000  Not implemented.
- 0b0001  T32EE instruction set implemented.
All other values are reserved.
In Armv8-A the only permitted value is 0b0000.

State2, bits [11:8]
Jazelle extension support. Defined values are:
- 0b0000  Not implemented.
- 0b0001  Jazelle extension implemented, without clearing of JOSCR.CV on exception entry.
- 0b0010  Jazelle extension implemented, with clearing of JOSCR.CV on exception entry.
All other values are reserved.
In Armv8-A the only permitted value is 0b0001.

State1, bits [7:4]
T32 instruction set support. Defined values are:
- 0b0000  T32 instruction set not implemented.
- 0b0001  T32 encodings before the introduction of Thumb-2 technology implemented:
  - All instructions are 16-bit.
  - A BL or BLX is a pair of 16-bit instructions
  - 32-bit instructions other than BL and BLX cannot be encoded.
- 0b0011  T32 encodings after the introduction of Thumb-2 technology implemented, for all 16-bit and 32-bit T32 basic instructions.
All other values are reserved.
In Armv8-A the only permitted value is 0b0011.
State0, bits [3:0]

A32 instruction set support. Defined values are:

0b0000   A32 instruction set not implemented.
0b0001   A32 instruction set implemented.

All other values are reserved.

In Armv8-A the only permitted value is 0b0001.

Accessing the ID_PFR0

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{c\}\{q\} <\text{coproc}>, \{#\}<\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}\}, \{#\}<\text{opc2}>

G8.2.94  ID_PFR1, Processor Feature Register 1

The ID_PFR1 characteristics are:

**Purpose**

Gives information about the AArch32 programmers' model.
Must be interpreted with ID_PFR0.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-5646.

**Configurations**

AArch32 System register ID_PFR1[31:0] is architecturally mapped to AArch64 System register ID_PFR1_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ID_PFR1 is a 32-bit register.

**Field descriptions**

The ID_PFR1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28</td>
<td>GIC</td>
</tr>
<tr>
<td>27-24</td>
<td>Virt_frac</td>
</tr>
<tr>
<td>23-20</td>
<td>Sec_frac</td>
</tr>
<tr>
<td>19-16</td>
<td>GenTimer</td>
</tr>
<tr>
<td>15-12</td>
<td>MProgMod</td>
</tr>
<tr>
<td>11-8</td>
<td>Security</td>
</tr>
<tr>
<td>7-4</td>
<td>ProgMod</td>
</tr>
<tr>
<td>3</td>
<td>Virtualization</td>
</tr>
</tbody>
</table>

**GIC, bits [31:28]**

System register GIC CPU interface. Defined values are:

- 0b0000 No System register interface to the GIC CPU interface is supported.
- 0b0001 System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.

All other values are reserved.

**Virt_frac, bits [27:24]**

Virtualization fractional field. When the Virtualization field is 0b0000, determines the support for features from the ARMv7 Virtualization Extensions. Defined values are:

- 0b0000 No features from the ARMv7 Virtualization Extensions are implemented.
- 0b0001 The following features of the ARMv7 Virtualization Extensions are implemented:
  - The SCR.SIF bit, if EL3 is implemented.
  - The modifications to the SCR.AW and SCR.FW bits described in the Virtualization Extensions, if EL3 is implemented.
  - The MSR (banked register) and MR S (banked register) instructions.
  - The ERET instruction.

All other values are reserved.

In Armv8-A the permitted values are:

- 0b0000 when EL2 is implemented.
- 0b0001 when EL2 is not implemented.

This field is only valid when the value of ID_PFR1.Virtualization is 0, otherwise it holds the value 0b0000.
Sec_frac, bits [23:20]

Security fractional field. When the Security field is 0b0000, determines the support for features from the ARMv7 Security Extensions. Defined values are:

- 0b0000: No features from the ARMv7 Security Extensions are implemented.
- 0b0001: The following features from the ARMv7 Security Extensions are implemented:
  - The VBAR register.
  - The TTBCR.PD0 and TTBCR.PD1 bits.
- 0b0010: As for 0b0001, plus the ability to access Secure or Non-secure physical memory is supported.

All other values are reserved.

In Armv8-A the permitted values are:
- 0b0000 when EL3 is implemented.
- 0b0001 or 0b0010 when EL3 is not implemented.

This field is only valid when the value of ID_PFR1.Security is 0, otherwise it holds the value 0b0000.

GenTimer, bits [19:16]

Generic Timer support. Defined values are:

- 0b0000: Not implemented.
- 0b0001: Generic Timer implemented.

All other values are reserved.

In Armv8-A the only permitted value is 0b0001.

Virtualization, bits [15:12]

Virtualization support. Defined values are:

- 0b0000: EL2, Hyp mode, and the HVC instruction not implemented.
- 0b0001: EL2, Hyp mode, the HVC instruction, and all the features described by Virt_frac == 0b0001 implemented.

All other values are reserved.

In Armv8-A the permitted values are:
- 0b0000 when EL2 is not implemented.
- 0b0001 when EL2 is implemented.

In an implementation that includes EL2, if EL2 cannot use AArch32 but EL1 can use AArch32 then this field has the value 0b0001.

Note

The ID_ISARs do not identify whether the HVC instruction is implemented.

MProgMod, bits [11:8]

M profile programmers' model support. Defined values are:

- 0b0000: Not supported.
- 0b0010: Support for two-stack programmers' model.

All other values are reserved.

In Armv8-A the only permitted value is 0b0000.
Security, bits [7:4]

Security support. Defined values are:

0b0000  EL3, Monitor mode, and the SMC instruction not implemented.
0b0001  EL3, Monitor mode, the SMC instruction, and all the features described by Sec_frac ==
         0b0011 implemented.
0b0010  As for 0b0001, and adds the ability to set the NSACR.RFR bit. Not permitted in Armv8
         as the NSACR.RFR bit is RES0.

All other values are reserved.

In Armv8-A the permitted values are:

• 0b0000 when EL3 is not implemented.
• 0b0001 when EL3 is implemented.

In an implementation that includes EL3, if EL3 cannot use AArch32 but EL1 can use AArch32 then
this field has the value 0b0001.

ProgMod, bits [3:0]

Support for the standard programmers' model for ARMv4 and later. Model must support User, FIQ,
IRQ, Supervisor, Abort, Undefined, and System modes. Defined values are:

0b0000  Not supported.
0b0001  Supported.

All other values are reserved.

In Armv8-A the only permitted value is 0b0001.

Accessing the ID_PFR1

Accesses to this register use the following encodings in the System instruction encoding space:

G8.2.96 IFAR, Instruction Fault Address Register

The IFAR characteristics are:

**Purpose**

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception.

**Configurations**

AArch32 System register IFAR[31:0] is architecturally mapped to AArch64 System register FAR_EL1[63:32].

AArch32 System register IFAR[31:0](S) is architecturally mapped to AArch32 System register HIFAR[31:0] when HaveEL(EL2), HaveEL(EL3) and HighestELUsingAArch32().

AArch32 System register IFAR[31:0](S) is architecturally mapped to AArch64 System register FAR_EL2[63:32] when HaveEL(EL2).

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

IFAR is a 32-bit register.

**Field descriptions**

The IFAR bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>VA of faulting address of synchronous Prefetch Abort exception</th>
</tr>
</thead>
</table>

**Accessing the IFAR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRC\{<c>\}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>} \]

<table>
<thead>

**G8.2.97  IFSR, Instruction Fault Status Register**

The IFSR characteristics are:

**Purpose**

Holds status information about the last instruction fault.

**Configurations**

AArch32 System register IFSR[31:0] is architecturally mapped to AArch64 System register IFSR32_EL2[31:0].

The current translation table format determines which format of the register is used.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

IFSR is a 32-bit register.

**Field descriptions**

The IFSR bit assignments are:

*When TTBCR.EAE == 0:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
| 16  | FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.  
   0b0   IFAR is valid.  
   0b1   IFAR is not valid, and holds an UNKNOWN value. |
| 13  | External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of External aborts.  
   In an implementation that does not provide any classification of External aborts, this bit is RES0.  
   For aborts other than External aborts this bit always returns 0.  
   This field resets to an architecturally UNKNOWN value. |

Reserved, RES0.
Bit [11]

Reserved, RES0.

FS[4], bit [10]

This field is bit[4] of FS[4:0].

- 0b00001: PC alignment fault
- 0b00010: Debug exception
- 0b00011: Access flag fault, level 1
- 0b00101: Translation fault, level 1
- 0b00110: Access flag fault, level 2
- 0b00111: Translation fault, level 2
- 0b01000: Synchronous External abort, not on translation table walk
- 0b01001: Domain fault, level 1
- 0b01011: Domain fault, level 2
- 0b01100: Synchronous External abort, on translation table walk, level 1
- 0b01101: Permission fault, level 1
- 0b01110: Synchronous External abort, on translation table walk, level 2
- 0b01111: Permission fault, level 2
- 0b10000: TLB conflict abort
- 0b10100: IMPLEMENTATION DEFINED fault (Lockdown fault)
- 0b11001: Synchronous parity or ECC error on memory access, not on translation table walk
- 0b11100: Synchronous parity or ECC error on translation table walk, level 1
- 0b11110: Synchronous parity or ECC error on translation table walk, level 2

All other values are reserved.

When the RAS Extension is implemented, 0b11001, 0b11100, and 0b11110, are reserved.

For more information about the lookup level associated with a fault, see The level associated with MMU faults on a Short-descriptor translation table lookup on page G5-5572.

The FS field is split as follows:
- FS[4] is IFSR[10].
- FS[3:0] is IFSR[3:0].

This field resets to an architecturally UNKNOWN value.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

- 0b0: Using the Short-descriptor translation table formats.
- 0b1: Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

This field resets to an architecturally UNKNOWN value.

Bits [8:4]

Reserved, RES0.

FS[3:0], bits [3:0]

This field is bits[3:0] of FS[4:0].

G8.2.98   ISR, Interrupt Status Register

The ISR characteristics are:

Purpose

Shows the pending status of the IRQ, FIQ, or SError.

When executing at EL2, EL3, or Secure EL1, when SCR_EL3.EEL2 == 0b0, this shows the pending status of the physical interrupts.

When executing at Non-secure EL1, or at Secure EL1, when SCR_EL3.EEL2 == 0b01:

• If the HCR.{IMO,FMO,AMO} bit has a value of 1, the corresponding ISR.{I,F,A} bit shows the pending status of the virtual IRQ, FIQ, or SError.

• If the HCR.{IMO,FMO,AMO} bit has a value of 0, the corresponding ISR.{I,F,A} bit shows the pending status of the physical IRQ, FIQ, or SError.

Configurations

AArch32 System register ISR[31:0] is architecturally mapped to AArch64 System register ISR_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ISR is a 32-bit register.

Field descriptions

The ISR bit assignments are:

<p>| | | | | | |</p>
<table>
<thead>
<tr>

<td></td>
<td></td>
</tr>
<tr>
<td>RES0</td>
<td>A</td>
<td>I</td>
<td>F</td>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:9]

Reserved, RES0.

A, bit [8]

SError interrupt pending bit:

0b0   No pending SError interrupt.
0b1   An SError interrupt is pending.

If the SError interrupt is edge-triggered, this field is cleared to zero when the physical SError interrupt is taken.

I, bit [7]

IRQ pending bit. Indicates whether an IRQ interrupt is pending:

0b0   No pending IRQ.
0b1   An IRQ interrupt is pending.

F, bit [6]

FIQ pending bit. Indicates whether an FIQ interrupt is pending.

0b0   No pending FIQ.
0b1   An FIQ interrupt is pending.

Bits [5:0]

Reserved, RES0.
Accessing the ISR

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRC\{c\}\{q\} \coproc, \{\#\}\opc1, \textit{<Rt>}, \textit{<CRn>}, \textit{<CRm>}, \{\#\}\opc2 \]

<table>

G8.2.99  ITLBIALL, Instruction TLB Invalidate All

The ITLBIALL characteristics are:

**Purpose**
Invalidate all cached copies of translation table entries from instruction TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at Secure EL1 when EL3 is using AArch64, all entries that would be required for the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at Non-secure EL1, all stage 1 translation table entries that would be required for the Non-secure PL1&0 translation regime and, if EL2 is implemented, they must match the current VMID.
- If executed at EL2, the stage 1 or stage 2 translation table entries that would be required for the Non-secure PL1&0 translation regime and matches the current VMID.

The invalidation only applies to the PE that executes this System instruction.

Arm deprecates the use of this System instruction. It is only provided for backwards compatibility with earlier versions of the Arm architecture.

**Configurations**
There are no configuration notes.

**Attributes**
ITLBIALL is a 32-bit System instruction.

**Field descriptions**
ITLBIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the ITLBIALL instruction**
Accesses to this register use the following encodings in the System instruction encoding space:

```
MCR({c}>{q}) <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>

elsif PSTATE.EL == EL2 then
  ITLBIALL();
elsif PSTATE.EL == EL3 then
  ITLBIALL();
G8.2.100 ITLBIASID, Instruction TLB Invalidate by ASID match

The ITLBIASID characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from instruction TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

Arm deprecates the use of this System instruction. It is only provided for backwards compatibility with earlier versions of the Arm architecture.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ITLBIASID is a 32-bit System instruction.

**Field descriptions**

The ITLBIASID input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RESERVED, RES0</td>
</tr>
<tr>
<td>8</td>
<td>7</td>
</tr>
<tr>
<td>0</td>
<td>ASID</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this System instruction.

**Executing the ITLBIASID instruction**

Accesses to this register use the following encodings in the System instruction encoding space:
MCR<coproc>,<Rt>,<CRn>,<CRm>;

<table>
<thead>
<tr>

G8.2.101 ITLBIMVA, Instruction TLB Invalidate by VA

The ITLBIMVA characteristics are:

Purpose

Invalidate all cached copies of translation table entries from instruction TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

Arm deprecates the use of this System instruction. It is only provided for backwards compatibility with earlier versions of the Arm architecture.

Configurations

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ITLBIMVA is a 32-bit System instruction.

Field descriptions

The ITLBIMVA input value bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.
Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

**Executing the ITLBIMVA instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MCR}\{<c}\}{<q}>\ <\text{coproc}, \ (#<opc1>, \ <Rt>, \ <CRn>, \ <CRm}\{, \ (#<opc2>\}
\]

<table>

  // no operation
elsif PSTATE.EL == EL3 then
  // no operation
G8.2.105  MAIR0, Memory Attribute Indirection Register 0

The MAIR0 characteristics are:

**Purpose**

Along with MAIR1, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations. AttrIndx[2] indicates the MAIR register to be used:

- When AttrIndx[2] is 0, MAIR0 is used.
- When AttrIndx[2] is 1, MAIR1 is used.

**Configurations**

AArch32 System register MAIR0[31:0] is architecturally mapped to AArch64 System register MAIR_EL1[31:0].

MAIR0 and PRRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in PRRR.
- When it is set to 1, the register is as described in MAIR0.

When EL3 is using AArch32, write access to MAIR0(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MAIR0 is a 32-bit register.

**Field descriptions**

The MAIR0 bit assignments are:

*When TTBCR.EAE == 1:*

<table>
<thead>
<tr>
<th>Field</th>
<th>Bit Assignments</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr&lt;3&gt;, bits [8<em>3+7:8</em>3]</td>
<td>31 24 23 16 15 8 7 0</td>
<td></td>
</tr>
<tr>
<td>Attr2</td>
<td>23 16</td>
<td></td>
</tr>
<tr>
<td>Attr1</td>
<td>15 8</td>
<td></td>
</tr>
<tr>
<td>Attr0</td>
<td>7 0</td>
<td></td>
</tr>
</tbody>
</table>

*Attr<n>, bits [8n+7:8n], for n = 0 to 3*

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>0b00RW, RW not 0b00</td>
<td>Normal memory, Outer Write-Through Transient.</td>
</tr>
<tr>
<td>0b0100</td>
<td>Normal memory, Outer Non-cacheable.</td>
</tr>
</tbody>
</table>
**Attr<n>[7:4]** | **Meaning**
--- | ---
0b01RW, RW not 0b0 | Normal memory, Outer Write-Back Transient.
0b10RW | Normal memory, Outer Write-Through Non-transient.
0b11RW | Normal memory, Outer Write-Back Non-transient.

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.
The meaning of bits [3:0] depends on the value of bits [7:4]:

| **Attr<n>[3:0]** | **Meaning when Attr<n>[7:4] is 0b0000** | **Meaning when Attr<n>[7:4] is not 0b0000** |
--- | --- | ---
0b0000 | Device-nGnRnE memory | UNPREDICTABLE |
0b00RW, RW not 0b0 | UNPREDICTABLE | Normal memory, Inner Write-Through Transient |
0b0100 | Device-nGnRE memory | Normal memory, Inner Non-cacheable |
0b01RW, RW not 0b0 | UNPREDICTABLE | Normal memory, Inner Write-Back Transient |
0b1000 | Device-nGRE memory | Normal memory, Inner Write-Through Non-transient (RW=0b00) |
0b10RW, RW not 0b0 | UNPREDICTABLE | Normal memory, Inner Write-Through Non-transient |
0b1100 | Device-GRE memory | Normal memory, Inner Write-Back Non-transient (RW=0b00) |
0b11RW, RW not 0b0 | UNPREDICTABLE | Normal memory, Inner Write-Back Non-transient |

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.
The R and W bits in some Attr<n> fields have the following meanings:

| R or W | Meaning |
--- | --- |
0b0 | No Allocate |
0b1 | Allocate |

This field resets to an architecturally UNKNOWN value.

**Accessing the MAIR0**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MRC\{c\}\{q\}\{coproc\}, \{#\}<opc1>, <Rt>, <CRn>, <CRm>\{, \{#\}<opc2>\}
\]

| coproc | opc1 | CRn | CRm | opc2 |
--- | --- | --- | --- | --- |
0b1111 | 0b000 | 0b1010 | 0b0010 | 0b000 |

MAIR1, Memory Attribute Indirection Register 1

The MAIR1 characteristics are:

**Purpose**

Along with **MAIR0**, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations.

AttrIndx[2] indicates the MAIR register to be used:

- When AttrIndx[2] is 0, **MAIR0** is used.
- When AttrIndx[2] is 1, **MAIR1** is used.

**Configurations**

AArch32 System register MAIR1[31:0] is architecturally mapped to AArch64 System register MAIR_EL1[63:32].

MAIR1 and NMRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in NMRR.
- When it is set to 1, the register is as described in MAIR1.

When EL3 is using AArch32, write access to MAIR1(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MAIR1 is a 32-bit register.

**Field descriptions**

The MAIR1 bit assignments are:

*When TTBCR.EAE == 1:*

<table>
<thead>
<tr>
<th>31</th>
<th>24 23</th>
<th>16 15</th>
<th>8 7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attr7</td>
<td>Attr6</td>
<td>Attr5</td>
<td>Attr4</td>
<td></td>
</tr>
</tbody>
</table>

**Attr<n><, bits [8(n-4)+7:8(n-4)], for n = 4 to 7**

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

<table>
<thead>
<tr>
<th>Attr&lt;n&gt;[7:4]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Device memory. See encoding of Attr&lt;n&gt;[3:0] for the type of Device memory.</td>
</tr>
<tr>
<td>0b00RW, RW not 0b0</td>
<td>Normal memory, Outer Write-Through Transient.</td>
</tr>
<tr>
<td>0b0100</td>
<td>Normal memory, Outer Non-cacheable.</td>
</tr>
</tbody>
</table>
### Accessing the MAIR1

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC\{\text{<c>}\{\text{<q>}\} \text{<coproc>, (#)<opc1>, <Rt>, <CRn>, <CRm>\{, (#)<opc2>\}}} \\
\]

G8.2.107   MIDR, Main ID Register

The MIDR characteristics are:

**Purpose**

Provides identification information for the PE, including an implementer code for the device and a device ID number.

**Configurations**

AArch32 System register MIDR[31:0] is architecturally mapped to AArch64 System register MIDR_EL1[31:0].

AArch32 System register MIDR[31:0] is architecturally mapped to External register MIDR_EL1[31:0].

Some fields of the MIDR are IMPLEMENTATION DEFINED. For details of the values of these fields for a particular Armv8 implementation, and any implementation-specific significance of these values, see the product documentation.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MIDR is a 32-bit register.

**Field descriptions**

The MIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24 23</th>
<th>20 19</th>
<th>16 15</th>
<th>4 3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implementer</td>
<td>Variant</td>
<td>PartNum</td>
<td>Revision</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Implementer, bits [31:24]**

The Implementer code. This field must hold an implementer code that has been assigned by Arm. Assigned codes include the following:

<table>
<thead>
<tr>
<th>Hex representation</th>
<th>Implementer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>Reserved for software use</td>
</tr>
<tr>
<td>0xC0</td>
<td>Ampere Computing</td>
</tr>
<tr>
<td>0x40</td>
<td>Arm Limited</td>
</tr>
<tr>
<td>0x42</td>
<td>Broadcom Corporation</td>
</tr>
<tr>
<td>0x43</td>
<td>Cavium Inc.</td>
</tr>
<tr>
<td>0x44</td>
<td>Digital Equipment Corporation</td>
</tr>
<tr>
<td>0x49</td>
<td>Infineon Technologies AG</td>
</tr>
<tr>
<td>0x4D</td>
<td>Motorola or Freescale Semiconductor Inc.</td>
</tr>
<tr>
<td>0x4E</td>
<td>NVIDIA Corporation</td>
</tr>
<tr>
<td>0x50</td>
<td>Applied Micro Circuits Corporation</td>
</tr>
<tr>
<td>Hex representation</td>
<td>Implementer</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>0x51</td>
<td>Qualcomm Inc.</td>
</tr>
<tr>
<td>0x56</td>
<td>Marvell International Ltd.</td>
</tr>
<tr>
<td>0x69</td>
<td>Intel Corporation</td>
</tr>
</tbody>
</table>

Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

**Variant, bits [23:20]**

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

**Architecture, bits [19:16]**

The permitted values of this field are:
- 0b0001  Armv4.
- 0b0010  Armv4T.
- 0b0011  Armv5 (obsolete).
- 0b0100  Armv5T.
- 0b0101  Armv5TE.
- 0b0110  Armv5TEJ.
- 0b0111  Armv6.
- 0b1111  Architectural features are individually identified in the ID_* registers, see ID registers on page K13-7433.

All other values are reserved.

**PartNum, bits [15:4]**

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

**Revision, bits [3:0]**

An IMPLEMENTATION DEFINED revision number for the device.

## Accessing the MIDR

Accesses to this register use the following encodings in the System instruction encoding space:

`MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}`

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>

  elsif EL2Enabled() & ELUsingAArch32(EL2) & HSTR.T0 == '1' then
    AArch32.TakeHypTrapException(0x03);
  elsif EL2Enabled() & ELUsingAArch32(EL2) then
    return VPIDR_EL2<31:0>;
elsif EL2Enabled() && ELUsingAArch32(EL2) then
  return VPIDR;
else
  return MIDR;
elsif PSTATE.EL == EL2 then
  return MIDR;
elsif PSTATE.EL == EL3 then
  return MIDR;
G8.2.108 MPIDR, Multiprocessor Affinity Register

The MPIDR characteristics are:

**Purpose**

In a multiprocessor system, provides an additional PE identification mechanism for scheduling purposes.

**Configurations**

AArch32 System register MPIDR[31:0] is architecturally mapped to AArch64 System register MPIDR_EL1[31:0].

In a uniprocessor system Arm recommends that each Aff<n> field of this register returns a value of 0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MPIDR is a 32-bit register.

**Field descriptions**

The MPIDR bit assignments are:

<p>| | | | | | | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>30</td>
<td>29</td>
<td>25</td>
<td>24</td>
<td>23</td>
<td>16</td>
<td>15</td>

<td>7</td>
<td>0</td>
</tr>
<tr>
<td>M</td>
<td>U</td>
<td>RES0</td>
<td>Aff2</td>
<td>Aff1</td>
<td>Aff0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**M, bit [31]**

Indicates whether this implementation includes the functionality introduced by the ARMv7 Multiprocessing Extensions. The possible values of this bit are:

0b0 This implementation does not include the ARMv7 Multiprocessing Extensions functionality.

0b1 This implementation includes the ARMv7 Multiprocessing Extensions functionality.

In Armv8, this bit is RAO.

**U, bit [30]**

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

0b0 Processor is part of a multiprocessor system.

0b1 Processor is part of a uniprocessor system.

**Bits [29:25]**

Reserved, RES0.

**MT, bit [24]**

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. See the description of Aff0 for more information about affinity levels. The possible values of this bit are:

0b0 Performance of PEs at the lowest affinity level is largely independent.

0b1 Performance of PEs at the lowest affinity level is very interdependent.
Aff2, bits [23:16]
Affinity level 2. See the description of Aff0 for more information.

Aff1, bits [15:8]
Affinity level 1. See the description of Aff0 for more information.

Aff0, bits [7:0]
Affinity level 0. This is the affinity level that is most significant for determining PE behavior. Higher affinity levels are increasingly less significant in determining PE behavior. The assigned value of the MPIDR. {Aff2, Aff1, Aff0} or MPIDR_EL1. {Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

**Accessing the MPIDR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}{<q>} <\text{coproc}>, \{\#<\text{opc1}\}, <\text{Rt}>, <\text{CRn}>, <\text{CRm}\}, \{\#<\text{opc2}\}
\]

<table>
<thead>
<tr>

    return VMPIDR;
  else
    return MPIDR;
elsif PSTATE.EL == EL2 then
  return MPIDR;
elsif PSTATE.EL == EL3 then
  return MPIDR;
G8.2.109 MVBAR, Monitor Vector Base Address Register

The MVBAR characteristics are:

Purpose

When EL3 is implemented and can use AArch32, holds the vector base address for any exception that is taken to Monitor mode.

Secure software must program the MVBAR with the required initial value as part of the PE boot sequence.

Configurations

It is IMPLEMENTATION DEFINED whether MVBAR[0] has a fixed value and ignored writes, or takes the last value written to it.

On a reset into EL3 using AArch32, the reset value of MVBAR is an IMPLEMENTATION DEFINED choice between:

- MVBAR[31:5] = an IMPLEMENTATION DEFINED value, which might be UNKNOWN.
- MVBAR[4:1] = RES0.
- MVBAR[0] = 0.

And:

- MVBAR[31:1] = an IMPLEMENTATION DEFINED value that is bits[31:1] of the AArch32 reset address.
- MVBAR[0] = 1.

Attributes

MVBAR is a 32-bit register.

Field descriptions

The MVBAR bit assignments are:

*When programmed with a vector base address:*

<table>
<thead>
<tr>
<th>31</th>
<th>5</th>
<th>4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector Base Address</td>
<td>Reserved</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to this Exception level. Bits[4:0] of an exception vector are the exception offset.

Reserved, bits [4:0]

Reserved, see Configurations.

Accessing the MVBAR

Accesses to this register use the following encodings in the System instruction encoding space:
### MRC<coproc>,<Rt>,<CRn>,<CRm>{, <opc2>}

    else
        MVBAR = R[t];
```
G8.2.110 MVFR0, Media and VFP Feature Register 0

The MVFR0 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR1 and MVFR2.

For general information about the interpretation of the ID registers see Principles of the ID scheme for fields in ID registers on page G8-5646.

**Configurations**

AArch32 System register MVFR0[31:0] is architecturally mapped to AArch64 System register MVFR0_EL1[31:0].

Implemented only if the implementation includes Advanced SIMD and floating-point instructions.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MVFR0 is a 32-bit register.

**Field descriptions**

The MVFR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPRound</td>
<td>FPShVec</td>
<td>FPSqrt</td>
<td>FPDivide</td>
<td>FPTrap</td>
<td>FPDP</td>
<td>FPSP</td>
<td>SIMDReg</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**FPRound, bits [31:28]**

Floating-Point Rounding modes. Indicates whether the floating-point implementation provides support for rounding modes. Defined values are:

- 0b0000: Not implemented, or only Round to Nearest mode supported, except that Round towards Zero mode is supported for VCVT instructions that always use that rounding mode regardless of the FPSCR setting.
- 0b0001: All rounding modes supported.

All other values are reserved.

In Armv8-A the permitted values are 0b0000 and 0b0001.

**FPShVec, bits [27:24]**

Short Vectors. Indicates whether the floating-point implementation provides support for the use of short vectors. Defined values are:

- 0b0000: Short vectors not supported.
- 0b0001: Short vector operation supported.

All other values are reserved.

In Armv8-A the only permitted value is 0b0000.

**FPSqrt, bits [23:20]**

Square Root. Indicates whether the floating-point implementation provides support for the ARMv6 VFP square root operations. Defined values are:

- 0b0000: Not supported in hardware.
- 0b0001: Supported.
All other values are reserved.
In Armv8-A the permitted values are 0b0000 and 0b0001.

The VSQRT.F32 instruction also requires the single-precision floating-point attribute, bits [7:4],
and the VSQRT.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

**FPDivide, bits [19:16]**
 Indicates whether the floating-point implementation provides support for VFP divide operations.
 Defined values are:
 0b0000  Not supported in hardware.
 0b0001  Supported.
All other values are reserved.
In Armv8-A the permitted values are 0b0000 and 0b0001.

The VDIV.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and
the VDIV.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

**FPTrap, bits [15:12]**
 Floating Point Exception Trapping. Indicates whether the floating-point implementation provides
support for exception trapping. Defined values are:
 0b0000  Not supported.
 0b0001  Supported.
All other values are reserved.
A value of 0b0001 indicates that, when the corresponding trap is enabled, a floating-point exception
generates an exception.

**FPDP, bits [11:8]**
 Double Precision. Indicates whether the floating-point implementation provides support for
double-precision operations. Defined values are:
 0b0000  Not supported in hardware.
 0b0001  Supported, VFPv2.
 0b0010  Supported, VFPv3, VFPv4, or Armv8. VFPv3 and Armv8 add an instruction to load a
double-precision floating-point constant, and conversions between double-precision
and fixed-point values.
All other values are reserved.
In Armv8-A the permitted values are 0b0000 and 0b0010.
A value of 0b0001 or 0b0010 indicates support for all VFP double-precision instructions in the
supported version of VFP, except that, in addition to this field being nonzero:
  • VSQRT.F64 is only available if the Square root field is 0b0001.
  • VDIV.F64 is only available if the Divide field is 0b0001.
  • Conversion between double-precision and single-precision is only available if the
    single-precision field is nonzero.

**FPSP, bits [7:4]**
 Single Precision. Indicates whether the floating-point implementation provides support for
single-precision operations. Defined values are:
 0b0000  Not supported in hardware.
 0b0001  Supported, VFPv2.
 0b0010  Supported, VFPv3 or VFPv4. VFPv3 adds an instruction to load a single-precision
floating-point constant, and conversions between single-precision and fixed-point
values.
All other values are reserved.

In Armv8-A the permitted values are 0b0000 and 0b0010.

A value of 0b0001 or 0b0010 indicates support for all VFP single-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F32 is only available if the Square root field is 0b0001.
- VDIV.F32 is only available if the Divide field is 0b0001.
- Conversion between double-precision and single-precision is only available if the double-precision field is nonzero.

SIMDReg, bits [3:0]

Advanced SIMD registers. Indicates whether the Advanced SIMD and floating-point implementation provides support for the Advanced SIMD and floating-point register bank. Defined values are:

- 0b0000: The implementation has no Advanced SIMD and floating-point support.
- 0b0001: The implementation includes floating-point support with 16 x 64-bit registers.
- 0b0010: The implementation includes Advanced SIMD and floating-point support with 32 x 64-bit registers.

All other values are reserved.

In Armv8-A the permitted values are 0b0000 and 0b0010.

Accessing the MVFR0

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{VMRS\{<c>\}{<q}> <Rt>, <spec\_reg>} \]

\[
\begin{array}{c}
\text{reg} \\
0b0111
\end{array}
\]

### MVFR1, Media and VFP Feature Register 1

The MVFR1 characteristics are:

**Purpose**

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR0 and MVFR2.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G8-5646.

**Configurations**

AArch32 System register MVFR1[31:0] is architecturally mapped to AArch64 System register MVFR1_EL1[31:0].

Implemented only if the implementation includes Advanced SIMD and floating-point instructions.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

MVFR1 is a 32-bit register.

**Field descriptions**

The MVFR1 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>FPHP</td>
</tr>
<tr>
<td>28</td>
<td>SIMDHP</td>
</tr>
<tr>
<td>27</td>
<td>SIMDSP</td>
</tr>
<tr>
<td>24</td>
<td>SIMDInt</td>
</tr>
<tr>
<td>23</td>
<td>SIMDLS</td>
</tr>
<tr>
<td>20</td>
<td>FPDNaN</td>
</tr>
<tr>
<td>19</td>
<td>FPFIZ</td>
</tr>
</tbody>
</table>

**SIMDFMAC, bits [31:28]**

Advanced SIMD Fused Multiply-Accumulate. Indicates whether the Advanced SIMD implementation provides fused multiply accumulate instructions. Defined values are:

- 0b0000 Not implemented.
- 0b0001 Implemented.

All other values are reserved.

In Armv8-A the permitted values are 0b0000 and 0b0001.

The Advanced SIMD and floating-point implementations must provide the same level of support for these instructions.

**FPHP, bits [27:24]**

Floating Point Half Precision. Indicates the level of half-precision floating-point support. Defined values are:

- 0b0000 Not supported.
- 0b0001 Floating-point half-precision conversion instructions are supported for conversion between single-precision and half-precision.
- 0b0010 As for 0b0001, and adds instructions for conversion between double-precision and half-precision.
- 0b0011 As for 0b0010, and adds support for half-precision floating-point arithmetic.

All other values are reserved.
In Armv8-A the permitted values are:

- 0b0000 in an implementation without floating-point support.
- 0b0010 in an implementation with floating-point support that does not include the ARMv8.2-FP16 extension.
- 0b0011 in an implementation with floating-point support that includes the ARMv8.2-FP16 extension.

The level of support indicated by this field must be equivalent to the level of support indicated by the SIMDHP field, meaning the permitted values are:

<table>
<thead>
<tr>
<th>Half Precision instructions supported</th>
<th>FPHP</th>
<th>SIMDHP</th>
</tr>
</thead>
<tbody>
<tr>
<td>No support</td>
<td>0b0000</td>
<td>0b0000</td>
</tr>
<tr>
<td>Conversions only</td>
<td>0b0010</td>
<td>0b0001</td>
</tr>
<tr>
<td>Conversions and arithmetic</td>
<td>0b0011</td>
<td>0b0010</td>
</tr>
</tbody>
</table>

**SIMDHP, bits [23:20]**

Advanced SIMD Half Precision. Indicates the level of half-precision floating-point support. Defined values are:

- 0b0000 Not supported.
- 0b0001 SIMD half-precision conversion instructions are supported for conversion between single-precision and half-precision.
- 0b0010 As for 0b0001, and adds support for half-precision floating-point arithmetic.

All other values are reserved.

In Armv8-A the permitted values are:

- 0b0000 in an implementation without SIMD floating-point support.
- 0b0010 in an implementation with SIMD floating-point support that does not include the ARMv8.2-FP16 extension.
- 0b0011 in an implementation with SIMD floating-point support that includes the ARMv8.2-FP16 extension.

The level of support indicated by this field must be equivalent to the level of support indicated by the FPHP field, meaning the permitted values are:

<table>
<thead>
<tr>
<th>Half Precision instructions supported</th>
<th>FPHP</th>
<th>SIMDHP</th>
</tr>
</thead>
<tbody>
<tr>
<td>No support</td>
<td>0b0000</td>
<td>0b0000</td>
</tr>
<tr>
<td>Conversions only</td>
<td>0b0010</td>
<td>0b0001</td>
</tr>
<tr>
<td>Conversions and arithmetic</td>
<td>0b0011</td>
<td>0b0010</td>
</tr>
</tbody>
</table>

**SIMDSP, bits [19:16]**

Advanced SIMD Single Precision. Indicates whether the Advanced SIMD and floating-point implementation provides single-precision floating-point instructions. Defined values are:

- 0b0000 Not implemented.
- 0b0001 Implemented. This value is permitted only if the SIMDInt field is 0b0001.

All other values are reserved.

In Armv8-A the permitted values are 0b0000 and 0b0001.
SIMDInt, bits [15:12]
Advanced SIMD Integer. Indicates whether the Advanced SIMD and floating-point implementation provides integer instructions. Defined values are:
0b0000  Not implemented.
0b0001  Implemented.
All other values are reserved.
In Armv8-A the permitted values are 0b0000 and 0b0001.

SIMDLS, bits [11:8]
Advanced SIMD Load/Store. Indicates whether the Advanced SIMD and floating-point implementation provides load/store instructions. Defined values are:
0b0000  Not implemented.
0b0001  Implemented.
All other values are reserved.
In Armv8-A the permitted values are 0b0000 and 0b0001.

FPDNaN, bits [7:4]
Default NaN mode. Indicates whether the floating-point implementation provides support only for the Default NaN mode. Defined values are:
0b0000  Not implemented, or hardware supports only the Default NaN mode.
0b0001  Hardware supports propagation of NaN values.
All other values are reserved.
In Armv8-A the permitted values are 0b0000 and 0b0001.

FPfZ, bits [3:0]
Flush to Zero mode. Indicates whether the floating-point implementation provides support only for the Flush-to-Zero mode of operation. Defined values are:
0b0000  Not implemented, or hardware supports only the Flush-to-Zero mode of operation.
0b0001  Hardware supports full denormalized number arithmetic.
All other values are reserved.
In Armv8-A the permitted values are 0b0000 and 0b0001.

G8.2.112 MVFR2, Media and VFP Feature Register 2

The MVFR2 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with MVFR0 and MVFR1.

For general information about the interpretation of the ID registers see "Principles of the ID scheme for fields in ID registers on page G8-5646."

Configurations

AArch32 System register MVFR2[31:0] is architecturally mapped to AArch64 System register MVFR2_EL1[31:0].

Implemented only if the implementation includes Advanced SIMD and floating-point instructions.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MVFR2 is a 32-bit register.

Field descriptions

The MVFR2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>FPMisc</td>
<td>SIMDMisc</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:8]

Reserved, RES0.

FPMisc, bits [7:4]

Indicates whether the floating-point implementation provides support for miscellaneous VFP features.

0b0000 Not implemented, or no support for miscellaneous features.

0b0001 Support for Floating-point selection.

0b0010 As 0b0001, and Floating-point Conversion to Integer with Directed Rounding modes.

0b0011 As 0b0010, and Floating-point Round to Integer Floating-point.

0b0100 As 0b0011, and Floating-point MaxNum and MinNum.

All other values are reserved.

In Armv8-A the permitted values are 0b0000 and 0b0100.

SIMDMisc, bits [3:0]

Indicates whether the Advanced SIMD implementation provides support for miscellaneous Advanced SIMD features.

0b0000 Not implemented, or no support for miscellaneous features.

0b0001 Floating-point Conversion to Integer with Directed Rounding modes.

0b0010 As 0b0001, and Floating-point Round to Integer Floating-point.

0b0011 As 0b0010, and Floating-point MaxNum and MinNum.

All other values are reserved.
In Armv8-A the permitted values are 0b0000 and 0b0011.

Accessing the MVFR2

Accesses to this register use the following encodings in the System instruction encoding space:

\[ VMRS\{c\}\{q\} \{Rt\}, \{spec\_reg\} \]

<table>
<thead>
<tr>
<th>reg</th>
<th>0b0101</th>

```
G8.2.113 NMRR, Normal Memory Remap Register

The NMRR characteristics are:

Purpose

Provides additional mapping controls for memory regions that are mapped as Normal memory by their entry in the PRRR.

Used in conjunction with the PRRR.

Configurations

AArch32 System register NMRR[31:0] is architecturally mapped to AArch64 System register MAIR_EL1[63:32].

MAIR1 and NMRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in NMRR.
- When it is set to 1, the register is as described in MAIR1.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

NMRR is a 32-bit register.

Field descriptions

The NMRR bit assignments are:

When TTBCR.EAE == 0:

</table>

OR<n>, bits [2n+17:2n+16], for n = 0 to 7

Outer Cacheable property mapping for memory attributes n, if the region is mapped as Normal memory by the PRRR.TR<n> entry. n is the value of the TEX[0], C, and B bits concatenated. The possible values of this field are:

- 0b00 Region is Non-cacheable.
- 0b01 Region is Write-Back, Write-Allocate.
- 0b10 Region is Write-Through, no Write-Allocate.
- 0b11 Region is Write-Back, no Write-Allocate.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination {TEX[0] = 1, C = 1, B = 0} is IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

IR<n>, bits [2n+1:2n], for n = 0 to 7

Inner Cacheable property mapping for memory attributes n, if the region is mapped as Normal memory by the PRRR.TR<n> entry. n is the value of the TEX[0], C, and B bits concatenated. The possible values of this field are:

- 0b00 Region is Non-cacheable.
- 0b01 Region is Write-Back, Write-Allocate.
- 0b10 Region is Write-Through, no Write-Allocate.
0b11 Region is Write-Back, no Write-Allocate.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning
given here. This is because the meaning of the attribute combination \{TEX[0] = 1, C = 1, B = 0\} is
IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

G8.2.114 NSACR, Non-Secure Access Control Register

The NSACR characteristics are:

**Purpose**

When EL3 is implemented and can use AArch32, defines the Non-secure access permissions to Trace, Advanced SIMD and floating-point functionality. Also includes IMPLEMENTATION DEFINED bits that can define Non-secure access permissions for IMPLEMENTATION DEFINED functionality.

**Configurations**

--- Note ---

In AArch64 state, the NSACR controls are replaced by controls in CPTR_EL3.

Some or all RW fields of this register have defined reset values. These apply whenever the register is accessible. This means they apply when the PE resets into EL3 using AArch32.

**Attributes**

NSACR is a 32-bit register.

**Field descriptions**

The NSACR bit assignments are:

</table>

If EL3 is implemented and is using AArch64 then:

- Any read of the NSACR from Non-secure EL2 or Non-secure EL1 returns a value of `0x00000C00`.
- Any read or write to NSACR from Secure EL1 is trapped as an exception to EL3.

If EL3 is not implemented, then any read of the NSACR from EL2 or EL1 returns a value of `0x00000C00`.

**Bits [31:21]**

Reserved, RES0.

**NSTRCDIS, bit [20]**

Disables Non-secure System register accesses to all implemented trace registers.

- **0b0** This control has no effect on:
  - System register access to implemented trace registers.
  - The behavior of `CPACR.TRCDIS` and `HCPTR.TTA`.

- **0b1** Non-secure System register accesses to all implemented trace registers are disabled, meaning:
  - `CPACR.TRCDIS` behaves as RAO/WI in Non-secure state, regardless of its actual value.
  - `HCPTR.TTA` behaves as RAO/WI, regardless of its actual value.
The implementation of this field must correspond to the implementation of the CPACR.TRCDIS field:

- If CPACR.TRCDIS is RAZ/WI, this field is RAZ/WI.
- If CPACR.TRCDIS is RW, this field is RW.

**Note**

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the implementation includes an ETMv4 implementation, EL0 accesses to the trace registers are **UNDEFINED**.
- The architecture does not provide Non-secure access controls on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

In a system where the PE resets into EL3, this field resets to $0$.

**Bit [19]**

Reserved, RES0.

**IMPLEMENTATION DEFINED, bits [18:16]**

IMPLEMENTATION DEFINED.

**NSASEDIS, bit [15]**

Disables Non-secure access to the Advanced SIMD functionality.

$0b0$ This control has no effect on:

- Non-secure access to Advanced SIMD functionality.
- The behavior of CPACR.ASEDIS and HCPTR.TASE.

$0b1$ Non-secure access to the Advanced SIMD functionality is disabled, meaning:

- CPACR.ASEDIS behaves as RAO/WI in Non-secure state, regardless of its actual value.
- HCPTR.TASE behaves as RAO/WI, regardless of its actual value.

The implementation of this field must correspond to the implementation of the CPACR.ASEDIS field:

- If CPACR.ASEDIS is RES0, this field is RES0. If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.
- If CPACR.ASEDIS is RAZ/WI, this field is RAZ/WI.
- If CPACR.ASEDIS is RW, this field is RW.

In a system where the PE resets into EL3, this field resets to $0$.

**Bits [14:12]**

Reserved, RES0.

**cp11, bit [11]**

The value of this field is ignored. If this field is programmed with a different value to the cp10 field then this field is **UNKNOWN** on a direct read of the NSACR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

In a system where the PE resets into EL3, this field resets to an architecturally **UNKNOWN** value.

### cp10, bit [10]

Enable Non-secure access to the Advanced SIMD and floating-point features. Possible values of the fields are:

- **0b0**
  
  Advanced SIMD and floating-point features can be accessed only from Secure state. Any attempt to access this functionality from Non-secure state is UNDEFINED.

  When the PE is in Non-secure state:
  
  - The CPACR.\{cp11, cp10\} fields ignore writes and read as 0b00, access denied.
  - The HCPTR.\{TCP11, TCP10\} fields behave as RAO/WI, regardless of their actual values.

- **0b1**
  
  Advanced SIMD and floating-point features can be accessed from both Security states.

  If Non-secure access to the Advanced SIMD and floating-point functionality is enabled, the CPACR must be checked to determine the level of access that is permitted.

  The Advanced SIMD and floating-point features controlled by these fields are:
  
  - Execution of any floating-point or Advanced SIMD instruction.
  - Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
  - Any access to the FPSCR, FPSID, MVFR0, MVFR1, MVFR2, or FPEXC System registers.

  If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

  In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

### Bits [9:0]

Reserved, RES0.

### Accessing the NSACR

Accesses to this register use the following encodings in the System instruction encoding space:

\[

G8.2.115  PAR, Physical Address Register

The PAR characteristics are:

**Purpose**

Returns the output address (OA) from an Address translation instruction that executed successfully, or fault information if the instruction did not execute successfully.

**Configurations**

AArch32 System register PAR[63:0] is architecturally mapped to AArch64 System register PAR_EL1[63:0].

PAR is accessed as a 32-bit value:
- When the PE is not in Hyp mode and is using the Short-descriptor translation table format.
- When the PE is in Hyp mode and executes an ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, or ATS12NSOUW instruction and the value of HCR.VM is 0 and the value of TTBCR.EAE is 0.

In these cases, PAR[63:32] is RES0.

Otherwise, the PAR is accessed as a 64-bit value, if any of the following is true:
- When using the Long-descriptor translation table format.
- If the stage 1 address translation is disabled and TTBCR.EAE is set to 1.
- In an implementation that includes EL2, for the result of an ATS1Cxx instruction performed from Hyp mode.

For PL1&0 stage 1 translations, TTBCR.EAE selects the translation table format.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits[31:0] and do not modify bits[63:32].

The Configurations section specifies the cases where each PAR format is used.

**Field descriptions**

The PAR bit assignments are:

*When the instruction returned a 32-bit value to the PAR, PAR.F==0:*

This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.
On a successful conversion, the PAR can return a value that indicates the resulting attributes, rather than the values that appear in the translation table descriptors. More precisely:

- Memory attribute fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the translation table descriptors. This applies to the NOS, SH, Inner, and Outer fields.

- See the NS bit description for constraints on the value it returns.

**Bits [63:32]**

Reserved, RES0.

**PA, bits [31:12]**

Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits[31:12].

This field resets to an architecturally UNKNOWN value.

**LPAE, bit [11]**

When updating the PAR with the result of the translation operation, this bit is set as follows:

- Short-descriptor translation table format used. This means the PAR returned a 32-bit value.

This field resets to an architecturally UNKNOWN value.

**NOS, bit [10]**

Not Outer Shareable. When the returned value of PAR.SH is 1, indicates the Shareability attribute for the physical memory region:

- Memory region is Outer Shareable.
- Memory region is Inner Shareable.

When the returned value of PAR.SH is 0 the value returned to this field is UNKNOWN.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

This field resets to an architecturally UNKNOWN value.

**NS, bit [9]**

Non-secure. The NS attribute for a translation table entry from a Secure translation regime.

For a result from a Secure translation regime, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.

For a result from a Non-secure translation regime, this bit is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

**IMPLEMENTATION DEFINED, bit [8]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**SH, bit [7]**

Shareability. Indicates whether the physical memory region is Non-shareable:

- Memory is Non-shareable.
- Memory is shareable, and PAR.NOS indicates whether the region is Outer Shareable or Inner Shareable.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.
This field resets to an architecturally UNKNOWN value.

**Inner[2:0], bits [6:4]**

Inner cacheability attribute for the region. Permitted values are:

- **0b00**  Non-cacheable.
- **0b01**  Device-nGnRnE.
- **0b11**  Device-nGnRE.
- **0b10**  Write-Back, Write-Allocate.
- **0b11**  Write-Back, no Write-Allocate.

The values **0b10** and **0b11** are reserved.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

This field resets to an architecturally UNKNOWN value.

**Outer[1:0], bits [3:2]**

Outer cacheability attribute for the region. Permitted values are:

- **0b00**  Non-cacheable.
- **0b01**  Write-Back, Write-Allocate.
- **0b10**  Write-Through, no Write-Allocate.
- **0b11**  Write-Back, no Write-Allocate.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

This field resets to an architecturally UNKNOWN value.

**SS, bit [1]**

Supersection. Used to indicate if the result is a Supersection:

- **0b0**  Result is not a Supersection. PAR[31:12] contains OA[31:12].
- **0b1**  Result is a Supersection, and:
  - PAR[15:12] contains 0b0000.

If an implementation supports less than 40 bits of physical address, the bits in the PAR field that correspond to physical address bits that are not implemented are UNKNOWN.

This field resets to an architecturally UNKNOWN value.

**F, bit [0]**

Indicates whether the instruction performed a successful address translation.

- **0b0**  Address translation completed successfully.

This field resets to an architecturally UNKNOWN value.
### When the instruction returned a 32-bit value to the PAR, PAR.F==1:

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>16</th>
<th>12</th>
<th>10</th>
<th>7</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>IMPLEMENTATION DEFINED</td>
<td>RES0</td>
<td>RES0</td>
<td>FS</td>
<td>F</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This section describes the register value returned by a fault on the execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

**Bits [63:32]**

Reserved, RES0.

**IMPLEMENTATION DEFINED, bits [31:16]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**Bits [15:12]**

Reserved, RES0.

**LPAE, bit [11]**

When updating the PAR with the result of the translation operation, this bit is set as follows:

- **0**: Short-descriptor translation table format used. This means the PAR returned a 32-bit value.

This field resets to an architecturally UNKNOWN value.

**Bits [10:7]**

Reserved, RES0.

**FS, bits [6:1]**

Fault status bits. Bits [12,10,3:0] from the DFSR, indicating the source of the abort.

This field resets to an architecturally UNKNOWN value.

**F, bit [0]**

Indicates whether the instruction performed a successful address translation.

- **0**: Address translation aborted.

This field resets to an architecturally UNKNOWN value.

### When the instruction returned a 64-bit value to the PAR, PAR.F==0:

<table>
<thead>
<tr>
<th>63</th>
<th>56</th>
<th>40</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATTR</td>
<td>RES0</td>
<td>PA</td>
<td>NS</td>
<td>SH</td>
<td>RES0</td>
<td>F</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.
On a successful conversion, the PAR can return a value that indicates the resulting attributes, rather than the values that appear in the translation table descriptors. More precisely:

- Memory attribute fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the translation table descriptors. This applies to the ATTR and SH fields.

- See the NS bit description for constraints on the value it returns.

**ATTR, bits [63:56]**

Memory attributes for the returned output address. This field uses the same encoding as the Attr<\textit{n}> fields in MAIR0 and MAIR1.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

This field resets to an architecturally UNKNOWN value.

**Bits [55:40]**

Reserved, RES0.

**PA, bits [39:12]**

Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits[39:12].

This field resets to an architecturally UNKNOWN value.

**LPAE, bit [11]**

When updating the PAR with the result of the translation operation, this bit is set as follows:

- \texttt{0b1} Long-descriptor translation table format used. This means the PAR returned a 64-bit value.

This field resets to an architecturally UNKNOWN value.

**IMPLEMENTATION DEFINED, bit [10]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**NS, bit [9]**

Non-secure. The NS attribute for a translation table entry from a Secure translation regime.

For a result from a Secure translation regime, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.

For a result from a Non-secure translation regime, this bit is UNKNOWN.

This field resets to an architecturally UNKNOWN value.

**SH, bits [8:7]**

Shareability attribute, for the returned output address. Permitted values are:

- \texttt{0b00} Non-shareable.
- \texttt{0b10} Outer Shareable.
- \texttt{0b11} Inner Shareable.

The value \texttt{0b11} is reserved.

--- Note ---

This field returns the value \texttt{0b10} for:

- Any type of Device memory.
• Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

This field resets to an architecturally UNKNOWN value.

**Bits [6:1]**

Reserved, RES0.

**F, bit [0]**

Indicates whether the instruction performed a successful address translation.

0b0 Address translation completed successfully.

This field resets to an architecturally UNKNOWN value.

*When the instruction returned a 64-bit value to the PAR, PAR.F==1:*

This section describes the register value returned by a fault on the execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

**IMPLEMENTATION DEFINED, bits [63:56]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**IMPLEMENTATION DEFINED, bits [55:52]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**IMPLEMENTATION DEFINED, bits [51:48]**

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

**Bits [47:12]**

Reserved, RES0.

**LPAE, bit [11]**

When updating the PAR with the result of the translation operation, this bit is set as follows:

0b1 Long-descriptor translation table format used. This means the PAR returned a 64-bit value.

This field resets to an architecturally UNKNOWN value.
Bit [10]
Reserved, RES0.

FSTAGE, bit [9]
Indicates the translation stage at which the translation aborted:
0b0 Translation aborted because of a fault in the stage 1 translation.
0b1 Translation aborted because of a fault in the stage 2 translation.
This field resets to an architecturally UNKNOWN value.

S2WLK, bit [8]
If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.
This field resets to an architecturally UNKNOWN value.

Bit [7]
Reserved, RES0.

FST, bits [6:1]
Fault status field. Values are as in the DFSR.STATUS and IFSR.STATUS fields when using the Long-descriptor translation table format.
This field resets to an architecturally UNKNOWN value.

F, bit [0]
Indicates whether the instruction performed a successful address translation.
0b1 Address translation aborted.
This field resets to an architecturally UNKNOWN value.

Accessing the PAR
Accesses to this register use the following encodings in the System instruction encoding space:

G8.2.116 PRRR, Primary Region Remap Register

The PRRR characteristics are:

**Purpose**

Controls the top level mapping of the TEX[0], C, and B memory region attributes.

**Configurations**

AArch32 System register PRRR[31:0] is architecturally mapped to AArch64 System register MAIR_EL1[31:0].

MAIR0 and PRRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in PRRR.
- When it is set to 1, the register is as described in MAIR0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PRRR is a 32-bit register.

**Field descriptions**

The PRRR bit assignments are:

*When TTBCR.EAE == 0:*

![Diagram of PRRR bit assignments](image)

NOS<\text{n}>, bit \([n+24]\), for \(n = 0\) to \(7\)

Not Outer Shareable. NOS<\text{n}> is the Outer Shareable property for memory attributes \(n\), if the region is mapped as Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, and the appropriate PRRR.{NS0, NS1} field identifies the region as shareable. \(n\) is the value of the concatenation of the \{TEX[0], C, B\} bits from the translation table descriptor. The possible values of each NOS<\text{n}> field other than NOS6 are:

- 00: Memory region is Outer Shareable.
- 01: Memory region is Inner Shareable.

The value of this bit is ignored if the region is:

- Device memory

NOS7
NOS6
NOS5
NOS4
NOS3
NOS2
NOS1
NOS0
NS1
NS0
DS1
DS0
RES0
TR7 TR6 TR5 TR4 TR3 TR2 TR1 TR0
- Normal memory that is at least one of:
  - Inner Non-cacheable, Outer Non-cacheable.
  - Identified by the appropriate PRRR.\{NS0, NS1\} field as Non-shareable.

The meaning of the NOS6 field is IMPLEMENTATION DEFINED.
This field resets to an architecturally UNKNOWN value.

**Bits [23:20]**

Reserved, RES0.

**NS1, bit [19]**

Mapping of S = 1 attribute for Normal memory regions. This field is used in determining the Shareability of a memory region that is mapped to Normal memory and both:
- Is not Inner Non-cacheable, Outer Non-cacheable.
- Has the S bit in the translation table descriptor set to 1.

The possible values of this bit are:
- 0b0 Region is Non-shareable.
- 0b1 Region is shareable. The value of the appropriate PRRR.NOS<n> field determines whether the region is Inner Shareable or Outer Shareable.

This field resets to an architecturally UNKNOWN value.

**NS0, bit [18]**

Mapping of S = 0 attribute for Normal memory regions. This field is used in determining the Shareability of a memory region that is mapped to Normal memory and both:
- Is not Inner Non-cacheable, Outer Non-cacheable.
- Has the S bit in the translation table descriptor set to 0.

The possible values of this bit are:
- 0b0 Region is Non-shareable.
- 0b1 Region is shareable. The value of the appropriate PRRR.NOS<n> field determines whether the region is Inner Shareable or Outer Shareable.

This field resets to an architecturally UNKNOWN value.

**DS1, bit [17]**

Mapping of S = 1 attribute for Device memory. In Armv8, all types of Device memory are Outer Shareable, and therefore this bit is RES1.
This field resets to an architecturally UNKNOWN value.

**DS0, bit [16]**

Mapping of S = 0 attribute for Device memory. In Armv8, all types of Device memory are Outer Shareable, and therefore this bit is RES1.
This field resets to an architecturally UNKNOWN value.

**TR<n>, bits [2n+1:2n], for n = 0 to 7**

TR<n> is the primary TEX mapping for memory attributes n, and defines the mapped memory type for a region with attributes n. n is the value of the concatenation of the \{TEX[0], C, B\} bits from the translation table descriptor. The possible values for each field other than TR6 are:
- 0b00 Device-nGnRnE memory
- 0b01 Device-nGnRE memory
- 0b10 Normal memory

The value 0b11 is reserved. The effect of programming a field to 0b11 is CONSTRAINED UNPREDICTABLE, see Reserved values in System and memory-mapped registers and translation table entries on page K1-7212.
The meaning of the TR6 field is IMPLEMENTATION DEFINED.
This field resets to an architecturally UNKNOWN value.

**Accessing the PRRR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{c\}\{q\} \text{ <coproc>,{#<opc1>,<Rt>,<CRn>,<CRm>,{#<opc2>}}}
\]

### G8.2.117 REVIDR, Revision ID Register

The REVIDR characteristics are:

**Purpose**

Provides implementation-specific minor revision information.

**Configurations**

AArch32 System register REVIDR[31:0] is architecturally mapped to AArch64 System register REVIDR_EL1[31:0].

If REVIDR has the same value as MIDR, then its contents have no significance.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

REVIDR is a 32-bit register.

**Field descriptions**

The REVIDR bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED, bits [31:0]</td>
<td>IMPLEMENTATION DEFINED</td>
</tr>
<tr>
<td>31 0</td>
<td>0b1111 0b000 0b0000 0b0000 0b110</td>
</tr>
</tbody>
</table>

**Accessing the REVIDR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}(<c>)(<q>) <\text{coproc}>, (<\#><\text{opc1}>)<\text{CRn}, <\text{CRm}>, (<\#><\text{opc2}>)
\]

If PSTATE.EL == EL0 then

UNDEFINED;

elsif PSTATE.EL == EL1 then

elsif EL2Enabled() & ELUsingAArch32(EL2) & HSTR.T0 == '1' then

AArch32.TakeHypTrapException(0x03);

elsif EL2Enabled() & ELUsingAArch32(EL2) & HCR_EL2.TID1 == '1' then

AArch64.AArch32SystemAccessTrap(EL2, 0x03);

elsif EL2Enabled() & ELUsingAArch32(EL2) & HCR.TID1 == '1' then

AArch32.TakeHypTrapException(0x03);

else

return REVIDR;

elsif PSTATE.EL == EL2 then

return REVIDR;

elsif PSTATE.EL == EL3 then

return REVIDR;
G8.2.118 RMR, Reset Management Register

The RMR characteristics are:

**Purpose**

If EL1 or EL3 is the highest implemented Exception level and this register is implemented:
- A write to the register at the highest implemented Exception level can request a Warm reset.
- If the highest implemented Exception level can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

**Configurations**

AArch32 System register RMR[31:0] is architecturally mapped to AArch64 System register RMR_EL1[31:0] when IsHighestEL(EL1).

AArch32 System register RMR[31:0] is architecturally mapped to AArch64 System register RMR_EL3[31:0] when HaveEL(EL3).

Only implemented if EL1 or EL3 is the highest implemented Exception level. In this case:
- If the highest implemented Exception level can use AArch32 and AArch64 then this register must be implemented.
- If the highest implemented Exception level cannot use AArch64 then it is IMPLEMENTATION DEFINED whether the register is implemented.

See the field descriptions for the reset values. These apply whenever the register is implemented.

**Attributes**

RMR is a 32-bit register.

**Field descriptions**

The RMR bit assignments are:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>RR</td>
<td></td>
</tr>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td>AA64</td>
</tr>
</tbody>
</table>

**Bits [31:2]**

Reserved, RES0.

**RR, bit [1]**

Reset Request. Setting this bit to 1 requests a Warm reset.
This field resets to 0.

**AA64, bit [0]**

When the highest implemented Exception level can use AArch64, determines which Execution state the PE boots into after a Warm reset:
- 0b0 AArch32.
- 0b1 AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If the highest implemented Exception level cannot use AArch64 this bit is RAZ/WI.

When implemented as a RW field, this field resets to 0 on a Cold reset.
Accessing the RMR

When EL3 is implemented, Arm deprecates accessing this register from any PE mode other than Monitor mode.

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MRC} \{<c>\} \{<q>\} \text{<coproc>}, \text{<Rt>}, \text{<CRn>}, \text{<CRm>}, \text{(#)<opc1>}, \text{(#)<opc2>} \]

<table>
<thead>
<tr>

if \( \text{PSTATE.EL} \in \{\text{EL3}, \text{EL1}\} \) && \( \text{IsHighestEL(PSTATE.EL)} \) then
  RMR = R[t];
else
  UNDEFINED;
G8.2.119 RVBAR, Reset Vector Base Address Register

The RVBAR characteristics are:

Purpose

If EL3 is not implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch32 state.

Configurations

This register is only implemented if the highest Exception level implemented is capable of using AArch32, and is not EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

RVBAR is a 32-bit register.

Field descriptions

The RVBAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>

</tbody>
</table>

if PSTATE.EL IN {EL2, EL1} && IsHighestEL(PSTATE.EL) then
return RVBAR;
else
UNDEFINED;

**G8.2.120 SCR, Secure Configuration Register**

The SCR characteristics are:

**Purpose**

When EL3 is implemented and can use AArch32, defines the configuration of the current Security state. It specifies:

- The Security state, either Secure or Non-secure.
- What mode the PE branches to if an IRQ, FIQ, or External abort occurs.
- Whether the CPSR.F or CPSR.A bits can be modified when SCR.NS==1.

**Configurations**

AArch32 System register SCR[31:0] can be mapped to AArch64 System register SCR_EL3[31:0], but this is not architecturally mandated.

Some or all RW fields of this register have defined reset values. These apply whenever the register is accessible. This means they apply when the PE resets into EL3 using AArch32.

**Attributes**

SCR is a 32-bit register.

**Field descriptions**

The SCR bit assignments are:

| 31 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|---|
| RES0 | | | | | | | | | | | | | | | | | | NS |

- **RES0**
  - Reserved, RES0.

- **TERR**, bit [15]
  - When RAS is implemented:
    - Reserve Error record accesses. Generate a Monitor Trap exception on accesses to the following registers from modes other than Monitor mode:
      - ERRIDR, ERXADDR, ERXADDR2, ERXCTRLR, ERXCTRL2, ERXFR, ERXFR2, ERXMISC0, ERXMISC1, ERXMISC2, ERXMISC3, and ERXSTATUS. When ARMv8.4-RAS is implemented, ERXMISC4, ERXMISC5, ERXMISC6, ERXMISC7.
    - **0b0** This control does not cause any instructions to be trapped.
Accesses to the specified registers from modes other than Monitor mode generate a Monitor Trap exception.

In a system where the PE resets into EL3, this field resets to 0.

**Otherwise:**
Reserved, RES0.

**Bit [14]**
Reserved, RES0.

**TWE, bit [13]**
Traps WFE instructions to Monitor mode.

- **0b0** This control does not cause any instructions to be trapped.
- **0b1** Any attempt to execute a WFE instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state and the attempted execution does not generate an exception that is taken to EL1 or EL2 by SCTLR.nTWE or HCR.TWE.

Any exception that is taken to EL1 or to EL2 has priority over this trap.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

**Note**
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

In a system where the PE resets into EL3, this field resets to 0.

**TWI, bit [12]**
Traps WFI instructions to Monitor mode.

- **0b0** This control does not cause any instructions to be trapped.
- **0b1** Any attempt to execute a WFI instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state and the attempted execution does not generate an exception that is taken to EL1 or EL2 by SCTLR.nTWI or HCR.TWI.

Any exception that is taken to EL1 or to EL2 has priority over this trap.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

**Note**
Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

In a system where the PE resets into EL3, this field resets to 0.

**Bits [11:10]**
Reserved, RES0.

**SIF, bit [9]**
Secure instruction fetch. When the PE is in Secure state, this bit disables instruction fetch from Non-secure memory. The possible values for this bit are:

- **0b0** Secure state instruction fetches from Non-secure memory are permitted.
Secure state instruction fetches from Non-secure memory are not permitted. This bit is permitted to be cached in a TLB.

In a system where the PE resets into EL3, this field resets to 0.

**HCE, bit [8]**

Hypervisor Call instruction enable. If EL2 is implemented, enables execution of HVC instructions at Non-secure EL1 and EL2.

- **0b0** HVC instructions are:
  - UNDEFINED at Non-secure EL1. The Undefined Instruction exception is taken from PL1 to PL1.
  - UNPREDICTABLE at EL2. Behavior is one of the following:
    - The instruction is UNDEFINED.
    - The instruction executes as a NOP.

- **0b1** HVC instructions are enabled at Non-secure EL1 and EL2.

**Note**

HVC instructions are always UNDEFINED at EL0 and in Secure state.

If EL2 is not implemented, this bit is RES0 and HVC is UNDEFINED.

In a system where the PE resets into EL3, this field resets to 0.

**SCD, bit [7]**

Secure Monitor Call disable. Disables SMC instructions.

- **0b0** SMC instructions are enabled.

- **0b1** In Non-secure state, SMC instructions are UNDEFINED. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.
  In Secure state, behavior is one of the following:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

**Note**

SMC instructions are always UNDEFINED at PL0.

In a system where the PE resets into EL3, this field resets to 0.

**nET, bit [6]**

Not Early Termination. This bit disables early termination. The possible values of this bit are:

- **0b0** Early termination permitted. Execution time of data operations can depend on the data values.

- **0b1** Disable early termination. The number of cycles required for data operations is forced to be independent of the data values.

This IMPLEMENTATION DEFINED mechanism can disable data dependent timing optimizations from multiplies and data operations. It can provide system support against information leakage that might be exploited by timing correlation types of attack.

On implementations that do not support early termination or do not support disabling early termination, this bit is RES0.

In a system where the PE resets into EL3, this field resets to 0.
**AW, bit [5]**

When the value of SCR.EA is 1 and the value of HCR.AMO is 0, this bit controls whether CPSR.A masks an External abort taken from Non-secure state, and the possible values of this bit are:

- **0b0**: External aborts taken from Non-secure state are not masked by CPSR.A, and are taken to EL3.
- **0b1**: External aborts taken from Secure state are masked by CPSR.A.
- **0b1**: External aborts taken from either Security state are masked by CPSR.A. When CPSR.A is 0, the abort is taken to EL3.

When SCR.EA is 0 or HCR.AMO is 1, this bit has no effect.

In a system where the PE resets into EL3, this field resets to `0`.

**FW, bit [4]**

When the value of SCR.FIQ is 1 and the value of HCR.FMO is 0, this bit controls whether CPSR.F masks an FIQ interrupt taken from Non-secure state, and the possible values of this bit are:

- **0b0**: An FIQ taken from Non-secure state is not masked by CPSR.F, and is taken to EL3.
- **0b1**: An FIQ taken from Secure state is masked by CPSR.F.
- **0b1**: An FIQ taken from either Security state is masked by CPSR.F. When CPSR.F is 0, the FIQ is taken to EL3.

When SCR.FIQ is 0 or HCR.FMO is 1, this bit has no effect.

In a system where the PE resets into EL3, this field resets to `0`.

**EA, bit [3]**

External Abort handler. This bit controls which mode takes External aborts. The possible values of this bit are:

- **0b0**: External aborts taken to Abort mode.
- **0b1**: External aborts taken to Monitor mode.

In a system where the PE resets into EL3, this field resets to `0`.

**FIQ, bit [2]**

FIQ handler. This bit controls which mode takes FIQ exceptions. The possible values of this bit are:

- **0b0**: FIQs taken to FIQ mode.
- **0b1**: FIQs taken to Monitor mode.

In a system where the PE resets into EL3, this field resets to `0`.

**IRQ, bit [1]**

IRQ handler. This bit controls which mode takes IRQ exceptions. The possible values of this bit are:

- **0b0**: IRQs taken to IRQ mode.
- **0b1**: IRQs taken to Monitor mode.

In a system where the PE resets into EL3, this field resets to `0`.

**NS, bit [0]**

Non-secure bit. Except when the PE is in Monitor mode, this bit determines the Security state of the PE:

- **0b0**: PE is in Secure state.
- **0b1**: PE is in Non-secure state.

If the HCR.TGE bit is set, an attempt to change from a Secure PL1 mode to a Non-secure EL1 mode by changing the SCR.NS bit from 0 to 1 results in the SCR.NS bit remaining as 0.

In a system where the PE resets into EL3, this field resets to `0`. 
Accessing the SCR

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\langle\{c\}\{q\}\rangle \langle\\text{coproc}\rangle, \langle\#\langle\text{opc1}\rangle, \langle\text{Rt}\rangle, \langle\text{CRn}\rangle, \langle\text{CRm}\rangle\rangle, \langle\#\langle\text{opc2}\rangle\rangle}
\]

### G8.2.121 SCTLR, System Control Register

The SCTLR characteristics are:

**Purpose**

Provides the top level control of the system, including its memory system.

**Configurations**

AArch32 System register SCTLR[31:0] is architecturally mapped to AArch64 System register SCTLR_EL1[31:0].

Some bits in the register are read-only. These bits relate to non-configurable features of an implementation, and are provided for compatibility with previous versions of the architecture.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply only to the Secure instance of the register. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SCTLR is a 32-bit register.

**Field descriptions**

The SCTLR bit assignments are:

<table>
<thead>
<tr>

</tbody>
</table>

The field resets to an IMPLEMENTATION DEFINED choice between:

- `0`
- A value determined by an input configuration signal.
AFE, bit [29]

Access Flag Enable. When using the Short-descriptor translation table format for the PL1&0 translation regime, this bit enables use of the AP[0] bit in the translation descriptors as the Access flag, and restricts access permissions in the translation descriptors to the simplified model. The possible values of this bit are:

0b0  In the translation table descriptors, AP[0] is an access permissions bit. The full range of access permissions is supported. No Access flag is implemented.

0b1  In the translation table descriptors, AP[0] is the Access flag. Only the simplified model for access permissions is supported.

When using the Long-descriptor translation table format, the VMSA behaves as if this bit is set to 1, regardless of the value of this bit.

The AFE bit is permitted to be cached in a TLB.

This field resets to 0.

TRE, bit [28]

TEX remap enable. This bit enables remapping of the TEX[2:1] bits in the PL1&0 translation regime for use as two translation table bits that can be managed by the operating system. Enabling this remapping also changes the scheme used to describe the memory region attributes in the VMSA. The possible values of this bit are:

0b0  TEX remap disabled. TEX[2:0] are used, with the C and B bits, to describe the memory region attributes.

0b1  TEX remap enabled. TEX[2:1] are reassigned for use as bits managed by the operating system. The TEX[0], C, and B bits are used to describe the memory region attributes, with the MMU remap registers.

When the value of TTBCR.EAE is 1, this bit is RES1.

The TRE bit is permitted to be cached in a TLB.

This field resets to 0.

Bits [27:26]

Reserved, RES0.

EE, bit [25]

The value of the PSTATE.E bit on branch to an exception vector or coming out of reset, and the endianness of stage 1 translation table walks in the PL1&0 translation regime.

The possible values of this bit are:

0b0  Little-endian. PSTATE.E is cleared to 0 on taking an exception or coming out of reset. Stage 1 translation table walks in the PL1&0 translation regime are little-endian.

0b1  Big-endian. PSTATE.E is set to 1 on taking an exception or coming out of reset. Stage 1 translation table walks in the PL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support for data accesses at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support for data accesses at Exception Levels higher than EL0, this bit is RES1.

This field resets to an IMPLEMENTATION DEFINED choice between:

- 0.
- a value determined by an input configuration signal.

Bit [24]

Reserved, RES0.
SPAN, bit [23]

When ARMv8.1-PAN is implemented:

Set Privileged Access Never, on taking an exception to EL1 from either Secure or Non-secure state, or to EL3 from Secure state when EL3 is using AArch32.

0b0  CPSR.PAN is set to 1 in the following situations:
  •  In Non-secure state, on taking an exception to EL1.
  •  In Secure state, when EL3 is using AArch64, on taking an exception to EL1.
  •  In Secure state, when EL3 is using AArch32, on taking an exception to EL3.

0b1  The value of CPSR.PAN is left unchanged on taking an exception to EL1.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

Bit [22]

Reserved, RES1.

Bit [21]

Reserved, RES0.

UWXN, bit [20]

Unprivileged write permission implies PL1 XN (Execute-never). This bit can force all memory regions that are writable at PL0 to be treated as XN for accesses from software executing at PL1. The possible values of this bit are:

0b0  This control has no effect on memory access permissions.

0b1  Any region that is writable at PL0 forced to XN for accesses from software executing at PL1.

The UWXN bit is permitted to be cached in a TLB.

This field resets to 0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the PL1&0 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

0b0  This control has no effect on memory access permissions.

0b1  Any region that is writable in the PL1&0 translation regime is forced to XN for accesses from software executing at PL1 or PL0.

The WXN bit is permitted to be cached in a TLB.

This field resets to 0.

nTWE, bit [18]

Traps EL0 execution of WFE instructions to Undefined mode.

0b0  Any attempt to execute a WFE instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

0b1  This control does not cause any instructions to be trapped.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.
--- Note ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

This field resets to 1.

**Bit [17]**

Reserved, RES0.

**nTWI, bit [16]**

Traps EL0 execution of WFI instructions to Undefined mode.

0b0 Any attempt to execute a WFI instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

0b1 This control does not cause any instructions to be trapped.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

--- Note ---

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

---

This field resets to 1.

**Bits [15:14]**

Reserved, RES0.

**V, bit [13]**

Vectors bit. This bit selects the base address of the exception vectors for exceptions taken to a PE mode other than Monitor mode or Hyp mode:

0b0 Normal exception vectors. Base address is held in VBAR.

0b1 High exception vectors, base address 0xFFFF0000. This base address cannot be remapped.

This field resets to an IMPLEMENTATION DEFINED choice between:

- 0.
- a value determined by an input configuration signal.

**I, bit [12]**

Instruction access Cacheability control, for accesses at EL1 and EL0:

0b0 All instruction access to Normal memory from PL1 and PL0 are Non-cacheable for all levels of instruction and unified cache.

If the value of SCTLR.M is 0, instruction accesses from stage 1 of the PL1&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

0b1 All instruction access to Normal memory from PL1 and PL0 can be cached at all levels of instruction and unified cache.

If the value of SCTLR.M is 0, instruction accesses from stage 1 of the PL1&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.
Instruction accesses to Normal memory from EL1 and EL0 are Cacheable regardless of the value of the SCTLR.I bit if either:

- EL2 is using AArch32 and the value of HCR.DC is 1.
- EL2 is using AArch64 and the value of HCR_EL2.DC is 1.

This field resets to 0.

**Bit [11]**

Reserved, RES1.

**Bits [10:9]**

Reserved, RES0.

**SED, bit [8]**

SETEND instruction disable. Disables SETEND instructions at PL0 and PL1.

- **0b0**: SETEND instruction execution is enabled at PL0 and PL1.
- **0b1**: SETEND instructions are **undefined** at PL0 and PL1.

If the implementation does not support mixed-endian operation at any Exception level, this bit is RES1.

This field resets to 0.

**ITD, bit [7]**

IT Disable. Disables some uses of IT instructions at PL1 and PL0.

- **0b0**: All IT instruction functionality is enabled at PL1 and PL0.
- **0b1**: Any attempt at PL1 or PL0 to execute any of the following is **undefined**:

  - All encodings of the IT instruction with hw1[3:0]=1000.
  - All encodings of the subsequent instruction with the following values for hw1:
    - 11xxxxxxxxxxxx: All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
    - 1011xxxxxxxxxxxx: All instructions in *Miscellaneous 16-bit instructions* on page F3-3695.
    - 10100xxxxxxxxxxx: ADD Rd, PC, #imm
    - 01001xxxxxxxxxxx: LDR Rd, [PC, #imm]
    - 0100x1xxx1111xxx: ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.
    - 010001xx1xxxx1111: ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers unpredictable cases with BLX Rn.

  These instructions are always **undefined**, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.

  It is **implementation defined** whether the IT instruction is treated as:

  - A 16-bit instruction, that can only be followed by another 16-bit instruction.
  - The first half of a 32-bit instruction.

  This means that, for the situations that are **undefined**, either the second 16-bit instruction or the 32-bit instruction is **undefined**.

  An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is **CONSTRAINED UNPREDICTABLE**. For more information see *Changes to an ITD control by an instruction in an IT block* on page E1-3546.

ITD is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAZ/WI.
This field resets to 0.

**UNK, bit [6]**

Writes to this bit are IGNORED. Reads of this bit return an UNKNOW value.

This field resets to an architecturally UNKNOWN value.

**CP15BEN, bit [5]**

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==0b1111) encoding space from PL1 and PL0:

- **0b0**: PL0 and PL1 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is UNDEFINED.
- **0b1**: PL0 and PL1 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is enabled.

CP15BEN is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAO/WI.

This field resets to 1.

**LSMAOE, bit [4]**

*When ARMv8.2-LSMAOC is implemented:*

Load Multiple and Store Multiple Atomicity and Ordering Enable.

- **0b0**: For all memory accesses at EL1 or EL0, A32 and T32 Load Multiple and Store Multiple can have an interrupt taken during the sequence memory accesses, and the memory accesses are not required to be ordered.
- **0b1**: The ordering and interrupt behavior of A32 and T32 Load Multiple and Store Multiple at EL1 or EL0 is as defined for Armv8.0.

This bit is permitted to be cached in a TLB.

This field resets to 1.

*Otherwise:*

Reserved, RES1.

**nTLSMD, bit [3]**

*When ARMv8.2-LSMAOC is implemented:*

No Trap Load Multiple and Store Multiple to Device-nGRE/Device-nGnRE/Device-nGnRnE memory.

- **0b0**: All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL1 or EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are trapped and generate a stage 1 Alignment fault.
- **0b1**: All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL1 or EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are not trapped.

This bit is permitted to be cached in a TLB.

This field resets to 1.

*Otherwise:*

Reserved, RES1.

**C, bit [2]**

Cacheability control, for data accesses at EL1 and EL0:

- **0b0**: All data access to Normal memory from PL1 and PL0, and all accesses to the PL1&0 stage 1 translation tables, are Non-cacheable for all levels of data and unified cache.
- **0b1**: All data access to Normal memory from PL1 and PL0, and all accesses to the PL1&0 stage 1 translation tables, can be cached at all levels of data and unified cache.
The PE ignores SCLTR.C for Non-secure state and data accesses to Normal memory from EL1 and EL0 are Cacheable if either:
- EL2 is using AArch32 and the value of HCR.DC is 1.
- EL2 is using AArch64 and the value of HCR_EL2.DC is 1.
This field resets to 0.

A, bit [1]
Alignment check enable. This is the enable bit for Alignment fault checking at PL1 and PL0:
- 0: Alignment fault checking disabled when executing at PL1 or PL0.
  Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.
- 1: Alignment fault checking enabled when executing at PL1 or PL0.
  All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.
This field resets to 0.

M, bit [0]
MMU enable for EL1 and EL0 stage 1 address translation. Possible values of this bit are:
- 0: EL1 and EL0 stage 1 address translation disabled.
  See the SCTLR.I field for the behavior of instruction accesses to Normal memory.
- 1: EL1 and EL0 stage 1 address translation enabled.
In the Non-secure state the PE behaves as if the value of the SCTLR.M field is 0 for all purposes other than returning the value of a direct read of the field if either:
- EL2 is using AArch32 and the value of HCR.{DC, TGE} is not {0, 0}.
- EL2 is using AArch64 and the value of HCR_EL2.{DC, TGE} is not {0, 0}.
This field resets to 0.

Accessing the SCTLR
Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}\{<q>\} <coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm>\}, \{#<opc2>\}
\]

G8.2.122  **SPSR, Saved Program Status Register**

The SPSR characteristics are:

**Purpose**

Holds the saved process state for the current mode.

**Configurations**

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SPSR is a 32-bit register.

**Field descriptions**

The SPSR bit assignments are:

```
  31 30 29 28 27 26 25 24 23 22 21 20 19 16 15 10  9  8  7  6  5  4  3  2  1  0
```

- **N, bit [31]**
  
  Set to the value of PSTATE.N on taking an exception to the current mode, and copied to PSTATE.N on executing an exception return operation in the current mode.

- **Z, bit [30]**
  
  Set to the value of PSTATE.Z on taking an exception to the current mode, and copied to PSTATE.Z on executing an exception return operation in the current mode.

- **C, bit [29]**
  
  Set to the value of PSTATE.C on taking an exception to the current mode, and copied to PSTATE.C on executing an exception return operation in the current mode.

- **V, bit [28]**
  
  Set to the value of PSTATE.V on taking an exception to the current mode, and copied to PSTATE.V on executing an exception return operation in the current mode.

- **Q, bit [27]**
  
  Set to the value of PSTATE.Q on taking an exception to the current mode, and copied to PSTATE.Q on executing an exception return operation in the current mode.

- **IT[1:0], bits [26:25]**
  
  IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

- **J, bit [24]**
  
  RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.
Bit [23]

Reserved, RES0.

PAN, bit [22]  

When ARMv8.1-PAN is implemented:

Privileged Access Never. This bit is set to the value of PSTATE.PAN on taking an exception to the current mode, and copied to PSTATE.PAN on executing an exception return operation in the current mode.

Otherwise:

Reserved, RES0.

DIT, bit [21]  

When ARMv8.4-DIT is implemented:

Data Independent Timing. This bit is set to the value of PSTATE.DIT on taking an exception to the current mode, and copied to PSTATE.DIT on executing an exception return operation in the current mode.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]  

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

• IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.

• IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

0b0 Little-endian operation
0b1 Big-endian operation.

Instruction fetches ignore this bit.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

A, bit [8]  

SError interrupt mask bit.

0b0 Exception not masked.
0b1  Exception masked.

I, bit [7]

IRQ mask bit.
0b0  Exception not masked.
0b1  Exception masked.

F, bit [6]

FIQ mask bit.
0b0  Exception not masked.
0b1  Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from.
0b0  Taken from A32 state.
0b1  Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from.
0b1  Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from.
0b0000  User.
0b0001  FIQ.
0b0010  IRQ.
0b0011  Supervisor.
0b0100  Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32).
0b0111  Abort.
0b1010  Hyp.
0b1011  Undefined.
0b1111  System.
Other values are reserved.
G8.2.123  SPSR_abt, Saved Program Status Register (Abort mode)

The SPSR_abt characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Abort mode.

**Configurations**

AArch32 System register SPSR_abt[31:0] is architecturally mapped to AArch64 System register SPSR_abt[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SPSR_abt is a 32-bit register.

**Field descriptions**

The SPSR_abt bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>N, Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Abort mode, and copied to PSTATE.N on executing an exception return operation in Abort mode. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>30</td>
<td>Z, Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Abort mode, and copied to PSTATE.Z on executing an exception return operation in Abort mode. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>29</td>
<td>C, Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Abort mode, and copied to PSTATE.C on executing an exception return operation in Abort mode. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>28</td>
<td>V, Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Abort mode, and copied to PSTATE.V on executing an exception return operation in Abort mode. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>27</td>
<td>Q, Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Abort mode, and copied to PSTATE.Q on executing an exception return operation in Abort mode. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Abort mode, and copied to PSTATE.N on executing an exception return operation in Abort mode. This field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Abort mode, and copied to PSTATE.Z on executing an exception return operation in Abort mode. This field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Abort mode, and copied to PSTATE.C on executing an exception return operation in Abort mode. This field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Abort mode, and copied to PSTATE.V on executing an exception return operation in Abort mode. This field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Abort mode, and copied to PSTATE.Q on executing an exception return operation in Abort mode. This field resets to an architecturally UNKNOWN value.
IT[1:0], bits [26:25]

If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to Abort mode, and copied to
PSTATE.IT[1:0] on executing an exception return operation in Abort mode.

On executing an exception return operation in Abort mode SPSR_abt.IT must contain a value that
is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state.
Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction
set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

When ARMv8.1-PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Abort mode,
and copied to PSTATE.PAN on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When ARMv8.4-DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Abort mode,
and copied to PSTATE.DIT on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Abort mode, and
copied to PSTATE.IL on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Abort mode,
and copied to PSTATE.GE on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

IT[7:2], bits [15:10]

If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to Abort mode, and copied to
PSTATE.IT[7:2] on executing an exception return operation in Abort mode.

SPSR_abt.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to Abort mode, and copied to
PSTATE.E on executing an exception return operation in Abort mode.
If the implementation does not support big-endian operation, SPSR_abt.E is RES0. If the implementation does not support little-endian operation, SPSR_abt.E is RES1. On executing an exception return operation in Abort mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_abt.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_abt.E is RES1.

This field resets to an architecturally UNKNOWN value.

**A, bit [8]**

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Abort mode, and copied to PSTATE.A on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

**I, bit [7]**

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Abort mode, and copied to PSTATE.I on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

**F, bit [6]**

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Abort mode, and copied to PSTATE.F on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

**T, bit [5]**

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Abort mode, and copied to PSTATE.T on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

**M[4:0], bits [4:0]**

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Abort mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Abort mode.

- 0b10000: User.
- 0b10001: FIQ.
- 0b10010: IRQ.
- 0b10011: Supervisor.
- 0b10111: Abort.
- 0b11011: Undefined.
- 0b11111: System.

Other values are reserved. If SPSR_abt.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Abort mode is an illegal return event, as described in *Illegal return events from AArch32 state* on page G1-5270.

This field resets to an architecturally UNKNOWN value.

**Accessing the SPSR_abt**

SPSR_abt is accessible in all modes other than User mode and Abort mode. For more details, see MRS (Banked register) and MSR (Banked register) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:
### G8 AArch32 System Register Descriptions

G8.2.124  SPSR_fiq, Saved Program Status Register (FIQ mode)

The SPSR_fiq characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to FIQ mode.

**Configurations**

AArch32 System register SPSR_fiq[31:0] is architecturally mapped to AArch64 System register SPSR_fiq[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SPSR_fiq is a 32-bit register.

**Field descriptions**

The SPSR_fiq bit assignments are:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 16 15 10 9 8 7 6 5 4 0
N  Z  C  V  Q  J  IL  GE  IT[7:2]  E  A  I  F  T  M[4:0]
```

- **N**, bit [31]
  
  Negative Condition flag. Set to the value of PSTATE.N on taking an exception to FIQ mode, and copied to PSTATE.N on executing an exception return operation in FIQ mode.
  
  This field resets to an architecturally UNKNOWN value.

- **Z**, bit [30]
  
  Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to FIQ mode, and copied to PSTATE.Z on executing an exception return operation in FIQ mode.
  
  This field resets to an architecturally UNKNOWN value.

- **C**, bit [29]
  
  Carry Condition flag. Set to the value of PSTATE.C on taking an exception to FIQ mode, and copied to PSTATE.C on executing an exception return operation in FIQ mode.
  
  This field resets to an architecturally UNKNOWN value.

- **V**, bit [28]
  
  Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to FIQ mode, and copied to PSTATE.V on executing an exception return operation in FIQ mode.
  
  This field resets to an architecturally UNKNOWN value.

- **Q**, bit [27]
  
  Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to FIQ mode, and copied to PSTATE.Q on executing an exception return operation in FIQ mode.
  
  This field resets to an architecturally UNKNOWN value.
IT[1:0], bits [26:25]

  If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to FIQ mode, and copied to PSTATE.IT[1:0] on executing an exception return operation in FIQ mode.

  On executing an exception return operation in FIQ mode SPSR_fiq.IT must contain a value that is valid for the instruction being returned to.

  This field resets to an architecturally UNKNOWN value.

J, bit [24]

  RES0.

  In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

  Reserved, RES0.

PAN, bit [22]

  When Armv8.1-PAN is implemented:

  Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to FIQ mode, and copied to PSTATE.PAN on executing an exception return operation in FIQ mode.

  This field resets to an architecturally UNKNOWN value.

  Otherwise:

  Reserved, RES0.

DIT, bit [21]

  When Armv8.4-DIT is implemented:

  Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to FIQ mode, and copied to PSTATE.DIT on executing an exception return operation in FIQ mode.

  This field resets to an architecturally UNKNOWN value.

  Otherwise:

  Reserved, RES0.

IL, bit [20]

  Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to FIQ mode, and copied to PSTATE.IL on executing an exception return operation in FIQ mode.

  This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

  Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to FIQ mode, and copied to PSTATE.GE on executing an exception return operation in FIQ mode.

  This field resets to an architecturally UNKNOWN value.

IT[7:2], bits [15:10]

  If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to FIQ mode, and copied to PSTATE.IT[7:2] on executing an exception return operation in FIQ mode.

  SPSR_fiq.IT must contain a value that is valid for the instruction being returned to.

  This field resets to an architecturally UNKNOWN value.

E, bit [9]

  Endianness. Set to the value of PSTATE.E on taking an exception to FIQ mode, and copied to PSTATE.E on executing an exception return operation in FIQ mode.
If the implementation does not support big-endian operation, SPSR_fiq.E is RES0. If the implementation does not support little-endian operation, SPSR_fiq.E is RES1. On executing an exception return operation in FIQ mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_fiq.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_fiq.E is RES1.

This field resets to an architecturally UNKNOWN value.

A, bit [8]
Secondary interrupt mask. Set to the value of PSTATE.A on taking an exception to FIQ mode, and copied to PSTATE.A on executing an exception return operation in FIQ mode.

This field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to FIQ mode, and copied to PSTATE.I on executing an exception return operation in FIQ mode.

This field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to FIQ mode, and copied to PSTATE.F on executing an exception return operation in FIQ mode.

This field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to FIQ mode, and copied to PSTATE.T on executing an exception return operation in FIQ mode.

This field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to FIQ mode, and copied to PSTATE.M[4:0] on executing an exception return operation in FIQ mode.

0b10000 User.
0b10001 FIQ.
0b10010 IRQ.
0b10011 Supervisor.
0b10111 Abort.
0b11011 Undefined.
0b11111 System.

Other values are reserved. If SPSR_fiq.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in FIQ mode is an illegal return event, as described in Illegal return events from AArch32 state on page G1-5270.

This field resets to an architecturally UNKNOWN value.

Accessing the SPSR_fiq

SPSR_fiq is accessible in all modes other than User mode and FIQ mode. For more details, see MRS (Banked register) and MSR (Banked register) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:
**MRS{<c>}{<q>} <Rd>, SPSR_fiq**

<table>

</table>
**G8.2.125  SPSR_hyp, Saved Program Status Register (Hyp mode)**

The SPSR_hyp characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Hyp mode.

**Configurations**

AArch32 System register SPSR_hyp[31:0] is architecturally mapped to AArch64 System register SPSR_EL2[31:0].

RW fields in this register reset to architecturally \textit{UNKNOWN} values.

**Attributes**

SPSR_hyp is a 32-bit register.

**Field descriptions**

The SPSR_hyp bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

- **N**, bit [31]
  
  Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Hyp mode, and copied to PSTATE.N on executing an exception return operation in Hyp mode.
  
  This field resets to an architecturally \textit{UNKNOWN} value.

- **Z**, bit [30]
  
  Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Hyp mode, and copied to PSTATE.Z on executing an exception return operation in Hyp mode.
  
  This field resets to an architecturally \textit{UNKNOWN} value.

- **C**, bit [29]
  
  Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Hyp mode, and copied to PSTATE.C on executing an exception return operation in Hyp mode.
  
  This field resets to an architecturally \textit{UNKNOWN} value.

- **V**, bit [28]
  
  Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Hyp mode, and copied to PSTATE.V on executing an exception return operation in Hyp mode.
  
  This field resets to an architecturally \textit{UNKNOWN} value.

- **Q**, bit [27]
  
  Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Hyp mode, and copied to PSTATE.Q on executing an exception return operation in Hyp mode.
  
  This field resets to an architecturally \textit{UNKNOWN} value.
IT[1:0], bits [26:25]

If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to Hyp mode, and copied to
PSTATE.IT[1:0] on executing an exception return operation in Hyp mode.

On executing an exception return operation in Hyp mode SPSR_hyp.IT must contain a value that is
valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state.
Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction
set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

When ARMv8.1-PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Hyp mode, and
copied to PSTATE.PAN on executing an exception return operation in Hyp mode.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When ARMv8.4-DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Hyp mode,
and copied to PSTATE.DIT on executing an exception return operation in Hyp mode.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Hyp mode, and
copied to PSTATE.IL on executing an exception return operation in Hyp mode.

This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Hyp mode,
and copied to PSTATE.GE on executing an exception return operation in Hyp mode.

This field resets to an architecturally UNKNOWN value.

IT[7:2], bits [15:10]

If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to Hyp mode, and copied to
PSTATE.IT[7:2] on executing an exception return operation in Hyp mode.

SPSR_hyp.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to Hyp mode, and copied to
PSTATE.E on executing an exception return operation in Hyp mode.
If the implementation does not support big-endian operation, SPSR_hyp.E is RES0. If the implementation does not support little-endian operation, SPSR_hyp.E is RES1. On executing an exception return operation in Hyp mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_hyp.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_hyp.E is RES1.

This field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Hyp mode, and copied to PSTATE.A on executing an exception return operation in Hyp mode.
This field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Hyp mode, and copied to PSTATE.I on executing an exception return operation in Hyp mode.
This field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Hyp mode, and copied to PSTATE.F on executing an exception return operation in Hyp mode.
This field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Hyp mode, and copied to PSTATE.T on executing an exception return operation in Hyp mode.
This field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Hyp mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Hyp mode.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b10000</td>
<td>User.</td>
</tr>
<tr>
<td>0b10001</td>
<td>FIQ.</td>
</tr>
<tr>
<td>0b10010</td>
<td>IRQ.</td>
</tr>
<tr>
<td>0b10011</td>
<td>Supervisor.</td>
</tr>
<tr>

<td>Hyp.</td>
</tr>
<tr>
<td>0b11011</td>
<td>Undefined.</td>
</tr>
<tr>
<td>0b11111</td>
<td>System.</td>
</tr>
</tbody>
</table>

Other values are reserved. If SPSR_hyp.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Hyp mode is an illegal return event, as described in *Illegal return events from AArch32 state on page G1-5270.*
This field resets to an architecturally UNKNOWN value.

### Accessing the SPSR_hyp

SPSR_hyp is accessible only in Monitor mode. For more details, see MRS (Banked register) and MSR (Banked register) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:
**MRS<qc><q> Rd, SPSR_hyp**

<table>
<thead>
<tr>

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to IRQ mode, and copied to PSTATE.N on executing an exception return operation in IRQ mode. This field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to IRQ mode, and copied to PSTATE.Z on executing an exception return operation in IRQ mode. This field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to IRQ mode, and copied to PSTATE.C on executing an exception return operation in IRQ mode. This field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to IRQ mode, and copied to PSTATE.V on executing an exception return operation in IRQ mode. This field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to IRQ mode, and copied to PSTATE.Q on executing an exception return operation in IRQ mode. This field resets to an architecturally UNKNOWN value.
IT[1:0], bits [26:25]

If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to IRQ mode, and copied to
PSTATE.IT[1:0] on executing an exception return operation in IRQ mode.

On executing an exception return operation in IRQ mode SPSR_irq.IT must contain a value that is
valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state.
Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction
set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

When ARMv8.1-PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to IRQ mode, and
copied to PSTATE.PAN on executing an exception return operation in IRQ mode.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

DIT, bit [21]

When ARMv8.4-DIT is implemented:
Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to IRQ mode,
and copied to PSTATE.DIT on executing an exception return operation in IRQ mode.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to IRQ mode, and
copied to PSTATE.IL on executing an exception return operation in IRQ mode.

This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to IRQ mode,
and copied to PSTATE.GE on executing an exception return operation in IRQ mode.

This field resets to an architecturally UNKNOWN value.

IT[7:2], bits [15:10]

If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to IRQ mode, and copied to
PSTATE.IT[7:2] on executing an exception return operation in IRQ mode.

SPSR_irq.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to IRQ mode, and copied to
PSTATE.E on executing an exception return operation in IRQ mode.
If the implementation does not support big-endian operation, SPSR_irq.E is RES0. If the implementation does not support little-endian operation, SPSR_irq.E is RES1. On executing an exception return operation in IRQ mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_irq.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_irq.E is RES1.

This field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to IRQ mode, and copied to PSTATE.A on executing an exception return operation in IRQ mode.
This field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to IRQ mode, and copied to PSTATE.I on executing an exception return operation in IRQ mode.
This field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to IRQ mode, and copied to PSTATE.F on executing an exception return operation in IRQ mode.
This field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to IRQ mode, and copied to PSTATE.T on executing an exception return operation in IRQ mode.
This field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to IRQ mode, and copied to PSTATE.M[4:0] on executing an exception return operation in IRQ mode.
0b10000 User.
0b10001 FIQ.
0b10010 IRQ.
0b10011 Supervisor.
0b10111 Abort.
0b11011 Undefined.
0b11111 System.
Other values are reserved. If SPSR_irq.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in IRQ mode is an illegal return event, as described in Illegal return events from AArch32 state on page G1-5270.
This field resets to an architecturally UNKNOWN value.

Accessing the SPSR_irq

SPSR_irq is accessible in all modes other than User mode and IRQ mode. For more details, see MRS (Banked register) and MSR (Banked register) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:
\textbf{MRS}\{c\}\{q\} \ <Rd>, SPSR\_irq

\begin{center}
\begin{tabular}{c c c}
R & M & M1 \\
0b1 & 0b1 & 0b0000 \\
\end{tabular}
\end{center}

\textbf{MSR}\{c\}\{q\} SPSR\_irq, \ <Rn>

\begin{tabular}{c c c}
R & M & M1 \\
0b1 & 0b1 & 0b0000 \\
\end{tabular}
\end{center}
G8.2.127  SPSR_mon, Saved Program Status Register (Monitor mode)

The SPSR_mon characteristics are:

Purpose
Holds the saved process state when an exception is taken to Monitor mode.

Configurations
AArch32 System register SPSR_mon[31:0] can be mapped to AArch64 System register
SPSR_EL3[31:0], but this is not architecturally mandated.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes
SPSR_mon is a 32-bit register.

Field descriptions
The SPSR_mon bit assignments are:

| N, bit [31] | Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Monitor mode, and copied to PSTATE.N on executing an exception return operation in Monitor mode. This field resets to an architecturally UNKNOWN value. |
| Z, bit [30] | Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Monitor mode, and copied to PSTATE.Z on executing an exception return operation in Monitor mode. This field resets to an architecturally UNKNOWN value. |
| C, bit [29] | Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Monitor mode, and copied to PSTATE.C on executing an exception return operation in Monitor mode. This field resets to an architecturally UNKNOWN value. |
| V, bit [28] | Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Monitor mode, and copied to PSTATE.V on executing an exception return operation in Monitor mode. This field resets to an architecturally UNKNOWN value. |
| Q, bit [27] | Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Monitor mode, and copied to PSTATE.Q on executing an exception return operation in Monitor mode. This field resets to an architecturally UNKNOWN value. |
IT[1:0], bits [26:25]

If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to Monitor mode, and copied to PSTATE.IT[1:0] on executing an exception return operation in Monitor mode.

On executing an exception return operation in Monitor mode SPSR_mon.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

When ARMv8.1-PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Monitor mode, and copied to PSTATE.PAN on executing an exception return operation in Monitor mode.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When ARMv8.4-DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Monitor mode, and copied to PSTATE.DIT on executing an exception return operation in Monitor mode.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Monitor mode, and copied to PSTATE.IL on executing an exception return operation in Monitor mode.

This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Monitor mode, and copied to PSTATE.GE on executing an exception return operation in Monitor mode.

This field resets to an architecturally UNKNOWN value.

IT[7:2], bits [15:10]

If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to Monitor mode, and copied to PSTATE.IT[7:2] on executing an exception return operation in Monitor mode.

SPSR_mon.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to Monitor mode, and copied to PSTATE.E on executing an exception return operation in Monitor mode.
If the implementation does not support big-endian operation, SPSR_mon.E is RES0. If the implementation does not support little-endian operation, SPSR_mon.E is RES1. On executing an exception return operation in Monitor mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_mon.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_mon.E is RES1.

This field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Monitor mode, and copied to PSTATE.A on executing an exception return operation in Monitor mode.

This field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Monitor mode, and copied to PSTATE.I on executing an exception return operation in Monitor mode.

This field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Monitor mode, and copied to PSTATE.F on executing an exception return operation in Monitor mode.

This field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Monitor mode, and copied to PSTATE.T on executing an exception return operation in Monitor mode.

This field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Monitor mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Monitor mode.

- 0b10000: User.
- 0b10001: FIQ.
- 0b10010: IRQ.
- 0b10011: Supervisor.
- 0b10100: Monitor.
- 0b10101: Abort.
- 0b10110: Hyp.
- 0b10111: Undefined.
- 0b11111: System.

Other values are reserved. If SPSR_mon.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Monitor mode is an illegal return event, as described in *Illegal return events from AArch32 state* on page G1-5270.

This field resets to an architecturally UNKNOWN value.

Accessing the SPSR_mon

SPSR_mon is only accessible in EL3 modes other than Monitor mode. For more details, see MRS (Banked register) and MSR (Banked register) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:
MRS\{c\}\{q\} \ R_{d}, \ SPSR_{mon}  \\

<table>
<thead>
<tr>
<th>R</th>
<th>M</th>
<th>M1</th>
</tr>
</thead>
<tbody>
<tr>

### G8.2.128  SPSR_svc, Saved Program Status Register (Supervisor mode)

The SPSR_svc characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Supervisor mode.

**Configurations**

AArch32 System register SPSR_svc[31:0] is architecturally mapped to AArch64 System register SPSR_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SPSR_svc is a 32-bit register.

**Field descriptions**

The SPSR_svc bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 0 |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| N   | Z  | C  | V  | Q  | J  | IL | GE | IT[7:2] | E | A | F | T | M[4:0] |

#### N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Supervisor mode, and copied to PSTATE.N on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.

#### Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Supervisor mode, and copied to PSTATE.Z on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.

#### C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Supervisor mode, and copied to PSTATE.C on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.

#### V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Supervisor mode, and copied to PSTATE.V on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.

#### Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Supervisor mode, and copied to PSTATE.Q on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.
IT[1:0], bits [26:25]

If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to Supervisor mode, and copied to PSTATE.IT[1:0] on executing an exception return operation in Supervisor mode.

On executing an exception return operation in Supervisor mode SPSR_svc.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

When ARMv8.1-PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Supervisor mode, and copied to PSTATE.PAN on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When ARMv8.4-DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Supervisor mode, and copied to PSTATE.DIT on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Supervisor mode, and copied to PSTATE.IL on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Supervisor mode, and copied to PSTATE.GE on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.

IT[7:2], bits [15:10]

If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to Supervisor mode, and copied to PSTATE.IT[7:2] on executing an exception return operation in Supervisor mode.

SPSR_svc.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to Supervisor mode, and copied to PSTATE.E on executing an exception return operation in Supervisor mode.
If the implementation does not support big-endian operation, SPSR_svc.E is RES0. If the implementation does not support little-endian operation, SPSR_svc.E is RES1. On executing an exception return operation in Supervisor mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_svc.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_svc.E is RES1.

This field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Supervisor mode, and copied to PSTATE.A on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Supervisor mode, and copied to PSTATE.I on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Supervisor mode, and copied to PSTATE.F on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Supervisor mode, and copied to PSTATE.T on executing an exception return operation in Supervisor mode.

This field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Supervisor mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Supervisor mode.

0b10000 User.
0b10001 FIQ.
0b10010 IRQ.
0b10011 Supervisor.
0b10111 Abort.
0b11011 Undefined.
0b11111 System.

Other values are reserved. If SPSR_svc.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Supervisor mode is an illegal return event, as described in Illegal return events from AArch32 state on page G1-5270.

This field resets to an architecturally UNKNOWN value.

**Accessing the SPSR_svc**

SPSR_svc is accessible in all modes other than User mode and Supervisor mode. For more details, see MRS (Banked register) and MSR (Banked register) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:
### G8.2 General system control registers

G8.2.129  SPSR_und, Saved Program Status Register (Undefined mode)

The SPSR_und characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Undefined mode.

**Configurations**

AArch32 System register SPSR_und[31:0] is architecturally mapped to AArch64 System register SPSR_und[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SPSR_und is a 32-bit register.

**Field descriptions**

The SPSR_und bit assignments are:

|   |   |   |   |   |   |   |   |   |   |   |   |   | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| N | Z | C | V | Q | J | IL | GE | IT[7:2] | E | A | I | F | T | M[4:0] |

**N, bit [31]**

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Undefined mode, and copied to PSTATE.N on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

**Z, bit [30]**

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Undefined mode, and copied to PSTATE.Z on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

**C, bit [29]**

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Undefined mode, and copied to PSTATE.C on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

**V, bit [28]**

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Undefined mode, and copied to PSTATE.V on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

**Q, bit [27]**

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Undefined mode, and copied to PSTATE.Q on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.
IT[1:0], bits [26:25]

If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to Undefined mode, and copied to PSTATE.IT[1:0] on executing an exception return operation in Undefined mode.

On executing an exception return operation in Undefined mode SPSR_und.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

When ARMv8.1-PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Undefined mode, and copied to PSTATE.PAN on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [21]

When ARMv8.4-DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Undefined mode, and copied to PSTATE.DIT on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Undefined mode, and copied to PSTATE.IL on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Undefined mode, and copied to PSTATE.GE on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

IT[7:2], bits [15:10]

If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to Undefined mode, and copied to PSTATE.IT[7:2] on executing an exception return operation in Undefined mode.

SPSR_und.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to Undefined mode, and copied to PSTATE.E on executing an exception return operation in Undefined mode.
If the implementation does not support big-endian operation, SPSR_und.E is RES0. If the implementation does not support little-endian operation, SPSR_und.E is RES1. On executing an exception return operation in Undefined mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_und.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_und.E is RES1.

This field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Undefined mode, and copied to PSTATE.A on executing an exception return operation in Undefined mode.
This field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Undefined mode, and copied to PSTATE.I on executing an exception return operation in Undefined mode.
This field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Undefined mode, and copied to PSTATE.F on executing an exception return operation in Undefined mode.
This field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Undefined mode, and copied to PSTATE.T on executing an exception return operation in Undefined mode.
This field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]
Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Undefined mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Undefined mode.

0b10000 User.
0b10001 FIQ.
0b10010 IRQ.
0b10011 Supervisor.
0b10111 Abort.
0b11011 Undefined.
0b11111 System.

Other values are reserved. If SPSR_und.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Undefined mode is an illegal return event, as described in Illegal return events from AArch32 state on page G1-5270.
This field resets to an architecturally UNKNOWN value.

**Accessing the SPSR_und**

SPSR_und is accessible in all modes other than User mode and Undefined mode. For more details, see MRS (Banked register) and MSR (Banked register) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:

G8.2.130 TCMTR, TCM Type Register

The TCMTR characteristics are:

**Purpose**

Provides information about the implementation of the TCM.

**Configurations**

If EL1 or above can use AArch32 then this register must be implemented.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TCMTR is a 32-bit register.

**Field descriptions**

The TCMTR bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td>bits [31:0]</td>
</tr>
</tbody>
</table>

**Accessing the TCMTR**

Accesses to this register use the following encodings in the System instruction encoding space:

```
MRC{<c>}{<q>}, <coproc>, (#)<opc1>, <Rt>, <CRn>, <CRm>{, (#)<opc2>}
```

```
coproc  opc1  CRn  CRm  opc2
 0b1111  0b000  0b0000  0b0000  0b010
```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() & ELusingAArch32(EL2) & HSTR_EL2.T0 == '1' then
        AArch64.AArch32SystemAccessTrap(EL2, 0x03);
    elsif EL2Enabled() & ELUsingAArch32(EL2) & HSTR.T0 == '1' then
        AArch32.TakeHypTrapException(0x03);
    elsif EL2Enabled() & ELUsingAArch32(EL2) & HCR_EL2.TID1 == '1' then
        AArch64.AArch32SystemAccessTrap(EL2, 0x03);
    elsif EL2Enabled() & ELUsingAArch32(EL2) & HCR.TID1 == '1' then
        AArch32.TakeHypTrapException(0x03);

    elsif PSTATE.EL == EL3 then
        return TCMTR;
```
G8.2.131 TLBIALL, TLB Invalidate All

The TLBIALL characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at Secure EL1 when EL3 is using AArch64, all entries that would be required for the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at Non-secure EL1, all stage 1 translation table entries that would be required for the Non-secure PL1&0 translation regime and, if EL2 is implemented, they must match the current VMID.
- If executed at EL2, and if EL2 is enabled in the current Security state, the stage 1 or stage 2 translation table entries that would be required for the PL1&0 translation regime and matches the current VMID.

The invalidation only applies to the PE that executes this System instruction.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBIALL is a 32-bit System instruction.

**Field descriptions**

TLBIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBIALL instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

$\text{MCR}\{<c>\}{<q>}<\text{coproc}>,\{#\}<\text{opc1}>,<\text{Rt}>,<\text{CRn}>,<\text{CRm}>,\{#\}<\text{opc2}>$

```

G8.2.133 TLBIALLHIS, TLB Invalidate All, Hyp mode, Inner Shareable

The TLBIALLHIS characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for the Non-secure EL2 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBIALLHIS is a 32-bit System instruction.

**Field descriptions**

TLBIALLHIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBIALLHIS instruction**

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MCR\langle c\rangle\langle q\rangle \langle coproc\rangle, \langle \#\rangle\langle opc1\rangle, \langle Rt\rangle, \langle CRn\rangle, \langle CRm\rangle, \langle \#\rangle\langle opc2\rangle \]

G8.2.137 TLBIASID, TLB Invalidate by ASID match

The TLBIASID characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- If EL2 is implemented and enabled in the current Security state, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

Configurations

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBIASID is a 32-bit System instruction.

Field descriptions

The TLBIASID input value bit assignments are:

| Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9  | Bit 8  |

G8.2.139   TLBIIPAS2, TLB Invalidate by Intermediate Physical Address, Stage 2

The TLBIIPAS2 characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- SCR.NS is 1.
- The entry would be used for the specified IPA.
- The entry would be used with the current VMID.
- The entry would be required for the PL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation only applies to the PE that executes this System instruction.

**Configurations**

--- Note ---

This System instruction is not implemented in architecture versions before Armv8.

---

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

TLBIIPAS2 is a 32-bit System instruction.

**Field descriptions**

The TLBIIPAS2 input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>Bit 28</th>
<th>Bit 27</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>IPA[39:12]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**IPA[39:12], bits [27:0]**

Bits[39:12] of the intermediate physical address to match.

**Executing the TLBIIPAS2 instruction**

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is **CONSTRAINED UNPREDICTABLE**, and one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction is treated as a **NOP**.
- The instruction executes as if it had been executed in Monitor mode.

Accesses to this register use the following encodings in the System instruction encoding space:
MCR<coproc>, <Rt>, <CRn>, <CRm>{, <opc2>}

G8.2.140 TLBIIPAS2IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Inner Shareable

The TLBIIPAS2IS characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- SCR.NS is 1.
- The entry would be used for the specified IPA.
- The entry would be used with the current VMID.
- The entry would be required for the PL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Configurations**

--- **Note** ---

This System instruction is not implemented in architecture versions before Armv8.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBIIPAS2IS is a 32-bit System instruction.

**Field descriptions**

The TLBIIPAS2IS input value bit assignments are:

<table>
<thead>
<tr>
<th>31 28 27</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>IPA[39:12]</td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**IPA[39:12], bits [27:0]**

Bits[39:12] of the intermediate physical address to match.

**Executing the TLBIIPAS2IS instruction**

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Accesses to this register use the following encodings in the System instruction encoding space:
MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

<table>

G8.2.143 TLBIMVA, TLB Invalidate by VA

The TLBIMVA characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented and enabled in the current Security state, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBIMVA is a 32-bit System instruction.

**Field descriptions**

The TLBIMVA input value bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA</td>
<td>RES0</td>
<td>ASID</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**VA, bits [31:12]**

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

**Bits [11:8]**

Reserved, RES0.

**ASID, bits [7:0]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.
Executing the TLBIMVA instruction

Accesses to this register use the following encodings in the System instruction encoding space:

```
MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

<table>

G8.2.148   TLBIMVAH, TLB Invalidate by VA, Hyp mode

The TLBIMVAH characteristics are:

**Purpose**

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for the Non-secure EL2 translation regime and used to translate the specified address.

The invalidation only applies to the PE that executes this System instruction.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBIMVAH is a 32-bit System instruction.

**Field descriptions**

The TLBIMVAH input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:12</td>
<td>VA</td>

G8.2.150 TLBIMVAIS, TLB Invalidate by VA, Inner Shareable

The TLBIMVAIS characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented and enabled in the current Security state, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBIMVAIS is a 32-bit System instruction.

**Field descriptions**

The TLBIMVAIS input value bit assignments are:

G8.2.151 TLBIMVAL, TLB Invalidate by VA, Last level

The TLBIMVAL characteristics are:

**Purpose**

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented and enabled in the current Security state, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

**Configurations**

This System instruction is not implemented in architecture versions before Armv8.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBIMVAL is a 32-bit System instruction.

**Field descriptions**

The TLBIMVAL input value bit assignments are:

G8.2.155 TLBTR, TLB Type Register

The TLBTR characteristics are:

**Purpose**

Provides information about the TLB implementation. The register must define whether the implementation provides separate instruction and data TLBs, or a unified TLB. Normally, the IMPLEMENTATION DEFINED information in this register includes the number of lockable entries in the TLB.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBTR is a 32-bit register.

**Field descriptions**

The TLBTR bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMPLEMENTATION DEFINED</td>
<td></td>
<td>nU</td>
</tr>
</tbody>
</table>

IMPLEMENTATION DEFINED, bits [31:1]

IMPLEMENTATION DEFINED.

nU, bit [0]

Not Unified TLB. Indicates whether the implementation has a unified TLB:

0b0  Unified TLB.
0b1  Separate Instruction and Data TLBs.

**Accessing the TLBTR**

Accesses to this register use the following encodings in the System instruction encoding space:

```

G8.2.156   TPIDRPRW, PL1 Software Thread ID Register

The TPIDRPRW characteristics are:

**Purpose**

Provides a location where software executing at EL1 or higher can store thread identifying information that is not visible to software executing at EL0, for OS management purposes.

The PE makes no use of this register.

**Configurations**

AArch32 System register TPIDRPRW[31:0] is architecturally mapped to AArch64 System register TPIDR_EL1[31:0].

--- Note ---

The PE never updates this register.

---

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TPIDRPRW is a 32-bit register.

**Field descriptions**

The TPIDRPRW bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Thread ID. Thread identifying information stored by software running at this Exception level. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the TPIDRPRW**

Accesses to this register use the following encodings in the System instruction encoding space:

```
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

<table>

G8.2.157  TPIDRURO, PL0 Read-Only Software Thread ID Register

The TPIDRURO characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

The PE makes no use of this register.

Configurations

AArch32 System register TPIDRURO[31:0] is architecturally mapped to AArch64 System register TPIDRRO_EL0[31:0].

— Note —

The PE never updates this register.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TPIDRURO is a 32-bit register.

Field descriptions

The TPIDRURO bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Thread ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 0</td>
<td></td>
</tr>
</tbody>
</table>

Thread ID. Thread identifying information stored by software running at this Exception level.

This field resets to an architecturally UNKNOWN value.

Accessing the TPIDRURO

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MRC\{<c>\}{<q>} \{#<opc1>, \<Rt>, <CRn>, <CRm>, \(\#<opc2>\)}
\]

end
G8.2.159 TTBCR, Translation Table Base Control Register

The TTBCR characteristics are:

**Purpose**

The control register for stage 1 of the PL1&0 translation regime. Its controls include:

- Where the VA range is split between addresses translated using TTBR0 and addresses translated using TTBR1.
- The translation table format used by this stage of translation.

In Armv8.2, when the value of TTBCR.{EAE, T2E} is {1, 1}, TTBCR is used with TTBCR2.

**Configurations**

AArch32 System register TTBCR[31:0] is architecturally mapped to AArch64 System register TCR_EL1[31:0].

The current translation table format determines which format of the register is used.

Some RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 then:

- The EAE bit resets to 0 in both the Secure and the Non-secure instances of the register.
- Other reset values apply only to the Secure instance of the register.

**Attributes**

TTBCR is a 32-bit register.

**Field descriptions**

The TTBCR bit assignments are:

*When TTBCR.EAE == 0:*

| 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   |      |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

**EAE, bit [31]**

Extended Address Enable. The meanings of the possible values of this bit are:

0b0 Use the VMSAv8-32 translation system with the Short-descriptor translation table format.

This field resets to 0.

**Bits [30:6]**

Reserved, RES0.

**PD1, bit [5]**

Translation table walk disable for translations using TTBR1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1. The encoding of this bit is:

0b0 Perform translation table walks using TTBR1.
A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed.

This field resets to 0.

PD0, bit [4]
Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss for an address that is translated using TTBR0. The encoding of this bit is:

0b0 Perform translation table walks using TTBR0.
0b1 A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed.

This field resets to 0.

Bit [3]
Reserved, RES0.

N, bits [2:0]
Indicate the width of the base address held in TTBR0. In TTBR0, the base address field is bits[31:14-N]. The value of N also determines:

- Whether TTBR0 or TTBR1 is used as the base address for translation table walks.
- The size of the translation table pointed to by TTBR0.

N can take any value from 0 to 7, that is, from 0b000 to 0b111.

When N has its reset value of 0, the translation table base is compatible with Armv5 and Armv6. This field resets to 0.

When TTBCR.EAE == 1:

EAE, bit [31]
Extended Address Enable. The meanings of the possible values of this bit are:

0b1 Use the VMSAv8-32 translation system with the Long-descriptor translation table format.

This field resets to 0.

IMPLEMENTATION DEFINED, bit [30]
IMPLEMENTATION DEFINED.
This field resets to 0.
SH1, bits [29:28]
Shareability attribute for memory associated with translation table walks using TTBR1. Defined values are:
0b00 Non-shareable.
0b10 Outer Shareable.
0b11 Inner Shareable.
Other values are reserved. The effect of programming this field to a Reserved value is that behavior is constrained unpredictable, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7212.
This field resets to 0.

ORGN1, bits [27:26]
Outer cacheability attribute for memory associated with translation table walks using TTBR1.
0b00 Normal memory, Outer Non-cacheable.
0b01 Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
0b10 Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11 Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.
This field resets to 0.

IRGN1, bits [25:24]
Inner cacheability attribute for memory associated with translation table walks using TTBR1.
0b00 Normal memory, Inner Non-cacheable.
0b01 Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
0b10 Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11 Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.
This field resets to 0.

EPD1, bit [23]
Translation table walk disable for translations using TTBR1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1. The encoding of this bit is:
0b0 Perform translation table walks using TTBR1.
0b1 A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed.
This field resets to 0.

A1, bit [22]
Selects whether TTBR0 or TTBR1 defines the ASID. The encoding of this bit is:
0b0 TTBR0.ASID defines the ASID.
0b1 TTBR1.ASID defines the ASID.
This field resets to 0.

Bits [21:19]
Reserved, RES0.

T1SZ, bits [18:16]
See Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G5-5499 for how TTBCR.{T1SZ, T0SZ} determine the input address ranges and memory region sizes translated using TTBR0 and TTBR1.
This field resets to 0.
Bits [15:14]
Reserved, RES0.

SH0, bits [13:12]
Shareability attribute for memory associated with translation table walks using TTBR0.
- 0b00: Non-shareable
- 0b10: Outer Shareable
- 0b11: Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7212.

This field resets to 0.

ORGN0, bits [11:10]
Outer cacheability attribute for memory associated with translation table walks using TTBR0.
- 0b00: Normal memory, Outer Non-cacheable.
- 0b01: Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10: Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11: Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to 0.

IRGN0, bits [9:8]
Inner cacheability attribute for memory associated with translation table walks using TTBR0.
- 0b00: Normal memory, Inner Non-cacheable.
- 0b01: Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- 0b10: Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- 0b11: Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to 0.

EPD0, bit [7]
Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0. The encoding of this bit is:
- 0b0: Perform translation table walks using TTBR0.
- 0b1: A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed.

This field resets to 0.

T2E, bit [6]
When ARMv8.2-AA32HPD is implemented:
- TTBCR2 Enable.
- 0b0: TTBCR2 is disabled. The contents of TTBCR2 are treated as 0 for all purposes other than reading or writing the register.
- 0b1: TTBCR2 is enabled.

If TTBCR.EAE==0, then the behavior is as if the bit is 0.

Otherwise:
Reserved, RES0.

Bits [5:3]
Reserved, RES0.
T0SZ, bits [2:0]

See *Selecting between TTBR0 and TTBR1, VMA* for how TTBCR.\{T1SZ, T0SZ\} determine the input address ranges and memory region sizes translated using TTBR0 and TTBR1.

This field resets to 0.

**Accessing the TTBCR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[\text{MRC}\{<c>\}<q>\ <\text{coproc},\ (#<opc1>,\ <Rt>,\ <CRn>,\ <CRm>{,\ (#<opc2>)}\]

G8.2.160  TTBCR2, Translation Table Base Control Register 2

The TTBCR2 characteristics are:

**Purpose**

The second control register for stage 1 of the PL1&0 translation regime.

If ARMv8.2-AA32HPD is not implemented then this register is not implemented and its encoding is unallocated. Otherwise:

- When the value of TTBCR.{EAE, T2E} is not \{1, 1\} the contents of TTBCR2 are treated as zero for all purposes other than reading or writing the register.
- When the value of TTBCR.{EAE, T2E} is \{1, 1\} TTBCR2 is used with TTBCR.

**Configurations**

AArch32 System register TTBCR2[31:0] is architecturally mapped to AArch64 System register TCR_EL1[63:32].

This register is present only from ARMv8.2. Otherwise, direct accesses to TTBCR2 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.2.

**Attributes**

TTBCR2 is a 32-bit register.

**Field descriptions**

The TTBCR2 bit assignments are:

**Bits [31:19]**

Reserved, RES0.

**HWU162, bit [18]**

*When ARMv8.2-TTPBHA is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR1.

- **0b0** For translations using TTBR1, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1** For translations using TTBR1, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD1 is 1.

The *Effective value* of this field is 0 if the value of TTBCR2.HPD1 is 0 or the value of TTBCR.T2E is 0.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU161, bit [17]

When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR1.

0b0 For translations using TTBR1, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR1, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD1 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD1 is 0 or the value of TTBCR.T2E is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU160, bit [16]

When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR1.

0b0 For translations using TTBR1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD1 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD1 is 0 or the value of TTBCR.T2E is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU159, bit [15]

When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR1.

0b0 For translations using TTBR1, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR1, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD1 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD1 is 0 or the value of TTBCR.T2E is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.
HWU062, bit [14]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR0.

- **0b0**: For translations using TTBR0, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1**: For translations using TTBR0, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD0 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD0 is 0 or the value of TTBCR.T2E is 0.

Otherwise:

Reserved, RES0.

HWU061, bit [13]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR0.

- **0b0**: For translations using TTBR0, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1**: For translations using TTBR0, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD0 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD0 is 0 or the value of TTBCR.T2E is 0.

Otherwise:

Reserved, RES0.

HWU060, bit [12]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR0.

- **0b0**: For translations using TTBR0, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1**: For translations using TTBR0, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD0 is 1.

The Effective value of this field is 0 if the value of TTBCR2.HPD0 is 0 or the value of TTBCR.T2E is 0.

Otherwise:

Reserved, RES0.
HWU059, bit [11]

**When ARMv8.2-TTPBHA is implemented:**

- **Hardware Use.** Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR0.
  - 0:0 For translations using TTBR0, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
  - 0:1 For translations using TTBR0, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TTBCR2.HPD0 is 1.

  The *Effective value* of this field is 0 if the value of TTBCR2.HPD0 is 0 or the value of TTBCR.T2E is 0.

  This field resets to an architecturally UNKNOWN value.

- **Otherwise:**
  - Reserved, RES0.

HPD1, bit [10]

**When ARMv8.2-AA32HPD is implemented:**

- **Hierarchical Permission Disables.** This affects the hierarchical control bits, APTable, XNTable, and PXNTable, in the translation tables pointed to by TTBR1.
  - 0:0 Hierarchical permissions are enabled.
  - 0:1 Hierarchical permissions are disabled if TTBCR.T2E == 1.

  When disabled, the permissions are treated as if the bits are 0.

  The *Effective value* of this field is 0 if the value of TTBCR.T2E is 0.

  This field resets to an architecturally UNKNOWN value.

- **Otherwise:**
  - Reserved, RES0.

HPD0, bit [9]

**When ARMv8.2-AA32HPD is implemented:**

- **Hierarchical Permission Disables.** This affects the hierarchical control bits, APTable, XNTable, and PXNTable, in the translation tables pointed to by TTBR0.
  - 0:0 Hierarchical permissions are enabled.
  - 0:1 Hierarchical permissions are disabled if TTBCR.T2E == 1.

  When disabled, the permissions are treated as if the bits are 0.

  The *Effective value* of this field is 0 if the value of TTBCR.T2E is 0.

  This field resets to an architecturally UNKNOWN value.

- **Otherwise:**
  - Reserved, RES0.

Bits [8:0]

- Reserved, RES0.

G8.2.161 TTBR0, Translation Table Base Register 0

The TTBR0 characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the lower VA range in the PL1&0 translation regime, and other information for this translation regime.

**Configurations**

AArch32 System register TTBR0[63:0] is architecturally mapped to AArch64 System register TTBR0_EL1[63:0].

TTBCR.EAE determines which TTBR0 format is used:

- TTBCR.EAE == 0b0: 32-bit format is used. TTBR0[63:32] are ignored.
- TTBCR.EAE == 0b1: 64-bit format is used.

When EL3 is using AArch32, write access to TTBR0(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

Used in conjunction with the TTBCR. When the 64-bit TTBR0 format is used, cacheability and shareability information is held in the TTBCR, not in TTBR0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TTBR0 is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

**Field descriptions**

The TTBR0 bit assignments are:

**When TTBCR.EAE == 0:**

<table>
<thead>
<tr>
<th>63</th>
<th>32 31</th>
<th>7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>TTB0</td>
<td>RGN</td>
</tr>
</tbody>
</table>

**Bits [63:32]**

Reserved, RES0.

**TTB0, bits [31:7]**

Translation table base address, bits[31:x], where x is 14-(TTBCR.N). Register bits [x-1:7] are RES0, with the additional requirement that if these bits are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:7] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

This field resets to an architecturally UNKNOWN value.
IRGN[0], bit [6]

This field is bit[0] of IRGN[1:0].

Inner region bits. Bits [0,6] of this register together indicate the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

- **0b00**: Normal memory, Inner Non-cacheable.
- **0b01**: Normal memory, Inner Write-Back Write-Allocate Cacheable.
- **0b10**: Normal memory, Inner Write-Through Cacheable.
- **0b11**: Normal memory, Inner Write-Back no Write-Allocate Cacheable.

**Note**

The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 without the Multiprocessing Extensions can run unmodified on an implementation that includes the functionality introduced by the ARMv7 Multiprocessing Extensions.

The IRGN field is split as follows:

- IRGN[0] is TTBR0[6].
- IRGN[1] is TTBR0[0].

This field resets to an architecturally UNKNOWN value.

NOS, bit [5]

Not Outer Shareable. When the value of TTBR0.S is 1, indicates whether the memory associated with a translation table walk is Inner Shareable or Outer Shareable:

- **0b0**: Memory is Outer Shareable.
- **0b1**: Memory is Inner Shareable.

This bit is ignored when the value of TTBR0.S is 0.

This field resets to an architecturally UNKNOWN value.

RGN, bits [4:3]

Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:

- **0b00**: Normal memory, Outer Non-cacheable.
- **0b01**: Normal memory, Outer Write-Back Write-Allocate Cacheable.
- **0b10**: Normal memory, Outer Write-Through Cacheable.
- **0b11**: Normal memory, Outer Write-Back no Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IMP, bit [2]

The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is RES0.

This field resets to an architecturally UNKNOWN value.

S, bit [1]

Shareable. Indicates whether the memory associated with the translation table walks is Non-shareable:

- **0b0**: Memory is Non-shareable.
- **0b1**: Memory is shareable. The TTBR0.NOS field indicates whether the memory is Inner Shareable or Outer Shareable.

This field resets to an architecturally UNKNOWN value.
IRGN[1], bit [0]

This field is bit[1] of IRGN[1:0].
See IRGN[0] for the field description.

When TTBCR.EAE == 1:

\[
\begin{array}{|c|c|c|c|c|}
\hline
63 & 56 & 55 & 48 & 47 \\
\hline
\text{RES0} & \text{ASID} & \text{BADDR} & \text{CnP} \\
\hline
\end{array}
\]

Bits [63:56]
Reserved, RES0.

ASID, bits [55:48]

An ASID for the translation table base address. The TTBCR.A1 field selects either TTBR0.ASID or TTBR1.ASID.
This field resets to an architecturally UNKNOWN value.

BADDR, bits [47:1]
Translation table base address, bits[47:x], Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of TTBCR.T0SZ as follows:

- If TTBCR.T0SZ is 0 or 1, \( x = 5 - \text{TTBCR}.T0SZ \).
- If TTBCR.T0SZ is greater than 1, \( x = 14 - \text{TTBCR}.T0SZ \).

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.
This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

When ARMv8.2-TTCNP is implemented:
Common not Private. When TTBCR.EAE == 1, this bit indicates whether each entry that is pointed to by TTBR0 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0.CnP is 1.

0b0 The translation table entries pointed to by this instance of TTBR0, for the current ASID, are permitted to differ from corresponding entries for this instance of TTBR0 for other PEs in the Inner Shareable domain. This is not affected by:

- The value of TTBR0.CnP on those other PEs.
- The value of TTBCR.EAE on those other PEs.
- The value of the current ASID or, for the Non-secure instance of TTBR0, the value of the current VMID.

0b1 The translation table entries pointed to by this instance of TTBR0 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0.CnP is 1 for this instance of TTBR0 and all of the following apply:

- The translation table entries are pointed to by this instance of TTBR0.
• The value of the applicable TTBCR.EAE field is 1.
• The ASID is the same as the current ASID.
• For the Non-secure instance of TTBR0, the VMID is the same as the current VMID.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

--- Note ---

If the value of the TTBR0.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see CONSTRANGED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7195.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the TTBR0

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\langle c\rangle\langle q\rangle, \langle coproc\rangle, \langle\#\rangle\langle opc1\rangle, \langle Rt\rangle, \langle CRn\rangle, \langle CRm\rangle, \langle\#\rangle\langle opc2\rangle
\]

### G8.2.162 TTBR1, Translation Table Base Register 1

The TTBR1 characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the higher VA range in the PL1&0 translation regime, and other information for this translation regime.

**Configurations**

AArch32 System register TTBR1[63:0] is architecturally mapped to AArch64 System register TTBR1_EL1[63:0].

TTBCR.EAE determines which TTBR1 format is used:

- TTBCR.EAE == 0b0: 32-bit format is used. TTBR1[63:32] are ignored.
- TTBCR.EAE == 0b1: 64-bit format is used.

Used in conjunction with the TTBCR. When the 64-bit TTBR1 format is used, cacheability and shareability information is held in the TTBCR, not in TTBR1.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TTBR1 is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

**Field descriptions**

The TTBR1 bit assignments are:

**When TTBCR.EAE == 0:**

![TTBR1 Bit Assignment Diagram]

- **Bits [63:32]**
  
  Reserved, RES0.

- **TTB1, bits [31:7]**
  
  Translation table base address, bits[31:14]. Register bits [13:7] are RES0, with the additional requirement that if these bits are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:
  
  - Register bits [13:7] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
  
  - The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

  This field resets to an architecturally UNKNOWN value.

- **IRGN[1], bit [6]**
  
  This field is bit[1] of IRGN[1:0].
Inner region bits. IRGN[1:0] indicate the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

0b00 Normal memory, Inner Non-cacheable.
0b01 Normal memory, Inner Write-Back Write-Allocate Cacheable.
0b10 Normal memory, Inner Write-Through Cacheable.
0b11 Normal memory, Inner Write-Back no Write-Allocate Cacheable.

--- Note ---
The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for Armv7 without the Multiprocessing Extensions can run unmodified on an implementation that includes the functionality introduced by the ARMv7 Multiprocessing Extensions.

The IRGN field is split as follows:
- IRGN[1] is TTBR1[6].
- IRGN[0] is TTBR1[0].

This field resets to an architecturally UNKNOWN value.

NOS, bit [5]
Not Outer Shareable. When the value of TTBR1.S is 1, indicates whether the memory associated with a translation table walk is Inner Shareable or Outer Shareable:

0b0 Memory is Outer Shareable.
0b1 Memory is Inner Shareable.

This bit is ignored when the value of TTBR1.S is 0.
This field resets to an architecturally UNKNOWN value.

RGN, bits [4:3]
Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:

0b00 Normal memory, Outer Non-cacheable.
0b01 Normal memory, Outer Write-Back Write-Allocate Cacheable.
0b10 Normal memory, Outer Write-Through Cacheable.
0b11 Normal memory, Outer Write-Back no Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IMP, bit [2]
The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is RES0.
This field resets to an architecturally UNKNOWN value.

S, bit [1]
Shareable. Indicates whether the memory associated with the translation table walks is Non-shareable:

0b0 Memory is Non-shareable.
0b1 Memory is shareable. The TTBR1.NOS field indicates whether the memory is Inner Shareable or Outer Shareable.

This field resets to an architecturally UNKNOWN value.

IRGN[0], bit [0]
This field is bit[0] of IRGN[1:0].
See IRGN[1] for the field description.

**When TTBCR.EAE == 1:**

<table>
<thead>
<tr>
<th>63</th>
<th>56</th>
<th>48</th>
<th>47</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>ASID</td>
<td>BADDR</td>
<td></td>
<td></td>
<td>CnP</td>
</tr>
</tbody>
</table>

**Bits [63:56]**

Reserved, RES0.

**ASID, bits [55:48]**

An ASID for the translation table base address. The TTBCR.A1 field selects either TTBR0.ASID or TTBR1.ASID.

This field resets to an architecturally UNKNOWN value.

**BADDR, bits [47:1]**

Translation table base address, bits[47:x], Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of TTBCR.T1SZ as follows:

- If TTBCR.T1SZ is 0 or 1, x = 5 - TTBCR.T1SZ.
- If TTBCR.T1SZ is greater than 1, x = 14 - TTBCR.T1SZ.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated. This field resets to an architecturally UNKNOWN value.

**CnP, bit [0]**

*When ARMv8.2-TTCNP is implemented:*

Common not Private. When TTBCR.EAE == 1, this bit indicates whether each entry that is pointed to by TTBR1 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR1.CnP is 1.

- **0b0** The translation table entries pointed to by this instance of TTBR1, for the current ASID, are permitted to differ from corresponding entries for this instance of TTBR1 for other PEs in the Inner Shareable domain. This is not affected by:
  - The value of TTBR1.CnP on those other PEs.
  - The value of TTBCR.EAE on those other PEs.
  - The value of the current ASID or, for the Non-secure instance of TTBR1, the value of the current VMID.

- **0b1** The translation table entries pointed to by this instance of TTBR1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR1.CnP is 1 for this instance of TTBR1 and all of the following apply:
  - The translation table entries are pointed to by this instance of TTBR1.
  - The value of the applicable TTBCR.EAE field is 1.
  - The ASID is the same as the current ASID.
• For the Non-secure instance of TTBR1, the VMID is the same as the current VMID.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

___ Note ___

If the value of the TTBR1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7195.

This field resets to an architecturally UNKNOWN value.

**Otherwise:**

Reserved, RES0.

### Accessing the TTBR1

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MRC\{c\}\{q\} <coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm>, \{#<opc2>\}
\]

G8.2.163 VBAR, Vector Base Address Register

The VBAR characteristics are:

**Purpose**

When high exception vectors are not selected, holds the vector base address for exceptions that are not taken to Monitor mode or to Hyp mode.

Software must program VBAR(NS) with the required initial value as part of the PE boot sequence.

**Configurations**

AArch32 System register VBAR[31:0] is architecturally mapped to AArch64 System register VBAR_EL1[31:0].

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply only to the Secure instance of the register. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VBAR is a 32-bit register.

**Field descriptions**

The VBAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:5]</td>
<td>Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to this Exception level. Bits[4:0] of an exception vector are the exception offset. This field resets to an IMPLEMENTATION DEFINED value.</td>
</tr>
<tr>
<td>[4:0]</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**Accessing the VBAR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}{<q>} \ <\text{coproc}>\, \{\#<opc1>\}, \ <\text{Rt}>, \ <\text{CRn}>, \ <\text{CRm}>\{, \{\#<opc2>\}\}
\]

G8.2.164 VMPIDR, Virtualization Multiprocessor ID Register

The VMPIDR characteristics are:

**Purpose**

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by Non-secure EL1 reads of MPIDR.

**Configurations**

AArch32 System register VMPIDR[31:0] is architecturally mapped to AArch64 System register VMPIDR_EL2[31:0].

If EL2 is not implemented but EL3 is implemented, this register takes the value of the MPIDR.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VMPIDR is a 32-bit register.

**Field descriptions**

The VMPIDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>U</td>
<td>RES0</td>
<td>Aff2</td>
<td>Aff1</td>
<td>Aff0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**M, bit [31]**

Indicates whether this implementation includes the functionality introduced by the ARMv7 Multiprocessing Extensions. The possible values of this bit are:

0b0  This implementation does not include the ARMv7 Multiprocessing Extensions functionality.

0b1  This implementation includes the ARMv7 Multiprocessing Extensions functionality.

In Armv8 this bit is RES1.

**U, bit [30]**

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

0b0  Processor is part of a multiprocessor system.

0b1  Processor is part of a uniprocessor system.

In a system where the PE resets into EL2 or EL3, this field resets to the value in MPIDR.U.

**Bits [29:25]**

Reserved, RES0.

**MT, bit [24]**

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. See the description of Aff0 for more information about affinity levels. The possible values of this bit are:

0b0  Performance of PEs at the lowest affinity level is largely independent.

0b1  Performance of PEs at the lowest affinity level is very interdependent.
In a system where the PE resets into EL2 or EL3, this field resets to the value in MPIDR.MT.

**Aff2, bits [23:16]**

Affinity level 2. See the description of Aff0 for more information.

In a system where the PE resets into EL2 or EL3, this field resets to the value in MPIDR.Aff2.

**Aff1, bits [15:8]**

Affinity level 1. See the description of Aff0 for more information.

In a system where the PE resets into EL2 or EL3, this field resets to the value in MPIDR.Aff1.

**Aff0, bits [7:0]**

Affinity level 0. This is the affinity level that is most significant for determining PE behavior. Higher affinity levels are increasingly less significant in determining PE behavior. The assigned value of the MPIDR.\{Aff2, Aff1, Aff0\} or MPIDR.EL1.\{Aff3, Aff2, Aff1, Aff0\} set of fields of each PE must be unique within the system as a whole.

In a system where the PE resets into EL2 or EL3, this field resets to the value in MPIDR.Aff0.

### Accessing the VMPIDR

Accesses to this register use the following encodings in the System instruction encoding space:

**MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}**

G8.2.165   VPIDR, Virtualization Processor ID Register

The VPIDR characteristics are:

Purpose

Holds the value of the Virtualization Processor ID. This is the value returned by Non-secure EL1 reads of MIDR.

Configurations

AArch32 System register VPIDR[31:0] is architecturally mapped to AArch64 System register VPIDR_EL2[31:0].

If EL2 is not implemented but EL3 is implemented, this register takes the value of the MIDR.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VPIDR is a 32-bit register.

Field descriptions

The VPIDR bit assignments are:

```
  31  24  23  20  19  16  15  4  3  0
  |   |   |   |   |   |   |   |   |
  | Implementer | Variant | PartNum | Revision |

Architecture
```

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by Arm. Assigned codes include the following:

<table>
<thead>
<tr>
<th>Hex representation</th>
<th>ASCII representation</th>
<th>Implementer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x41</td>
<td>A</td>
<td>Arm Limited</td>
</tr>
<tr>
<td>0x42</td>
<td>B</td>
<td>Broadcom Corporation</td>
</tr>
<tr>
<td>0x43</td>
<td>C</td>
<td>Cavium Inc.</td>
</tr>
<tr>
<td>0x44</td>
<td>D</td>
<td>Digital Equipment Corporation</td>
</tr>
<tr>
<td>0x49</td>
<td>I</td>
<td>Infineon Technologies AG</td>
</tr>
<tr>
<td>0x4D</td>
<td>M</td>
<td>Motorola or Freescale Semiconductor Inc.</td>
</tr>
<tr>
<td>0x4E</td>
<td>N</td>
<td>NVIDIA Corporation</td>
</tr>
<tr>
<td>0x50</td>
<td>P</td>
<td>Applied Micro Circuits Corporation</td>
</tr>
<tr>
<td>0x51</td>
<td>Q</td>
<td>Qualcomm Inc.</td>
</tr>
<tr>
<td>0x56</td>
<td>V</td>
<td>Marvell International Ltd.</td>
</tr>
<tr>
<td>0x69</td>
<td>i</td>
<td>Intel Corporation</td>
</tr>
</tbody>
</table>
Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

In a system where the PE resets into EL2 or EL3, this field resets to the value in MIDR.Implementer.

**Variant, bits [23:20]**

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

In a system where the PE resets into EL2 or EL3, this field resets to the value in MIDR.Variant.

**Architecture, bits [19:16]**

The permitted values of this field are:

- 0b0001  Armv4.
- 0b0010  Armv4T.
- 0b0011  Armv5 (obsolete).
- 0b0100  Armv5T.
- 0b0101  Armv5TE.
- 0b0110  Armv5TEJ.
- 0b0111  Armv6.
- 0b1111  Architectural features are individually identified in the ID_* registers, see ID registers on page K13-7433.

All other values are reserved.

In a system where the PE resets into EL2 or EL3, this field resets to the value in MIDR.Architecture.

**PartNum, bits [15:4]**

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

In a system where the PE resets into EL2 or EL3, this field resets to the value in MIDR.PartNum.

**Revision, bits [3:0]**

An IMPLEMENTATION DEFINED revision number for the device.

In a system where the PE resets into EL2 or EL3, this field resets to the value in MIDR.Revision.

### Accessing the VPIDR

Accesses to this register use the following encodings in the System instruction encoding space:

```
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

<table>

VTCR, Virtualization Translation Control Register

The VTCR characteristics are:

**Purpose**

The control register for stage 2 of the Non-secure PL1&0 translation regime.

---

**Note**

This stage of translation always uses the Long-descriptor translation table format.

---

**Configurations**

AArch32 System register VTCR[31:0] is architecturally mapped to AArch64 System register VTCR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VTCR is a 32-bit register.

**Field descriptions**

The VTCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit [31]</th>
<th>31 30 29 28 27 26 25 24</th>
<th>14 13 12 11 10 9 8 7 6 5 4 3 0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RES0</td>
<td>SH0</td>

<tr>
<td></td>
<td>RES0</td>
<td>SL0</td>
</tr>
<tr>
<td></td>
<td>S</td>
<td>T0SZ</td>
</tr>
</tbody>
</table>

| RES1 | RES0 | HWU62 | HWU61 | HWU60 | HWU59 |

**Bit [31]**

Reserved, RES1.

**Bits [30:29]**

Reserved, RES0.

**HWU62, bit [28]**

*When ARMv8.2-TTPBHA is implemented:*

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 2 translation table Block or Page entry.

- **0b0** Bit[62] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- **0b1** Bit[62] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.
HWU61, bit [27]

When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 2 translation table Block or Page entry.
- 0b0: Bit[61] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- 0b1: Bit[61] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU60, bit [26]

When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 2 translation table Block or Page entry.
- 0b0: Bit[60] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- 0b1: Bit[60] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

HWU59, bit [25]

When ARMv8.2-TTPBHA is implemented:
Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 2 translation table Block or Page entry.
- 0b0: Bit[59] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
- 0b1: Bit[59] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

Bits [24:14]
Reserved, RES0.

SH0, bits [13:12]
Shareability attribute for memory associated with translation table walks using VTTBR.
- 0b00: Non-shareable.
- 0b10: Outer Shareable.
- 0b11: Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNPREDICTABLE, as described in Reserved values in System and memory-mapped registers and translation table entries on page K1-7212.

This field resets to an architecturally UNKNOWN value.
ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using VTTBR.

- **0b00**: Normal memory, Outer Non-cacheable.
- **0b01**: Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
- **0b10**: Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
- **0b11**: Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using VTTBR.

- **0b00**: Normal memory, Inner Non-cacheable.
- **0b01**: Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
- **0b10**: Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
- **0b11**: Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

SL0, bits [7:6]

Starting level for translation table walks using VTTBR.

- **0b00**: Start at level 2
- **0b01**: Start at level 1

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of T0SZ, then a stage 2 level 1 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

S, bit [4]

Sign extension bit. This bit must be programmed to the value of T0SZ[3]. If it is not, then the behavior is CONSTRAINED UNPREDICTABLE and the stage 2 T0SZ value is treated as an UNKNOWN value, see Misprogramming VTCR.S on page K1-7209.

This field resets to an architecturally UNKNOWN value.

T0SZ, bits [3:0]

The size offset of the memory region addressed by VTTBR. The region size is 2^(32-T0SZ) bytes.

This field holds a four-bit signed integer value, meaning it supports values from -8 to 7.

Note

This is different from the other translation control registers, where TnSZ holds a three-bit unsigned integer, supporting values from 0 to 7.

If this field is programmed to a value that is not consistent with the programming of SL0 then a stage 2 level 1 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

Accessing the VTCR

Accesses to this register use the following encodings in the System instruction encoding space:
MRC<\langle c\rangle><\langle q\rangle> <coproc>, (#<opc1>, <Rt>, <CRn>, <CRm>, (#<opc2>)

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>

G8.2.167 VTTBR, Virtualization Translation Table Base Register

The VTTBR characteristics are:

**Purpose**

Holds the base address of the translation table for the initial lookup for stage 2 of an address translation in the Non-secure PL1&0 translation regime, and other information for this translation regime.

**Configurations**

AArch32 System register VTTBR[63:0] is architecturally mapped to AArch64 System register VTTBR_EL2[63:0].

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VTTBR is a 64-bit register.

**Field descriptions**

The VTTBR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:56]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>VMID, bits [55:48]</td>
<td>The VMID for the translation table. In a system where the PE resets into EL2 or EL3, this field resets to 0.</td>
</tr>
<tr>
<td>BADDR, bits [47:1]</td>
<td>Translation table base address, bits[47:x], Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following: • Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero. • The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.</td>
</tr>
</tbody>
</table>

x is determined from the value of VTCR.SL0 and VTCR.T0SZ as follows:

* If VTCR.SL0 is 0b00, meaning that lookup starts at level 2, then x is 14 - VTCR.T0SZ.
* If VTCR.SL0 is 0b01, meaning that lookup starts at level 1, then x is 5 - VTCR.T0SZ.
* If VTCR.SL0 is either 0b10 or 0b11 then a stage 2 level 1 Translation fault is generated.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.

In a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.
CnP, bit [0]

When ARMv8.2-TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by VTTBR is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of VTTBR.CnP is 1.

0b0 The translation table entries pointed to by VTTBR are permitted to differ from the entries for VTTBR for other PEs in the Inner Shareable domain. This is not affected by the value of the current VMID.

0b1 The translation table entries pointed to by VTTBR are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of VTTBR.CnP is 1 and the VMID is the same as the current VMID.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

Note

If the value of the VTTBR.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those VTTBRs do not point to the same translation table entries when the VMID value is the same as the current VMID, then the results of translations are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-7195.

In a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the VTTBR

Accesses to this register use the following encodings in the System instruction encoding space:

MRRC{<c>}{<q>} <coproc>, (#)<opc1>, <Rt>, <Rt2>, <CRm>

G8.3 Debug registers

This section lists the Debug System registers in AArch32 state, in alphabetic order.
G8.3.1 *DBGAUTHSTATUS, Debug Authentication Status register*

The DBGAUTHSTATUS characteristics are:

**Purpose**

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

**Configurations**

AArch32 System register DBGAUTHSTATUS[31:0] is architecturally mapped to AArch64 System register DBGAUTHSTATUS_EL1[31:0].

AArch32 System register DBGAUTHSTATUS[31:0] is architecturally mapped to External register DBGAUTHSTATUS_EL1[31:0].

This register is required in all implementations.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGAUTHSTATUS is a 32-bit register.

**Field descriptions**

The DBGAUTHSTATUS bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>7-6</td>
<td>SNID</td>
</tr>
<tr>
<td>5-4</td>
<td>SID</td>
</tr>
<tr>
<td>1-0</td>
<td>NSID</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**SNID, bits [7:6]**

*When ARMv8.4-Debug is implemented:*

Secure Non-Invasive Debug.

This field has the same value as DBGAUTHSTATUS.SID.

*Otherwise:*

Secure Non-Invasive Debug.

0b00 Not implemented. EL3 is not implemented and the Effective value of SCR.NS is 1.

0b10 Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.

0b11 Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

**SID, bits [5:4]**

Secure Invasive Debug.

0b00 Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 1.

0b10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.

0b11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

All other values are reserved.
NSID, bits [3:2]

When ARMv8.4-Debug is implemented:
Non-secure Non-invasive debug.

0b00  Not implemented. EL3 is not implemented and the Effective value of SCR.NS is 0.
0b11  Implemented and enabled. EL3 is implemented or the Effective value of SCR.NS is 1.

All other values are reserved.

Otherwise:
Non-secure Non-Invasive Debug.

0b00  Not implemented. EL3 is not implemented and the Effective value of SCR.NS is 0
0b10  Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
0b11  Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

NSID, bits [1:0]

Non-secure Invasive Debug.

0b00  Not implemented. EL3 is not implemented or the Effective value of SCR_EL3.NS is 0.
0b10  Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
0b11  Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

All other values are reserved.

Accessing the DBGAUTHSTATUS

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MRC}(c,q) \text{ coproc}, \{#\text{opc1}\}, \text{<Rt>}, \text{<CRn>}, \text{<CRm>}, \{#\text{opc2}\} \]

<table>
<thead>
<tr>

<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1110</td>
<td>0b000</td>
<td>0b0111</td>
<td>0b1110</td>
<td>0b110</td>
</tr>
</tbody>
</table>

if PSTATE_EL == EL0 then
    UNDEFINED;
elsif PSTATE_EL == EL1 then
    if EL2Enabled() && !ELUsingAArch32(EL2) && MDCR_EL2.<TDE,TDA> != '00' then
        AArch64.AArch32SystemAccessTrap(EL2, 0x05);
    elsif EL2Enabled() && ELUsingAArch32(EL2) && HDCR.<TDE,TDA> != '00' then
        AArch32.TakeHypTrapException(0x05);
    elsif HaveEL(EL3) && !ELUsingAArch32(EL3) && MDCR_EL3.TDA == '1' then
        AArch64.AArch32SystemAccessTrap(EL3, 0x05);
    else
        return DBGAUTHSTATUS;
    end if
elsif PSTATE_EL == EL2 then
    if HaveEL(EL3) && !ELUsingAArch32(EL3) && MDCR_EL3.TDA == '1' then
        AArch64.AArch32SystemAccessTrap(EL3, 0x05);
    else
        return DBGAUTHSTATUS;
    end if
elsif PSTATE_EL == EL3 then
    return DBGAUTHSTATUS;
### G8.3.2 DBGBCR<n>, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n> characteristics are:

**Purpose**

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register DBGBXVR<n> for VMID matching.

**Configurations**

AArch32 System register DBGBCR<n>[31:0] is architecturally mapped to AArch64 System register DBGBCR<n>_EL1[31:0].

AArch32 System register DBGBCR<n>[31:0] is architecturally mapped to External register DBGBCR<n>_EL1[31:0].

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGBCR<n> is a 32-bit register.

**Field descriptions**

The DBGBCR<n> bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>24</td>
<td>BT</td>
</tr>
<tr>
<td>23</td>
<td></td>
</tr>
<tr>
<td>20</td>
<td>LBN</td>
</tr>
<tr>
<td>19</td>
<td></td>
</tr>
<tr>
<td>16</td>
<td>SSC</td>
</tr>
<tr>
<td>15</td>
<td>RES0</td>
</tr>
<tr>
<td>14</td>
<td>BAS</td>
</tr>
<tr>
<td>13</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td></td>
</tr>
<tr>

<tr>
<td>4</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

When the E field is zero, all the other fields in the register are ignored.

**Bits [31:24]**

Reserved, RES0.

**BT, bits [23:20]**

Breakpoint Type. Possible values are:

- **00000** Unlinked instruction address match. DBGBVR<n> is the address of an instruction.
- **00001** As **00000** with linking enabled.
- **00010** Unlinked Context ID match. When ARMv8.1-VHE is implemented, EL2 is using AArch64, and the Effective value of HCR_EL2.E2H is 1, if either the PE is executing at EL0 with HCR_EL2.TGE set to 0 or the PE is executing at EL2, then DBGBVR<n>.ContextID must match the CONTEXTIDR_EL2 value. Otherwise DBGBVR<n>.ContextID must match the CONTEXTIDR value.
- **00011** As **00010** with linking enabled.
- **00100** Unlinked instruction address mismatch. DBGBVR<n> is the address of an instruction to be stepped.
- **00101** As **00100** with linking enabled.
- **00110** Unlinked CONTEXTIDR_EL1 match. DBGBVR<n>.ContextID is a Context ID compared against CONTEXTIDR.
0b0111  As 0b0110 with linking enabled.
0b1000  Unlinked VMID match. DBGBXVR<n>.VMID is a VMID compared against VTTBR.VMID.
0b1001  As 0b1000 with linking enabled.
0b1010  Unlinked VMID and Context ID match. DBGBVR<n>.ContextID is a Context ID compared against CONTEXTIDR, and DBGBXVR<n>.VMID is a VMID compared against VTTBR.VMID.
0b1011  As 0b1010 with linking enabled.
0b1100  Unlinked CONTEXTIDR_EL2 match. DBGBXVR<n>.ContextID2 is a Context ID compared against CONTEXTIDR_EL2.
0b1101  As 0b1100 with linking enabled.
0b1110  Unlinked Full Context ID match. DBGBVR<n>.ContextID is compared against CONTEXTIDR, and DBGBXVR<n>.ContextID2 is compared against CONTEXTIDR_EL2.
0b1111  As 0b1110 with linking enabled.

For more information on Breakpoints and their constraints, see Breakpoint exceptions on page G2-5374 and Reserved DBGBCR<n>.BT values on page G2-5394.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]
Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.
For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.
This field is ignored when the value of DBGBCR<n>.E is 0.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]
Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields.
For more information, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-5383, and Reserved DBGBCR<n>.{SSC, HMC, PMC} values on page G2-5395.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]
Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the SSC, bits [15:14] description.
For more information on the operation of the SSC, HMC, and PMC fields, see Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-5383.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [12:9]
Reserved, RES0.

BAS, bits [8:5]
Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state.
The permitted values depend on the breakpoint type.
For Address match breakpoints, the permitted values are:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Match instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0011</td>
<td>DBGBVR&lt;n&gt;</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBVR&lt;n&gt;+2</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBVR&lt;n&gt;</td>
<td>Use for A32 instructions</td>
</tr>
</tbody>
</table>

All other values are reserved. For more information, see *Reserved DBGBCR<n>.{SSC, HMC, PMC} values on page G2-5395.*

For more information on using the BAS field in Address Match breakpoints, see *Using the BAS field in Address Match breakpoints on page G2-5387.*

For Address mismatch breakpoints in an AArch32 stage 1 translation regime, the permitted values are:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Step instruction at</th>
<th>Constraint for debuggers</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>-</td>
<td>Use for a match anywhere breakpoint</td>
</tr>
<tr>
<td>0b0011</td>
<td>DBGBVR&lt;n&gt;</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1100</td>
<td>DBGBVR&lt;n&gt;+2</td>
<td>Use for T32 instructions</td>
</tr>
<tr>
<td>0b1111</td>
<td>DBGBVR&lt;n&gt;</td>
<td>Use for A32 instructions</td>
</tr>
</tbody>
</table>

All other values are reserved. For more information, see *Reserved DBGBCR<n>.{SSC, HMC, PMC} values on page G2-5395.*

For more information on using the BAS field in address mismatch breakpoints, see *Using the BAS field in Address Match breakpoints on page G2-5387.*

For Context matching breakpoints, this field is RES1 and ignored.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Bits [4:3]**

Reserved, RES0.

**PMC, bits [2:1]**

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the DBGBCR<n>.SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see *Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-5383.*

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**E, bit [0]**

Enable breakpoint DBGBVR<n>. Possible values are:

- 0b0 Breakpoint disabled.
- 0b1 Breakpoint enabled.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing the DBGBCR<n>**

G8-6109
else
    DBGBCR[UInt(CRm<3:0>)] = R[t];
G8.3.3 DBGBVR<n>, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n> characteristics are:

Purpose
Holds a value for use in breakpoint matching, either the virtual address of an instruction or a context ID. Forms breakpoint n together with control register DBGBCR<n>. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register DBGBXVR<n> for VMID matching.

Configurations
AArch32 System register DBGBVR<n>[31:0] is architecturally mapped to AArch64 System register DBGBVR<n>_EL1[31:0].
AArch32 System register DBGBVR<n>[31:0] is architecturally mapped to External register DBGBVR<n>_EL1[31:0].

Note
Writes to DBGBVR<n> do not modify DBGBVR<n>_EL1[63:32].

If breakpoint n is not implemented then this register is unallocated.
This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes
How this register is interpreted depends on the value of DBGBCR<n>.BT.
• When DBGBCR<n>.BT is 0b0x0x, this register holds a virtual address.
• When DBGBCR<n>.BT is 0bxx1x, this register holds a Context ID.
For other values of DBGBCR<n>.BT, this register is RES0.
Some breakpoints might not support Context ID comparison. For more information, see the description of the DBGDIDR.CTX_CMPs field.

Field descriptions
The DBGBVR<n> bit assignments are:

When DBGBCR<n>.BT == 0b0x0x:

<table>
<thead>
<tr>
<th>31</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA[31:2]</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

VA[31:2], bits [31:2]
Bits[31:2] of the address value for comparison.
On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]
Reserved, RES0.
When DBGBCR\(n\).BT == 0b001x:

<table>
<thead>
<tr>
<th>ContextID, bits [31:0]</th>
</tr>
</thead>
</table>

Context ID value for comparison.
The value is compared against CONTEXTIDR_EL2 when all of the following are true:

- ARMv8.1-VHE is implemented.
- HCR_EL2.{E2H, TGE} is \{1,1\}.
- The PE is executing at EL0.
- EL2 is enabled in the current Security state, and is using AArch64.

Otherwise, the value is compared against CONTEXTIDR.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR\(n\).BT == 0b101x and HaveEL(EL2):

<table>
<thead>
<tr>
<th>ContextID, bits [31:0]</th>
</tr>
</thead>
</table>

Context ID value for comparison against CONTEXTIDR.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR\(n\).BT == 0bx11x, HaveEL(EL2) and ARMv8.1-VHE is implemented:

<table>
<thead>
<tr>
<th>ContextID, bits [31:0]</th>
</tr>
</thead>
</table>

Context ID value for comparison against CONTEXTIDR.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the DBGBVR\(n\)

G8.3.4  DBGBXVR<\(n\)>, Debug Breakpoint Extended Value Registers, \(n = 0 - 15\)

The DBGBXVR<\(n\)> characteristics are:

**Purpose**

Holds a value for use in breakpoint matching, to support VMID matching. Used in conjunction with a control register DBGBCR<\(n\)> and a value register DBGBVR<\(n\)>\(), where EL2 is implemented and breakpoint \(n\) supports Context matching.

**Configurations**

AArch32 System register DBGBXVR<\(n\)>[31:0] is architecturally mapped to AArch64 System register DBGBVR<\(n\)>\_EL1[63:32].

AArch32 System register DBGBXVR<\(n\)>[31:0] is architecturally mapped to External register DBGBVR<\(n\)>\_EL1[63:32].

--- Note ---

Writes to DBGBXVR<\(n\)> do not modify DBGBVR<\(n\)>\_EL1[31:0].

---

This register is unallocated in any of the following cases:

- Breakpoint \(n\) is not implemented.
- Breakpoint \(n\) does not support Context matching.
- EL2 is not implemented.

For more information, see the description of the DBGDIDR.CTX_CMPs field.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

How this register is interpreted depends on the value of DBGBCR<\(n\)>\_.BT.

- When DBGBCR<\(n\)>\_.BT is 0b10xx, this register holds a VMID.
- When DBGBCR<\(n\)>\_.BT is 0b11xx, this register holds a Context ID.

For other values of DBGBCR<\(n\)>\_.BT, this register is RES0.

**Field descriptions**

The DBGBXVR<\(n\)> bit assignments are:

*When DBGBCR<\(n\)>\_.BT == 0b10xx and HaveEL(EL2):*

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>15</th>
<th>14</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>VMID[15:8]</td>
<td>VMID[7:0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:16]**

Reserved, RES0.

**VMID[15:8], bits [15:8]**

*When ARMv8.1-VMID16 is implemented:*

Extension to VMID[7:0]. See VMID[7:0] for more details.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.
VMID[7:0], bits [7:0]

VMID value for comparison.

The VMID is 8 bits in the following cases.

- EL2 is using AArch32.
- ARMv8.1-VMID16 is not implemented.

When ARMv8.1-VMID16 is implemented and EL2 is using AArch64, it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

VMID[15:8] is RES0 if any of the following applies:

- The implementation has an 8-bit VMID.
- VTCR_EL2.VS has a value of 0.
- EL2 is using AArch32.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>.BT == 0b11xx and HaveEL(EL2):

ContextID2, bits [31:0]

When ARMv8.1-VHE is implemented:

Context ID value for comparison against CONTEXTIDR_EL2.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the DBGBXVR<n>

G8.3.5  **DBGCLAIMCLR, Debug Claim Tag Clear register**

The DBGCLAIMCLR characteristics are:

**Purpose**

Used by software to read the values of the CLAIM tag bits, and to clear these bits to 0.

The architecture does not define any functionality for the CLAIM tag bits.

--- Note ---

CLAIM tags are typically used for communication between the debugger and target software.

---

Used in conjunction with the DBGCLAIMSET register.

**Configurations**

AArch32 System register DBGCLAIMCLR[31:0] is architecturally mapped to AArch64 System register DBGCLAIMCLR_EL1[31:0].

AArch32 System register DBGCLAIMCLR[31:0] is architecturally mapped to External register DBGCLAIMCLR_EL1[31:0].

An implementation must include 8 CLAIM tag bits.

This register is in the Cold reset domain. See the CLAIM field description for the effect of a Cold reset on the value returned by this register. This register is not affected by a Warm reset.

**Attributes**

DBGCLAIMCLR is a 32-bit register.

**Field descriptions**

The DBGCLAIMCLR bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th>CLAIM</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RAZ/SBZ</td>
<td>8</td>
<td>7</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

**CLAIM, bits [7:0]**

Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits.

Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0.

Writing 0 to one of these bits has no effect.

On a Cold reset, this field resets to 0.

**Accessing the DBGCLAIMCLR**

Accesses to this register use the following encodings in the System instruction encoding space:
MRC<c>{q}<coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

<table>
<thead>

G8.3.6 DBGCLAIMSET, Debug Claim Tag Set register

The DBGCLAIMSET characteristics are:

**Purpose**

Used by software to set the CLAIM tag bits to 1.

The architecture does not define any functionality for the CLAIM tag bits.

--- Note ---

CLAIM tags are typically used for communication between the debugger and target software.

---

CLAIM tags are typically used for communication between the debugger and target software.

---

Used in conjunction with the DBGCLAIMCLR register.

**Configurations**

AArch32 System register DBGCLAIMSET[31:0] is architecturally mapped to AArch64 System register DBGCLAIMSET_EL1[31:0].

AArch32 System register DBGCLAIMSET[31:0] is architecturally mapped to External register DBGCLAIMSET_EL1[31:0].

An implementation must include 8 CLAIM tag bits.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGCLAIMSET is a 32-bit register.

**Field descriptions**

The DBGCLAIMSET bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RAZ/SBZ</td>
</tr>
<tr>
<td>8</td>
<td>7</td>
</tr>
<tr>
<td>0</td>
<td>CLAIM</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

**CLAIM, bits [7:0]**

Set CLAIM tag bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM tag bit to 1. This is an indirect write to the CLAIM tag bits. A single write operation can set multiple CLAIM tag bits to 1.

Writing 0 to one of these bits has no effect.

On a Cold reset, this field resets to 0.

**RX, bit [30]**

DCC interrupt request enable control for DTRRX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

- 0b0: No interrupt request generated by DTRRX.
- 0b1: Interrupt request will be generated on RXfull == 1.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

On a Warm reset, this field resets to 0.

**TX, bit [29]**

DCC interrupt request enable control for DTRTX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

- 0b0: No interrupt request generated by DTRTX.
- 0b1: Interrupt request will be generated on TXfull == 0.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

On a Warm reset, this field resets to 0.

**Bits [28:0]**

Reserved, RES0.

G8.3.8  DBGDEVID, Debug Device ID register 0

The DBGDEVID characteristics are:

**Purpose**

Adds to the information given by the DBGDIDR by describing other features of the debug implementation.

**Configurations**

This register is required in all implementations.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGDEVID is a 32-bit register.

**Field descriptions**

The DBGDEVID bit assignments are:

<table>
<thead>
<tr>
<th>Bit 31-28</th>
<th>Bit 27-24</th>
<th>Bit 23-20</th>
<th>Bit 19-16</th>
<th>Bit 15-12</th>
<th>Bit 11-8</th>
<th>Bit 7-4</th>
<th>Bit 3-0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIDMask</td>
<td>AuxRegs</td>
<td>DoubleLock</td>
<td>VirtExtns</td>
<td></td>
<td></td>
<td></td>
<td>PCSample</td>
</tr>
</tbody>
</table>

**CIDMask, bits [31:28]**

Indicates the level of support for the Context ID matching breakpoint masking capability. Permitted values of this field are:

- 0b0000  Context ID masking is not implemented.
- 0b0001  Context ID masking is implemented.

All other values are reserved. The value of this for Armv8 is 0b0000.

**AuxRegs, bits [27:24]**

Indicates support for Auxiliary registers. Permitted values for this field are:

- 0b0000  None supported.
- 0b0001  Support for External Debug Auxiliary Control Register, EDACR.

All other values are reserved.

**DoubleLock, bits [23:20]**

OS Double Lock implemented. This field indicates the presence of the OS Double Lock and the behavior of the DBGOSDLR, OS Double Lock Register. Permitted values of this field are:

- 0b0000  The OS Double Lock is not implemented. DBGOSDLR is RAZ/WI.
- 0b0001  The OS Double Lock is implemented. DBGOSDLR is RW.

All other values are reserved.

**VirtExtns, bits [19:16]**

Indicates whether EL2 is implemented. Permitted values of this field are:

- 0b0000  EL2 is not implemented.
- 0b0001  EL2 is implemented.

All other values are reserved.
VectorCatch, bits [15:12]
Defines the form of Vector Catch exception implemented. Permitted values of this field are:
- 0b0000  Address matching Vector Catch exception implemented.
- 0b0001  Exception matching Vector Catch exception implemented.
All other values are reserved.

BPAddrMask, bits [11:8]
Indicates the level of support for the instruction address matching breakpoint masking capability. Permitted values of this field are:
- 0b0000  Breakpoint address masking might be implemented. If not implemented, DBGBCR<n>[28:24] is RAZ/WI.
- 0b0001  Breakpoint address masking is implemented.
- 0b1111  Breakpoint address masking is not implemented. DBGBCR<n>[28:24] is RES0.
All other values are reserved. The value of this for Armv8 is 0b1111.

WPAddrMask, bits [7:4]
Indicates the level of support for the data address matching watchpoint masking capability. Permitted values of this field are:
- 0b0000  Watchpoint address masking might be implemented. If not implemented, DBGWCR<n>.MASK (Address mask) is RAZ/WI.
- 0b0001  Watchpoint address masking is implemented.
- 0b1111  Watchpoint address masking is not implemented. DBGWCR<n>.MASK (Address mask) is RES0.
All other values are reserved. The value of this for Armv8 is 0b0001.

PCSample, bits [3:0]
Indicates the level of PC Sample-based Profiling support using external debug registers. Permitted values of this field are:
- 0b0000  PC Sample-based Profiling Extension is not implemented in the external debug registers space.
- 0b0010  Only EDPCSR and EDCIDSR are implemented. This option is only permitted if EL3 and EL2 are not implemented.
- 0b0011  EDPCSR, EDCIDSR, and EDVIDSR are implemented.
All other values are reserved.
When ARMv8.2-PCSample is implemented, the only permitted value is 0b0000.

--- Note ---
ARMv8.2-PCSample implements the PC Sample-based Profiling Extension in the Performance Monitors register space, as indicated by the value of PMDEVID.PCSample.

Accessing the DBGDEVID
Accesses to this register use the following encodings in the System instruction encoding space:
if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then
  if EL2Enabled() && !ELUsingAArch32(EL2) && MDCR_EL2.<TDE,TDA> != '00' then
    AArch64.AArch32SystemAccessTrap(EL2, 0x05);

  else
    return DBGDEVID;
  end
elsif PSTATE.EL == EL3 then
  return DBGDEVID;
### G8.3.9 DBGDEVID1, Debug Device ID register 1

The DBGDEVID1 characteristics are:

#### Purpose
Add to the information given by the DBGDIDR by describing other features of the debug implementation.

#### Configurations
This register is required in all implementations.

#### Attributes
DBGDEVID1 is a 32-bit register.

### Field descriptions

The DBGDEVID1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [31:4]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>PCSROffset, bits [3:0]</td>
<td>This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in Armv8 are:</td>
</tr>
<tr>
<td>0b0000</td>
<td>EDPCSR is not implemented.</td>
</tr>
<tr>
<td>0b0010</td>
<td>EDPCSR implemented. Samples have no offset applied and do not sample the instruction set state in AArch32 state.</td>
</tr>
</tbody>
</table>

When Armv8.2-PCSample is implemented, the only permitted value is 0b0000.

---

#### Note
Armv8.2-PCSample implements the PC Sample-based Profiling Extension in the Performance Monitors register space, as indicated by the value of PMDEVID.PCSample.

---

### Accessing the DBGDEVID1

Accesses to this register use the following encodings in the System instruction encoding space:

G8.3.10 DBGDEVID2, Debug Device ID register 2

The DBGDEVID2 characteristics are:

**Purpose**
Reserved for future descriptions of features of the debug implementation.

**Configurations**
There are no configuration notes.

**Attributes**
DBGDEVID2 is a 32-bit register.

**Field descriptions**
The DBGDEVID2 bit assignments are:

```
   31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
RES0
```

**Bits [31:0]**
Reserved, RES0.

**Accessing the DBGDEVID2**

Accesses to this register use the following encodings in the System instruction encoding space:

```
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

```
coproc  opc1  CRn  CRm  opc2
0b1110  0b000  0b0111  0b0000  0b111
```

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then

        else
            return DBGDEVID2;
    elsif PSTATE.EL == EL3 then
        return DBGDEVID2;
```
### G8.3.11 DBGDIDR, Debug ID Register

The DBGDIDR characteristics are:

**Purpose**

Specifies which version of the Debug architecture is implemented, and some features of the debug implementation.

**Configurations**

If EL1 cannot use AArch32 then the implementation of this register is **OPTIONAL** and deprecated.

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

DBGDIDR is a 32-bit register.

**Field descriptions**

The DBGDIDR bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WRPs</td>
<td>bits [31:28]</td>
<td>The number of watchpoints implemented, minus 1.</td>
</tr>
<tr>
<td>BRPs</td>
<td>bits [27:24]</td>
<td>The number of breakpoints implemented, minus 1.</td>
</tr>
<tr>
<td>CTX_CMPs</td>
<td>bits [23:20]</td>
<td>The number of breakpoints that can be used for Context matching, minus 1.</td>
</tr>
<tr>
<td>Version</td>
<td></td>
<td></td>
</tr>
<tr>
<td>RES0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SE_imp</td>
<td></td>
<td></td>
</tr>
<tr>
<td>RES1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>nSUHD_imp</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**WRPs, bits [31:28]**

The number of watchpoints implemented, minus 1.

Permitted values of this field are from `0b0001` for 2 implemented watchpoints, to `0b1111` for 16 implemented watchpoints.

The value of `0b0000` is reserved.

If AArch64 is implemented, this field has the same value as `ID_AA64DFR0_EL1.WRPs`.

**BRPs, bits [27:24]**

The number of breakpoints implemented, minus 1.

Permitted values of this field are from `0b0001` for 2 implemented breakpoints, to `0b1111` for 16 implemented breakpoints.

The value of `0b0000` is reserved.

If AArch64 is implemented, this field has the same value as `ID_AA64DFR0_EL1.BRPs`.

**CTX_CMPs, bits [23:20]**

The number of breakpoints that can be used for Context matching, minus 1.

Permitted values of this field are from `0b0000` for 1 Context matching breakpoint, to `0b1111` for 16 Context matching breakpoints.

The Context matching breakpoints must be the highest addressed breakpoints. For example, if six breakpoints are implemented and two are Context matching breakpoints, they must be breakpoints 4 and 5.

If AArch64 is implemented, this field has the same value as `ID_AA64DFR0_EL1.CTX_CMPs`. 
Version, bits [19:16]

The Debug architecture version. Defined values are:

- **0b0001**: Armv6, v6 Debug architecture.
- **0b0010**: Armv6, v6.1 Debug architecture.
- **0b0011**: Armv7, v7 Debug architecture, with baseline CP14 registers implemented.
- **0b0100**: Armv7, v7 Debug architecture, with all CP14 registers implemented.
- **0b0101**: Armv7, v7.1 Debug architecture.
- **0b0110**: Armv8, v8 Debug architecture.
- **0b0111**: Armv8.1, v8 Debug architecture, with Virtualization Host Extensions.
- **0b1000**: Armv8.2, v8.2 Debug architecture.
- **0b1001**: Armv8.4, v8.4 Debug architecture.

All other values are reserved.

In any Armv8 implementation, the values **0b0001**, **0b0010**, **0b0011**, **0b0100**, and **0b0101** are not permitted.

- If ARMv8.1-VHE is not implemented, the only permitted value is **0b0110**.
- In an Armv8.0 implementation, the value **0b1000** or higher is not permitted.

Bit [15]

Reserved, **RES1**.

nSUHD_imp, bit [14]

In Armv7-A, Secure User Halting Debug not implemented.
The value of this bit must match the value of the **SE_imp** bit.

Bit [13]

Reserved, **RES0**.

SE_imp, bit [12]

EL3 implemented. The meanings of the values of this bit are:

- **0b0**: EL3 not implemented.
- **0b1**: EL3 implemented.

The value of this bit must match the value of the nSUHD_imp bit.

Bits [11:0]

Reserved, **RES0**.

Accessing the DBGDIDR

Arm deprecates any access to this register from EL0.

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRC\{<c>\}<q>\ <coproc>, \{#\}<opc1>, <Rt>, <CRn>, <CRm>, \{#\}<opc2> \]

<table>

G8.3.12  DBGDRAR, Debug ROM Address Register

The DBGDRAR characteristics are:

**Purpose**

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. Armv8 deprecates any use of this register.

**Configurations**

AArch32 System register DBGDRAR[63:0] is architecturally mapped to AArch64 System register MDRAR_EL1[63:0].

If EL1 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGDRAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, bits [31:0] are read.

**Field descriptions**

The DBGDRAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Field Description</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-48</td>
<td>ROMADDR[47:12]</td>
<td>Bits 47-12</td>
</tr>
<tr>
<td>12-11</td>
<td>RES0</td>
<td>Reserved</td>
</tr>
</tbody>
</table>
| 10            | Valid             | This field indicates whether the ROM Table address is valid. The permitted values of this field are:
|               | 0b00              | ROM Table address is not valid. Software must ignore ROMADDR. |
|               | 0b11              | ROM Table address is valid. |
|               | Other values are reserved. |

**Accessing the DBGDRAR**

Accesses to this register use the following encodings in the System instruction encoding space:
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

<table>

G8.3.13  DBGDSAR, Debug Self Address Register

The DBGDSAR characteristics are:

Purpose

In earlier versions of the Arm Architecture, this register defines the offset from the base address defined in DBGDRAR of the physical base address of the debug registers for the PE. Armv8 deprecates any use of this register.

Configurations

If EL1 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated. RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGDSAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, bits [31:0] are read.

Field descriptions

The DBGDSAR bit assignments are:

<table>
<thead>
<tr>
<th>Offset, bits [63:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>This register value is RAZ.</td>
</tr>
</tbody>
</table>

Accessing the DBGDSAR

Accesses to this register use the following encodings in the System instruction encoding space:

```
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

<table>
<thead>

G8.3.14 DBGDSCRext, Debug Status and Control Register, External View

The DBGDSCRext characteristics are:

**Purpose**

Main control register for the debug implementation.

**Configurations**

AArch32 System register DBGDSCRext[31:0] is architecturally mapped to AArch64 System register MDSCR_EL1[31:0].

AArch32 System register DBGDSCRext[15:2] is architecturally mapped to AArch32 System register DBGSCRint[15:2].

This register is required in all implementations.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGDSCRext is a 32-bit register.

**Field descriptions**

The DBGDSCRext bit assignments are:

**TFO, bit [31]**

*When ARMv8.4-Trace is implemented:*

Trace Filter override. Used for save/restore of ESCR.TFO.

When the OS Lock is unlocked, OSLSR_EL1.OSLK == 0, this bit ignores writes and software must treat it as UNK/SBZP.

When the OS Lock is locked, OSLSR_EL1.OSLK == 1, this bit is RW and holds the value of ESCR.TFO.

Reads and writes of this bit are indirect accesses to ESCR.TFO.

*Otherwise:*

Reserved, RES0.
RXfull, bit [30]
DTRRX full. Used for save/restore of EDSCR.RXfull.
When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/ SBZP.
When OSLSR_EL1.OSLK == 1, this bit is RW and holds the value of EDSCR.RXfull.
Arm deprecates use of this bit other than for save/restore. Use DBGDSCRint to access the DTRRX full status.
Reads and writes of this bit are indirect accesses to EDSCR.RXfull.
The architected behavior of this field determines the value it returns after a reset.

TXfull, bit [29]
DTRTX full. Used for save/restore of EDSCR.TXfull.
When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/ SBZP.
When DBGOSLSR.OSLK == 1, this bit is RW and holds the value of EDSCR.TXfull.
Arm deprecates use of this bit other than for save/restore. Use DBGDSCRint to access the DTRTX full status.
Reads and writes of this bit are indirect accesses to EDSCR.TXfull.
The architected behavior of this field determines the value it returns after a reset.

Bit [28]
Reserved, RES0.

RXO, bit [27]
Used for save/restore of EDSCR.RXO.
When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/ SBZP.
When DBGOSLSR.OSLK == 1, this bit is RW and holds the value of EDSCR.RXO.
Reads and writes of this bit are indirect accesses to EDSCR.RXO.
The architected behavior of this field determines the value it returns after a reset.

TXU, bit [26]
Used for save/restore of EDSCR.TXU.
When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/ SBZP.
When DBGOSLSR.OSLK == 1, this bit is RW and holds the value of EDSCR.TXU.
Reads and writes of this bit are indirect accesses to EDSCR.TXU.
The architected behavior of this field determines the value it returns after a reset.

Bits [25:24]
Reserved, RES0.

INTdis, bits [23:22]
Used for save/restore of EDSCR.INTdis.
When OSLSR_EL1.OSLK == 0, this field is RO, and software must treat it as UNK/ SBZP.
When DBGOSLSR.OSLK == 1, this field is RW and holds the value of EDSCR.INTdis.
Reads and writes of this field are indirect accesses to EDSCR.INTdis.
The architected behavior of this field determines the value it returns after a reset.

TDA, bit [21]
Used for save/restore of EDSCR.TDA.
When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/ SBZP.
When DBGOSLSR.OSLK == 1, this bit is RW and holds the value of EDSCR.TDA.
Reads and writes of this bit are indirect accesses to \texttt{EDSCR.TDA}.
The architected behavior of this field determines the value it returns after a reset.

**Bit [20]**

Reserved, \texttt{RES0}.

**SC2, bit [19]**

\textit{When ARMv8.0-PCSample is implemented, ARMv8.1-VHE is implemented and ARMv8.2-PCSample is not implemented:}

Used for save/restore of \texttt{EDSCR.SC2}.

When \texttt{DBGOSLSR.OSLK == 0}, this bit is \texttt{RO}, and software must treat it as \texttt{UNK/SBZP}.

When \texttt{DBGOSLSR.OSLK == 1}, this bit is \texttt{RW} and holds the value of \texttt{EDSCR.SC2}.

\textit{Otherwise:}

Reserved, \texttt{RES0}.

**NS, bit [18]**

Non-secure status. Returns the inverse of IsSecure(). This bit is \texttt{RO}.

Arm deprecates use of this field.

**SPNIDdis, bit [17]**

Secure privileged profiling disabled status bit. This bit is \texttt{RO}. Permitted values are:

\begin{itemize}
  \item \texttt{0b0} \quad If EL3 is implemented, profiling allowed in Secure privileged modes.
  \item \texttt{0b1} \quad If EL3 is implemented, profiling prohibited in Secure privileged modes.
\end{itemize}

This field is \texttt{RES0} if EL3 is not implemented.

- Otherwise, the field reads as zero if any of the following applies, and reads as one otherwise:
  - ARMv8.2-Debug is not implemented and ExternalSecureNoninvasiveDebugEnabled() returns \texttt{TRUE}.
  - EL3 is using AArch32 and the value of \texttt{SDCR.SPME} is 1.
  - EL3 is using AArch64 and the value of \texttt{MDCR_EL3.SPME} is 1.

Arm deprecates use of this field.

**SPIDdis, bit [16]**

Secure privileged AArch32 invasive self-hosted debug disabled status bit. This bit is \texttt{RO} and depends on the value of \texttt{SDCR.SPD} and the pseudocode function AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled(). Permitted values are:

\begin{itemize}
  \item \texttt{0b0} \quad Self-hosted debug enabled in Secure privileged AArch32 modes.
  \item \texttt{0b1} \quad Self-hosted debug disabled in Secure privileged AArch32 modes.
\end{itemize}

This bit reads as 1 if any of the following is true and reads as 0 otherwise:

- \texttt{SDCR.SPD} has the value \texttt{0b10}.
- \texttt{SDCR.SPD} has the value \texttt{0b00} and SelfHostedSecurePrivilegedInvasiveDebugEnabled() returns \texttt{FALSE}.

Arm deprecates use of this field.

**MDBGen, bit [15]**

Monitor debug events enable. Enable Breakpoint, Watchpoint, and Vector Catch exceptions.

\begin{itemize}
  \item \texttt{0b0} \quad Breakpoint, Watchpoint, and Vector Catch exceptions disabled.
  \item \texttt{0b1} \quad Breakpoint, Watchpoint, and Vector Catch exceptions enabled.
\end{itemize}

On a Warm reset, this field resets to \texttt{0}.
HDE, bit [14]

Used for save/restore of EDSCR.HDE.

When OSLR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.
When DBGOSLR.OSLK == 1, this bit is RW and holds the value of EDSCR.HDE.
Reads and writes of this bit are indirect accesses to EDSCR.HDE.
The architected behavior of this field determines the value it returns after a reset.

Bit [13]

Reserved, RES0.

UDCCdis, bit [12]

Traps EL0 accesses to the DCC registers to Undefined mode.
0b0 This control does not cause any instructions to be trapped.
0b1 EL0 accesses to the DBGDSCRint, DBGDTRRXint, DBGDTRTXint, DBGDIDR, DBGDSAR, and DBGDRAR are trapped to Undefined mode.

— Note —
All accesses to these registers are trapped, including LDC and STC accesses to DBGDTRTXint and DBGDTRRXint, and MRRC accesses to DBGDSAR and DBGDRAR.

Traps of EL0 accesses to the DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

On a Warm reset, this field resets to 0.

Bits [11:7]

Reserved, RES0.

ERR, bit [6]

Used for save/restore of EDSCR.ERR.

When OSLR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.
When DBGOSLR.OSLK == 1, this bit is RW and holds the value of EDSCR.ERR.
Reads and writes of this bit are indirect accesses to EDSCR.ERR.
The architected behavior of this field determines the value it returns after a reset.

MOE, bits [5:2]

Method of Entry for debug exception. When a debug exception is taken to an Exception level using AArch32, this field is set to indicate the event that caused the exception:
0b0001 Breakpoint.
0b0011 Software breakpoint (BKPT) instruction.
0b0101 Vector catch.
0b1010 Watchpoint.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

Accessing the DBGDSCRext

Individual fields within this register might have restricted accessibility when the OS lock is unlocked, DBGOSLR.OSLK == 0. See the field descriptions for more detail.

Accesses to this register use the following encodings in the System instruction encoding space:
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.3.15   DBGDSCRint, Debug Status and Control Register, Internal View

The DBGDSCRint characteristics are:

Purpose

Main control register for the debug implementation. This is an internal, read-only view.

Configurations

AArch32 System register DBGDSCRint[30:29] is architecturally mapped to AArch64 System register MDCCSR_EL0[30:29].

AArch32 System register DBGDSCRint[15:2] is architecturally mapped to AArch32 System register DBGDSCRext[15:2].

This register is required in all implementations.

DBGDSCRint. {NS, SPNIDdis, SPIDdis, MDBGen, UDCCdis, MOE} are UNKNOWN when the register is accessed at EL0. However, although these values are not accessible at EL0 by instructions that are neither UNPREDICTABLE nor return UNKNOWN values, it is permissible for an implementation to return the values of DBGDSCRext. {NS, SPNIDdis, SPIDdis, MDBGen, UDCCdis, MOE} for these fields at EL0.

It is also permissible for an implementation to return the same values as defined for a read of DBGDSCRint at EL1 or above. (This is the case even if the implementation does not support AArch32 at EL1 or above.)

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGDSCRint is a 32-bit register.

Field descriptions

The DBGDSCRint bit assignments are:

G8.3.16 DBGDTRRXext, Debug OS Lock Data Transfer Register, Receive, External View

The DBGDTRRXext characteristics are:

**Purpose**

Used for save/restore of DBGDTRRXint. It is a component of the Debug Communications Channel.

**Configurations**

AArch32 System register DBGDTRRXext[31:0] is architecturally mapped to AArch64 System register OSDTRRX_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGDTRRXext is a 32-bit register.

**Field descriptions**

The DBGDTRRXext bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Update DTRRX without side-effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>Update DTRRX without side-effect.</td>
</tr>
<tr>
<td></td>
<td>Writes to this register update the value in DTRRX and do not change RXfull.</td>
</tr>
<tr>
<td></td>
<td>Reads of this register return the last value written to DTRRX and do not change RXfull.</td>
</tr>
<tr>
<td></td>
<td>For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.</td>
</tr>
<tr>
<td></td>
<td>This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the DBGDTRRXext**

Arm deprecates reads and writes of DBGDTRRXext through the System register interface when the OS Lock is unlocked, DBGOSLSR.OSLK = 0.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}\{<q>\} <coproc>, \{#\}<opc1>, <Rt>, <CRn>, <CRm>\{, \{#\}<opc2>\}
\]

\[
\begin{array}{cccccc}

G8.3.17  DBGDTRRXint, Debug Data Transfer Register, Receive

The DBGDTRRXint characteristics are:

**Purpose**

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. See Arch64-DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communications Channel.

**Configurations**

AArch32 System register DBGDTRRXint[31:0] is architecturally mapped to AArch64 System register DBGDTR_EL0[63:32].

AArch32 System register DBGDTRRXint[31:0] is architecturally mapped to AArch64 System register DBGDTR_EL0[31:0] when read.

AArch32 System register DBGDTRRXint[31:0] is architecturally mapped to External register DBGDTRRX_EL0[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGDTRRXint is a 32-bit register.

**Field descriptions**

The DBGDTRRXint bit assignments are:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>Update DTRRX</td>
</tr>
</tbody>
</table>

**Bits [31:0]**

Update DTRRX.
Reads of this register:

- If RXfull is set to 1, return the last value written to DTRRX.
- If RXfull is set to 0, return an UNKNOWN value.

After the read, RXfull is cleared to 0.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing the DBGDTRRXint**

Data can be stored to memory from this register using STC.

Accesses to this register use the following encodings in the System instruction encoding space:
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

<table>

G8.3.18   DBGDTRTXext, Debug OS Lock Data Transfer Register, Transmit

The DBGDTRTXext characteristics are:

**Purpose**

Used for save/restore of DBGDTRTXint. It is a component of the Debug Communication Channel.

**Configurations**

AArch32 System register DBGDTRTXext[31:0] is architecturally mapped to AArch64 System register OSDTRTX_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGDTRTXext is a 32-bit register.

**Field descriptions**

The DBGDTRTXext bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Return DTRTX without side-effect.</td>
</tr>
<tr>
<td>0</td>
<td>Return DTRTX without side-effect.</td>
</tr>
</tbody>
</table>

Reads of this register return the value in DTRTX and do not change TXfull.

Writes of this register update the value in DTRTX and do not change TXfull.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing the DBGDTRTXext**

Arm deprecates reads and writes of DBGDTRTXext through the System register interface when the OS Lock is unlocked, DBGOSLSR.OSLK == 0.

G8.3.19 DBGDTRTXint, Debug Data Transfer Register, Transmit

The DBGDTRTXint characteristics are:

**Purpose**

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communication Channel.

**Configurations**

AArch32 System register DBGDTRTXint[31:0] is architecturally mapped to AArch64 System register DBGDTR_EL0[31:0].

AArch32 System register DBGDTRTXint[31:0] is architecturally mapped to External register DBGDTRTX_EL0[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGDTRTXint is a 32-bit register.

**Field descriptions**

The DBGDTRTXint bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 0</td>
<td>Return DTRTX</td>
</tr>
</tbody>
</table>

Writes to this register:

- If TXfull is set to 1, set DTRTX to UNKNOWN.
- If TXfull is set to 0, update the value in DTRTX.

After the write, TXfull is set to 1.

For the full behavior of the Debug Communications Channel, see Chapter H4 The Debug Communication Channel and Instruction Transfer Register.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing the DBGDTRTXint**

Data can be loaded from memory into this register using LDC (immediate) and LDC (literal).

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MCR}<c><q><\text{coproc}>, \{\text{#}\text{opc1}}, <\text{Rt}>., <\text{CRn}>., <\text{CRm}>, \{\text{#}\text{opc2}}
\]

G8.3.20 DBGOSDLR, Debug OS Double Lock Register

The DBGOSDLR characteristics are:

**Purpose**

Locks out the external debug interface.

**Configurations**

AArch32 System register DBGOSDLR[31:0] is architecturally mapped to AArch64 System register OSDLR_EL1[31:0].

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGOSDLR is a 32-bit register.

**Field descriptions**

The DBGOSDLR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [31:1]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>DLK, bit [0]</td>
<td>OS Double Lock control bit.</td>
</tr>
</tbody>
</table>

When ARMv8.0-DoubleLock is implemented:

- 0b0 OS Double Lock unlocked.
- 0b1 OS Double Lock locked, if DBGPRCR.CORENPDREQ (Core no powerdown request) bit is set to 0 and the PE is in Non-debug state.

On a Warm reset, this field resets to 0.

Otherwise:

- Reserved, RAZ/WI.

**Accessing the DBGOSDLR**

Accesses to this register use the following encodings in the System instruction encoding space:
MRC{c}<q> {coproc}, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

<table>
<thead>
<tr>

G8.3.21 DBGOSECCR, Debug OS Lock Exception Catch Control Register

The DBGOSECCR characteristics are:

**Purpose**

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

**Configurations**

AArch32 System register DBGOSECCR[31:0] is architecturally mapped to AArch64 System register OSECCR_EL1[31:0].

AArch32 System register DBGOSECCR[31:0] is architecturally mapped to External register EDECCR[31:0].

If DBGOSLSR.OSLK == 0 then DBGOSECCR returns an UNKNOWN value on reads and ignores writes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGOSECCR is a 32-bit register.

**Field descriptions**

The DBGOSECCR bit assignments are:

*When DBGOSLSR.OSLK == 1:*

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>EDECCR</td>
</tr>
</tbody>
</table>

EDECCR, bits [31:0]

Used for save/restore to EDECCR over powerdown.

Reads or writes to this field are indirect accesses to EDECCR.

**Accessing the DBGOSECCR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRC{\langle c\rangle}{\langle q\rangle} <coproc>, {\#}<opc1>, <Rt>, <CRn>, <CRm>{, {\#}<opc2>} \]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1110</td>
<td>0b000</td>
<td>0b0000</td>
<td>0b0110</td>
<td>0b010</td>
</tr>
</tbody>
</table>

If PSTATE_EL == EL0 then UNDEFINED;

elsif PSTATE_EL == EL1 then

if EL2Enabled() && !ELUsingAArch32(EL2) && MDCR_EL2.<TDE,TDA> != '00' then AArch64.AArch32SystemAccessTrap(EL2, 0x05);

elsif EL2Enabled() && ELUsingAArch32(EL2) && HDCR.<TDE,TDA> != '00' then AArch32.TakeHypTrapException(0x05);

elsif HaveEL(EL3) && !ELUsingAArch32(EL3) && MDCR_EL3.TDA == '1' then AArch64.AArch32SystemAccessTrap(EL3, 0x05);

else

Declaring DBGOSECCR as a system register in the System instruction encoding space provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

### G8.3.22 DBGOSLAR, Debug OS Lock Access Register

The DBGOSLAR characteristics are:

#### Purpose
Provides a lock for the debug registers. The OS Lock also disables some debug exceptions and debug events.

#### Configurations
- AArch32 System register DBGOSLAR[31:0] is architecturally mapped to AArch64 System register OSLAR_EL1[31:0].
- AArch32 System register DBGOSLAR[31:0] is architecturally mapped to External register OSLAR_EL1[31:0].
- RW fields in this register reset to architecturally UNKNOWN values.

#### Attributes
DBGOSLAR is a 32-bit register.

#### Field descriptions
The DBGOSLAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>OS Lock Access</td>
<td>0xC5ACCE55</td>
</tr>
<tr>
<td>30-0</td>
<td></td>
<td>0</td>
</tr>
</tbody>
</table>

OS Lock Access, bits [31:0]

OS Lock Access. Writing the value 0xC5ACCE55 to the DBGOSLAR sets the OS lock to 1. Writing any other value sets the OS lock to 0.

Use DBGOSLAR.OSLK to check the current status of the lock.

#### Accessing the DBGOSLAR
Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MCR}\{<c>\}<q>\{\#<opc1>, <Rt>, <CRn>, <CRm>\{, \#<opc2>\}
\]

<table>
<thead>
<tr>

DBGOSLR = R[t];
eelsif PSTATE_EL == EL3 then
  DBGOSLR = R[t];

**G8.3.23 DBGOSLSR, Debug OS Lock Status Register**

The DBGOSLSR characteristics are:

**Purpose**

Provides status information for the OS Lock.

**Configurations**

AArch32 System register DBGOSLSR[31:0] is architecturally mapped to AArch64 System register OSLR_EL1[31:0].

The OS Lock status is also visible in the external debug interface through EDPRSR.

This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGOSLSR is a 32-bit register.

**Field descriptions**

The DBGOSLSR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>OSLM[1]</td>
<td>OSLK</td>
<td>nTT</td>
<td>OSLM[0]</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:4]**

Reserved, RES0.

**OSLM[1], bit [3]**

This field is bit[1] of OSLM[1:0].

OS lock model implemented. Identifies the form of OS save and restore mechanism implemented.

- 0b00: OS Lock not implemented.
- 0b10: OS Lock implemented.

All other values are reserved. In an Armv8 implementation the value 0b00 is not permitted.

The OSLM field is split as follows:

- OSLM[1] is DBGOSLSR[3].
- OSLM[0] is DBGOSLSR[0].

**nTT, bit [2]**

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

**OSLK, bit [1]**

OS Lock Status. The possible values are:

- 0b0: OS Lock unlocked.
0b1  OS Lock locked.
The OS Lock is locked and unlocked by writing to the OS Lock Access Register.
On a Cold reset, this field resets to 1.

OSLM[0], bit [0]
This field is bit[0] of OSLM[1:0].
See OSLM[1] for the field description.

Accessing the DBGOSLSR

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{c\}\{q\} <\text{coproc}>\{\#<\text{opc1}>\}, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>\{\#<\text{opc2}>\}
\]

<table>
<thead>
<tr>

elsf
    return DBGOSLSR;
elsf PSTATE.EL == EL3 then
  return DBGOSLSR;
### 8.3.24 DBGPRCR, Debug Power Control Register

The DBGPRCR characteristics are:

**Purpose**

Controls behavior of the PE on powerdown request.

**Configurations**

AArch32 System register DBGPRCR[31:0] is architecturally mapped to AArch64 System register DBGPRCR_EL1[31:0].

Bit [0] of this register is mapped to EDPRCR.CORENPDRQ, bit [0] of the external view of this register.

The other bits in these registers are not mapped to each other.

This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGPRCR is a 32-bit register.

**Field descriptions**

The DBGPRCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>30</td>
<td>CORENPDRQ, bit [0]</td>
</tr>
<tr>
<td></td>
<td>Core no powerdown request. Requests emulation of powerdown.</td>
</tr>
<tr>
<td></td>
<td>This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.</td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>If the system responds to a powerdown request, it powers down Core power domain.</td>
</tr>
<tr>
<td>1</td>
<td>If the system responds to a powerdown request, it does not power down the Core power domain, but instead emulates a powerdown of that domain.</td>
</tr>
<tr>
<td></td>
<td>In an implementation that includes the recommended external debug interface, this bit drives the DBGNOPWRDWN signal.</td>
</tr>
<tr>
<td></td>
<td>It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see Core power domain power states on page H6-6522.</td>
</tr>
</tbody>
</table>

**Note**

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.
On a Cold reset, this field resets to the value in EDPRCR.COREPURQ.

**Accessing the DBGPRCR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MRC}\{c\}\{q\} \text{ <coproc>, \{#\}<opc1>, <Rt>, <CRn>, <CRm>\{, \{#\}<opc2>\} } \]

<table>

G8.3.25 DBGVC, Debug Vector Catch Register

The DBGVC characteristics are:

**Purpose**

Controls Vector Catch debug events.

**Configurations**

AArch32 System register DBGVC[31:0] is architecturally mapped to AArch64 System register DBGVC32_EL2[31:0].

This register is required in all implementations.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DBGVC is a 32-bit register.

**Field descriptions**

The DBGVC bit assignments are:

*When HaveEL(EL3) and ELUsingAArch32(EL3):*

```
  31 30 29 28 27 26 25 24  16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
```

**NSF, bit [31]**

FIQ vector catch enable in Non-secure state.

The exception vector offset is 0x1C.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**NSI, bit [30]**

IRQ vector catch enable in Non-secure state.

The exception vector offset is 0x18.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [29]**

Reserved, RES0.

**NSD, bit [28]**

Data Abort vector catch enable in Non-secure state.

The exception vector offset is 0x10.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**NSP, bit [27]**

Prefetch Abort vector catch enable in Non-secure state.
The exception vector offset is 0x0C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**NSS, bit [26]**

Supervisor Call (SVC) vector catch enable in Non-secure state.
The exception vector offset is 0x08.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**NSU, bit [25]**

Undefined Instruction vector catch enable in Non-secure state.
The exception vector offset is 0x04.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [24:16]**

Reserved, RES0.

**MF, bit [15]**

FIQ vector catch enable in Monitor mode.
The exception vector offset is 0x1C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**MI, bit [14]**

IRQ vector catch enable in Monitor mode.
The exception vector offset is 0x18.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bit [13]**

Reserved, RES0.

**MD, bit [12]**

Data Abort vector catch enable in Monitor mode.
The exception vector offset is 0x10.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**MP, bit [11]**

Prefetch Abort vector catch enable in Monitor mode.
The exception vector offset is 0x0C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**MS, bit [10]**

Secure Monitor Call (SMC) vector catch enable in Monitor mode.
The exception vector offset is 0x08.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

**Bits [9:8]**

Reserved, RES0.

**SF, bit [7]**

FIQ vector catch enable in Secure state.
The exception vector offset is 0x1C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

SI, bit [6]
IRQ vector catch enable in Secure state.
The exception vector offset is 0x18.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]
Reserved, RES0.

SD, bit [4]
Data Abort vector catch enable in Secure state.
The exception vector offset is 0x10.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

SP, bit [3]
Prefetch Abort vector catch enable in Secure state.
The exception vector offset is 0x0C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

SS, bit [2]
Supervisor Call (SVC) vector catch enable in Secure state.
The exception vector offset is 0x08.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

SU, bit [1]
Undefined Instruction vector catch enable in Secure state.
The exception vector offset is 0x04.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]
Reserved, RES0.

When HaveEL(EL3) and !ELUsingAArch32(EL3):

NSF, bit [31]
FIQ vector catch enable in Non-secure state.
The exception vector offset is 0x1C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSI, bit [30]
IRQ vector catch enable in Non-secure state.
The exception vector offset is 0x18.
On a Warm reset, this field resets to an architecturally UNKNOWN value.
Bit [29]
Reserved, RES0.

NSD, bit [28]
Data Abort vector catch enable in Non-secure state.
The exception vector offset is 0x10.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSP, bit [27]
Prefetch Abort vector catch enable in Non-secure state.
The exception vector offset is 0x0C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSS, bit [26]
Supervisor Call (SVC) vector catch enable in Non-secure state.
The exception vector offset is 0x08.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSU, bit [25]
Undefined Instruction vector catch enable in Non-secure state.
The exception vector offset is 0x04.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [24:8]
Reserved, RES0.

SF, bit [7]
FIQ vector catch enable in Secure state.
The exception vector offset is 0x1C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

SI, bit [6]
IRQ vector catch enable in Secure state.
The exception vector offset is 0x18.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]
Reserved, RES0.

SD, bit [4]
Data Abort vector catch enable in Secure state.
The exception vector offset is 0x10.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

SP, bit [3]
Prefetch Abort vector catch enable in Secure state.
The exception vector offset is 0x0C.
On a Warm reset, this field resets to an architecturally UNKNOWN value.

SS, bit [2]
Supervisor Call (SVC) vector catch enable in Secure state.
The exception vector offset is 0x08.
On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**SU, bit [1]**

Undefined Instruction vector catch enable in Secure state.
The exception vector offset is 0x04.
On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Bit [0]**

Reserved, **RES0**.

*When !HaveEL(EL3):*

**Bits [31:8]**

Reserved, **RES0**.

**F, bit [7]**

FIQ vector catch enable.
The exception vector offset is 0x1C.
On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**I, bit [6]**

IRQ vector catch enable.
The exception vector offset is 0x18.
On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**Bit [5]**

Reserved, **RES0**.

**D, bit [4]**

Data Abort vector catch enable.
The exception vector offset is 0x10.
On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**P, bit [3]**

Prefetch Abort vector catch enable.
The exception vector offset 0x0c.
On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**S, bit [2]**

Supervisor Call (SVC) vector catch enable.
The exception vector offset is 0x08.
On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

**U, bit [1]**

Undefined Instruction vector catch enable.
The exception vector offset is 0x04.
On a Warm reset, this field resets to an architecturally **UNKNOWN** value.
Bit [0]

Reserved, RES0.

G8.3.26  **DBGWCR<n>, Debug Watchpoint Control Registers, n = 0 - 15**

The DBGWCR<n> characteristics are:

**Purpose**

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>.

**Configurations**

AArch32 System register DBGWCR<n>[31:0] is architecturally mapped to AArch64 System register DBGWCR<n>_EL1[31:0].

AArch32 System register DBGWCR<n>[31:0] is architecturally mapped to External register DBGWCR<n>_EL1[31:0].

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGWCR<n> is a 32-bit register.

**Field descriptions**

The DBGWCR<n> bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-29</td>
<td>RESERVED, RES0</td>
</tr>
<tr>
<td>28-24</td>
<td>ADDRESS MASK</td>
</tr>
<tr>
<td>23-21</td>
<td>RESERVED, RES0</td>
</tr>
<tr>
<td>19-16</td>
<td>LINE INDEX (LBN)</td>
</tr>
<tr>
<td>15-14</td>
<td>SCALAR CONTEXT (SSC)</td>
</tr>
<tr>
<td>13</td>
<td>BASE ADDRESS (BAS)</td>
</tr>
<tr>
<td>12-5</td>
<td>LOGICAL SCALAR CONTEXT (LSC)</td>
</tr>
<tr>
<td>4-3</td>
<td>PHYSICAL ADDRESS CONTEXT (PAC)</td>
</tr>
<tr>
<td>0</td>
<td>ENABLE (E)</td>
</tr>
</tbody>
</table>

When the E field is zero, all the other fields in the register are ignored.

**Bits [31:29]**

Reserved, RES0.

**MASK, bits [28:24]**

Address mask. Only objects up to 2GB can be watched using a single mask.

- 0b00000  No mask.
- 0b00001  Reserved.
- 0b00010  Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from 0b00000001 masking 3 address bits (0x00000007 mask for address) to 0b111111 masking 31 address bits (0xFFFFFFFF mask for address).

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Bits [23:21]**

Reserved, RES0.
WT, bit [20]

Watchpoint type. Possible values are:

- 0b0: Unlinked data address match.
- 0b1: Linked data address match.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

For more information, see *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page G2-5383, and *Reserved DBGCR<n>.{SSC, HMC, PMC} values* on page G2-5395.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see *Execution conditions for which a watchpoint generates Watchpoint exceptions* on page G2-5401.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n> is being watched.

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0bxxxxxx1</td>
<td>Match byte at DBGWVR&lt;n&gt;</td>
</tr>
<tr>
<td>0bxxxxxxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+1</td>
</tr>
<tr>
<td>0bxxxxxx1x</td>
<td>Match byte at DBGWVR&lt;n&gt;+2</td>
</tr>
<tr>
<td>0bxxxx1xxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+3</td>
</tr>
</tbody>
</table>

In cases where DBGWVR<n> addresses a double-word:

<table>
<thead>
<tr>
<th>BAS</th>
<th>Description, if DBGWVR&lt;n&gt;[2] == 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0bxxxx1xxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+4</td>
</tr>
<tr>
<td>0bxxxx1xxxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+5</td>
</tr>
<tr>
<td>0bx1xxxxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+6</td>
</tr>
<tr>
<td>0b1xxxxxxx</td>
<td>Match byte at DBGWVR&lt;n&gt;+7</td>
</tr>
</tbody>
</table>

The valid values for BAS are non-zero binary numbers all of whose set bits are contiguous. All other values are reserved and must not be used by software. See Reserved DBGWCR<n>.BAS values IS on page G2-5409.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**LSC, bits [4:3]**

Load/store control. This field enables watchpoint matching on the type of access being made.

Possible values of this field are:

- **0b01**: Match instructions that load from a watchpointed address.
- **0b10**: Match instructions that store to a watchpointed address.
- **0b11**: Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**PAC, bits [2:1]**

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see Execution conditions for which a watchpoint generates Watchpoint exceptions IS on page G2-5401.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**E, bit [0]**

Enable watchpoint n. Possible values are:

- **0b0**: Watchpoint disabled.
- **0b1**: Watchpoint enabled.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Accessing the DBGWCR<n>**

Accesses to this register use the following encodings in the System instruction encoding space:

```
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

<table>

G8.3.28  **DBGWVR<n>, Debug Watchpoint Value Registers, n = 0 - 15**  

The DBGWVR<n> characteristics are:

**Purpose**

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>.

**Configurations**

AArch32 System register DBGWVR<n>[31:0] is architecturally mapped to AArch64 System register DBGWVR<n>_EL1[31:0].

AArch32 System register DBGWVR<n>[31:0] is architecturally mapped to External register DBGWVR<n>_EL1[31:0].

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

**Attributes**

DBGWVR<n> is a 32-bit register.

**Field descriptions**

The DBGWVR<n> bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>VA</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**VA, bits [31:2]**

- Bits[31:2] of the address value for comparison.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

**Bits [1:0]**

Reserved, RES0.

**Accessing the DBGWVR<n>**

Accesses to this register use the following encodings in the System instruction encoding space:

G8.3.29   DLR, Debug Link Register

The DLR characteristics are:

Purpose

In Debug state, holds the address to restart from.

Configurations

AArch32 System register DLR[31:0] is architecturally mapped to AArch64 System register DLR_EL0[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DLR is a 32-bit register.

Field descriptions

The DLR bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>Restart address</td>
</tr>
</tbody>
</table>

Accessing the DLR

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}{<q>}, \{#\}<opc1>, <Rt>, <CRn>, <CRm>, \{#\}<opc2> \\
\]

G8.3.30 DSPSR, Debug Saved Program Status Register

The DSPSR characteristics are:

**Purpose**

Holds the saved process state for Debug state. On entering Debug state, PSTATE information is written to this register. On exiting Debug state, values are copied from this register to PSTATE.

**Configurations**

AArch32 System register DSPSR[31:0] is architecturally mapped to AArch64 System register DSPSR_EL0[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DSPSR is a 32-bit register.

**Field descriptions**

The DSPSR bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| N  | Z  | C  | V  | Q  | SS | IL | GE | IT[7:2] | E | A | I | F | T | M[4:0] |

**N, bit [31]**

Negative Condition flag. Set to the value of PSTATE.N on entering Debug state, and copied to PSTATE.N on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

**Z, bit [30]**

Zero Condition flag. Set to the value of PSTATE.Z on entering Debug state, and copied to PSTATE.Z on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

**C, bit [29]**

Carry Condition flag. Set to the value of PSTATE.C on entering Debug state, and copied to PSTATE.C on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

**V, bit [28]**

Overflow Condition flag. Set to the value of PSTATE.V on entering Debug state, and copied to PSTATE.V on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

**Q, bit [27]**

Overflow or saturation flag. Set to the value of PSTATE.Q on entering Debug state, and copied to PSTATE.Q on exiting Debug state.

This field resets to an architecturally UNKNOWN value.
IT[1:0], bits [26:25]
If-Then. Set to the value of PSTATE.IT[1:0] on entering Debug state, and copied to PSTATE.IT[1:0] on exiting Debug state.
On exiting Debug state DSPSR.IT must contain a value that is valid for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

DIT, bit [24]
When ARMv8.4-DIT is implemented:
Data Independent Timing. Set to the value of PSTATE.DIT on entering Debug state, and copied to PSTATE.DIT on exiting Debug state.
This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

Bit [23]
Reserved, RES0.

PAN, bit [22]
When ARMv8.1-PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on entering Debug state, and copied to PSTATE.PAN on exiting Debug state.
This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

SS, bit [21]
Software Step. Set to the value of PSTATE.SS on entering Debug state, and conditionally copied to PSTATE.SS on exiting Debug state.
This field resets to an architecturally UNKNOWN value.

IL, bit [20]
Illegal Execution state. Set to the value of PSTATE.IL on entering Debug state, and copied to PSTATE.IL on exiting Debug state.
This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]
Greater than or Equal flags. Set to the value of PSTATE.GE on entering Debug state, and copied to PSTATE.GE on exiting Debug state.
This field resets to an architecturally UNKNOWN value.

IT[7:2], bits [15:10]
If-Then. Set to the value of PSTATE.IT[7:2] on entering Debug state, and copied to PSTATE.IT[7:2] on exiting Debug state.
DSPSR.IT must contain a value that is valid for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

E, bit [9]
Endianness. Set to the value of PSTATE.E on entering Debug state, and copied to PSTATE.E on exiting Debug state.
If the implementation does not support big-endian operation, DSPSR.E is RES0. If the implementation does not support little-endian operation, DSPSR.E is RES1. On exiting Debug state, if the implementation does not support big-endian operation at the Exception level being returned to, DSPSR.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, DSPSR.E is RES1.

This field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on entering Debug state, and copied to PSTATE.A on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on entering Debug state, and copied to PSTATE.I on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on entering Debug state, and copied to PSTATE.F on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on entering Debug state, and copied to PSTATE.T on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]

Mode. Set to the value of PSTATE.M[4:0] on entering Debug state, and copied to PSTATE.M[4:0] on exiting Debug state.

- 0b10000 User.
- 0b10001 FIQ.
- 0b10010 IRQ.
- 0b10011 Supervisor.
- 0b10100 Monitor.
- 0b10101 Abort.
- 0b11010 Hyp.
- 0b11011 Undefined.
- 0b11111 System.

Other values are reserved. If DSPSR.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, exiting Debug state is an illegal return event, as described in Illegal return events from AArch32 state on page G1-5270.

This field resets to an architecturally UNKNOWN value.

Accessing the DSPSR

Accesses to this register use the following encodings in the System instruction encoding space:
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

if !Halted() then
  UNDEFINED;
else
  return DSPSR;

MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

if !Halted() then
  UNDEFINED;
else
  DSPSR = R[t];
G8.3.31 HDCR, Hyp Debug Control Register

The HDCR characteristics are:

**Purpose**

Controls the trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to functions provided by the debug and trace architectures and the Performance Monitors Extension.

**Configurations**

AArch32 System register HDCR[31:0] is architecturally mapped to AArch64 System register MDCR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3, and other than for a direct read of the register, the PE behaves as if HDCR.HPMN == PMCR.N.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HDCR is a 32-bit register.

**Field descriptions**

The HDCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>20</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>19</td>
<td>TTRF, bit [19]</td>
</tr>
<tr>
<td>18</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>17</td>
<td>HPMD</td>
</tr>
<tr>
<td>16</td>
<td>HPMN</td>
</tr>
<tr>
<td>15</td>
<td>TPMCR</td>
</tr>
<tr>
<td>14</td>
<td>TPM</td>
</tr>
<tr>
<td>13</td>
<td>HPME</td>

</tr>
<tr>
<td>10</td>
<td>TDOSA</td>
</tr>
<tr>
<td>9</td>
<td>TDRA</td>
</tr>
</tbody>
</table>

**Bits [31:20]**

Reserved, RES0.

**TTRF, bit [19]**

*When ARMv8.4-Trace is implemented:*

Traps use of the Trace Filter Control registers at EL1 to EL2.

- **0**: Accesses to TRFCR at EL1 are not affected by this control bit.
- **1**: Accesses to TRFCR at EL1 generate a Hyp Trap exception.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

**Otherwise:**

Reserved, RES0.

**Bit [18]**

Reserved, RES0.
HPMD, bit [17]

When ARMv8.1-PMU is implemented:

Guest Performance Monitors Disable. This control prohibits event counting at EL2.

0b0  Event counting allowed in Hyp mode.
0b1  Event counting prohibited in Hyp mode.

In an Armv8.1 implementation, event counting is prohibited unless enabled by the IMPLEMENTATION DEFINED authentication interface ExternalSecureNoninvasiveDebugEnabled().

This control applies only to:

- The event counters in the range [0:(HDCR.HPMN-1)].
- If PMCR.DP is set to 1, PMCCNTR.

The other event counters are unaffected. When PMCR.DP is set to 0, PMCCNTR is unaffected.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

Otherwise:

Reserved, RES0.

Bits [16:12]

Reserved, RES0.

TDRA, bit [11]

Trap Debug ROM Address register access. Traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to Hyp mode.

0b0  This control does not cause any instructions to be trapped.
0b1  Non-secure EL0 and EL1 System register accesses to the DBGDRAR or DBGDSAR are trapped to Hyp mode, unless it is trapped by DBGDSCRext.UDCCdis.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

TDOSA, bit [10]

When ARMv8.0-DoubleLock is implemented:

Trap debug OS-related register access. Traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode.

0b0  This control does not cause any instructions to be trapped.
0b1  Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.

The registers for which accesses are trapped are as follows:

- DBGOSLSR, DBGOSLR, DBGOSDLR, and DBGPRCR.
- Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

Note

These registers are not accessible at EL0.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.
Otherwise:

Trap debug OS-related register access. Traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode.

- \(0b0\) This control does not cause any instructions to be trapped.
- \(0b1\) Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.

The registers for which accesses are trapped are as follows:
- \(\text{DBGOSLSR, DBGOSLAR, and DBGPRCR.}\)
- Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

It is IMPLEMENTATION DEFINED whether accesses to \(\text{DBGOSDLR}\) are trapped.

--- Note

These registers are not accessible at EL0.

If \(\text{HCR.TGE}\) or \(\text{HDCR.TDE}\) is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

TDA, bit [9]

Trap debug access. Traps Non-secure EL0 and EL1 System register accesses to those debug System registers in the \(\text{coproc==0b1110}\) encoding space that are not trapped by either of the following:
- \(\text{HDCR.TDRA.}\)
- \(\text{HDCR.TDOSA.}\)

- \(0b0\) This control does not cause any instructions to be trapped.
- \(0b1\) Non-secure EL0 or EL1 System register accesses to the debug registers, other than the registers trapped by HDCR.TDRA and HDCR.TDOSA, are trapped to Hyp mode, unless it is trapped by \(\text{DBGDSCRx}.\text{UDCCdis.}\)

Traps of AArch32 accesses to \(\text{DBGDTRRXint}\) and \(\text{DBGDTRTXint}\) are ignored in Debug state.

If \(\text{HCR.TGE}\) or \(\text{HDCR.TDE}\) is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

TDE, bit [8]

Trap Debug exceptions. The possible values of this bit are:

- \(0b0\) This control has no effect on the routing of debug exceptions, and has no effect on Non-secure accesses to debug registers.
- \(0b1\) Debug exceptions generated at EL1 or EL0 are routed to EL2 when enabled in the current Security state. The \(\text{HDCR.\{TDRA, TDOSA, TDA\}}\) fields are treated as being 1 for all purposes other than returning the result of a direct read of the register.

When \(\text{HCR.TGE == 1}\), the PE behaves as if the value of this field is 1 for all purposes other than returning the value of a direct read of the register.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

HPME, bit [7]

When PMUv3 is implemented:

\[\text{HDCR.HPMN:(N-1)}\] event counters enable.

- \(0b0\) Event counters in the range \[\text{HDCR.HPMN:(PMCR.N-1)}\] are disabled.
- \(0b1\) Event counters in the range \[\text{HDCR.HPMN:(PMCR.N-1)}\] are enabled by \(\text{PMCINTENSE.}\)
If HDCR.HPMN is less than PMCR.N, the event counters in the range [HDCR.HPMN:(PMCR.N-1)], are enabled and disabled by this bit. Otherwise this bit has no effect on the operation of the event counters.

--- Note ---
The effect of HDCR.HPMN on the operation of this bit applies regardless of whether EL2 is enabled in the current Security state.
---

For more information see the description of the HPMN field.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

TPM, bit [6]

When PMUv3 is implemented:
Trap Performance Monitors accesses. Traps Non-secure EL0 and EL1 accesses to all Performance Monitors registers to Hyp mode.

0b0    This control does not cause any instructions to be trapped.
0b1    Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to Hyp mode.

--- Note ---
EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.
---

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

Otherwise:
Reserved, RES0.

TPMCR, bit [5]

When PMUv3 is implemented:
Trap PMCR accesses. Traps Non-secure EL0 and EL1 accesses to the PMCR to Hyp mode.

0b0    This control does not cause any instructions to be trapped.
0b1    Non-secure EL0 and EL1 accesses to the PMCR are trapped to Hyp mode, unless it is trapped by PMUSERENR.EN.

--- Note ---
EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.
---

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

Otherwise:
Reserved, RES0.

HPMN, bits [4:0]

When PMUv3 is implemented:
Defines the number of event counters that are accessible from Non-secure EL1 modes, and from Non-secure EL0 modes if unprivileged access is enabled.

If HPMN is less than PMCR.N, HPMN divides the event counters into two ranges, [0:(HPMN-1)] and [HPMN:(PMCR.N-1)].
For an event counter in the range \( [0:\text{HPMN}-1] \):

- The counter is accessible from EL1 and EL2, and from EL0 if unprivileged access to the
counters is enabled.

- \text{PMCR.E} enables the operation of counters in this range.

\[ \text{Note} \]

If \text{HPMN} is equal to \text{PMCR.N}, this applies to all event counters.

If \text{HPMN} is less than \text{PMCR.N}, for an event counter in the range \( [\text{HPMN}:(\text{PMCR.N}-1)] \):

- The counter is accessible only from EL2 and from Secure state.

- \text{HDCR.HPME} enables the operation of counters in this range.

If this field is set to 0, or to a value larger than \text{PMCR.N}, then the following constrained
unpredictable behavior applies:

- The value returned by a direct read of \text{HDCR.HPMN} is \text{UNKNOWN}.

- Either:
  - An \text{UNKNOWN} number of counters are reserved for EL2 use. That is, the PE behaves
    as if \text{HDCR.HPMN} is set to an \text{UNKNOWN} non-zero value less than or equal to
    \text{PMCR.N}.
  - All counters are reserved for EL2 use, meaning no counters are accessible from
    Non-secure EL1 and Non-secure EL0.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to the value in
\text{PMCR.N}.

\[ \text{Otherwise} : \]

Reserved, \text{RES0}.

\[ \text{Accessing the HDCR} \]

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MRC}\{<c>\}\{<q>\} <\text{coproc}> , \{#\}<\text{opc1}> , <\text{Rt}> , <\text{CRn}> , <\text{CRm}>\{, \{#\}<\text{opc2}> \} \]

\[
\begin{array}{ccccccc}
\text{coproc} & \text{opc1} & \text{CRn} & \text{CRm} & \text{opc2} \\
0b1111 & 0b100 & 0b0001 & 0b0001 & 0b001 \\
\end{array}
\]

### G8.3.32 HTRFCR, Hyp Trace Filter Control Register

The HTRFCR characteristics are:

**Purpose**

Provides EL2 controls for Trace.

**Configurations**

AArch32 System register HTRFCR[31:0] is architecturally mapped to AArch64 System register TRFCR_EL2[31:0].

This register is present only when ARMv8.4-Trace is implemented. Otherwise, direct accesses to HTRFCR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from Monitor mode when SCR.NS == 1.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE reset into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

HTRFCR is a 32-bit register.

**Field descriptions**

The HTRFCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>

</tbody>
</table>

**CX, bit [3]**

VMID Trace Enable.

0b0 VMID tracing is not allowed.
VMID tracing is allowed.
When SelfHostedTraceEnabled() == FALSE, this field is ignored.
On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

**Bit [2]**
Reserved, RES0.

**E2TRE, bit [1]**
EL2 Trace Enable.

0b0 Tracing is prohibited at EL2.
0b1 Tracing is allowed at EL2.

When SelfHostedTraceEnabled() == FALSE, this field is ignored.
On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

**E0HTRE, bit [0]**
EL0 Trace Enable.

0b0 Tracing is prohibited at EL0 when HCR.TGE == 1.
0b1 Tracing is allowed at EL0 when HCR.TGE == 1.

This field is ignored if any of the following are true:
- The PE is in Secure state.
- SelfHostedTraceEnabled() == FALSE.
- HCR.TGE == 0.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

### Accessing the HTRFCR

    UNDEFINED;  

G8.3.33  PMMIR, Performance Monitors Machine Identification Register

The PMMIR characteristics are:

Purpose

Describes Performance Monitors parameters specific to the implementation to software.

Configurations

This register is present only when ARMv8.4-PMU is implemented. Otherwise, direct accesses to PMMIR are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMMIR is a 32-bit register.

Field descriptions

The PMMIR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>8</td>
<td>SLOTS</td>
</tr>
<tr>
<td>7-0</td>
<td>Operation width. The largest value by which the STALL_SLOT event might increment by in a single cycle. If the STALL_SLOT event is not implemented, this field might read as zero.</td>
</tr>
</tbody>
</table>

Accessing the PMMIR

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}{<q>} <\text{coproc}, \{#\}<\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>\{, \{#\}<\text{opc2}\}}

G8.3.34 SDCR, Secure Debug Control Register

The SDCR characteristics are:

**Purpose**

Provides EL3 configuration options for self-hosted debug, trace, and the Performance Monitors Extension.

**Configurations**

AArch32 System register SDCR[31:0] can be mapped to AArch64 System register MDCR_EL3[31:0], but this is not architecturally mandated.

Some or all RW fields of this register have defined reset values. These apply whenever the register is accessible. This means they apply when the PE resets into EL3 using AArch32.

**Attributes**

SDCR is a 32-bit register.

**Field descriptions**

The SDCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>22</td>
<td>EPMAD, bit [21]</td>
</tr>
<tr>
<td>21</td>
<td>EDAD</td>
</tr>
<tr>
<td>20</td>
<td>TTRF</td>
</tr>
<tr>
<td>19</td>
<td>STE</td>
</tr>
<tr>
<td>18</td>
<td>SPME</td>
</tr>
<tr>
<td>17</td>
<td>RES0</td>
</tr>
<tr>
<td>16</td>
<td>SPD</td>
</tr>
<tr>
<td>15</td>
<td>RES0</td>
</tr>
</tbody>
</table>

**Bits [31:22]**

Reserved, RES0.

**EPMAD, bit [21]**

*When ARMv8.4-Debug is implemented and PMUv3 is implemented:*

External debug interface Performance Monitors registers disable. This controls Non-secure access to Performance Monitors registers by an external debugger.

- **0b0**: Non-secure access to the Performance Monitors registers from an external debugger is permitted.
- **0b1**: Non-secure access to the Performance Monitors registers from an external debugger is not permitted.

If the Performance Monitors Extension does not support external debug interface accesses this bit is RES0.

In a system where the PE resets into EL3, this field resets to 0.

*When PMUv3 is implemented:*

External debug interface Performance Monitors registers disable. This controls access to Performance Monitors registers by an external debugger.

- **0b0**: Access to Performance Monitors registers from an external debugger is permitted.
- **0b1**: Access to Performance Monitors registers from an external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.
If the Performance Monitors Extension does not support external debug interface accesses this bit is RES0.

In a system where the PE resets into EL3, this field resets to 0.

**Otherwise:**
Reserved, RES0.

**EDAD, bit [20]**

*When ARMv8.4-Debug is implemented:*
External debug register Non-secure access disable. Controls access to debug registers by an external debugger.

0b0 Non-secure access to debug registers from an external debugger is permitted.

0b1 Non-secure access to breakpoint registers, watchpoint registers, and OSLAR_EL1 from an external debugger is not permitted.

In a system where the PE resets into EL3, this field resets to 0.

*When ARMv8.2-Debug is implemented:*
External debug access disable. This disables access to debug registers by an external debugger.

0b0 Access to debug registers from an external debugger is permitted.

0b1 Access to breakpoint registers, watchpoint registers and OSLAR_EL1 from an external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

In a system where the PE resets into EL3, this field resets to 0.

**Otherwise:**
External debug access disable. This disables access to debug registers by an external debugger.

0b0 Access to debug registers from an external debugger is permitted.

0b1 Access to breakpoint registers and watchpoint registers from an external debugger is not permitted, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

It is IMPLEMENTATION DEFINED whether access to the OSLAR_EL1 register from an external debugger is also not permitted.

In a system where the PE resets into EL3, this field resets to 0.

**TTRF, bit [19]**

*When ARMv8.4-Trace is implemented:*
Trap Trace Filter controls. Controls whether accesses at EL2 and EL1 to the trace filter control registers are trapped to EL3.

0b0 Accesses to HTRFCR and TRFCR registers are not affected by this control bit.

0b1 When not in Monitor mode, accesses to HTRFCR and TRFCR registers generate a Monitor trap exception.

In a system where the PE resets into EL3, this field resets to 0.

**Otherwise:**
Reserved, RES0.

**STE, bit [18]**

*When ARMv8.4-Trace is implemented:*
Secure Trace Enable. This bit enables tracing in Secure state and controls the level of authentication required by an external debugger to enable external tracing.

0b0 Trace is prohibited in Secure state unless overridden by the IMPLEMENTATION DEFINED authentication interface.

0b1 Trace is allowed in Secure state unless prohibited by the Trace Filter control registers.

If EL3 is not implemented and the PE executes in Secure state, the PE behaves as if this bit is set to 1.
In a system where the PE resets into EL3, this field resets to 0.

**Otherwise:**
Reserved, RES0.

**SPME, bit [17]**

*When ARMv8.2-Debug is implemented and PMUv3 is implemented:*

Secure Performance Monitors enable. This allows event counting in Secure state.

- **0b0** Event counting prohibited in Secure state.
- **0b1** Event counting allowed in Secure state.

If EL3 is not implemented and the PE is executing in Secure state, then the *Effective value* of this bit is 0b1.

In a system where the PE resets into EL3, this field resets to 0.

*When PMUv3 is implemented:*

Secure Performance Monitors enable. This allows event counting in Secure state.

- **0b0** Event counting prohibited in Secure state, unless ExternalSecureNoninvasiveDebugEnabled() is TRUE.
- **0b1** Event counting allowed in Secure state.

If EL3 is not implemented and the PE is executing in Secure state, then the *Effective value* of this bit is 0b1.

In a system where the PE resets into EL3, this field resets to 0.

**Otherwise:**
Reserved, RES0.

**Bit [16]**

Reserved, RES0.

**SPD, bits [15:14]**

AArch32 Secure privileged debug. Enables or disables debug exceptions from Secure state, other than Breakpoint Instruction exceptions. Valid values for this field are:

- **0b00** Legacy mode. Debug exceptions from Secure EL1 are enabled by the authentication interface.
- **0b10** Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.
- **0b11** Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.

Other values are reserved, and have the *CONstrained UNpredictable* behavior that they must have the same behavior as 0b00. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.

Otherwise, debug exceptions from Secure EL0 are enabled only if SDER32_EL3.SUIDEN == 1.

If EL3 is using AArch32, SDCR.SPD controls debug exceptions from EL3 and not from Secure EL1, as there is no Secure EL1.

Ignored in Non-secure state. Debug exceptions from Breakpoint Instruction exceptions are always enabled.

In a system where the PE resets into EL3, this field resets to 0.

**Bits [13:0]**

Reserved, RES0.

G8.3.35  SDER, Secure Debug Enable Register

The SDER characteristics are:

Purpose

Controls invasive and non-invasive debug in the Secure EL0 mode.

Configurations

AArch32 System register SDER[31:0] is architecturally mapped to AArch64 System register
SDER32_EL3[31:0].

If EL3 is not implemented and EL1 supports AArch32, SDER is implemented only if the
implemented Security state is Secure state.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset
values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is
using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to
architecturally UNKNOWN values.

Attributes

SDER is a 32-bit register.

Field descriptions

The SDER bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>SUIDEN</td>
</tr>
<tr>
<td>0</td>
<td>SUNIDEN</td>
</tr>
</tbody>
</table>

Bits [31:2]

Reserved, RES0.

SUNIDEN, bit [1]

Secure User Non-Invasive Debug Enable:

0b0  Performance Monitors event counting prohibited in Secure EL0 unless allowed by
AArc64-MDCR_EL3.SPME, SDCR.SPME.
In an Armv8.0 or Armv8.1 implementation, event counting can also be allowed using
the IMPLEMENTATION DEFINED authentication interface
ExternalSecureNoninvasiveDebugEnabled().

0b1  Performance Monitors event counting allowed in Secure EL0.
On a Warm reset, this field resets to 0.

SUIDEN, bit [0]

Secure User Invasive Debug Enable:

0b0  Debug exceptions other than Breakpoint Instruction exceptions from Secure EL0 are
disabled, unless enabled by MDCR_EL3.SPD32 or SDCR.SPD.

0b1  Debug exceptions from Secure EL0 are enabled.
On a Warm reset, this field resets to 0.
Accessing the SDER

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MRC}(<c>){<q>} \langle \#\rangle<\text{coproc}>, <\#\rangle<\text{opc}_1>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>, \langle \#\rangle<\text{opc}_2> \]

G8.3.36   TRFCR, Trace Filter Control Register

The TRFCR characteristics are:

Purpose

Provides EL1 controls for Trace.

Configurations

AArch32 System register TRFCR[31:0] is architecturally mapped to AArch64 System register TRFCR_EL1[31:0].

This register is present only when ARMv8.4-Trace is implemented. Otherwise, direct accesses to TRFCR are UNDEFINED.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TRFCR is a 32-bit register.

Field descriptions

The TRFCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:7</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>6:5</td>
<td>Timestamp Control. Controls which timebase is used for trace timestamps.</td>
</tr>
<tr>
<td>01</td>
<td>Virtual timestamp. The traced timestamp is the physical counter value minus the value of CNTVOFF.</td>
</tr>
<tr>
<td>11</td>
<td>Physical timestamp. The traced timestamp is the physical counter value.</td>
</tr>
<tr>
<td>2:0</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

TS, bits [6:5]

Timestamp Control. Controls which timebase is used for trace timestamps.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Virtual timestamp. The traced timestamp is the physical counter value minus the value of CNTVOFF.</td>
</tr>
<tr>
<td>0b1</td>
<td>Physical timestamp. The traced timestamp is the physical counter value.</td>
</tr>
</tbody>
</table>

All other values are reserved.

This field is ignored if any of the following are true:

- SelfHostedTraceEnabled() == FALSE.
- HTRFCR.TS is not 0b00.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [4:2]

Reserved, RES0.

E1TRE, bit [1]

EL1 Trace Enable.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Tracing is prohibited in PL1 modes.</td>
</tr>
<tr>
<td>1</td>
<td>Tracing is allowed in PL1 modes.</td>
</tr>
</tbody>
</table>
When SelfHostedTraceEnabled() == FALSE, this field is ignored.
On a Warm reset, this field resets to 0.

E0TRE, bit [0]

EL0 Trace Enable.

0b0   Tracing is prohibited at EL0.
0b1   Tracing is allowed at EL0.

This field is ignored if any of the following are true:
• SelfHostedTraceEnabled() == FALSE.
• EL2 is implemented and enabled in the current security state and HCR.TGE == 1.

On a Warm reset, this field resets to 0.

Accessing the TRFCR

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRC\{c\}\{q\} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>} \]

<table>
<thead>
<tr>

G8.4 Performance Monitors registers

This section lists the Performance Monitors registers in AArch32.
G8.4.1   PMCCFILTR, Performance Monitors Cycle Count Filter Register

The PMCCFILTR characteristics are:

**Purpose**

Determines the modes in which the Cycle Counter, PMCCNTR, increments.

**Configurations**

AArch32 System register PMCCFILTR[31:0] is architecturally mapped to AArch64 System register PMCCFILTR_EL0[31:0].

AArch32 System register PMCCFILTR[31:0] is architecturally mapped to External register PMCCFILTR_EL0[31:0].

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMCCFILTR is a 32-bit register.

**Field descriptions**

The PMCCFILTR bit assignments are:

```
 31 30 29 28 27 26  0
 P  U RES0
```

**P, bit [31]**

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0b0  Count cycles in EL1.
- 0b1  Do not count cycles in EL1.

On a Warm reset, this field resets to 0.

**U, bit [30]**

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

- 0b0  Count cycles in EL0.
- 0b1  Do not count cycles in EL0.

On a Warm reset, this field resets to 0.

**NSK, bit [29]**

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

On a Warm reset, this field resets to 0.
NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.
Otherwise, cycles in Non-secure EL0 are not counted.

On a Warm reset, this field resets to 0.

NSH, bit [27]

Non-secure EL2 (Hyp mode) filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0b0 Do not count cycles in EL2.
0b1 Count cycles in EL2.

On a Warm reset, this field resets to 0.

Bits [26:0]

Reserved, RES0.

Accessing the PMCCFILTR

PMCCFILTR can also be accessed by using PMXEVTYPER with PMSELR.SEL set to 0b11111.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC\{<c>\}{<q>} <coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm>\}, \{#<opc2>\}}
\]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b111</td>
<td>0b000</td>
<td>0b1110</td>
<td>0b111</td>
<td>0b111</td>
</tr>
</tbody>

G8.4.2 PMCCNTR, Performance Monitors Cycle Count Register

The PMCCNTR characteristics are:

**Purpose**

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See *Time as measured by the Performance Monitors cycle counter* on page D6-2527 for more information. PMCCFILTR determines the modes and states in which the PMCCNTR can increment.

**Configurations**

AArch32 System register PMCCNTR[63:0] is architecturally mapped to AArch64 System register PMCCNTR_EL0[63:0].

AArch32 System register PMCCNTR[63:0] is architecturally mapped to External register PMCCNTR_EL0[63:0].

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONSTRAINED UNPREDICTABLE whether or not PMCCNTR continues to increment when clocks are stopped by WFI and WFE instructions.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMCCNTR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

**Field descriptions**

The PMCCNTR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:0</td>
<td>CCNT, Cycle count</td>
</tr>
</tbody>
</table>

**CCNT, bits [63:0]**

Cycle count. Depending on the values of PMCR.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR.C sets this field to 0.

This field resets to an architecturally UNKNOWN value.

**Accessing the PMCCNTR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{c\}\{q\} <\text{coproc}>, \{#\}<\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>, \{#\}<\text{opc2}>\
\]

G8.4.3 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range 0x0000 to 0x001F

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

——— Note ————
Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEIDn registers see The PMU event number space and common events on page D6-2545.

Configurations

AArch32 System register PMCEID0[31:0] is architecturally mapped to AArch64 System register PMCEID0_EL0[31:0].

AArch32 System register PMCEID0[31:0] is architecturally mapped to External register PMCEID0[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCEID0 is a 32-bit register.

Field descriptions

The PMCEID0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID&lt;n&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

ID<n>, bit [n], for n = 0 to 31

ID[n] corresponds to common event n.

For each bit:

0b0 The common event is not implemented, or not counted.
0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

——— Note ————
Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

Accessing the PMCEID0

Accesses to this register use the following encodings in the System instruction encoding space:

G8.4.4 PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range 0x0020 to 0x003F.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

Note

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEIDn registers see The PMU event number space and common events on page D6-2545.

Configurations

AArch32 System register PMCEID1[31:0] is architecturally mapped to AArch64 System register PMCEID1_EL0[31:0].

AArch32 System register PMCEID1[31:0] is architecturally mapped to External register PMCEID1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCEID1 is a 32-bit register.

Field descriptions

The PMCEID1 bit assignments are:

<table>
<thead>
<tr>
<th>ID&lt;n&gt;, bit [n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 0</td>
</tr>
</tbody>
</table>

ID<n>, bit [n], for n = 0 to 31

ID[n] corresponds to common event (0x0020 + n).

For each bit:

0b0 The common event is not implemented, or not counted.

0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

Accessing the PMCEID1

Accesses to this register use the following encodings in the System instruction encoding space:
### MRC(<c>){<q>} <coproc>, (#)<opc1>, <Rt>, <CRn>, <CRm>{, (#)<opc2>}

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b111</td>
<td>0b000</td>
<td>0b1001</td>
<td>0b100</td>
<td>0b111</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
  if EL2Enabled() & !ELUsingAArch32(EL2) & HCR_EL2.<E2H,TGE> != '1' then
    AArch64.AArch32SystemAccessTrap(EL2, 0x03);

  else
    AArch64.AArch32SystemAccessTrap(EL1, 0x03);
  end;
G8.4.5 PMCEID2, Performance Monitors Common Event Identification register 2

The PMCEID2 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range 0x4000 to 0x401F.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

Note

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEIDn registers see The PMU event number space and common events on page D6-2545.

Configurations

AArch32 System register PMCEID2[31:0] is architecturally mapped to AArch64 System register PMCEID0_EL0[63:32].

AArch32 System register PMCEID2[31:0] is architecturally mapped to External register PMCEID2[63:32].

This register is present only from ARMv8.1. Otherwise, direct accesses to PMCEID2 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

Attributes

PMCEID2 is a 32-bit register.

Field descriptions

The PMCEID2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDhi&lt;n&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

IDhi<n>, bit [n], for n = 0 to 31

IDhi[n] corresponds to common event (0x4000 + n).

For each bit:

0b0 The common event is not implemented, or not counted.
0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.
### Accessing the PMCEID2

G8.4.6   PMCEID3, Performance Monitors Common Event Identification register 3

The PMCEID3 characteristics are:

**Purpose**

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range 0x4020 to 0x403F.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

--- Note

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

---

For more information about the common events and the use of the PMCEIDn registers see *The PMU event number space and common events on page D6-2545*.

**Configurations**

AArch32 System register PMCEID3[31:0] is architecturally mapped to AArch64 System register PMCEID1_EL0[63:32].

AArch32 System register PMCEID3[31:0] is architecturally mapped to External register PMCEID3[63:32].

This register is present only from ARMv8.1. Otherwise, direct accesses to PMCEID3 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

**Attributes**

PMCEID3 is a 32-bit register.

**Field descriptions**

The PMCEID3 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDhi&lt;n&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

IDhi<n>, bit [n], for n = 0 to 31

IDhi[n] corresponds to common event (0x4020 + n).

For each bit:

- 0b0    The common event is not implemented, or not counted.
- 0b1    The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

--- Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.
Accessing the PMCEID3

G8.4.7 PMCNTENCLR, Performance Monitors Count Enable Clear register

The PMCNTENCLR characteristics are:

Purpose

Disables the Cycle Count Register, PMCCNTR, and any implemented event counters PMEVCNTR<\text{n}>. Reading this register shows which counters are enabled. PMCNTENCLR is used in conjunction with the PMCNTENSE\text{T} register.

Configurations

AArch32 System register PMCNTENCLR[31:0] is architecturally mapped to AArch64 System register PMCNTENCLR_EL0[31:0].

AArch32 System register PMCNTENCLR[31:0] is architecturally mapped to External register PMCNTENCLR_EL0[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCNTENCLR is a 32-bit register.

Field descriptions

The PMCNTENCLR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;\text{n}&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

C, bit [31]

PMCCNTR disable bit. Disables the cycle counter register. Possible values are:

\(0b0\) When read, means the cycle counter is disabled. When written, has no effect.

\(0b1\) When read, means the cycle counter is enabled. When written, disables the cycle counter.

This field resets to an architecturally UNKNOWN value.

P<\text{n}>, bit [n], for \(n = 0 \text{ to } 30\)

Event counter disable bit for PMEVCNTR<\text{n}>.

If \(N\) is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, \(N\) is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, \(N\) is the value in PMCR.N.

\(0b0\) When read, means that PMEVCNTR<\text{n}> is disabled. When written, has no effect.

\(0b1\) When read, means that PMEVCNTR<\text{n}> is enabled. When written, disables PMEVCNTR<\text{n}>.

This field resets to an architecturally UNKNOWN value.

Accessing the PMCNTENCLR

Accesses to this register use the following encodings in the System instruction encoding space:
### MRC(\textless c\textgreater,\textless q\textgreater, \textless\text{coproc}\textgreater, \textless\text{opc1}\textgreater, \textless R_{t}\textgreater, \textless CR_{n}\textgreater, \textless CR_{m}\textgreater, \textless\text{opc2}\textgreater)

### G8.4.8 PMCNTENSET, Performance Monitors Count Enable Set register

The PMCNTENSET characteristics are:

**Purpose**

Enables the Cycle Count Register, PMCCNTR, and any implemented event counters PMEVCNTR<\text{n}>. Reading this register shows which counters are enabled. PMCNTENSET is used in conjunction with the PMCNTENCLR register.

**Configurations**

AArch32 System register PMCNTENSET[31:0] is architecturally mapped to AArch64 System register PMCNTENSET_EL0[31:0].

AArch32 System register PMCNTENSET[31:0] is architecturally mapped to External register PMCNTENSET_EL0[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMCNTENSET is a 32-bit register.

**Field descriptions**

The PMCNTENSET bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;\text{n}&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

\text{C}, bit [31]

PMCCNTR enable bit. Enables the cycle counter register. Possible values are:

- \text{0b0} When read, means the cycle counter is disabled. When written, has no effect.
- \text{0b1} When read, means the cycle counter is enabled. When written, enables the cycle counter.

This field resets to an architecturally UNKNOWN value.

\text{P<\text{n}>}, bit [n], for \text{n} = 0 to 30

Event counter enable bit for PMEVCNTR<\text{n}>.

If \text{N} is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, \text{N} is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, \text{N} is the value in PMCR.N.

- \text{0b0} When read, means that PMEVCNTR<\text{n}> is disabled. When written, has no effect.
- \text{0b1} When read, means that PMEVCNTR<\text{n}> event counter is enabled. When written, enables PMEVCNTR<\text{n}>.

This field resets to an architecturally UNKNOWN value.

**Accessing the PMCNTENSET**

Accesses to this register use the following encodings in the System instruction encoding space:
MRC<q> coproc, {#<opc1>, <Rt>, <CRn>, <CRm>{, {#<opc2>}}

<table>
<thead>
<tr>
<th>coproc</th>

G8.4.9 PMCR, Performance Monitors Control Register

The PMCR characteristics are:

**Purpose**

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

**Configurations**

AArch32 System register PMCR[31:0] is architecturally mapped to AArch64 System register PMCR_EL0[31:0].

AArch32 System register PMCR[7:0] is architecturally mapped to External register PMCR_EL0[7:0].

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMCR is a 32-bit register.

**Field descriptions**

The PMCR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24 23</th>
<th>16 15</th>
<th>11 10</th>
<th>7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMP</td>
<td>IDCODE</td>
<td>N</td>
<td>RES0</td>
<td>L0D0 X D C P E</td>
</tr>
</tbody>
</table>

**IMP, bits [31:24]**

Implementer code. This field is RO with an IMPLEMENTATION DEFINED value.

If this field is zero, then PMCR.IDCODE is RES0 and software must use MIDR to identify the PE.

Otherwise this field and PMCR.IDCODE identify the PMU implementation to software. The implementer codes are allocated by Arm. A non-zero value has the same interpretation as MIDR. Implementer.

**IDCODE, bits [23:16]**

*When PMCR.IMP != 0x00:*

Identification code. This field is RO with an IMPLEMENTATION DEFINED value.

Each implementer must maintain a list of identification codes that are specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

*Otherwise:*

Reserved, RES0.

**N, bits [15:11]**

An RO field that indicates the number of event counters implemented. This value is in the range of 0b00000-0b11111. If the value is 0b00000 then only PMCCNTR_EL0 is implemented. If the value is 0b11111 PMCCNTR_EL0 and 31 event counters are implemented.

In an implementation that includes EL2:

- If EL2 is using AArch32, reads of this field from Non-secure EL1 and Non-secure EL0 return the value of HDCR.HPMN.
• If EL2 is using AArch64 and enabled in the current Security state, reads of this field from EL1 and EL0 return the value of MDCR_EL2.HPMN.

Access to this field is RO.

**Bits [10:7]**

Reserved, RES0.

**LC, bit [6]**

Long cycle counter enable. Determines when unsigned overflow is recorded by the cycle counter overflow bit.

- 0b0 Cycle counter overflow on increment that causes unsigned overflow of PMCCNTR[31:0].
- 0b1 Cycle counter overflow on increment that causes unsigned overflow of PMCCNTR[63:0].

Arm deprecates use of PMCR.LC = 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

**DP, bit [5]**

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

- 0b0 Cycle counting by PMCCNTR is not affected by this bit.
- 0b1 When event counting for counters in the range [0..(HDCR.HPMN-1)] or [0..(MDCR_EL2.HPMN-1)] is prohibited, cycle counting by PMCCNTR is disabled.

For more information about the interaction between the Performance Monitors and EL3, see *Effect of EL3 and EL2* on page D6-2533.

When EL3 is not implemented, this field is RES0:

• When ARMv8.1-PMU is not implemented.
• When ARMv8.1-PMU is implemented, only if EL2 is not implemented.

Otherwise this field is RW.

On a Warm reset, this field resets to 0.

**X, bit [4]**

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

- 0b0 Do not export events.
- 0b1 Export events where not prohibited.

This field enables the exporting of events over an event bus to another device, for example to an OPTIONAL PE trace unit. If the implementation does not include such an event bus then this field is RAZ/WI, otherwise it is an RW field.

In an implementation that includes an event bus, no events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

On a Warm reset, this field resets to 0.

**D, bit [3]**

Clock divider. The possible values of this bit are:

- 0b0 When enabled, PMCCNTR counts every clock cycle.
- 0b1 When enabled, PMCCNTR counts once every 64 clock cycles.

This bit is RW.

If PMCR.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

Arm deprecates use of PMCR.D = 1.
On a Warm reset, this field resets to 0.

**C, bit [2]**

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

- **0b0** No action.
- **0b1** Reset PMCCNTR to zero.

This bit is always RAZ.

--- **Note** ---

Resetting PMCCNTR does not change the cycle counter overflow bit.

---

**P, bit [1]**

Event counter reset. This bit is WO. The effects of writing to this bit are:

- **0b0** No action.
- **0b1** Reset all event counters accessible in the current Exception level, not including PMCCNTR, to zero.

This bit is always RAZ.

In EL0 and EL1:

- If EL2 is implemented and enabled in the current Security state, and HDCR.HPMN or MDCR_EL2.HPMN is less than PMCR_EL0.N, a write of 1 to this bit does not reset event counters in the range [HDCR.HPMN:(PMCR.N-1)] or [MDCR_EL2.HPMN:(PMCR.N-1)].
- If EL2 is not implemented, EL2 is disabled in the current Security state, or HDCR.HPMN or MDCR_EL2.HPMN is equal to PMCR_EL0.N, a write of 1 to this bit resets all the event counters.

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

--- **Note** ---

Resetting the event counters does not change the event counter overflow bits.

---

**E, bit [0]**

Enable.

- **0b0** All event counters in the range [0:(PMN-1)] and PMCCNTR, are disabled.
- **0b1** All event counters in the range [0:(PMN-1)] and PMCCNTR, are enabled by PMCNTENSET.

This bit is RW.

If EL2 is implemented then:

- If EL2 is using AArch32, PMN is HDCR.HPMN.
- If EL2 is using AArch64, PMN is MDCR_EL2.HPMN.
- If PMN is less than PMCR.N, this bit does not affect the operation of event counters in the range [PMN:(PMCR.N-1)].

If EL2 is not implemented, PMN is PMCR.N.

--- **Note** ---

The effect of MDCR_EL2.HPMN or HDCR.HPMN on the operation of this bit applies if EL2 is implemented regardless of whether EL2 is enabled in the current Security state. For more information, see the description of MDCR_EL2.HPMN or HDCR.HPMN.

---

On a Warm reset, this field resets to 0.
## Accessing the PMCR

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}(<c>)(<q>) \text{ <coproc>, (#<opc1>, <Rt>, <CRn>, <CRm>, (#<opc2>)}
\]

<table>

G8.10 PMEVCNTR<n>, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n> characteristics are:

**Purpose**
Holds event counter n, which counts events, where n is 0 to 30.

**Configurations**
AArch32 System register PMEVCNTR<n>[31:0] is architecturally mapped to AArch64 System register PMEVCNTR<n>_EL0[31:0].
AArch32 System register PMEVCNTR<n>[31:0] is architecturally mapped to External register PMEVCNTR<n>_EL0[31:0].
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
PMEVCNTR<n> is a 32-bit register.

**Field descriptions**
The PMEVCNTR<n> bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Event counter n</th>
</tr>
</thead>
</table>

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.
This field resets to an architecturally UNKNOWN value.

**Accessing the PMEVCNTR<n>**
PMEVCNTR<n> can also be accessed by using PMXEVCNTR with PMSELR.SEL set to the value of <n>.
If <n> is greater than or equal to the number of accessible counters, reads and writes of PMEVCNTR<n> are CONstrained UNPredictable, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP
- If EL2 is implemented and enabled in the current Security state, and <n> is less than the number of implemented counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

--- Note ---
In EL0, an access is permitted if it is enabled by PMUSERENR.{ER,EN} or PMUSERENR_EL0.{ER,EN}.
If EL2 is implemented and enabled in the current Security state, at EL0 and EL1:

- If EL2 is using AArch32, HIDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.
Otherwise, the number of accessible counters is the number of implemented counters. See HDCR.HPMN and MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{c\}\{q\} <\text{coproc}>, \{#\}<\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>, \{#\}<\text{opc2}>
\]

<table>
<thead>
<tr>

G8.4.11  PMEVTYPER<n>, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n> characteristics are:

**Purpose**

Configures event counter n, where n is 0 to 30.

**Configurations**

AArch32 System register PMEVTYPER<n>[31:0] is architecturally mapped to AArch64 System register PMEVTYPER<n>_EL0[31:0].

AArch32 System register PMEVTYPER<n>[31:0] is architecturally mapped to External register PMEVTYPER<n>_EL0[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMEVTYPER<n> is a 32-bit register.

**Field descriptions**

The PMEVTYPER<n> bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>P</td>
</tr>
<tr>
<td>30</td>
<td>U</td>
</tr>
<tr>
<td>29</td>
<td>NSK</td>
</tr>
<tr>
<td>28</td>
<td>NSU</td>
</tr>
<tr>
<td>27</td>
<td>NSH</td>
</tr>
<tr>
<td>26</td>
<td>RES0</td>
</tr>
<tr>
<td>25</td>
<td>MT</td>
</tr>
<tr>
<td>15-10</td>
<td>evtCount[15:10]</td>
</tr>
<tr>
<td>9-0</td>
<td>evtCount[9:0]</td>
</tr>
</tbody>
</table>

**P, bit [31]**

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

0b0  Count events in EL1.
0b1  Do not count events in EL1.

This field resets to an architecturally UNKNOWN value.

**U, bit [30]**

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

0b0  Count events in EL0.
0b1  Do not count events in EL0.

This field resets to an architecturally UNKNOWN value.

**NSK, bit [29]**

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

This field resets to an architecturally UNKNOWN value.
NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted. Otherwise, events in Non-secure EL0 are not counted.

This field resets to an architecturally UNKNOWN value.

NSH, bit [27]

Non-secure EL2 (Hyp mode) filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0b0 Do not count events in EL2.

0b1 Count events in EL2.

This field resets to an architecturally UNKNOWN value.

Bit [26]

Reserved, RES0.

MT, bit [25]

Multithreading. When the implementation is multi-threaded, the valid values for this bit are:

0b0 Count events only on controlling PE.

0b1 Count events from any PE with the same affinity at level 1 and above as this PE.

When the implementation is not multi-threaded, this bit is RES0.

--- Note ---

• When the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach, an implementation is described as multi-threaded. That is, the performance of PEs at the lowest affinity level is highly interdependent. On such an implementation, when read at the highest implemented Exception level, the value of MPIDR_EL1.MT is 1.

• Events from a different thread of a multithreaded implementation are not Attributable to the thread counting the event.

This field resets to an architecturally UNKNOWN value.

Bits [24:16]

Reserved, RES0.

evtCount[15:10], bits [15:10]

From ARMv8.1:

Extension to evtCount[9:0]. See evtCount[9:0] for more details.

Otherwise:

Reserved, RES0.

evtCount[9:0], bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<n>. Software must program this field with an event that is supported by the PE being programmed.

There are three types of event:

• Common architectural and microarchitectural events.

• Arm recommended common architectural and microarchitectural events.

• IMPLEMENTATION DEFINED events.
The ranges of event numbers allocated to each type of event are shown in Table D6-6 on page D6-2545.

If evtCount is programmed to an event that is reserved or not supported by the PE, the behavior depends on the event type:

- For the range 0x000 to 0x03F, no events are counted, and the value returned by a direct or external read of the evtCount field is the value written to the field.
- For IMPLEMENTATION DEFINED events, it is UNPREDICTABLE what event, if any, is counted, and the value returned by a direct or external read of the evtCount field is UNKNOWN.

--- Note ---

UNPREDICTABLE means the event must not expose privileged information.

---

Arm recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

This field resets to an architecturally UNKNOWN value.

### Accessing the PMEVTYPER<n>

PMEVTYPER<n> can also be accessed by using PMXEVTYPER with PMSELR.SEL set to n.

If <n> is greater or equal to the number of accessible counters, reads and writes of PMEVTYPER<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- If EL2 is implemented and enabled in the current Security state, and <n> is less than the number of implemented counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

--- Note ---

In EL0, an access is permitted if it is enabled by PMUSERENR.EN or PMUSERENR_EL0.EN.

If EL2 is implemented and enabled in the current Security state, at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters. See HDCR.HPMN and MDCR_EL2.HPMN for more details.

---

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}{<q>} \text{ coproc, }\{\#\text{opc1}\}, <Rt>, <CRn>, <CRm>\{, \{\#\text{opc2}\}\}
\]

PMINTENCLR, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR characteristics are:

**Purpose**

Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR, and the event counters PMEVCNTR<n>. Reading the register shows which overflow interrupt requests are enabled.

PMINTENCLR is used in conjunction with the PMINTENSET register.

**Configurations**

AArch32 System register PMINTENCLR[31:0] is architecturally mapped to AArch64 System register PMINTENCLR_EL1[31:0].

AArch32 System register PMINTENCLR[31:0] is architecturally mapped to External register PMINTENCLR_EL1[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMINTENCLR is a 32-bit register.

**Field descriptions**

The PMINTENCLR bit assignments are:

<table>
<thead>
<tr>
<th>Field Description</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C, bit [31]</td>
<td>0</td>
<td>When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.</td>
</tr>
</tbody>
</table>

This field resets to an architecturally UNKNOWN value.

<table>
<thead>

G8.4.13 PMINTENSET, Performance Monitors Interrupt Enable Set register

The PMINTENSET characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR, and the event counters PMEVCNTR<n>. Reading the register shows which overflow interrupt requests are enabled.

PMINTENSET is used in conjunction with the PMINTENCLR register.

Configurations

AArch32 System register PMINTENSET[31:0] is architecturally mapped to AArch64 System register PMINTENSET_EL1[31:0].

AArch32 System register PMINTENSET[31:0] is architecturally mapped to External register PMINTENSET_EL1[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMINTENSET is a 32-bit register.

Field descriptions

The PMINTENSET bit assignments are:

<table>
<thead>
<tr>
<th>31 30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;n&gt;, bit [n]</td>
</tr>
</tbody>
</table>

C, bit [31]

PMCCNTR overflow interrupt request enable bit. Possible values are:

0b0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

0b1 When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request enable bit for PMEVCNTR<n>.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N.

0b0 When read, means that the PMEVCNTR<n> event counter interrupt request is disabled. When written, has no effect.

0b1 When read, means that the PMEVCNTR<n> event counter interrupt request is enabled. When written, enables the PMEVCNTR<n> interrupt request.

This field resets to an architecturally UNKNOWN value.

Accessing the PMINTENSET

G8.4.14 PMOVSR, Performance Monitors Overflow Flag Status Register

The PMOVSR characteristics are:

**Purpose**

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR, and each of the implemented event counters PMEVCNTR<\(n\)>. Writing to this register clears these bits.

**Configurations**

AArch32 System register PMOVSR[31:0] is architecturally mapped to AArch64 System register PMOVSCLR_EL0[31:0].

AArch32 System register PMOVSR[31:0] is architecturally mapped to External register PMOVSCLR_EL0[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMOVSR is a 32-bit register.

**Field descriptions**

The PMOVSR bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>C, bit [31]</th>
<th>P&lt;(n)&gt;, bit [n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>C</td>
<td>P&lt;(n)&gt;</td>
</tr>
<tr>
<td>30</td>
<td></td>
<td>P&lt;(n)&gt;</td>
</tr>
<tr>
<td>30 0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

C, bit [31]

Cycle counter overflow clear bit. Possible values are:

- \(0b0\) When read, means the cycle counter has not overflowed since this bit was last cleared. When written, has no effect.
- \(0b1\) When read, means the cycle counter has overflowed since this bit was last cleared. When written, clears the cycle counter overflow bit to 0.

PMCR.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR[31:0] or unsigned overflow of PMCCNTR[63:0]. This field resets to an architecturally UNKNOWN value.

P<\(n\)> bit [n], for \(n = 0 \text{ to } 30\)

Event counter overflow clear bit for PMEVCNTR<\(n\)>.

If \(N\) is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, \(N\) is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, \(N\) is the value in PMCR.N.

- \(0b0\) When read, means that PMEVCNTR<\(n\)> has not overflowed since this bit was last cleared. When written, has no effect.
- \(0b1\) When read, means that PMEVCNTR<\(n\)> has overflowed since this bit was last cleared. When written, clears the PMEVCNTR<\(n\)> overflow bit to 0.

This field resets to an architecturally UNKNOWN value.

**Accessing the PMOVSR**

G8.4.15 PMOVSSET, Performance Monitors Overflow Flag Status Set register

The PMOVSSET characteristics are:

**Purpose**

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR, and each of the implemented event counters PMEVCNTR<n>.

**Configurations**

AArch32 System register PMOVSSET[31:0] is architecturally mapped to AArch64 System register PMOVSSET_EL0[31:0].

AArch32 System register PMOVSSET[31:0] is architecturally mapped to External register PMOVSSET_EL0[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMOVSSET is a 32-bit register.

**Field descriptions**

The PMOVSSET bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>P&lt;n&gt;, bit [n]</td>
<td></td>
</tr>
</tbody>
</table>

**C, bit [31]**

Cycle counter overflow set bit.

0b0  When read, means the cycle counter has not overflowed since this bit was last cleared. When written, has no effect.

0b1  When read, means the cycle counter has overflowed since this bit was last cleared. When written, sets the cycle counter overflow bit to 1.

**P<n>, bit [n], for n = 0 to 30**

Event counter overflow set bit for PMEVCNTR<n>.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N.

0b0  When read, means that PMEVCNTR<n> has not overflowed since this bit was last cleared. When written, has no effect.

0b1  When read, means that PMEVCNTR<n> has overflowed since this bit was last cleared. When written, sets the PMEVCNTR<n> overflow bit to 1.

This field resets to an architecturally UNKNOWN value.

**Accessing the PMOVSSET**

Accesses to this register use the following encodings in the System instruction encoding space:

G8.4.16 PMSELR, Performance Monitors Event Counter Selection Register

The PMSELR characteristics are:

**Purpose**

Selects the current event counter PMEVCNTR\(<n>\) or the cycle counter, CCNT.

PMSELR is used in conjunction with PMXEVTYPER to determine the event that increments a selected event counter, and the modes and states in which the selected counter increments.

It is also used in conjunction with PMXEVNCNTR, to determine the value of a selected event counter.

**Configurations**

AArch32 System register PMSELR[31:0] is architecturally mapped to AArch64 System register PMSELR_EL0[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMSELR is a 32-bit register.

**Field descriptions**

The PMSELR bit assignments are:

\[
\begin{array}{cccc}
31 & 5 & 4 & 0 \\
\hline
RES0 & & & SEL \\
\end{array}
\]

**Bits [31:5]**

Reserved, RES0.

**SEL, bits [4:0]**

Selects event counter, PMEVCNTR\(<n>\), where \(n\) is the value held in this field. This value identifies which event counter is accessed when a subsequent access to PMXEVTYPER or PMXEVNCNTR occurs.

This field can take any value from 0 (0b00000) to (PMCR.N)-1, or 31 (0b11111).

When PMSELR.SEL is 0b11111, it selects the cycle counter and:

- A read of the PMXEVTYPER returns the value of PMCCFILTR.
- A write of the PMXEVTYPER writes to PMCCFILTR.
- A read or write of PMXEVNCNTR has CONSTRAINED UNPREDICTABLE effects. See PMXEVNCNTR for more details.

If this field is set to a value greater than or equal to the number of counters accessible at the current Exception level, but not equal to 31:

- Direct reads of this field return an UNKNOWN value.
- The results of access to PMXEVTYPER or PMXEVNCNTR are CONSTRAINED UNPREDICTABLE. See PMXEVTYPER or PMXEVNCNTR for more details.

For information about the number of counters accessible at each Exception level, see HDCR.HPMN and MDCR_EL2.HPMN.

This field resets to an architecturally UNKNOWN value.
Accessing the PMSELR

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\langle\text{<c>}\rangle\langle\text{<q>}\rangle \text{ <coproc>, \#<opc1>, <Rt>, <CRn>, <CRm>, \#<opc2>}
\]

PMSWINC, Performance Monitors Software Increment register

The PMSWINC characteristics are:

**Purpose**

Increments a counter that is configured to count the Software increment event, event 0x00. For more information, see SW_INCR.

**Configurations**

AArch32 System register PMSWINC[31:0] is architecturally mapped to AArch64 System register PMSWINC_EL0[31:0].

AArch32 System register PMSWINC[31:0] is architecturally mapped to External register PMSWINC_EL0[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMSWINC is a 32-bit register.

**Field descriptions**

The PMSWINC bit assignments are:

<table>
<thead>
<tr>
<th>Bit [31]</th>
<th>Reserved, RES0.</th>
</tr>
</thead>
<tbody>
<tr>
<td>P&lt;n&gt;, bit [n], for n = 0 to 30</td>
<td>Event counter software increment bit for PMEVCNTR&lt;n&gt;. If N is less than 31, then bits [30:N] are WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N.</td>
</tr>
<tr>
<td>0b0</td>
<td>No action. The write to this bit is ignored.</td>
</tr>
<tr>
<td>0b1</td>
<td>If PMEVCNTR&lt;n&gt; is enabled and configured to count the software increment event, increments PMEVCNTR&lt;n&gt; by 1. If PMEVCNTR&lt;n&gt; is disabled, or not configured to count the software increment event, the write to this bit is ignored.</td>
</tr>
</tbody>
</table>

**Accessing the PMSWINC**

Accesses to this register use the following encodings in the System instruction encoding space:

| MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>} |
|---|---|---|---|---|

G8.4.18 PMUSERENR, Performance Monitors User Enable Register

The PMUSERENR characteristics are:

**Purpose**

Enables or disables User mode access to the Performance Monitors.

**Configurations**

AArch32 System register PMUSERENR[31:0] is architecturally mapped to AArch64 System register PMUSERENR_EL0[31:0].

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PMUSERENR is a 32-bit register.

**Field descriptions**

The PMUSERENR bit assignments are:

| Bits [31:4] | Reserved, RES0. |
| ER, bit [3] | Event counter read trap control: |
| 0b0 | EL0 reads of the PMXEVCNTR and PMEVCNTR<\text{n}> are trapped to Undefined mode if PMUSERENR.EN is also 0. |
| 0b1 | Overrides PMUSERENR.EN and enables RO access to PMXEVCNTR and PMEVCNTR<\text{n}>, and RW access to PMSEL. |
| On a Warm reset, this field resets to 0. |
| CR, bit [2] | Cycle counter read trap control: |
| 0b0 | EL0 reads of the PMCCNTR are trapped to Undefined mode if PMUSERENR.EN is also 0. |
| 0b1 | Overrides PMUSERENR.EN and enables access to PMCCNTR. |
| On a Warm reset, this field resets to 0. |
| SW, bit [1] | Software increment write trap control: |
| 0b0 | EL0 writes to the PMSWINC are trapped to Undefined mode if PMUSERENR.EN is also 0. |
0b1  Overrides PMUSERENR.EN and enables access to PMSWINC.

On a Warm reset, this field resets to 0.

**EN, bit [0]**

Traps EL0 accesses to the Performance Monitors registers to Undefined mode:

0b0  While at EL0, PMUSERENR is always RO. Accesses to the other Performance Monitors registers are trapped to Undefined mode, unless enabled by one of PMUSERENR.{ER, CR, SW}.

0b1  While at EL0, software can access all PMU registers except PMINTENSET and PMINTENCLR.

On a Warm reset, this field resets to 0.

**Accessing the PMUSERENR**

Accesses to this register use the following encodings in the System instruction encoding space:

$$\text{MRC}\{c\}\{q\} \text{ <coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm>\}, \{#<opc2>\}}$$

## G8.4.19 PMXEVCNTR, Performance Monitors Selected Event Count Register

The PMXEVCNTR characteristics are:

### Purpose

Reads or writes the value of the selected event counter, PMEVCNTR<\text{n}>. PMSELR.SEL determines which event counter is selected.

### Configurations

AArch32 System register PMXEVCNTR[31:0] is architecturally mapped to AArch64 System register PMXEVCNTR_EL0[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

### Attributes

PMXEVCNTR is a 32-bit register.

### Field descriptions

The PMXEVCNTR bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>PMEVCNTR&lt;\text{n}&gt;</td>
</tr>
</tbody>
</table>

PMEVCNTR<\text{n}>, bits [31:0]

Value of the selected event counter, PMEVCNTR<\text{n}>, where \( \text{n} \) is the value stored in PMSELR.SEL.

This field resets to an architecturally UNKNOWN value.

### Accessing the PMXEVCNTR

If PMSELR.SEL is greater than or equal to the number of accessible counters then reads and writes of PMXEVCNTR are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP
- Accesses to the register behave as if PMSELR.SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- If EL2 is implemented and enabled in the current Security state, and PMSELR.SEL is less than the number of implemented counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

#### Note

In EL0, an access is permitted if it is enabled by PMUSERENR.\{ER,EN\} or PMUSERENR_EL0.\{ER,EN\}.

If EL2 is implemented and enabled in the current Security state, at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters. See HDCR.HPMN and MDCR_EL2.HPMN for more details.
Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRC\{<c>\}<q>\{\#<opc1>, <Rt>, <CRn>, <CRm}\{, \#<opc2>\} \]

G8.4.20 PMXEVTYPER, Performance Monitors Selected Event Type Register

The PMXEVTYPER characteristics are:

Purpose
When PMSELR.SEL selects an event counter, this accesses a PMEVTYPER<\texttt{\text少}n\texttt{\text多}> register. When PMSELR.SEL selects the cycle counter, this accesses PMCCFILTR.

Configurations
AArch32 System register PMXEVTYPER[31:0] is architecturally mapped to AArch64 System register PMXEVTYPER_EL0[31:0].

When the value of PMSELR.SEL is 31, to select the cycle counter, RW fields in this register have defined reset values that apply only when the PE resets into an Exception level that is using AArch32. See PMCCFILTR for the reset values.

Otherwise, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN. This applies whenever PMSELR.SEL selects an event counter.

Attributes
PMXEVTYPER is a 32-bit register.

Field descriptions
The PMXEVTYPER bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event type register or PMCCFILTR</td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:0]
Event type register or PMCCFILTR.
When PMSELR.SEL == 31, this register accesses PMCCFILTR.
Otherwise, this register accesses PMEVTYPER<\texttt{\text少}n\texttt{\text多}> where \( n \) is the value in PMSELR.SEL.

Accessing the PMXEVTYPER
If PMSELR.SEL is not 31, and is greater than or equal to the number of accessible counters then reads and writes of PMXEVTYPER are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

• Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP
• Accesses to the register behave as if PMSELR.SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
• Accesses to the register behave as if PMSELR.SEL is 31.
• If EL2 is implemented and enabled in the current Security state, and PMSELR.SEL is less than the number of implemented counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

——— Note ————
In EL0, an access is permitted if it is enabled by PMUSERENR.EN or PMUSERENR_EL0.EN.
If EL2 is implemented and enabled in the current Security state, at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters. See HDCR.HPMN and MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRC\langle c\rangle\langle q\rangle <\text{coproc}, \langle \#\rangle <\text{opc1}, <Rt>, <CRn>, <CRm\rangle, \langle \#\rangle <\text{opc2}\rangle \]

G8.5 Activity Monitors registers

This section lists the Activity Monitoring registers in AArch32.
G8.5.1 AMCFGR, Activity Monitors Configuration Register

The AMCFGR characteristics are:

**Purpose**

Global configuration register for the activity monitors.

Provides information on supported features, the number of counter groups implemented, the total number of activity monitor event counters implemented, and the size of the counters. AMCFGR is applicable to both the architected and the auxiliary counter groups.

**Configurations**

AArch32 System register AMCFGR[31:0] is architecturally mapped to AArch64 System register AMCFGR_EL0[31:0].

AArch32 System register AMCFGR[31:0] is architecturally mapped to External register AMCFGR[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCFGR are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMCFGR is a 32-bit register.

**Field descriptions**

The AMCFGR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28</th>
<th>27</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>14</th>
<th>13</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>NCG</td>
<td>RES0</td>
<td>RAZ</td>
<td>SIZE</td>
<td>N</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**NCG, bits [31:28]**

Defines the number of counter groups.

The number of implemented counter groups is defined as [AMCFGR.NCG + 1].

If the number of implemented auxiliary activity monitor event counters is zero, this field has a value of 0b0000. Otherwise, this field has a value of 0b0001.

**Bits [27:25]**

Reserved, RES0.

**HDBG, bit [24]**

Halt-on-debug supported.

In Armv8, this feature must be supported, and so this bit is 0b1.

0b0 AMCR.HDBG is RES0.

0b1 AMCR.HDBG is read/write.

**Bits [23:14]**

Reserved, RAZ.

**SIZE, bits [13:8]**

Defines the size of activity monitor event counters.
The size of the activity monitor event counters implemented by the Activity Monitors Extension is defined as \[\text{AMCFGR.SIZE} + 1\].

In Armv8, the counters are 64-bit, and so this field is 0b111111.

--- Note ---
Software also uses this field to determine the spacing of counters in the memory-map. In Armv8, the counters are at doubleword-aligned addresses.

\[\text{N, bits [7:0]}\]
Defines the number of activity monitor event counters.

The total number of counters implemented in all groups by the Activity Monitors Extension is defined as \[\text{AMCFGR.N} + 1\].

**Accessing the AMCFGR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}{<q>} \text{<coproc>, \{#<opc1>, <Rt>, <CRn>, <CRm>{, \{#<opc2>\}}
\]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>
<th>CRn</th>
<th>CRm</th>
<th>opc2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>0b000</td>
<td>0b1101</td>
<td>0b0010</td>
<td>0b001</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then

G8.5.2 AMCGCR, Activity Monitors Counter Group Configuration Register

The AMCGCR characteristics are:

Purpose

Provides information on the number of activity monitor event counters implemented within each counter group.

Configurations

AArch32 System register AMCGCR[31:0] is architecturally mapped to AArch64 System register AMCGCR_EL0[31:0].

AArch32 System register AMCGCR[31:0] is architecturally mapped to External register AMCGCR[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCGCR are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCGCR is a 32-bit register.

Field descriptions

The AMCGCR bit assignments are:

<p>| | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>16</td>
<td>15</td>
<td>8</td>
<td>7</td>
<td>0</td>
</tr>
<tr>
<td>RES0</td>
<td>CG1NC</td>
<td>CG0NC</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [31:16]

Reserved, RES0.

CG1NC, bits [15:8]

Counter Group 1 Number of Counters. The number of counters in the auxiliary counter group.

In AMUv1, the permitted range of values is 0 to 16.

CG0NC, bits [7:0]

Counter Group 0 Number of Counters. The number of counters in the architected counter group.

In AMUv1, the value of this field is 4.

Accessing the AMCGCR

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c}\{<q}\} <\text{crocproc}, \{#<opc1>, <Rt>, <CRn}, <CRm}>{, \{#<opc2>}
\]

<table>

G8.5.3 AMCNTENCLR0, Activity Monitors Count Enable Clear Register 0

The AMCNTENCLR0 characteristics are:

**Purpose**

Disable control bits for the architected activity monitors event counters, AMEVCNTR0<n>.

**Configurations**

AArch32 System register AMCNTENCLR0[31:0] is architecturally mapped to AArch64 System register AMCNTENCLR0_EL0[31:0].

AArch32 System register AMCNTENCLR0[31:0] is architecturally mapped to External register AMCNTENCLR0[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR0 are UNDEFINED.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMCNTENCLR0 is a 32-bit register.

**Field descriptions**

The AMCNTENCLR0 bit assignments are:

<table>
<thead>
<tr>
<th>P&lt;n&gt;, bit [n]</th>
<th>31</th>
<th>0</th>
</tr>
</thead>
</table>

P<n>, bit [n], for n = 0 to 31

Activity monitor event counter disable bit for AMEVCNTR0<n>.

Bits [31:N] are RAZ/W1. N is the value in AMCGCR.CG0NC.

Possible values of each bit are:

0b0 When read, means that AMEVCNTR0<n> is disabled. When written, has no effect.

0b1 When read, means that AMEVCNTR0<n> is enabled. When written, disables AMEVCNTR0<n>.

On a Cold reset, this field resets to 0.

**Accessing the AMCNTENCLR0**

Accesses to this register use the following encodings in the System instruction encoding space:

\[

G8.5.4 AMCNTENCLR1, Activity Monitors Count Enable Clear Register 1

The AMCNTENCLR1 characteristics are:

Purpose

Disable control bits for the auxiliary activity monitors event counters, AMEVCNTR1<n>.

Configurations

AArch32 System register AMCNTENCLR1[31:0] is architecturally mapped to AArch64 System register AMCNTENCLR1_EL0[31:0].

AArch32 System register AMCNTENCLR1[31:0] is architecturally mapped to External register AMCNTENCLR1[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR1 are UNDEFINED.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCNTENCLR1 is a 32-bit register.

Field descriptions

The AMCNTENCLR1 bit assignments are:

P<n>, bit [n], for n = 0 to 31

Activity monitor event counter disable bit for AMEVCNTR1<n>.

Bits [31:N] are RAZ/WI. N is the value in AMCGCR_EL0.CG1NC.

Possible values of each bit are:

0b0 When read, means that AMEVCNTR1<n> is disabled. When written, has no effect.

0b1 When read, means that AMEVCNTR1<n> is enabled. When written, disables AMEVCNTR1<n>.

On a Cold reset, this field resets to 0.

Accessing the AMCNTENCLR1

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENCLR1 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

Note

The number of auxiliary activity monitor event counters implemented is zero exactly when AMCFGR.NCG == 0b0000.

Accesses to this register use the following encodings in the System instruction encoding space:

G8.5.6 AMCNTENSET1, Activity Monitors Count Enable Set Register 1

The AMCNTENSET1 characteristics are:

**Purpose**

Enable control bits for the auxiliary activity monitors event counters, AMEVCNTR1<n>.

**Configurations**

AArch32 System register AMCNTENSET1[31:0] is architecturally mapped to AArch64 System register AMCNTENSET1_EL0[31:0].

AArch32 System register AMCNTENSET1[31:0] is architecturally mapped to External register AMCNTENSET1[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENSET1 are UNDEFINED.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMCNTENSET1 is a 32-bit register.

**Field descriptions**

The AMCNTENSET1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>P&lt;n&gt;, bit [n], for n = 0 to 31</td>
</tr>
</tbody>
</table>

P<n>, bit [n], for n = 0 to 31

Activity monitor event counter enable bit for AMEVCNTR1<n>.

Bits [31:N] are RAZ/WI. N is the value in AMCGCR.CG1NC.

Possible values of each bit are:

- **0b0** When read, means that AMEVCNTR1<n> is disabled. When written, has no effect.
- **0b1** When read, means that AMEVCNTR1<n> is enabled. When written, enables AMEVCNTR1<n>.

On a Cold reset, this field resets to 0.

**Accessing the AMCNTENSET1**

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENSET1 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

--- **Note** ---

The number of auxiliary activity monitor counters implemented is zero when AMCFGR.NCG == 0b0000.

Accesses to this register use the following encodings in the System instruction encoding space:
MRC(cq)(cq) <coproc>, (#)opc1, <Rt>, <CRn>, <CRm>,(#)opc2

G8.5.7 AMCR, Activity Monitors Control Register

The AMCR characteristics are:

**Purpose**

Global control register for the activity monitors implementation. AMCR is applicable to both the architectured and the auxiliary counter groups.

**Configurations**

AArch32 System register AMCR[31:0] is architecturally mapped to AArch64 System register `AMCR_EL0[31:0]`.

AArch32 System register AMCR[31:0] is architecturally mapped to External register AMCR[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCR are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMCR is a 32-bit register.

**Field descriptions**

The AMCR bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-11</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>HDBG, bit 10</td>
<td></td>
</tr>
<tr>
<td>9-0</td>
<td>Reserved, RAZ/WI</td>
<td></td>
</tr>
<tr>
<td></td>
<td>HDBG</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:11]**

Reserved, RES0.

**HDBG, bit 10**

This bit controls whether activity monitor counting is halted when the PE is halted in Debug state.

- **0b0**: Activity monitors do not halt counting when the PE is halted in Debug state.
- **0b1**: Activity monitors halt counting when the PE is halted in Debug state.

**Bits [9:0]**

Reserved, RAZ/WI.

**Accessing the AMCR**

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRC\langle c\rangle\langle q\rangle <coproc>, \langle\#\rangle<opc1>, <Rt>, <CRn>, <CRm>, \langle\#\rangle<opc2> \]

```
<table>

G8.5.8 AMEVCNTR0<n>, Activity Monitors Event Counter Registers 0, n = 0 - 15

The AMEVCNTR0<n> characteristics are:

**Purpose**

Provides access to the architected activity monitor event counters.

**Configurations**

AArch32 System register AMEVCNTR0<n>[63:0] is architecturally mapped to AArch64 System register AMEVCNTR0<n>_EL0[63:0].

AArch32 System register AMEVCNTR0<n>[63:0] is architecturally mapped to External register AMEVCNTR0<n>[63:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVCNTR0<n> are UNDEFINED.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMEVCNTR0<n> is a 64-bit register.

**Field descriptions**

The AMEVCNTR0<n> bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACNT</td>
<td>Architected activity monitor event counter n.</td>
</tr>
</tbody>
</table>

ACNT, bits [63:0]

Architected activity monitor event counter n.

Value of architected activity monitor event counter n, where n is the number of this register and is a number from 0 to 15.

If the counter is enabled, writes to this register have UNPREDICTABLE results.

On a Cold reset, this field resets to 0.

**Accessing the AMEVCNTR0<n>**

If <n> is greater than or equal to the number of architected activity monitor event counters, reads and writes of AMEVCNTR0<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

**Note**

AMCGCR.CG0NC identifies the number of architected activity monitor event counters.

Accesses to this register use the following encodings in the System instruction encoding space:
**MRRC{<c>}{<q>} <coproc>, (#)<opc1>, <Rt>, <Rt2>, <CRm>**

G8.5.10 AMEVTYPER0<n>, Activity Monitors Event Type Registers 0, n = 0 - 15

The AMEVTYPER0<n> characteristics are:

**Purpose**

Provides information on the events that an architected activity monitor event counter AMEVCNTR0<n> counts.

**Configurations**

AArch32 System register AMEVTYPER0<n>[31:0] is architecturally mapped to AArch64 System register AMEVTYPER0<n>_EL0[31:0].

AArch32 System register AMEVTYPER0<n>[31:0] is architecturally mapped to External register AMEVTYPER0<n>[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVTYPER0<n> are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AMEVTYPER0<n> is a 32-bit register.

**Field descriptions**

The AMEVTYPER0<n> bit assignments are:

![Bit assignments](image)

**Bits [31:25]**

Reserved, RAZ.

**Bits [24:16]**

Reserved, RES0.

**evtCount, bits [15:0]**

Event to count. The event number of the event that is counted by the architected activity monitor event counter AMEVCNTR0<n>. The value of this field is architecturally mandated for each architected counter.

The following table shows the mapping between required event numbers and the corresponding counters:

- 0x0011 When n == 0 Processor frequency cycles
- 0x4004 When n == 1 Constant frequency cycles
- 0x0008 When n == 2 Instructions retired
- 0x4005 When n == 3 Memory stall cycles

**Accessing the AMEVTYPER0<n>**

If <n> is greater than or equal to the number of architected activity monitor event counters, reads and writes of AMEVTYPER0<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- **Accesses to the register are UNDEFINED.**
- **Accesses to the register behave as RAZ/WI.**
- Accesses to the register execute as a NOP.

--- Note ---

AMCGCR.CG0NC identifies the number of architected activity monitor event counters.

---

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}(<c>){[(<q>)} <\text{coproc}>, {[\#} <\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>{, [\#<\text{opc2}>]}

</tbody>
</table>

**Bits [31:25]**

Reserved, RAZ.

**Bits [24:16]**

Reserved, RES0.

**evtCount, bits [15:0]**

Event to count. The event number of the event that is counted by the auxiliary activity monitor event counter AMEVCNTR1<n>.

It is IMPLEMENTATION DEFINED what values are supported by each counter.

If software writes a value to this field which is not supported by the corresponding counter AMEVCNTR1<n>, then:

- It is UNPREDICTABLE which event will be counted.
- The value read back is UNKNOWN.

The event counted by AMEVCNTR1<n> might be fixed at implementation. In this case, the field is read-only and writes are UNDEFINED.

If the corresponding counter AMEVCNTR1<n> is enabled, writes to this register have UNPREDICTABLE results.

**Accessing the AMEVTYPER1<n>**

If <n> is greater than or equal to the number of auxiliary activity monitor event counters, reads and writes of AMEVTYPER1<n> are CONstrained UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
• Accesses to the register behave as RAZ/WI.
• Accesses to the register execute as a NOP.

--- Note ---
AMCGCR.CG1NC identifies the number of auxiliary activity monitor event counters.

Accesses to this register use the following encodings in the System instruction encoding space:

G8.5.12 AMUSERENR, Activity Monitors User Enable Register

The AMUSERENR characteristics are:

**Purpose**
Global user enable register for the activity monitors. Enables or disables EL0 access to the activity monitors. AMUSERENR is applicable to both the architected and the auxiliary counter groups.

**Configurations**
AArch32 System register AMUSERENR[31:0] is architecturally mapped to AArch64 System register AMUSERENR_EL0[31:0].
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMUSERENR are UNDEFINED.
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
AMUSERENR is a 32-bit register.

**Field descriptions**
The AMUSERENR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>4-0</td>
<td>Reserved, RAZ/WI.</td>
</tr>
</tbody>
</table>

**Bits [31:4]**
Reserved, RES0.

**Bits [3:1]**
Reserved, RAZ/WI.

**EN, bit [0]**
Traps EL0 accesses to the activity monitors registers to EL1.

- **0b0** EL0 accesses to the activity monitors registers are trapped to EL1.
- **0b1** This control does not cause any instructions to be trapped. Software can access all activity monitor registers at EL0.

**Note**
- AMUSERENR can always be read at EL0 and is not governed by this bit.

**Accessing the AMUSERENR**
Accesses to this register use the following encodings in the System instruction encoding space:
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.6 RAS registers

This section lists the RAS Extension registers in AArch32.
G8.6.1 DISR, Deferred Interrupt Status Register

The DISR characteristics are:

**Purpose**

Records that an SError interrupt has been consumed by an ESB instruction.

**Configurations**

AArch32 System register DISR[31:0] is architecturally mapped to AArch64 System register DISR_EL1[31:0] when the highest implemented Exception level is using AArch64.

This register is present only when RAS is implemented. Otherwise, direct accesses to DISR are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DISR is a 32-bit register.

**Field descriptions**

The DISR bit assignments are:

*When the ESB instruction is executed at EL2:*

</tbody>
</table>

A, bit [31]

Set to 1 when an ESB instruction defers an asynchronous SError interrupt. If the implementation does not include any sources of SError interrupt that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

This field resets to an architecturally UNKNOWN value.

Bits [30:12]

Reserved, RES0.

AET, bits [11:10]

Asynchronous Error Type. See the description of HSR.AET for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort Type. See the description of HSR.EA for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

Bits [8:6]

Reserved, RES0.

DFSC, bits [5:0]

Fault Status Code. See the description of HSR.DFSC for an SError interrupt.

This field resets to an architecturally UNKNOWN value.
**When the ESB instruction is executed at EL0 or EL1 and where TTBCR.EAE == 0:**

**A, bit [31]**
Set to 1 when an ESB instruction defers an asynchronous SError interrupt. If the implementation does not include any sources of SError interrupt that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

This field resets to an architecturally UNKNOWN value.

**Bits [30:16]**
Reserved, RES0.

**AET, bits [15:14]**
Asynchronous Error Type. See the description of DFSR.AET for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

**Bit [13]**
Reserved, RES0.

**ExT, bit [12]**
External abort Type. See the description of DFSR.ExT for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

**Bit [11]**
Reserved, RES0.

**FS[4], bit [10]**
This field is bit[4] of FS[4:0].
Fault Status Code. See the description of DFSR.FS for an SError interrupt.

The FS field is split as follows:
- FS[4] is DISR[10].
- FS[3:0] is DISR[3:0].

This field resets to an architecturally UNKNOWN value.

**LPAE, bit [9]**
Format.

0b0 Using the Short-descriptor translation table format.

This field resets to an architecturally UNKNOWN value.

**Bits [8:4]**
Reserved, RES0.
FS[3:0], bits [3:0]
This field is bits[3:0] of FS[4:0].

When the ESB instruction is executed at EL0 or EL1 and where TTBCR.EAE == 1:

<table>

This field resets to an architecturally UNKNOWN value.

Bit [13]
Reserved, RES0.

ExT, bit [12]
External abort Type. See the description of DFSR.ExT for an SError interrupt.
This field resets to an architecturally UNKNOWN value.

Bits [11:10]
Reserved, RES0.

LPAE, bit [9]
Format.
0b1 Using the Long-descriptor translation table format.
This field resets to an architecturally UNKNOWN value.

Bits [8:6]
Reserved, RES0.

STATUS, bits [5:0]
Fault Status Code. See the description of DFSR.DFSC for an SError interrupt.
This field resets to an architecturally UNKNOWN value.
Accessing the DISR

An indirect write to DISR made by an ESB instruction does not require an explicit synchronization operation for the value that is written to be observed by a direct read of DISR occurring in program order after the ESB instruction.

DISR is RAZ/WI if EL3 is implemented, the PE is in Non-debug state, and any of the following apply:

- EL3 is using AArch64, SCR_EL3.EA == 1, and any of the following apply:
  - The PE is executing at EL2.
  - The PE is executing at EL1 and ((SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0) || HCR_EL2.AMO == 0).
- EL3 is using AArch32, SCR.EA == 1, and any of the following apply:
  - The PE is executing at EL2.
  - The PE is executing at EL1 and (SCR.NS == 0 || HCR.AMO == 0).

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\begin{align*}
\text{MRC}\{<c>\}{<q}> \text{coproc}, \{\#\}<opc1>, \langle Rt\rangle, \langle CRn\rangle, \langle CRm\rangle, \{\#\}<opc2> & \\
\hline 
coproc & opc1 & CRn & CRm & opc2 \\
0b1111 & 0b000 & 0b1100 & 0b0001 & 0b001 \\
\end{align*}
\]

if PSTATE.EL == EL0 then
  UNDEFINED;

G8.6.2 ERRIDR, Error Record ID Register

The ERRIDR characteristics are:

Purpose

Defines the highest numbered index of the error records that can be accessed through the Error Record System registers.

Configurations

AArch32 System register ERRIDR[31:0] is architecturally mapped to AArch64 System register ERRIDR_EL1[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRIDR are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERRIDR is a 32-bit register.

Field descriptions

The ERRIDR bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:16]</th>
<th></th>
<th>NUM, bits [15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved, RES0</td>
<td></td>
<td>Highest numbered index of the records that can be accessed through the Error Record System registers plus one. Zero indicates that no records can be accessed through the Error Record System registers. Each implemented record is owned by a node. A node might own multiple records.</td>
</tr>
</tbody>
</table>

Accessing the ERRIDR

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC\{<c>\}{<q> <coproc>, (#<opc1>, <Rt>, <CRn>, <CRm>{, (#<opc2>})

if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then

        AArch32.TakeMonitorTrapException();
    else
        return ERRIDR;
G8.6.3 ERRSELR, Error Record Select Register

The ERRSELR characteristics are:

**Purpose**

Selects an error record to be accessed through the Error Record System registers.

**Configurations**

AArch32 System register ERRSELR[31:0] is architecturally mapped to AArch64 System register ERRSELR_EL1[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRSELR are UNDEFINED.

If ERRIDR indicates that zero error records are implemented, then it is IMPLEMENTATION DEFINED whether ERRSELR is UNDEFINED or RES0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ERRSELR is a 32-bit register.

**Field descriptions**

The ERRSELR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>16</th>
<th>15</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SEL</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:16]**

Reserved, RES0.

**SEL, bits [15:0]**

Selects the error record accessed through the ERX registers.

If ERRSELR.SEL is set to a value greater than or equal to ERRIDR.NUM, then all of the following apply:

- The value read back from ERRSELR.SEL is UNKNOWN.
- One of the following occurs:
  - An unknown error record is selected.
  - The ERX* registers are RAZ/WI.
  - ERX* register reads and writes are NOPs.
  - ERX* register reads and writes are UNDEFINED.

This field resets to an architecturally UNKNOWN value.

**Accessing the ERRSELR**

Accesses to this register use the following encodings in the System instruction encoding space:
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

<table>
<thead>

ERXADDR, Selected Error Record Address Register

The ERXADDR characteristics are:

**Purpose**

Accesses bits [31:0] of ERR<\text{n}>ADDR for the error record selected by ERRSELR.SEL.
For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

AArch32 System register ERXADDR[31:0] is architecturally mapped to AArch64 System register ERXADDR_EL1[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXADDR are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ERXADDR is a 32-bit register.

**Field descriptions**

The ERXADDR bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
</table>

Bits [31:0]

ERXADDR accesses bits [31:0] of ERR<\text{n}>ADDR, where n is the value in ERRSELR.SEL.

**Accessing the ERXADDR**

If ERRIDR.NUM == 0 or ERRSELR.SEL is set to a value greater than or equal to ERRIDR.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXADDR is RAZ/WI.
- Direct reads and writes of ERXADDR are NOPs.
- Direct reads and writes of ERXADDR are UNDEFINED.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{<c>\}{<q>} <\text{coproc}>, \{#\}<\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>\{, \{#\}<\text{opc2}>\}

G8.6.5  ERXADDR2, Selected Error Record Address Register 2

The ERXADDR2 characteristics are:

**Purpose**

Accesses bits [63:32] of ERR<n>ADDR for the error record selected by ERRSELR.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

AArch32 System register ERXADDR2[31:0] is architecturally mapped to AArch64 System register ERXADDR_EL1[63:32].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXADDR2 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ERXADDR2 is a 32-bit register.

**Field descriptions**

The ERXADDR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 0</td>
<td>ERXADDR2 accesses bits [63:32] of ERR&lt;n&gt;ADDR, where n is the value in ERRSELR.SEL.</td>
</tr>
</tbody>
</table>

**Accessing the ERXADDR2**

If ERRIDR.NUM == 0 or ERRSELR.SEL is set to a value greater than or equal to ERRIDR.NUM, then one of the following occurs:

- **An UNKNOWN record is selected.**
- **ERXADDR2 is RAZ/WI.**
- **Direct reads and writes of ERXADDR2 are NOPs.**
- **Direct reads and writes of ERXADDR2 are UNDEFINED.**

Accesses to this register use the following encodings in the System instruction encoding space:

G8.6.10 ERXMISC0, Selected Error Record Miscellaneous Register 0

The ERXMISC0 characteristics are:

**Purpose**

Accesses bits [31:0] of ERR<\textit{n}>MISC0 for the error record selected by ERRSELR.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

AArch32 System register ERXMISC0[31:0] is architecturally mapped to AArch64 System register ERXMISC0.EL1[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXMISC0 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ERXMISC0 is a 32-bit register.

**Field descriptions**

The ERXMISC0 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERXMISC0 accesses bits [31:0] of ERR&lt;\textit{n}&gt;MISC0, where \textit{n} is the value in ERRSELR.SEL.</td>
<td></td>
</tr>
</tbody>
</table>

**Accessing the ERXMISC0**

If ERRIDR.NUM == 0 or ERRSELR.SEL is set to a value greater than or equal to ERRIDR.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXMISC0 is RAZ/WI.
- Direct reads and writes of ERXMISC0 are NOPs.
- Direct reads and writes of ERXMISC0 are UNDEFINED.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}(<c>)(<q>) <\text{coproc}>, (#)<\text{opc1}>, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>(, (#)<\text{opc2}>)
\]

G8.6.14 ERXMISC4, Selected Error Record Miscellaneous Register 4

The ERXMISC4 characteristics are:

Purpose

Accesses bits [31:0] of ERR<n>MISC2 for the error record selected by ERRSELR.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

Configurations

AArch32 System register ERXMISC4[31:0] is architecturally mapped to AArch64 System register ERXMISC2_EL1[31:0].

This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERXMISC4 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERXMISC4 is a 32-bit register.

Field descriptions

The ERXMISC4 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [31:0] of ERR&lt;n&gt;MISC2</td>
<td></td>
</tr>
</tbody>
</table>

Accessing the ERXMISC4

If ERRIDR.NUM == 0 or ERRSELR.SEL is set to a value greater than or equal to ERRIDR.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXMISC4 is RAZ/WI.
- Direct reads and writes of ERXMISC4 are NOPs.
- Direct reads and writes of ERXMISC4 are UNDEFINED.

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>} \]

if PSTATE.EL == EL0 then

G8.6.15 ERXMISC5, Selected Error Record Miscellaneous Register 5

The ERXMISC5 characteristics are:

**Purpose**

Accesses bits [63:32] of ERR<n>MISC2 for the error record selected by ERRSEL.RSel.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

AArch32 System register ERXMISC5[31:0] is architecturally mapped to AArch64 System register ERXMISC2_EL1[63:32].

This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERXMISC5 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ERXMISC5 is a 32-bit register.

**Field descriptions**

The ERXMISC5 bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

### G8.6.18 ERXSTATUS, Selected Error Record Primary Status Register

The ERXSTATUS characteristics are:

**Purpose**

Accesses bits [31:0] of ERR<\(<n>\)STATUS for the error record selected by ERRSEL.R.SEL.

For details of this, see the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.

**Configurations**

AArch32 System register ERXSTATUS[31:0] is architecturally mapped to AArch64 System register ERXSTATUS_EL1[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXSTATUS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ERXSTATUS is a 32-bit register.

**Field descriptions**

The ERXSTATUS bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERXSTATUS accesses bits [31:0] of ERR&lt;(&lt;n&gt;)STATUS, where n is the value in ERRSEL.R.SEL.</td>
<td></td>
</tr>
</tbody>
</table>

**Accessing the ERXSTATUS**

If ERRIDR.NUM == 0 or ERRSEL.R.SEL is set to a value greater than or equal to ERRIDR.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXSTATUS is RAZ/WI.
- Direct reads and writes of ERXSTATUS are NOPs.
- Direct reads and writes of ERXSTATUS are UNDEFINED.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRC{<c>{<q}> <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}}**

G8.6.19 VDFSR, Virtual SError Exception Syndrome Register

The VDFSR characteristics are:

**Purpose**

Provides the syndrome value reported to software on taking a virtual SError interrupt exception to EL1, or on executing an ESB instruction at EL1.

When a virtual SError interrupt is taken, the syndrome value is reported in DFSR.{AET, ExT} and the remainder of the DFSR is set as defined by VMSAv8-32. For more information, see Chapter G5 *The AArch32 Virtual Memory System Architecture*.

If the virtual SError interrupt is deferred by an ESB instruction, then the syndrome value is written to VDISR.

**Configurations**

AArch32 System register VDFSR[31:0] is architecturally mapped to AArch64 System register VSESR_EL2[31:0] when the highest implemented Exception level is using AArch64.

This register is present only when RAS is implemented. Otherwise, direct accesses to VDFSR are UNDEFINED.

If EL2 is not implemented, then VDFSR is RES0 from Monitor mode when SCR.NS == 1.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VDFSR is a 32-bit register.

**Field descriptions**

The VDFSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>

</tr>
</tbody>
</table>

**Bits [31:16]**

Reserved, RES0.

**AET, bits [15:14]**

When a virtual SError interrupt is taken to EL1 using AArch32, DFSR[15:4] is set to VDFSR.AET.

When a virtual SError interrupt is deferred by an ESB instruction, VDISR[15:4] is set to VDFSR.AET.

This field resets to an architecturally UNKNOWN value.

**Bit [13]**

Reserved, RES0.

**ExT, bit [12]**

When a virtual SError interrupt is taken to EL1 using AArch32, DFSR[12] is set to VDFSR.ExT.

When a virtual SError interrupt is deferred by an ESB instruction, VDISR[12] is set to VDFSR.ExT.

This field resets to an architecturally UNKNOWN value.
Bits [11:0]

Reserved, RES0.

Accessing the VDFSR

Direct reads and writes of VDFSR are UNDEFINED if EL3 is implemented and using AArch32 in all Secure privileged modes other than Monitor mode.

If EL2 is not implemented, then VDFSR is RES0 from Monitor mode when SCR.NS == 1.

Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{MRC}\{<\text{c}\}\{<\text{q}\} \text{ <coproc>, \{#<\text{opc1}\}, \langle Rt\rangle, \langle CRn\rangle, \langle CRm\rangle, \{#<\text{opc2}\>}} \]

G8.6.20 VDISR, Virtual Deferred Interrupt Status Register

The VDISR characteristics are:

**Purpose**

Records that an SError interrupt has been consumed by an ESB instruction.

**Configurations**

AArch32 System register VDISR[31:0] is architecturally mapped to AArch64 System register VDISR_EL2[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to VDISR are UNDEFINED.

If EL2 is not implemented, then VDISR is RES0 from Monitor mode when SCR.NS == 1.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

VDISR is a 32-bit register.

**Field descriptions**

The VDISR bit assignments are:

*When TTBCR.EAE == 0:*

```
  31 30  16 15 14 13 12 11 10  9  8  4  3  0
   A RES0 AET RES0 FS[3:0]
```

**A, bit [31]**

Set to 1 when an ESB instruction defers a virtual SError interrupt.

This field resets to an architecturally UNKNOWN value.

**Bits [30:16]**

Reserved, RES0.

**AET, bits [15:14]**

The value copied from VDFSR.AET.

This field resets to an architecturally UNKNOWN value.

**Bit [13]**

Reserved, RES0.

**Ext, bit [12]**

The value copied from VDFSR.Ext.

This field resets to an architecturally UNKNOWN value.

**Bit [11]**

Reserved, RES0.
FS[4], bit [10]

This field is bit[4] of FS[4:0].
Fault status code. Set to 0b10110 when an E58 instruction defers a virtual SError interrupt.
  0b10110  Asynchronous SError interrupt.
All other values are reserved.
The FS field is split as follows:
  - FS[4] is VDISR[10].
  - FS[3:0] is VDISR[3:0].
This field resets to an architecturally UNKNOWN value.

LPAE, bit [9]

Format.
Set to TTBCR.EAE when an E58 instruction defers a virtual SError interrupt.
  0b0  Using the Short-descriptor translation table format.
This field resets to an architecturally UNKNOWN value.

Bits [8:4]

Reserved, RES0.

FS[3:0], bits [3:0]

This field is bits[3:0] of FS[4:0].

When TTBCR.EAE == 1:

A, bit [31]

Set to 1 when an E58 instruction defers a virtual SError interrupt.
This field resets to an architecturally UNKNOWN value.

Bits [30:16]

Reserved, RES0.

AET, bits [15:14]

The value copied from VDFSR.AET.
This field resets to an architecturally UNKNOWN value.

Bit [13]

Reserved, RES0.

ExT, bit [12]

The value copied from VDFSR.ExT.
This field resets to an architecturally UNKNOWN value.
Bits [11:10]
Reserved, RES0.

LPAE, bit [9]
Format.
Set to TTBCR.EAE when an ESB instruction defers a virtual SError interrupt.
0b1 Using the Long-descriptor translation table format.
This field resets to an architecturally UNKNOWN value.

Bits [8:6]
Reserved, RES0.

STATUS, bits [5:0]
Fault status code. Set to 0b010001 when an ESB instruction defers a virtual SError interrupt.
0b010001 Asynchronous SError interrupt.
All other values are reserved.
This field resets to an architecturally UNKNOWN value.

Accessing the VDISR

Direct reads and writes of VDFSR are UNDEFINED if EL3 is implemented and using AArch32 in all Secure privileged modes other than Monitor mode.

An indirect write to VDISR made by an ESB instruction does not require an explicit synchronization operation for the value that is written to be observed by a direct read of DISR occurring in program order after the ESB instruction.

If EL2 is not implemented, then VDISR is RES0 from Monitor mode when SCR.NS == 1.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\begin{array}{cccc}
\text{coproc} & \text{opc1} & \text{CRn} & \text{CRm} \\ 
0b1111 & 0b100 & 0b1100 & 0b0001 & 0b001 \\
\end{array}
\]

G8.7  Generic Timer registers

This section lists the Generic Timer registers in AArch32.
G8.7.1 CNTFRQ, Counter-timer Frequency register

The CNTFRQ characteristics are:

**Purpose**

This register is provided so that software can discover the frequency of the system counter. It must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

**Configurations**

AArch32 System register CNTFRQ[31:0] is architecturally mapped to AArch64 System register CNTFRQ_EL0[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTFRQ is a 32-bit register.

**Field descriptions**

The CNTFRQ bit assignments are:

<table>
<thead>
<tr>
<th>Bits [31:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>Clock frequency. Indicates the system counter clock frequency, in Hz.</td>
</tr>
<tr>
<td></td>
<td>This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the CNTFRQ**

Accesses to this register use the following encodings in the System instruction encoding space:

\[ MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>} \]

<table>
<thead>
<tr>
<th>coproc</th>

</tr>
</tbody>
</table>
G8.7.2 CNTHCTL, Counter-timer Hyp Control register

The CNTHCTL characteristics are:

**Purpose**
Controls the generation of an event stream from the physical counter, and access from Non-secure EL1 modes to the physical counter and the Non-secure EL1 physical timer.

**Configurations**
AArch32 System register CNTHCTL[31:0] is architecturally mapped to AArch64 System register CNTHCTL_EL2[31:0].
If EL2 is not implemented, this register is RES0 from EL3.
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
CNTHCTL is a 32-bit register.

**Field descriptions**
The CNTHCTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>7-4</td>
<td>EVNTI, bits [7:4]</td>
</tr>
<tr>
<td>3</td>
<td>EVNTDIR, bit [3]</td>
</tr>
<tr>
<td>2</td>
<td>EVNTEN, bit [2]</td>
</tr>
</tbody>
</table>

**EVNTI, bits [7:4]**
Selects which bit (0 to 15) of the counter register CNTPCT is the trigger for the event stream generated from that counter, when that stream is enabled.
This field resets to an architecturally UNKNOWN value.

**EVNTDIR, bit [3]**
Controls which transition of the counter register CNTPCT trigger bit, defined by EVNTI, generates an event when the event stream is enabled:
0b0 A 0 to 1 transition of the trigger bit triggers an event.
0b1 A 1 to 0 transition of the trigger bit triggers an event.
This field resets to an architecturally UNKNOWN value.

**EVNTEN, bit [2]**
Enables the generation of an event stream from the counter register CNTPCT:
0b0 Disables the event stream.
0b1 Enables the event stream.
This field resets to an architecturally UNKNOWN value.
**PL1PCEN, bit [1]**

Traps Non-secure EL0 and EL1 accesses to the physical timer registers to Hyp mode.

- **0b0**: Non-secure EL0 and EL1 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TV AL are trapped to Hyp mode, unless it is trapped by CNTKCTL.PL0PTEN.
- **0b1**: This control does not cause any instructions to be trapped.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

This field resets to an architecturally UNKNOWN value.

**PL1PCTEN, bit [0]**

Traps Non-secure EL0 and EL1 accesses to the physical counter register to Hyp mode.

- **0b0**: Non-secure EL0 and EL1 accesses to the CNTPCT are trapped to Hyp mode, unless it is trapped by CNTKCTL.PL0PCTEN.
- **0b1**: This control does not cause any instructions to be trapped.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

This field resets to an architecturally UNKNOWN value.

---

**Accessing the CNTHCTL**

Accesses to this register use the following encodings in the System instruction encoding space:

**MRC{c>}{q<} <coproc>, (#)<opc1>, <Rt>, <CRn>, <CRm>{, (#)<opc2>}**

<table>
<thead>
<tr>

**G8.7.3 CNTHP_CTL, Counter-timer Hyp Physical Timer Control register**

The CNTHP_CTL characteristics are:

**Purpose**
Control register for the Hyp mode physical timer.

**Configurations**
AArch32 System register CNTHP_CTL[31:0] is architecturally mapped to AArch64 System register CNTHP_CTL_EL2[31:0].
If EL2 is not implemented, this register is RES0 from EL3.
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
CNTHP_CTL is a 32-bit register.

**Field descriptions**
The CNTHP_CTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>3</td>
<td>ENABLE</td>
</tr>
<tr>
<td>2</td>
<td>IMASK</td>
</tr>
<tr>
<td>1</td>
<td>ISTATUS</td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:3]**
Reserved, RES0.

**ISTATUS, bit [2]**
The status of the timer. This bit indicates whether the timer condition is met:

- **0b0** Timer condition is not met.
- **0b1** Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.
For more information see Operation of the CompareValue views of the timers on page D10-2641 and Operation of the TimerValue views of the timers on page D10-2641.
This bit is read-only.

**IMASK, bit [1]**
Timer interrupt mask bit. Permitted values are:

- **0b0** Timer interrupt is not masked by the IMASK bit.
- **0b1** Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.
In a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.
ENABLE, bit [0]

Enables the timer. Permitted values are:
- 0b0 Timer disabled.
- 0b1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHP_TVAL continues to count down.

--- Note ---

Disabling the output signal might be a power-saving option.

In a system where the PE resets into EL2 or EL3, this field resets to 0.

Accessing the CNTHP_CTL

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.7.4  **CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register**

The CNTHP_CVAL characteristics are:

**Purpose**

Holds the compare value for the Hyp mode physical timer.

**Configurations**

AArch32 System register CNTHP_CVAL[63:0] is architecturally mapped to AArch64 System register CNTHP_CVAL_EL2[63:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTHP_CVAL is a 64-bit register.

**Field descriptions**

The CNTHP_CVAL bit assignments are:

![CNTHP_CVAL Diagram]

**CompareValue, bits [63:0]**

Holds the EL2 physical timer CompareValue.

When CNTHP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer.

When the timer condition is met:

- CNTHP_CTL.ISTATUS is set to 1.
- If CNTHP_CTL.IMASK is 0, an interrupt is generated.

When CNTHP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTHP_CVAL**

G8.7.5 **CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register**

The CNTHP_TVAL characteristics are:

**Purpose**

Holds the timer value for the Hyp mode physical timer.

**Configurations**

AArch32 System register CNTHP_TVAL[31:0] is architecturally mapped to AArch64 System register CNTHP_TVAL_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTHP_TVAL is a 32-bit register.

**Field descriptions**

The CNTHP_TVAL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>TimerValue</td>
</tr>
</tbody>
</table>

**TimerValue, bits [31:0]**

The TimerValue view of the EL2 physical timer.

On a read of this register:

* If CNTHP_CTL.ENABLE is 0, the value returned is UNKNOWN.
* If CNTHP_CTL.ENABLE is 1, the value returned is (CNTHP_CVAL - CNTPCT).

On a write of this register, CNTHP_CVAL is set to (CNTPCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CNTHP_CVAL) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer.

When the timer condition is met:

* CNTHP_CTL.ISTATUS is set to 1.
* If CNTHP_CTL.IMASK is 0, an interrupt is generated.

When CNTHP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTHP_TVAL**

Accesses to this register use the following encodings in the System instruction encoding space:
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.7.6   CNTHPS_CTL, Counter-timer Secure Physical Timer Control Register (EL2)

The CNTHPS_CTL characteristics are:

**Purpose**

Provides AArch32 access to the Secure EL2 physical timer.

--- Note ---

The Secure EL2 timer is implemented by ARMv8.4-SecEL2. It is only accessible from AArch32 state when EL2 is using AArch64 and the value of SCR_EL3.{EEL2, NS} is {1, 0}.

---

**Configurations**

AArch32 System register CNTHPS_CTL[31:0] is architecturally mapped to AArch64 System register CNTHPS_CTL_EL2[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHPS_CTL are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTHPS_CTL is a 32-bit register.

**Field descriptions**

The CNTHPS_CTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>32</td>
<td>ENABLE</td>
</tr>
<tr>
<td>31</td>
<td>IMASK</td>
</tr>
<tr>
<td>2</td>
<td>ISTATUS</td>
</tr>
</tbody>
</table>

**Bits [31:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is met:

0b0  Timer condition is not met.
0b1  Timer condition is met.

When the value of the CNTHPS_CTL.ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the CNTHPS_CTL.ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers on page D10-2641* and *Operation of the TimerValue views of the timers on page D10-2641*.

This bit is read-only.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

0b0  Timer interrupt is not masked by the IMASK bit.
0b1  Timer interrupt is masked by the IMASK bit.
For more information, see the description of the ISTATUS bit.
This field resets to an architecturally UNKNOWN value.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>Timer disabled.</td>
</tr>
<tr>
<td>0b1</td>
<td>Timer enabled.</td>
</tr>
</tbody>
</table>

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHPS_TV AL_EL2 continues to count down.

--- Note ---
Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTHPS_CTL**

This register is accessed using the encoding for CNTP_CTL.

Accesses to this register use the following encodings in the System instruction encoding space:

```
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

<table>

G8.7.7 CNTHPS_CVAL, Counter-timer Secure Physical Timer CompareValue Register (EL2)

The CNTHPS_CVAL characteristics are:

**Purpose**

Provides AArch32 access to the compare value for the Secure EL2 physical timer.

--- Note ---

The Secure EL2 timer is implemented by ARMv8.4-SecEL2. It is only accessible from AArch32 state when EL2 is using AArch64 and the value of SCR_EL3.{EEL2, NS} is {1, 0}.

**Configurations**

AArch32 System register CNTHPS_CVAL[63:0] is architecturally mapped to AArch64 System register CNTHPS_CVAL_EL2[63:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHPS_CVAL are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTHPS_CVAL is a 64-bit register.

**Field descriptions**

The CNTHPS_CVAL bit assignments are:

```
+-------+-------+
| 63    | 0     |
+-------+-------+
       | CompareValue       |
```

**CompareValue, bits [63:0]**

Holds the EL2 physical timer CompareValue.

When CNTHPS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHPS_CTL_EL2.ISTATUS is set to 1.
- If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHPS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTHPS_CVAL**

This register is accessed using the encoding for CNTP_CVAL.

Accesses to this register use the following encodings in the System instruction encoding space:
 MRRC{<c>}{<q>} <coproc>, (#)<opc1>, <Rt>, <Rt2>, <CRm>

G8.7.8  **CNTHPS_TVAL, Counter-timer Secure Physical Timer TimerValue Register (EL2)**

The CNTHPS_TVAL characteristics are:

**Purpose**

Provides AArch32 access to the timer value for the Secure EL2 physical timer.

--- Note ---

The Secure EL2 timer is implemented by ARMv8.4-SecEL2. It is only accessible from AArch32 state when EL2 is using AArch64 and the value of SCR_EL3.{EEL2, NS} is {1, 0}.

**Configurations**

AArch32 System register CNTHPS_TVAL[31:0] is architecturally mapped to AArch64 System register CNTHPS_TVAL_EL2[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHPS_TVAL are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTHPS_TVAL is a 32-bit register.

**Field descriptions**

The CNTHPS_TVAL bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimerValue</td>
<td></td>
</tr>
</tbody>
</table>

**TimerValue, bits [31:0]**

The TimerValue view of the EL2 physical timer.

On a read of this register:

- If CNTHPS_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHPS_CTL_EL2.ENABLE is 1, the value returned is (CNTHPS_CVAL_EL2 - CNTPCT_EL0).

On a write of this register, CNTHPS_CVAL_EL2 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHPS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTHPS_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHPS_CTL_EL2.ISTATUS is set to 1.
- If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHPS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTHPS_TVAL**

This register is accessed using the encoding for CNTP_TVAL.

Accesses to this register use the following encodings in the System instruction encoding space:
The given code snippet is an excerpt from a technical document describing the AArch32 System Register Descriptions, specifically focusing on the Generic Timer registers (G8.7). The code is a part of a larger context that involves handling exceptions and traps in the AArch32 architecture. The snippet includes conditional logic involving flags and memory access control, showcasing how system interrupts and exceptions are managed in this context.

The code snippet is structured as follows:

```assembly
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

This section is followed by a table and some conditional statements that define the behavior of the system under different conditions. The table provides values for certain registers and conditions that determine the system's response to various exceptions or system calls. The conditions involve flags like `PSTATE.EL`, `ELUsingAArch32(EL1)`, `EL2Enabled()`, etc., and the actions include triggering traps or returning specific values.

The code is designed to handle complex scenarios where multiple levels of exceptions or traps are nested, ensuring that the system can respond appropriately based on the current state and the context of the operation being performed.

G8.7.9 CNTHV_CTL, Counter-timer Virtual Timer Control register (EL2)

The CNTHV_CTL characteristics are:

**Purpose**

Provides AArch32 access to the control register for the EL2 virtual timer.

--- **Note** ---

The EL2 virtual timer is implemented by ARMv8.1-VHE. It is only accessible from AArch32 state when EL0 is using AArch32, EL2 is using AArch64, and the value of HCR_EL2.{E2H, TGE} is \{1, 1\}.

**Configurations**

AArch32 System register CNTHV_CTL[31:0] is architecturally mapped to AArch64 System register CNTHV_CTL_EL2[31:0].

This register is present only from ARMv8.1. Otherwise, direct accesses to CNTHV_CTL are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

**Attributes**

CNTHV_CTL is a 32-bit register.

**Field descriptions**

The CNTHV_CTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>3</td>
<td>ENABLE</td>
</tr>
<tr>
<td>2</td>
<td>IMASK</td>
</tr>
<tr>
<td>1</td>
<td>ISTATUS</td>
</tr>
<tr>
<td>0</td>
<td>ISTATUS</td>
</tr>
</tbody>
</table>

**Bits [31:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is met:

- 0b0 Timer condition is not met.
- 0b1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D10-2641 and *Operation of the TimerValue views of the timers* on page D10-2641.

This bit is read-only.
IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:
- 0b0  Timer interrupt is not masked by the IMASK bit.
- 0b1  Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:
- 0b0  Timer disabled.
- 0b1  Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHV_TVVAL continues to count down.

--- Note ---
Disabling the output signal might be a power-saving option.

Accessing the CNTHV_CTL

This register is accessed using the encoding for CNTV_CTL.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\{\langle c\rangle}\{\langle q\rangle\} \langle coproc\rangle, \{#\langle opc1\rangle\}, \langle Rt\rangle, \langle CRn\rangle, \langle CRm\rangle\{, \{#\langle opc2\rangle\}\}
\]

G8.7.10   CNTHV_CVAL, Counter-timer Virtual Timer CompareValue register (EL2)

The CNTHV_CVAL characteristics are:

**Purpose**

Provides AArch32 access to the compare value for the EL2 virtual timer.

--- Note ---

The EL2 virtual timer is implemented by ARMv8.1-VHE. It is only accessible from AArch32 state when EL0 is using AArch32, EL2 is using AArch64, and the value of HCR_EL2.[E2H, TGE] is {1, 1}.

**Configurations**

AArch32 System register CNTHV_CVAL[63:0] is architecturally mapped to AArch64 System register CNTHV_CVAL_EL2[63:0].

This register is present only from ARMv8.1. Otherwise, direct accesses to CNTHV_CVAL are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

**Attributes**

CNTHV_CVAL is a 64-bit register.

**Field descriptions**

The CNTHV_CVAL bit assignments are:

![CompareValue bit assignments](image)

**CompareValue, bits [63:0]**

Holds the EL2 virtual timer CompareValue.

When CNTHV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHV_CTL.ISTATUS is set to 1.
- If CNTHV_CTL.IMASK is 0, an interrupt is generated.

When CNTHV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count.

**Accessing the CNTHV_CVAL**

G8.7.11 CNTHV_TV AL, Counter-timer Virtual Timer TimerValue register (EL2)

The CNTHV_TV AL characteristics are:

**Purpose**

Provides AArch32 access to the timer value for the EL2 virtual timer.

**Note**

The EL2 virtual timer is implemented by ARMv8.1-VHE. It is only accessible from AArch32 state when EL0 is using AArch32, EL2 is using AArch64, and the value of HCR_EL2.{E2H, TGE} is {1, 1}.

**Configurations**

AArch32 System register CNTHV_TV AL[31:0] is architecturally mapped to AArch64 System register CNTHV_TV AL_EL2[31:0].

This register is present only from ARMv8.1. Otherwise, direct accesses to CNTHV_TV AL are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.1.

**Attributes**

CNTHV_TV AL is a 32-bit register.

**Field descriptions**

The CNTHV_TV AL bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimerValue</td>
<td></td>
</tr>
</tbody>
</table>

**TimerValue, bits [31:0]**

The TimerValue view of the EL2 virtual timer.

On a read of this register:

- If CNTHV_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHV_CTL.ENABLE is 1, the value returned is (CNTHV_CVAL - CNTVCT).

On a write of this register, CNTHV_CVAL is set to (CNTVCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CNTHV_CVAL) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer.

When the timer condition is met:

- CNTHV_CTL.ISTATUS is set to 1.
- If CNTHV_CTL.IMASK is 0, an interrupt is generated.

When CNTHV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count, so the TimerValue view appears to continue to count down.

**Accessing the CNTHV_TV AL**

This register is accessed using the encoding for CNTV_TV AL.

Accesses to this register use the following encodings in the System instruction encoding space:
### MRC{<c>}{<q>} <coproc>, (#)opc1<, <Rt>, <CRn>, <CRm>{, (#)opc2}>)

G8.7.12 CNTHVS_CTL, Counter-timer Secure Virtual Timer Control Register (EL2)

The CNTHVS_CTL characteristics are:

**Purpose**

Provides AArch32 access to the Secure EL2 virtual timer.

--- Note ---

The Secure EL2 timer is implemented by ARMv8.4-SecEL2. It is only accessible from AArch32 state when EL2 is using AArch64 and the value of SCR_EL3.{EEL2, NS} is {1, 0}.

**Configurations**

AArch32 System register CNTHVS_CTL[31:0] is architecturally mapped to AArch64 System register CNTHVS_CTL_EL2[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHVS_CTL are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTHVS_CTL is a 32-bit register.

**Field descriptions**

The CNTHVS_CTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>3</td>
<td>ENABLE</td>
</tr>
<tr>
<td>2</td>
<td>IMASK</td>
</tr>
<tr>
<td>1</td>
<td>ISTATUS</td>
</tr>
<tr>
<td>0</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

**Bits [31:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is met:

| 0   | Timer condition is not met. |
| 1   | Timer condition is met.     |

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers on page D10-2641* and *Operation of the TimerValue views of the timers on page D10-2641*.

This bit is read-only.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

| 0   | Timer interrupt is not masked by the IMASK bit. |
| 1   | Timer interrupt is masked by the IMASK bit.    |
For more information, see the description of the ISTATUS bit.

**ENABLE, bit [0]**

Enables the timer. Permitted values are:

0b0 Timer disabled.

0b1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHSV_TVAL continues to count down.

--- Note ---

Disabling the output signal might be a power-saving option.

**Accessing the CNTHSV_CTL**

This register is accessed using the encoding for CNTV_CTL.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRC}\langle c\rangle\langle q\rangle\ \langle\text{coproc}\rangle, \langle \#\text{opc1}\rangle, \langle Rt\rangle, \langle CRn\rangle, \langle CRm\rangle, \langle \#\text{opc2}\rangle
\]

G8.7.13  CNTHVS_CVAL, Counter-timer Secure Virtual Timer CompareValue Register (EL2)

The CNTHVS_CVAL characteristics are:

**Purpose**

Provides AArch32 access to the compare value for the Secure EL2 virtual timer.

**Note**

The Secure EL2 timer is implemented by ARMv8.4-SecEL2. It is only accessible from AArch32 state when EL2 is using AArch64 and the value of SCR_EL3.EEL2, NS is {1, 0}.

**Configurations**

AArch32 System register CNTHVS_CVAL[63:0] is architecturally mapped to AArch64 System register CNTHVS_CVAL_EL2[63:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHVS_CVAL are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTHVS_CVAL is a 64-bit register.

**Field descriptions**

The CNTHVS_CVAL bit assignments are:

<table>
<thead>
<tr>
<th>Bit Width</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 0</td>
<td>CompareValue</td>
</tr>
</tbody>
</table>

**CompareValue, bits [63:0]**

Holds the EL2 virtual timer CompareValue.

When CNTHVS_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer.

When the timer condition is met:

- CNTHVS_CTL.ISTATUS is set to 1.
- If CNTHVS_CTL.IMASK is 0, an interrupt is generated.

When CNTHVS_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count.

**Accessing the CNTHVS_CVAL**

This register is accessed using the encoding for CNTV_CVAL.

Accesses to this register use the following encodings in the System instruction encoding space:
**MRRC{<c>}{<q>} <coproc>, (<#><opc1>, <Rt>, <Rt2>, <CRm>**

G8.7.14   CNTHVS_TVAL, Counter-timer Secure Virtual Timer TimerValue Register (EL2)

The CNTHVS_TVAL characteristics are:

**Purpose**

Provides AArch32 access to the timer value for the Secure EL2 virtual timer.

--- **Note** ---

The Secure EL2 timer is implemented by ARMv8.4-SecEL2. It is only accessible from AArch32 state when EL2 is using AArch64 and the value of SCR_EL3.{EEL2, NS} is {1, 0}.

**Configurations**

AArch32 System register CNTHVS_TVAL[31:0] is architecturally mapped to AArch64 System register CNTHVS_TVAL_EL2[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHVS_TVAL are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTHVS_TVAL is a 32-bit register.

**Field descriptions**

The CNTHVS_TVAL bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimerValue</td>
<td></td>
</tr>
</tbody>
</table>

**TimerValue, bits [31:0]**

The TimerValue view of the EL2 virtual timer.

On a read of this register:

- If CNTHVS_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHVS_CTL.ENABLE is 1, the value returned is (CNTHVS_CVAL - CNTVCT).

On a write of this register, CNTHVS_CVAL is set to (CNTVCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHVS_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CNTHVS_CVAL) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHVS_CTL.ISTATUS is set to 1.
- If CNTHVS_CTL.IMASK is 0, an interrupt is generated.

When CNTHVS_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count, so the TimerValue view appears to continue to count down.

**Accessing the CNTHVS_TVAL**

This register is accessed using the encoding for CNTV_TVAL.

Accesses to this register use the following encodings in the System instruction encoding space:
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.7.15  CNTKCTL, Counter-timer Kernel Control register

The CNTKCTL characteristics are:

**Purpose**

 Controls the generation of an event stream from the virtual counter, and access from EL0 modes to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

**Configurations**

AArch32 System register CNTKCTL[31:0] is architecturally mapped to AArch64 System register CNTKCTL_EL1[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTKCTL is a 32-bit register.

**Field descriptions**

The CNTKCTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit Positions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-10</td>
<td>RES0</td>
</tr>
<tr>
<td>9</td>
<td>PL0PTEN</td>
</tr>
<tr>
<td>8</td>
<td>PL0VTEN</td>
</tr>
<tr>
<td>7-4</td>
<td>EVNTI</td>
</tr>
<tr>
<td>3</td>
<td>PL0PCTEN</td>
</tr>
<tr>
<td>2</td>
<td>PL0VCTEN</td>
</tr>
<tr>
<td>1</td>
<td>EVNTEN</td>
</tr>
<tr>
<td>0</td>
<td>EVNTDIR</td>
</tr>
<tr>
<td>31-10</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

**Bits [31:10]**

Reserved, RES0.

**PL0PTEN, bit [9]**

Traps PL0 accesses to the physical timer registers to Undefined mode.

0b0  PL0 accesses to the CNTP_CTL, CNTP_CV, and CNTP_TV registers are trapped to Undefined mode.

0b1  This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

**PL0VTEN, bit [8]**

Traps PL0 accesses to the virtual timer registers to Undefined mode.

0b0  PL0 accesses to the CNTV_CTL, CNTV_CV, and CNTV_TV registers are trapped to Undefined mode.

0b1  This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

**EVNTI, bits [7:4]**

Selects which bit (0 to 15) of the counter register CNTVCT is the trigger for the event stream generated from that counter, when that stream is enabled.

This field resets to an architecturally UNKNOWN value.
EVNTDIR, bit [3]
Controls which transition of the counter register CNTVCT trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

0b0  A 0 to 1 transition of the trigger bit triggers an event.
0b1  A 1 to 0 transition of the trigger bit triggers an event.

This field resets to an architecturally UNKNOWN value.

EVNTEN, bit [2]
Enables the generation of an event stream from the counter register CNTVCT:

0b0  Disables the event stream.
0b1  Enables the event stream.

This field resets to an architecturally UNKNOWN value.

PL0VCTEN, bit [1]
Traps PL0 accesses to the frequency register and virtual counter register to Undefined mode.

0b0  PL0 accesses to the CNTVCT are trapped to Undefined mode.
    PL0 accesses to the CNTFRQ register are trapped to Undefined mode, if CNTKCTL.PL0VCTEN is also 0.
0b1  This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

PL0PCTEN, bit [0]
Traps PL0 accesses to the frequency register and physical counter register to Undefined mode.

0b0  PL0 accesses to the CNTPCT are trapped to Undefined mode.
    PL0 accesses to the CNTFRQ register are trapped to Undefined mode, if CNTKCTL.PL0PCTEN is also 0.
0b1  This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTKCTL
Accesses to this register use the following encodings in the System instruction encoding space:

$$\text{MRC}<{c}>\{<q>\} <\text{coproc}>, \{#<\text{opc1}>\}, <\text{Rt}>, <\text{CRn}>, <\text{CRm}>, \{#<\text{opc2}>\}$$

G8.7.16  **CNTP_CTL, Counter-timer Physical Timer Control register**

The CNTP_CTL characteristics are:

**Purpose**

Control register for the EL1 physical timer.

**Configurations**

AArch32 System register CNTP_CTL[31:0] is architecturally mapped to AArch64 System register CNTP_CTL_EL0[31:0].

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply only to the Secure instance of the register. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTP_CTL is a 32-bit register.

**Field descriptions**

The CNTP_CTL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>3</td>
<td>ISTATUS, bit [2]</td>
</tr>
<tr>
<td>2</td>
<td>IMASK, bit [1]</td>
</tr>
<tr>
<td>1</td>
<td>ENABLE</td>
</tr>
</tbody>
</table>

**Bits [31:3]**

Reserved, RES0.

**ISTATUS, bit [2]**

The status of the timer. This bit indicates whether the timer condition is met:

0b0  Timer condition is not met.
0b1  Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see [Operation of the CompareValue views of the timers](#) on page D10-2641 and [Operation of the TimerValue views of the timers](#) on page D10-2641.

This bit is read-only.

**IMASK, bit [1]**

Timer interrupt mask bit. Permitted values are:

0b0  Timer interrupt is not masked by the IMASK bit.
0b1  Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.
ENABLE, bit [0]

Enables the timer. Permitted values are:

0b0  Timer disabled.
0b1  Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTP_TV_AL continues to count down.

--- Note ---

Disabling the output signal might be a power-saving option.

This field resets to 0.

Accessing the CNTP_CTL

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MRC\{c\}\{q\}\ \{coproc\}, \{#\}\{opc1\}, \{Rt\}, \{CRn\}, \{CRm\}\{, \{#\}\{opc2\}\}
\]

<table>

G8.7.17 CNTP_CVAL, Counter-timer Physical Timer CompareValue register

The CNTP_CVAL characteristics are:

**Purpose**
Holds the compare value for the EL1 physical timer.

**Configurations**
AArch32 System register CNTP_CVAL[63:0] is architecturally mapped to AArch64 System register CNTP_CVAL_EL0[63:0].
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
CNTP_CVAL is a 64-bit register.

**Field descriptions**
The CNTP_CVAL bit assignments are:

- **CompareValue, bits [63:0]**
  Holds the EL1 physical timer CompareValue.
  When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer.
  When the timer condition is met:
  - CNTP_CTL.ISTATUS is set to 1.
  - If CNTP_CTL.IMASK is 0, an interrupt is generated.
  When CNTP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count.
  This field resets to an architecturally UNKNOWN value.

**Accessing the CNTP_CVAL**
Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{MRRC}\{<c>\}\{<q>\} <\text{coproc}>, \{#\}<\text{opc1}>, <\text{Rt}>, <\text{Rt2}>, <\text{CRm}>
\]

G8.7.18  CNTP_TVAL, Counter-timer Physical Timer TimerValue register

The CNTP_TVAL characteristics are:

**Purpose**

Holds the timer value for the EL1 physical timer.

**Configurations**

AArch32 System register CNTP_TVAL[31:0] is architecturally mapped to AArch64 System register CNTP_TVAL_EL0[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTP_TVAL is a 32-bit register.

**Field descriptions**

The CNTP_TVAL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>TimerValue</td>
</tr>
</tbody>
</table>

TimerValue, bits [31:0]

The TimerValue view of the EL1 physical timer.

On a read of this register:

- If CNTP_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTP_CTL.ENABLE is 1, the value returned is (CNTP_CV AL - CNTPCT).

On a write of this register, CNTP_CV AL is set to (CNTPCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CNTP_CV AL) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTP_CTL.ISTATUS is set to 1.
- If CNTP_CTL.IMASK is 0, an interrupt is generated.

When CNTP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

**Accessing the CNTP_T VAL**

G8.7.19   CNTPCT, Counter-timer Physical Count register

The CNTPCT characteristics are:

**Purpose**

Holds the 64-bit physical count value.

**Configurations**

AArch32 System register CNTPCT[63:0] is architecturally mapped to AArch64 System register CNTPCT_EL0[63:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTPCT is a 64-bit register.

**Field descriptions**

The CNTPCT bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Physical count value</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 0</td>
<td></td>
</tr>
</tbody>
</table>

**Accessing the CNTPCT**

Accesses to this register use the following encodings in the System instruction encoding space:

```
MRRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

<table>
<thead>
<tr>
<th>coproc</th>
<th>CRm</th>
<th>opc1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b111</td>
<td>0b110</td>
<td>0b0000</td>
</tr>
</tbody>
</table>

```c

G8.7.20 CNTV_CTL, Counter-timer Virtual Timer Control register

The CNTV_CTL characteristics are:

Purpose
   Control register for the virtual timer.

Configurations
   AArch32 System register CNTV_CTL[31:0] is architecturally mapped to AArch64 System register CNTV_CTL_EL0[31:0].
   Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes
   CNTV_CTL is a 32-bit register.

Field descriptions
   The CNTV_CTL bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   Bits [31:3]  
               Reserved, RES0.

   ISTATUS, bit [2]  
   The status of the timer. This bit indicates whether the timer condition is met:  
   0b0 Timer condition is not met. 
   0b1 Timer condition is met.  
   When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.  
   When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.  
   For more information see Operation of the CompareValue views of the timers on page D10-2641 and Operation of the TimerValue views of the timers on page D10-2641.  
   This bit is read-only.

   IMASK, bit [1]  
   Timer interrupt mask bit. Permitted values are:  
   0b0 Timer interrupt is not masked by the IMASK bit. 
   0b1 Timer interrupt is masked by the IMASK bit. 
   For more information, see the description of the ISTATUS bit.  
   This field resets to an architecturally UNKNOWN value.
ENABLE, bit [0]

Enables the timer. Permitted values are:

- **0b0** Timer disabled.
- **0b1** Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from `CNTV_TV_AL` continues to count down.

--- Note ---

Disabling the output signal might be a power-saving option.

This field resets to 0.

### Accessing the CNTV_CTL

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
\]

<table>
<thead>
<tr>
<th>coproc</th>
<th>opc1</th>

### G8.7.21 CNTV_CVAL, Counter-timer Virtual Timer CompareValue register

The CNTV_CVAL characteristics are:

**Purpose**
Holds the compare value for the virtual timer.

**Configurations**
AArch32 System register CNTV_CVAL[63:0] is architecturally mapped to AArch64 System register CNTV_CVAL_EL0[63:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
CNTV_CVAL is a 64-bit register.

**Field descriptions**
The CNTV_CVAL bit assignments are:

- **CompareValue**, bits [63:0]
  - Holds the EL1 virtual timer CompareValue.
  - When CNTV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer.
  - When the timer condition is met:
    - CNTV_CTL.ISTATUS is set to 1.
    - If CNTV_CTL.IMASK is 0, an interrupt is generated.
  - When CNTV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count.
  - This field resets to an architecturally UNKNOWN value.

**Accessing the CNTV_CVAL**
Accesses to this register use the following encodings in the System instruction encoding space:

```markdown
MRRC{{c}{{q}}} <coproc>, {{#}<opc1>, <Rt>, <Rt2>, <CRm>
```

<table>

G8.7.22 CNTV_TVAL, Counter-timer Virtual Timer TimerValue register

The CNTV_TVAL characteristics are:

**Purpose**

Holds the timer value for the virtual timer.

**Configurations**

AArch32 System register CNTV_TVAL[31:0] is architecturally mapped to AArch64 System register CNTV_TVAL_EL0[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTV_TVAL is a 32-bit register.

**Field descriptions**

The CNTV_TVAL bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimerValue</td>
<td>The TimerValue view of the virtual timer. On a read of this register:</td>
</tr>
<tr>
<td></td>
<td>• If CNTV_CTL.ENABLE is 0, the value returned is UNKNOWN.</td>
</tr>
<tr>
<td></td>
<td>• If CNTV_CTL.ENABLE is 1, the value returned is (CNTV_CVAL - CNTVCT).</td>
</tr>
<tr>
<td></td>
<td>On a write of this register, CNTV_CVAL is set to (CNTVCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.</td>
</tr>
<tr>
<td></td>
<td>When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CNTP_CVAL) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:</td>
</tr>
<tr>
<td></td>
<td>• CNTV_CTL.ISTATUS is set to 1.</td>
</tr>
<tr>
<td></td>
<td>• If CNTV_CTL.IMASK is 0, an interrupt is generated.</td>
</tr>
<tr>
<td></td>
<td>When CNTV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count, so the TimerValue view appears to continue to count down. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>

**Accessing the CNTV_TVAL**

Accesses to this register use the following encodings in the System instruction encoding space:

G8.7.23 CNTVCT, Counter-timer Virtual Count register

The CNTVCT characteristics are:

**Purpose**

Holds the 64-bit virtual count value. The virtual count value is equal to the physical count value visible in CNTPCT minus the virtual offset visible in CNTVOFF.

**Configurations**

AArch32 System register CNTVCT[63:0] is architecturally mapped to AArch64 System register CNTVCT_EL0[63:0].

The value of this register is the same as the value of CNTPCT in the following conditions:

- When EL2 is not implemented.
- When EL2 is implemented and is using AArch64, HCR_EL2.{E2H, TGE} is \{1, 1\}, and this register is read from Non-secure EL0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CNTVCT is a 64-bit register.

**Field descriptions**

The CNTVCT bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 0</td>
<td>Virtual count value</td>
</tr>
</tbody>
</table>

**Accessing the CNTVCT**

elsif PSTATE_EL == EL1 then
    return CNTVCT;
elsif PSTATE_EL == EL2 then
    return CNTVCT;
elsif PSTATE_EL == EL3 then
    return CNTVCT;
G8.7.24  CNTVOFF, Counter-timer Virtual Offset register

The CNTVOFF characteristics are:

**Purpose**

Holds the 64-bit virtual offset. This is the offset between the physical count value visible in CNTPCT and the virtual count value visible in CNTVCT.

**Configurations**

AArch32 System register CNTVOFF[63:0] is architecturally mapped to AArch64 System register CNTVOFF_EL2[63:0].

If EL2 is not implemented, this register is RES0 from EL3 and the virtual counter uses a fixed virtual offset of zero.

--- Note ---

When EL2 is implemented and is using AArch64, if HCR_EL2.{E2H, TGE} is {1, 1}, the virtual counter uses a fixed virtual offset of zero when CNTVCT is read from Non-secure EL0.

When EL2 is implemented and can use AArch32, on a reset into an Exception level that is using AArch32 this register resets to an IMPLEMENTATION DEFINED value that might be UNKNOWN.

**Attributes**

CNTVOFF is a 64-bit register.

**Field descriptions**

The CNTVOFF bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>0</td>
</tr>
</tbody>
</table>

**Accessing the CNTVOFF**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
MRRC\{c\}\{q\} \langle coproc \rangle, \{#\}\langle opc1 \rangle, \langle Rt \rangle, \langle Rt2 \rangle, \langle CRm \rangle
\]

<table>
<thead>
<tr>
<th>coproc CRm opc1</th>
</tr>
</thead>
<tbody>
<tr>
<td>b111 b110 b0100</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    return CNTVOFF;
elsif PSTATE.EL == EL3 then
    return CNTVOFF;
MCRR{<c>}{<q>} <coproc>, (#<opc1>, <Rt>, <Rt2>, <CRm>

<table>
<thead>
<tr>
<th>coproc</th>
<th>CRm</th>
<th>opc1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b1111</td>
<td>0b1110</td>
<td>0b0100</td>
</tr>
</tbody>
</table>

if PSTATE.E == EL0 then
  UNDEFINED;
elsif PSTATE.E == EL1 then
  UNDEFINED;
elsif PSTATE.E == EL2 then
  CNTVOFF = R[t2]:R[t];
elsif PSTATE.E == EL3 then
  CNTVOFF = R[t2]:R[t];
Chapter H1
About External Debug

This chapter gives an overview of ARMv8 external debug, and specifies the required debug authentication. It contains the following sections:

- *Introduction to external debug* on page H1-6414.
- *External debug* on page H1-6415.
- *Required debug authentication* on page H1-6416.

**Note**

For information about self-hosted debug, see Chapter D2 *AArch64 Self-hosted Debug* and Chapter G2 *AArch32 Self-hosted Debug*. 
H1.1 Introduction to external debug

ARMv8 supports both:

Self-hosted debug
The PE itself hosts a debugger. That is, developers developing software to run on the PE use debugger software running on the same PE.

External debug
The debugger is external to the PE. The debugging might be either on-chip, for example in a second PE, or off-chip, for example a JTAG debugger that accesses the chip through a Debug Access Port. External debug is particularly useful for:
- Hardware bring-up. That is, debugging during development when a system is first powered up and not all of the software functionality is available.
- PEs that are deeply embedded inside systems.

To support external debug, the ARM architecture defines required features that are called external debug features.

--- Note ---
An external debugger has a potentially high level of control over and visibility into the PE. The system sets this level using debug authentication. See Required debug authentication on page H1-6416.

If the debug authentication level is set too low, agents may be able to bypass elements of the security and privilege models. This includes both off-chip agents and on-chip agents such as unprivileged or Non-secure software.

H1.1.1 Definition and constraints of a debugger in the context of external debug

When the description of external debug in this Part of the manual describes a debugger as controlling external debug this debugger might be a second on-chip PE or an off-chip device such as a JTAG debugger using a Debug Access Port (DAP).

If a Debug Access Port is implemented:
- When debug is prohibited at the Debug Access Port, the port must not generate accesses to the external debug interface of the PE.
- When Secure debug is prohibited at the Debug Access Port, the port must not generate Secure accesses to the external debug interface of the PE.
- When Secure accesses are allowed at the Debug Access Port, the port must be able to generate Secure accesses.

If ARMv8.4-Debug is not implemented, accesses to the PE are controlled by the external authentication interface functions, ExternalInvasiveDebugEnabled(), ExternalNoninvasiveDebugEnabled(), ExternalSecureNoninvasiveDebugEnabled() and ExternalSecureInvasiveDebugEnabled(). The external authentication interface functions override MDCR_EL3.{EPMAD, EDAD}.

If ARMv8.4-Debug is implemented, the bus master, which may be the Debug Access Port, controls the accesses it makes to the PE and MDCR_EL3.{EPMAD, EDAD} control Non-secure access to registers.

The Debug Access Port is not required to use the same authentication interface as the PE.

ARM recommends the following authentication interface:
- When ExternalSecureInvasiveDebugEnabled() == FALSE at the PE, Secure debug is disabled at the DAP.
- When ExternalInvasiveDebugEnabled() == FALSE at the PE, all debug is prohibited at the DAP.
H1.2 External debug

Debug events allow an external debugger to halt the PE. ARMv8 provides the following debug events:

- **Halting Step debug events on page H3-6460:**
  - The debugger can use this resource to make the PE step through code one line at a time.

- **Halt Instruction debug event on page H3-6470:**
  - This might occur when software executes the Halting breakpoint instruction, HLT.

- **Exception Catch debug event on page H3-6471:**
  - This can be programmed to occur on all entries to a given Exception level.

- **External Debug Request debug event on page H3-6475:**
  - An embedded cross-trigger can signal this debug event.

- **OS Unlock Catch debug event on page H3-6476:**
  - This might occur when the state of the OS Lock changes from locked to unlocked.

- **Reset Catch debug events on page H3-6477:**
  - This might occur when the PE exits reset state.

- **Software Access debug event on page H3-6478:**
  - This can be programmed to occur when software tries to access the Breakpoint Value registers, the Breakpoint Control registers, the Watchpoint value registers, or the Watchpoint Control registers. It caused a trap to Debug state.

Breakpoints and watchpoints can also halt the PE.

When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.

- The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state:
  - The ITR contains a single register, EDITR, and associated flow-control flags.

- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger:
  - The DCC includes the data transfer registers, DTRRX and DTRTX, and associated flow-control flags.
  - Although the DCC is an essential part of Debug state operation, it can also be used in Non-debug state.

- The PE cannot service any interrupts in Debug state.

Chapter H2 Debug State describes Debug state in more detail.
H1.3 Required debug authentication

Any implementation must provide the debug authentication defined in this section, that controls:

- Whether the PE can halt.
- Whether non-invasive debug is permitted.
- Some legacy aspects of the AArch32 self-hosted debug model.

The pseudocode functions shown in Table H1-1, and the conditions that follow that table, define the architectural requirements for debug authentication.

### Table H1-1 Debug authentication functions

<table>
<thead>
<tr>
<th>Pseudocode function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ExternalSecureNoninvasiveDebugEnabled()</td>
<td>Returns TRUE if Secure non-invasive debug is enabled.</td>
</tr>
<tr>
<td>AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()</td>
<td>Returns TRUE if Secure invasive self-hosted debug is enabled in AArch32 state.</td>
</tr>
<tr>
<td>ExternalSecureInvasiveDebugEnabled()</td>
<td>Returns TRUE if Secure invasive debug is enabled.</td>
</tr>
<tr>
<td>ExternalNoninvasiveDebugEnabled()</td>
<td>Returns TRUE if Non-secure non-invasive debug is enabled.</td>
</tr>
<tr>
<td>ExternalInvasiveDebugEnabled()</td>
<td>Returns TRUE if Non-secure invasive debug is enabled.</td>
</tr>
</tbody>
</table>

The following conditions always apply:

- If ExternalInvasiveDebugEnabled() is FALSE then ExternalSecureInvasiveDebugEnabled() is FALSE.
- If ExternalNoninvasiveDebugEnabled() is FALSE then ExternalSecureNoninvasiveDebugEnabled() is FALSE.
- If ExternalInvasiveDebugEnabled() is TRUE then ExternalNoninvasiveDebugEnabled() is TRUE.
- If ExternalSecureInvasiveDebugEnabled() is TRUE then ExternalSecureNoninvasiveDebugEnabled() is TRUE.

If ARMv8.4-Debug is implemented:

- ExternalNoninvasiveDebugEnabled() always returns TRUE.
- ExternalSecureNoninvasiveDebugEnabled() returns the same as ExternalSecureInvasiveDebugEnabled().

ARM recommends the use of the interface described in Recommended authentication interface on page K2-7235 to provide this debug authentication. The pseudocode functions in Chapter J1 ARMv8 Pseudocode, that are linked to by the entries in the Pseudocode function column of Table H1-1, assume that this interface is implemented.
Chapter H2
Debug State

This chapter describes Debug state. It contains the following sections:

- *About Debug state* on page H2-6418.
- *Halting the PE on debug events* on page H2-6419.
- *Entering Debug state* on page H2-6426.
- *Behavior in Debug state* on page H2-6429.
- *Exiting Debug state* on page H2-6454.

**Note**

Table K13-1 on page K13-7390 disambiguates the general register references used in this chapter.
H2.1 About Debug state

In external debug, debug events allow an external debugger to halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The Instruction Transfer Register, ITR, passes instructions to the PE to execute in Debug state.
- The Debug Communications Channel, DCC, passes data between the PE and the debugger.

The PE cannot service any interrupts in Debug state.
H2.2 Halting the PE on debug events

For details of debug events, see Introduction to Halting debug events on page H3-6458 and Breakpoint and Watchpoint debug events on page H2-6420.

On a debug event, the PE must do one of the following:
- Enter Debug state.
- Pend the debug event.
- Generate a debug exception.
- Ignore the debug event.

This behavior depends on both:
- Whether halting is allowed by the current state of the debug authentication interface. See Halting allowed and halting prohibited.
- The type of debug event and the programming of the debug control registers.
  - See Halting debug events for all Halting debug events.
  - See Breakpoint and Watchpoint debug events on page H2-6420 for Breakpoint and Watchpoint debug events.

See also Other debug exceptions on page H2-6421.

This means that behavior can be CONSTRAINED UNPREDICTABLE if the conditions change. See Synchronization and Halting debug events on page H3-6479.

Summary of debug events and possible outcomes on page H3-6458 summarizes the possible outcomes of each type of debug event.

H2.2.1 Halting allowed and halting prohibited

Halting can be either allowed or prohibited:
- Halting is always prohibited in Debug state.
- Halting is always prohibited when DoubleLockStatus() == TRUE.
  - This means that OS Double Lock is implemented and locked.
- Halting is also controlled by the IMPLEMENTATION DEFINED authentication interface, and is prohibited when either:
  - The PE is in Non-secure state and ExternalInvasiveDebugEnabled() == FALSE.
  - The PE is in Secure state and ExternalSecureInvasiveDebugEnabled() == FALSE.

  **Note**
  
  See Appendix K2 Recommended External Debug Interface for more information on these functions.

  Otherwise, halting is allowed.

  For more information see:
  - Pseudocode description of Halting on debug events on page H2-6425
  - Required debug authentication on page H1-6416.

H2.2.2 Halting debug events

The Halting debug events are described in Chapter H3 Halting Debug Events.

When a Halting debug event is generated, it causes entry to Debug state if all of:
- Halting is allowed. See Halting allowed and halting prohibited.
The Halting debug event is one of:
- A Halt Instruction debug event and EDSCR.HDE == 1.
- A Software Access debug event and OSLSR_EL1.OSLK == 0, meaning that the OS Lock is unlocked.
- Neither a Halt Instruction debug event nor a Software Access debug event.

Note
- A Halt Instruction debug event is the only Halting debug event that relies on EDSCR.HDE == 1.
- Halting on Breakpoint and Watchpoint debug events is also controlled by EDSCR.HDE. See Breakpoint and Watchpoint debug events.
- EDSCR.HDE can be written by software when the OS Lock is locked. Privileged code can use SDCR.TDOSA and HDCR.TDOSA to trap writes to these registers.

If a Halting debug event does not generate entry to Debug state because the conditions listed in this section do not hold, then:
- If the Halting debug event is a Halt Instruction debug event, the instruction that generated the Halting debug event is treated as UNDEFINED.
- If the Halting debug event is an Exception Catch debug event or a Software Access debug event, it is ignored.

In all other cases the Halting debug event is pended, see Pending Halting debug events on page H3-6479.

Summary of actions from debug events on page H2-6423 summarizes the possible outcome for each type of Debug event.

Note
Halting debug events never generate debug exceptions.

H2.2.3 Breakpoint and Watchpoint debug events

A breakpoint or watchpoint generates an entry to Debug state if all of the following conditions hold:
- Halting debug is enabled, that is EDSCR.HDE == 1.
- Halting is allowed. See Halting allowed and halting prohibited on page H2-6419.
- The OS Lock is unlocked, that is OSLSR.OSLK == 0.

The Address Mismatch breakpoint type is reserved when all of these conditions are met.

MDSCR_EL1.MDE or DBGDSCRExt.MDBGen is ignored when determining whether to enter Debug state. A breakpoint or watchpoint that generates entry to Debug state is a Breakpoint or Watchpoint debug event and does not generate a debug exception.

A breakpoint or watchpoint that does not generate an entry to Debug state either:
- Generates a Breakpoint or Watchpoint exception.
- Is ignored.

Note
EDSCR.HDE is ignored when determining whether to generate a debug exception. The debug exception is suppressed only if the PE enters Debug state. This means that the use of Halting debug mode in Non-secure state does not affect the Exception model in Secure state.

See Chapter D2 AArch64 Self-hosted Debug, Chapter G2 AArch32 Self-hosted Debug, and the Note in Other debug exceptions on page H2-6421.
H2.2.4 Other debug exceptions

The following events never generate entry to Debug state:

- Breakpoint Instruction exceptions.
- Software Step exceptions.
- Vector Catch exceptions.

The behavior of these events is unchanged when Halting debug mode is enabled, that is when \texttt{EDSCR.HDE == 1}. This means that these events can do one of the following:

- They can generate a debug exception.
- They can be ignored.

For additional information, see Chapter D2 AArch64 Self-hosted Debug and Chapter G2 AArch32 Self-hosted Debug.

H2.2.5 Debug state entry and debug event prioritization

The following are synchronous debug events:

- Breakpoint debug event.
- Watchpoint debug event.
- Halting Step debug event.
- Halt Instruction debug event.
- Exception Catch debug event.
- Software Access debug event.
- Reset Catch debug event.

Each of these synchronous debug events are treated as a synchronous exception generated by an instruction, or by the taking of an exception or reset. That is, if halting is allowed, the synchronous debug event must be taken before any subsequent instructions are executed. Reset Catch debug events must be taken before the PE executes the instruction at the reset vector.

--- Note ---

- Reset Catch and Exception Catch debug events might be generated asynchronously, because they can result from an asynchronous exception. However, if halting is allowed after the reset or asynchronous exception has been processed, the Reset Catch or Exception Catch debug event is taken synchronously.
- The Halting Step debug event is generated by the instruction after the stepped instruction. Therefore, if the stepped instruction generates any other synchronous exceptions or debug events these are taken first.

---

If halting is prohibited then Halting Step debug events and Reset Catch debug events might be pended and taken asynchronously. OS Unlock Catch debug events are always pended and taken asynchronously. See Pending Halting debug events on page H3-6479.

The architecture does not define when asynchronous debug events are taken, and therefore the prioritization of asynchronous debug events is IMPLEMENTATION DEFINED. See Synchronization and Halting debug events on page H3-6479.

The following list shows how the synchronous debug events are prioritized, with 1 being the highest priority.

--- Note ---

The priority numbering is the same as the numbering for AArch64 synchronous exception priorities listed in Synchronous exception types, routing and priorities on page D1-2178, and in particular Prioritization and recognition of interrupts on page D1-2194. This numbering correlates with the equivalent AArch32 list in Exception prioritization for exceptions taken to AArch32 state on page G1-5250.

The priority for synchronous debug events is as follows:

1 Reset Catch debug event. See Reset Catch debug events on page H3-6477.
This debug event has a higher priority than the synchronous exceptions listed in Synchronous exception types, routing and priorities on page D1-2178.

2 Exception Catch debug event. See Exception Catch debug event on page H3-6471.
This debug event can be assigned one of two priorities. When it has a priority of 2, it has a higher priority than the synchronous exceptions listed in the Exception model. See Exception Catch debug event on page H3-6471.

3 Halting Step debug event. See Halting Step debug events on page H3-6460.
This debug event has a higher priority than the synchronous exceptions listed in the Exception model.

4 These events are not debug events.

5 Exception Catch debug event. See Exception Catch debug event on page H3-6471.
This debug event can be assigned one of two priorities, 0 or 5. See Exception Catch debug event on page H3-6471.

6 - 7 These events are not debug events.

8 Breakpoint exception or debug event or Address Matching Vector Catch exception. See Breakpoint exceptions on page D2-2284, and Vector Catch exceptions on page G2-5413.
These two debug events have the same priority.

9 - 10 These events are not debug events.

11 Halt Instruction debug event. See Halt Instruction debug event on page H3-6470.

12 - 24 These events are not debug events.

26 - 27 These events are not debug events.

28 Watchpoint exception or debug event. See Watchpoint exceptions on page D2-2302 for exceptions taken from AArch64 state, or Watchpoint exceptions on page G2-5399 for exceptions taken from AArch32 state.

29 This event is not a debug event.

For Reset Catch debug events and Halting Step debug events the priorities listed in this section only apply when halting is allowed at the time the event is generated. This means that the event is taken synchronously and not pended.

For more information on the prioritization of exceptions see:
• Synchronous exception types, routing and priorities on page D1-2178.
• Prioritization and recognition of interrupts on page D1-2194.
• Exception prioritization for exceptions taken to AArch32 state on page G1-5250. This section covers synchronous and asynchronous exceptions.

**Breakpoint debug events and Vector Catch exception**

An Address Matching Vector Catch exception has the same priority as a Breakpoint debug event. See Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2179.

The prioritization of these events is unchanged even if the breakpoint generates entry to Debug state instead of a Breakpoint exception. This means that if a single instruction generates both an Address Matching Vector Catch exception and a Breakpoint debug event, there is a CONSTRAINED UNPREDICTABLE choice of:
• The PE entering Debug state due to the Breakpoint debug event.
• A Vector Catch exception.
This only applies if all of the following are true:

- Halting debug is enabled.
- Halting is allowed.
- The OS Lock is unlocked.

An Exception Trapping Vector Catch exception must be generated immediately following the exception that generated it. This means that it does not appear in the priority table.

### H2.2.6 Imprecise entry to Debug state

Entry to Debug state is normally precise, meaning that the PE cannot enter Debug state if it can neither complete nor abandon all currently executing instructions and leave the PE in a precise state.

A debugger can write a value of 1 to EDRCR.CBRRQ to allow imprecise entry to Debug state. An External Debug Request debug event must be pending before writing 1 to this bit. Support for this feature is OPTIONAL and it is IMPLEMENTATION DEFINED when it is effective at forcing entry to Debug state.

The PE ignores writes to this bit if either:

- External debugging is not enabled, meaning `ExternalInvasiveDebugEnabled()` == FALSE.
- Secure external debugging is not enabled, meaning `ExternalSecureInvasiveDebugEnabled()` == FALSE, and either:
  - EL3 is not implemented and the implemented Security state is Secure state.
  - EL3 is implemented.

Example H2-1 shows how entry to Debug state can be forced.

#### Example H2-1 Forcing entry to Debug state

The debugger pends an External Debug Request debug event through the CTI to halt a program that has stopped responding. However, the memory system is not responding and a memory access instruction cannot complete. This means that Debug state cannot be entered precisely. The debugger writes a value of 1 to EDRCR.CBRRQ. The PE cancels all outstanding memory accesses and enters Debug state. As some instructions might not have completed correctly, entry to Debug state is imprecise.

When Debug state is entered imprecisely, all memory access instructions executed through the ITR have UNPREDICTABLE behavior. The value of all registers is UNKNOWN, but might be useful for diagnostic purposes.

### H2.2.7 Summary of actions from debug events

Table H2-1 on page H2-6424 shows the Software and Halting debug events. In Table H2-1 on page H2-6424 the columns have the following meaning:

#### Debug event type

This means the type of debug event where:

<table>
<thead>
<tr>
<th>Other software</th>
<th>Means one of:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Software Step exceptions on page D2-2317.</td>
</tr>
<tr>
<td></td>
<td>• Breakpoint Instruction exceptions on page D2-2282.</td>
</tr>
<tr>
<td></td>
<td>• Vector Catch exceptions on page D2-2316 for AArch64 state or</td>
</tr>
<tr>
<td></td>
<td>Vector Catch exceptions on page G2-5413 for AArch32 state.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Other Halting</th>
<th>Means one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Halting Step debug events on page H3-6460.</td>
</tr>
<tr>
<td></td>
<td>• External Debug Request debug event on page H3-6475.</td>
</tr>
<tr>
<td></td>
<td>• Reset Catch debug events on page H3-6477.</td>
</tr>
</tbody>
</table>
Other debug events are referred to explicitly.

**Authentication**

This means halting is allowed by the IMPLEMENTATION DEFINED external authentication interface. It is the result of one of the following pseudocode functions:

- **In Secure state** `ExternalSecureInvasiveDebugEnabled()`.
- **In Non-secure state** `ExternalInvasiveDebugEnabled()`.

**DLK**

This indicates whether the OS Double Lock is implemented and locked, `doubleLockStatus()` == TRUE.

**OSLK**

This is the value of `OSLSR.OSLK`. It indicates whether the OS Lock is locked.

**HDE**

This is the value of `EDSCR.HDE`. It indicates whether Halting debug is enabled.

The letter X in Table H2-1 indicates that the value can be either 0 or 1.

### Table H2-1  Debug authentication for external debug

H2.2.8 Pseudocode description of Halting on debug events

The `Halted()`, `Restarting()`, `HaltingAllowed()`, and `HaltOnBreakpointOrWatchpoint()` functions are described in the ARMv8 pseudocode.
H2.3 Entering Debug state

On entry to Debug state, the preferred restart address and PSTATE are saved in DLR and DSPSR. The PE remains in the mode and security state from which it entered Debug state.

If EDRCR.CBRRQ has a value of 0, entry to Debug state is precise. If EDRCR.CBRRQ has a value of 1, then imprecise entry to Debug state is permitted.

If a Watchpoint debug event causes an entry to Debug state, the address of the access that generated the Watchpoint debug event is recorded in EDWAR.

For more information see:

- Determining the memory location that caused a Watchpoint exception on page D2-2310 for a debug event taken from AArch64 state.
- Determining the memory location that caused a Watchpoint exception on page G2-5406 for a debug event taken from AArch32 state.

Other than the effect on PSTATE and EDSCR, entry to Debug state is not a Context synchronization event. The effects of entry to Debug state on PSTATE and EDSCR are synchronized.

H2.3.1 Entering Debug state from AArch32 state

When entering Debug state from AArch32 state, the PE remains in AArch32 state. In AArch32 Debug state the PE executes T32 instructions, regardless of the value of PSTATE.T before entering Debug state.

To allow the debugger to determine the state of the PE, the current Execution state for all four Exception levels can be read from EDSCR.RW, and the current Exception level can be read from EDSCR.EL.

The current endianness state, PSTATE.E, is unchanged on entry to Debug state.

--- Note ---

- If EL1 is using AArch32 state, the current endianness state can differ from that indicated by SCTLR.EE.
- If EL2 is using AArch32 state, the current endianness state can differ from that indicated by HSCTLR.EE.
- On entry to Debug state from AArch32 state, PSTATE.SS is copied to DSPSR.SS, even though the PE remains in AArch32 state.

See also Effect of entering Debug state on PSTATE on page H2-6427.

H2.3.2 Effect of Debug state entry on DLR and DSPSR

DLR is set to the preferred restart address for the debug event, that depends on the event type. The value of PSTATE is saved in DSPSR. For entry to Debug state from AArch32 state, the values saved in DSPSR.IT are always correct for the preferred restart address.

For synchronous Halting debug events, the preferred restart address is the address of the instruction that generated the debug event.

For asynchronous Halting debug events, including pending Halting debug events taken asynchronously, the preferred restart address is the address of the first instruction that must be executed on exit from Debug state.

This means that:

- For Breakpoint and Watchpoint debug events, the preferred restart address is the same as the preferred return address for a debug exception, as described in Chapter D2 AArch64 Self-hosted Debug and Chapter G2 AArch32 Self-hosted Debug.
- For Halt Instruction debug events DLR is set to the address of the HLT instruction and DSPSR.IT is correct for the HLT instruction.
For Software Access debug events, DLR is set to the address of the accessing instruction and DSPSR.IT is correct for this instruction.

For Halting Step debug events taken synchronously, DLR and DSPSR are set as the ELR and SPSR would be set for a Software Step exception. This is usually the address of, and PSTATE for, the instruction after the one that was stepped.

For Exception Catch debug events:

— If the debug event is generated on taking an exception to a trapped Exception level, the DLR is set to the address of the exception vector the PE would have started fetching from. This is UNKNOWN if the VBAR for the Exception level has never been initialized. The DSPSR records the value of PSTATE after taking the exception. The Exception Catch occurs after the SPSR and the Link register are set, and the debugger can use these registers to determine where in the application program the exception occurred.

Note

Depending on the target Exception level and Execution state for the exception, the Link register is one of ELR_EL1, ELR_EL2, ELR_EL3, ELR_hyp, or LR (R14).

— If the debug event is generated on an exception return to a trapped Exception level, the DLR is set to the target address of the exception return and the DSPSR records the value of PSTATE after the exception return.

Reset Catch debug events taken synchronously behave like Exception Catch debug events.

For Reset Catch debug events and Exception Catch debug events generated on reset to a trapped Exception level, the DLR is set to the reset address and the DSPSR records the reset value of PSTATE.

For pending Halting debug events and External Debug Request debug events, DLR is set to the address of the first instruction that must be executed on exit from Debug state and DSPSR.IT is correct for this instruction. See Pending Halting debug events on page H3-6479.

Normally DLR is aligned according to the instruction set state indicated in DSPSR. However, a debug event might be taken at a point where the PC is not aligned.

Effect of Debug state entry on System registers, the Event register, and Exclusives monitors

Entering Debug state has no effect on System registers other than DLR and DSPSR. In particular, ESRs, FARs, and FSRs are not updated on entering Debug state. SCR is unchanged, even when entering Debug state from EL3.

Entering Debug state has no architecturally-defined effect on the Event Register and Exclusives monitors.

Note

Entry to Debug state might set the Event Register or clear the Exclusives monitors, or both. However, this is not a requirement, and debuggers must not rely on any implementation specific behavior.

Unless otherwise described in this reference manual, instructions executed in Debug state have their architecturally-defined effects on the System registers, the Event register, and Exclusives monitors.

Effect of entering Debug state on PSTATE

The effect of an entry to Debug state on PSTATE is described in Entering Debug state on page H2-6426 and Entering Debug state from AArch32 state on page H2-6426. On entry to Debug state:

- PSTATE.\{E, M, nRW, EL, SP, DIT\} are unchanged.
- PSTATE.IL is cleared to 0, after being saved in DSPSR_EL0.IL.
- PSTATE.PAN is saved in DSPSR_EL0.PAN.
- PSTATE.UAO is saved in DSPSR_EL0.UAO.
The other \texttt{PSTATE} fields are ignored and not observable in Debug state:

- \texttt{PSTATE.\{N, Z, C, V, Q, GE\}} are unchanged.
- \texttt{PSTATE.\{IT, T, SS, D, A, I, F\}} are set to \textbf{UNKNOWN} values, after being saved in \texttt{DSPSR_EL0}.

For more information see \textit{Process state (PSTATE) in Debug state} on page H2-6429.

\section*{H2.3.5 Entering Debug state during loads and stores}

The PE can enter Debug state during instructions that perform a sequence of memory accesses, as opposed to a single single-copy atomic access, because of a Watchpoint debug event. The effect of entering Debug state on such an instruction is the same as taking a Data Abort exception during such an instruction.

In addition, when executing in AArch64 state, the PE can enter Debug state during instructions that perform a sequence of memory accesses because of an External Debug Request debug event. The effect of entering Debug state on such an instruction is the same as taking an interrupt exception during such an instruction.

This applies to all memory types.

\section*{H2.3.6 Entering Debug state and Software Step}

When Software Step is active, a debug event that causes entry to Debug state behaves like an exception taken to an Exception level above the debug target Exception level. That is:

- If the instruction that is stepped generates a synchronous debug event that causes entry to Debug state, or an asynchronous debug event is taken before the step completes, the PE enters Debug state with \texttt{DSPSR.SS} set to 1.
- A pending Halting debug event or an asynchronous debug event can be taken after the step has completed. In this case the PE enters Debug state with \texttt{DSPSR.SS} set to 0.

In addition:

- If the instruction that is stepped generates an exception trapped by an Exception Catch debug event, the PE enters Debug state at the exception vector with \texttt{DSPSR.SS} set to 0. This is because \texttt{PSTATE.SS} is set to 0 by taking the exception.
- If the PE is reset, \texttt{PSTATE.SS} is reset to 0. If the following debug events are enabled, the PE enters Debug state with \texttt{DSPSR.SS} set to 0:
  - Reset Catch debug event at the reset Exception level.
  - Exception Catch debug event at the reset Exception level.
  - Halting Step debug event.
- If Halting Step is also active, then Halting Step and Software Step operate in parallel and can both become active-pending. In this case Halting step has a higher priority than Software step. This means that the PE enters Debug state and \texttt{DSPSR.SS} is set to 0.

\section*{H2.3.7 Pseudocode description of entering Debug state}

The \texttt{Debug\_halt} constants are described in \texttt{shared/debug/halting/DebugHalt} on page J1-7092 in the ARMv8 pseudocode. The \texttt{UpdateEDCSRFields()} and \texttt{Halt()} functions are described in Chapter J1 \textit{ARMv8 Pseudocode}. 
H2.4 Behavior in Debug state

Instructions are executed in Debug state from the Instruction Transfer Register, ITR. The debugger controls which instructions are executed in Debug state by writing the instructions to the External Debug Instruction Transfer register, EDITR. The Execution state of the PE determines which instruction set is executed:

- If the PE is in AArch64 state it executes A64 instructions.
- If the PE is in AArch32 state it executes T32 instructions:
  - For a 32-bit T32 instruction, EDITR[15:0] specifies the first halfword and EDITR[31:16] specifies the second halfword.
  - For a 16-bit T32 instruction, EDITR[15:0] contains the instruction and EDITR[31:16] is ignored. All 16-bit T32 instructions are UNPREDICTABLE in Debug state.

The PE does not execute A32 instructions in Debug state.

Some instructions are available only in Debug state. See Debug state operations, DCPS, DRPS, MRS, MSR on page H2-6445. In Non-debug state these instructions are UNDEFINED.

The following sections describe behavior in Debug state:

- Process state (PSTATE) in Debug state.
- Executing instructions in Debug state on page H2-6430.
- Decode tables on page H2-6440.
- Security in Debug state on page H2-6444.
- Privilege in Debug state on page H2-6445.
- Debug state operations, DCPS, DRPS, MRS, MSR on page H2-6445.
- Exceptions in Debug state on page H2-6448.
- Accessing registers in Debug state on page H2-6450.
- Accessing memory in Debug state on page H2-6453.

This section specifies the CONSTRAINED UNPREDICTABLE behaviors that apply in Debug state, but see Changing the value of EDECR.SS when not in Debug state on page H3-6467 for a change in Non-debug state that causes CONSTRAINED UNPREDICTABLE behavior.

H2.4.1 Process state (PSTATE) in Debug state

PSTATE.{N, Z, C, V, GE, IT, T, SS, D, A, I, F} are all ignored in Debug state:

- There are no conditional instructions in Debug state.
- In AArch32 state, the PE only executes T32 instructions and PSTATE.IT is ignored.
- Asynchronous exceptions and debug events are ignored.
- Software step is inactive.

Instructions executed in Debug state indirectly read PSTATE.{UAO, PAN, IL, E, M, nRW, EL, SP} as they would in Non-debug state.

Note

PSTATE.DIT is not guaranteed to have any effect in Debug state.

In Debug state:

- PSTATE.PAN is set to 1 by:
  - A DCPS instruction to EL1 using AArch64 if SCTLR_EL1.SPAN == 0.
  - A DCPS instruction to EL2 using AArch64 if SCTLR_EL2.SPAN == 0.
- PSTATE.UAO is set to 0 by a DCPS instruction to AArch64.
- PSTATE can also be changed by taking exceptions in Debug state, and by the execution of DCPS and DRPS instructions.
H2.4.2 Executing instructions in Debug state

The instructions executed in Debug state must be either A64 instructions or T32 instructions, depending on the current Execution state.

Each instruction falls into one of the following groups:

• Debug state instructions. These are instructions that are changed in Debug state. See A64 instructions that are changed in Debug state and T32 instructions that are changed in Debug state on page H2-6435.

• Instructions that are unchanged in Debug state. See A64 instructions that are unchanged in Debug state and T32 instructions that are unchanged in Debug state on page H2-6436.

• Instructions that are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Debug state. See A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state on page H2-6432 and T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state on page H2-6438.

All T32 instructions are treated as unconditional, regardless of PSTATE.IT. See Process state (PSTATE) in Debug state on page H2-6429.

If EDSCR.SDD == 1 then an instruction executed in Non-secure state cannot cause entry into Secure state. See Security in Debug state on page H2-6444.

Executing A64 instructions in Debug state

The following sections describe the behavior of the A64 instructions in Debug state:

• A64 instructions that are changed in Debug state.
• A64 instructions that are unchanged in Debug state.
• A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state on page H2-6432.

A64 instructions that are changed in Debug state

The following A64 instructions are defined in Debug state, but are undefined in Non-debug state:

• DCPS.

Note

DCPS can be UNDEFINED in certain conditions in Debug state. See DCPS<n> on page H2-6445.

• DRPS.

• MRS (DLR_EL0), MSR (DSPSR_EL0), MSR (DLR_EL0), MSR (DSPSR_EL0)

For more information see Debug state operations, DCPS, DRPS, MRS, MSR on page H2-6445.

A64 instructions that are unchanged in Debug state

The following list shows the instructions that are unchanged in Debug state:

Any instruction that is UNDEFINED in Non-debug state

This list of instructions excludes:

• Any instruction listed in A64 instructions that are changed in Debug state.
• Any instruction listed in A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state on page H2-6432 that is UNDEFINED because an enable or disable bit is not RES0 or RES1

Instructions that move System or Special-purpose registers to or from a general-purpose register

This list of instructions:

• Includes the instructions to transfer a general-purpose register to or from the DTR, which can be executed at any Exception level.
• Excludes PSTATE access instructions.
These instructions are:

- `MRS <special_reg>, MSR <special_reg>.

--- Note ---

This does not include NZCV, DAIF, DAIFSet, DAIFClr, SPSel, and CurrentEL.

---

- `MRS <system_reg>, MSR <system_reg>.

**Floating-point moves between a SIMD&FP register and a general-purpose register**

These instructions are:

- `FMOV (between a general-purpose register and a half-precision register).
- `FMOV (between a general-purpose register and a single-precision register).
- `FMOV (between a general-purpose register and a double-precision register).
- `FMOV (between a general-purpose register and a SIMD element).

**SIMD moves between a SIMD&FP register and a general-purpose register**

These instructions are:

- `INS (from a general-purpose register to a SIMD element).
- `UMOV (from a SIMD element to a general-purpose register).

**Barriers**

These instructions are:

- `DMB.
- `DSB.
- `ESB, when the RAS Extension is implemented.
- `ISB.
- `PSB, when the Statistical Profiling Extension is implemented.

**Memory access instructions at various access sizes**

The following constraints apply:

- General purpose-registers only.
- One of the following addressing modes:
  - Unscaled (9-bit signed) immediate offset.
  - Immediate (9-bit signed) post-indexed.
  - Immediate (9-bit signed) pre-indexed.
  - Unprivileged (9-bit signed).
- Not literal.
- One of the following types:
  - (Single) register.
  - Exclusive.
  - Exclusive pair.
  - Acquire/Release.
  - Acquire/Release Exclusive.
  - Acquire/Release Exclusive pair.
- 32-bit and 64-bit target register variants.

These instructions are:

- `LDR, LDRB, LDRH, LDRSB, LDRSH, LDRSW (immediate, not literal).
- `LDUR, LDURB, LDURH, LDURSB, LDURSH, LDURSW (immediate).
- `LDTR, LDTREB, LDTREH, LDTSRB, LDTSRSH, LDTSRW (immediate).
- `LDAR, LDARB, LDARH, LDAXR, LDAXRB, LDAXRH, LDAXRSH, LDAXRSH.
- `LDXP, LDAXP.
- `STR, STRB, STRH (immediate).
- `STUR, STURB, STURH (immediate).
H2 Debug State
H2.4 Behavior in Debug state

- STTR, STTRB, STTRH (immediate).
- STLR, STLRB, STLHR, STXR, STXRB, STXRH, STLXR, STLXRH, STLXR.
- STXP, STLXP.
- LDLAR, LDLARB, LDLARH - ARMv8.1 instructions.
- STLLR, STLLRBB, STLLRH - ARMv8.1 instructions.
- CAS, CASB, CASH, CASP - ARMv8.1 instructions.
- SWP, SWPB, SWPH - ARMv8.1 instructions.
- LDADD, LDADDB, LDADDH - ARMv8.1 instructions.
- LDCLR, LDCLB, LDCLRH - ARMv8.1 instructions.
- LDEOR, LDEORB, LDEORH - ARMv8.1 instructions.
- LDSET, LDSETB, LDSETH - ARMv8.1 instructions.
- LDSMAX, LDSMAXB, LDSMAXH - ARMv8.1 instructions.
- LDSMIN, LDSMINB, LDSMINH - ARMv8.1 instructions.
- LDUMAX, LDUMAXB, LDUMAXH - ARMv8.1 instructions.
- LDUMIN, LDUMINB, LDUMINH - ARMv8.1 instructions.
- STADD, STADDB, STADDH - ARMv8.1 instructions.
- STEOR, STEORB, STEORH - ARMv8.1 instructions.
- STSET, STSETH, STSE TB - ARMv8.1 instructions.
- STSMAX, STSMAXB, STSMAXH - ARMv8.1 instructions.
- STSMIN, STSMINB, STSMINH - ARMv8.1 instructions.
- STUMAX, STUMAXB, STUMAXH - ARMv8.1 instructions.
- STUMIN, STUMINB, STUMINH - ARMv8.1 instructions.
- LDAPR, LDAPRB, LDAPRH - ARMv8.3 instructions.
- LDAPURH, LDAPURSH, LDAPUR, LDAPURSW, LDAPURSB, LDAPURB - ARMv8.4 instructions.
- STLUR, STLURH, STLURB - ARMv8.4 instructions.

Move immediate to general-purpose register

These instructions are:
- MOVZ, MOVN, MOVK (immediate).
- MOV (between a general-purpose register and the stack pointer).

System instructions, Send Event, NOP, and Clear Exclusive

In this context, the System instructions are the Cache maintenance instructions, TLB maintenance instructions, and the Address translation instructions.

These instructions are:
- IC.
- DC.
- TLBI.
- AT.
- SEV, SEVL.
- NOP.
- CLREX.

A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state

This subsection describes all instruction not listed in either:
- A64 instructions that are changed in Debug state on page H2-6430.
- A64 instructions that are unchanged in Debug state on page H2-6430.
These instructions are CONSTRAINED UNPREDICTABLE in Debug state. In general, the permissible behaviors are:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- If the instruction reads the PC or PSTATE, it uses an UNKNOWN value.
- If the instruction modifies the PC or PSTATE, other than by advancing the PC to the sequentially next instruction, it sets DLR_EL0 and DSPSR_EL0 to UNKNOWN values.
- If the instruction is similar to a Debug state instruction, it executes as that Debug state instruction.
- The instruction has the same behavior as in Non-debug state.

The following list shows the permissible behaviors for A64 instruction in Debug state. An instruction might appear multiple times in the list, in which case the choice of permissible behaviors is any of those listed. An example of this is COMP.

**Exception-generating instructions**

These instructions are:

- SVC.
- HVC.
- SMC.
- BRK.
- HLT.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- SVC behaves as DCPS1.
- HVC behaves as DCPS2.
- SMC behaves as DCPS3.
- They generate the exception that the instruction would generate in Non-debug state. The exception is taken as described in Exceptions in Debug state on page H2-6448

--- **Note**

SMC must not generate a Secure Monitor Call exception from Non-secure state if EDSCE.R.SDD is set to 1.

---

**Instructions that explicitly write to the PC (branches)**

These instructions are:

- B, B . cond, BL, BLR, BR, CBZ, CBNZ, RET, TBZ, TBNZ.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching and set DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

**Exception return and related instructions**

These instructions are:

- ERET.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
They execute as in Non-debug state without branching. They set DSPSR_EL0 and DLR_EL0 to UNKNOWN values, and either:
- Execute the DRPS operation instead of performing an exception return, using UNKNOWN SPSR values.
- Not change the Exception level.

**Instructions that request entry to a low-power state**

These instructions are:
- WFE, WFI.

These instructions behave in one of the following ways:
- They are UNDEFINED.
- They execute as a NOP.
- They generate a synchronous exception if the corresponding instruction would be trapped in Non-debug state. See *Configurable instruction enables and disables, and trap controls* on page D1-2196.
- A WFE instruction clears the Event register if it is set.

**Note**

This means that these instructions must not suspend execution.

**Instructions that read the PC**

These instructions are:
- LDR (literal), LDRSW (literal).
- ADR, ADRP.
- PRFM (literal).

These instructions behave in one of the following ways:
- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state, using an UNKNOWN value for the PC operand.

**Instructions that explicitly modify PSTATE, other than DCPS and DRPS**

These instructions are:
- ADDS, SUBS, ADCS, SBCS, ANDS, BICS, CCON, CCOMP.
- FCMP, FCMP, FCOMP, FCOMPE.
- MSR DAIFSet (immediate), MSR DAIFClr (immediate), MSR SPSEL (immediate).
- MSR NZCV (register), MSR DAIF (register), MSR SPSEL (register).
- When ARMv8.1-PAN is implemented, MSR PAN (immediate) and MSR PAN (register).
- When ARMv8.2-UAO is implemented, MSR UA0 (immediate) and MSR UA0 (register).
- When ARMv8.4-CondM is implemented, CFINV, RMIF, SETF8, SETF16.
- When ARMv8.4-DIT is implemented, MSR DIT.

These instructions behave in one of the following ways:
- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state, setting DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

**Instructions that read PSTATE.{N, Z, C, V} or other PSTATE fields**

These instructions are:
- CSEL, CSINC, CSINV, CSNEG, COMN, CCOMP, FCSEL, FCOMP, FCOMPE.
- ADC, ADCS, SBC, SBCS.
- CFINV.
- MRS NZCV, MRS DAIF, MRS SPSEL, MRS CurrentEL.
• When ARMv8.1-PAN is implemented, MRS PAN.
• When ARMv8.2-UAO is implemented, MRS UAO.
• When ARMv8.4-CondM is implemented, CFINV.
• When ARMv8.4-DIT is implemented, MRS DIT.

These instructions behave in one of the following ways:
• They are UNDEFINED.
• They execute as a NOP.
• They execute as in Non-debug state:
  — For the conditional operations and those using the PSTATE.C flag as an input, these instructions use an UNKNOWN value for the Condition flag.
  — For the MRS instruction, they return an UNKNOWN value.

**All other instructions**

These instructions behave in one of the following ways:
• They are UNDEFINED.
• They execute as a NOP.
• They have the same behavior as in Non-debug state.

__________Note__________

This includes instructions defined as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state. These instructions are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Debug state.

---

**Executing T32 instructions in Debug state**

The following sections describe the behavior of the T32 instructions in Debug state:
• T32 instructions that are changed in Debug state.
• T32 instructions that are unchanged in Debug state on page H2-6436.
• T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state on page H2-6438.

**T32 instructions that are changed in Debug state**

The following T32 instructions are defined in Debug state, but are undefined in Non-debug state:
• DCPS

__________Note__________

DCPS can be UNDEFINED in certain conditions in Debug state. See DCPS<n> on page H2-6445.

• MRC p15,3,<Rt>,c4,c5,0 (DSPSR).
• MCR p15,3,<Rt>,c4,c5,0 (DSPSR).
• MRC p15,3,<Rt>,c4,c5,1 (DLR).
• MCR p15,3,<Rt>,c4,c5,1 (DLR).

In addition, ERET executes the DRPS operation in Debug state.

For more information see Debug state operations, DCPS, DRPS, MRS, MSR on page H2-6445.
T32 instructions that are unchanged in Debug state

The following list shows the instructions that are unchanged in Debug state. Any T32 instruction that uses the PC or APSR, \{N, Z, C, V\} as the source or destination register is not included in the list. Moreover, the list only includes the 32-bit T32 encodings.

Any instruction that is UNDEFINED in Non-debug state

The list of instructions:

- Excludes any instruction listed in T32 instructions that are changed in Debug state on page H2-6435.
- Excludes any instruction listed in T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state on page H2-6438 that is UNDEFINED because an enable or disable bit is not RES0 or RES1.

Instructions that move System or Special-purpose registers to or from a general-purpose register

The list of instructions:

- Includes the instructions to transfer a general-purpose register to or from the DTR, which can be executed at any Exception level.
- Excludes APSR and CPSR access instructions.
- Excludes instructions for accessing banked registers for the current mode.

These instructions are:

- MRS <banked_reg>, MSR <banked_reg>.  
  
  \textbf{Note} 
  This does not apply to cases which are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state in the current mode.

- MRC, MCR.  
  
  \textbf{Note} 
  This includes all allocated System registers in the (coproc==0b111x) encoding space other than an MRC move to APSR_nzcv.

- MRS SPSR, MSR SPSR.
- VMRS <vfp_system_reg>, VMSR <vfp_system_reg>.  
  
  \textbf{Note} 
  This includes all allocated Advanced SIMD and floating-point System registers, other than an a VMRS move to APSR_nzcv.

Floating-point moves between a SIMD&FP register and a general-purpose register

These instructions are:

- \texttt{VMOV} (between a general-purpose register and a single-precision register).
- \texttt{VMOV} (between a general-purpose register and a doubleword floating-point register).

SIMD moves between a SIMD&FP register and a general-purpose register

These instructions are:

- \texttt{VMOV} (between a general-purpose register and a scalar).

Barriers

These instructions are:

- DMB.
- DSB.
- ESB, when the RAS Extension is implemented.
- ISB.
Memory access instructions at various access sizes

The following constraints apply:

• General purpose-registers only.
• One of the following addressing modes:
  — Immediate (8-bit or 12-bit) offset.
  — Immediate (8-bit) post-indexed.
  — Immediate (8-bit) pre-indexed.
  — Unprivileged (8-bit).
• Not literal.
• One of the following types:
  — (Single) register.
  — Dual.
  — Exclusive.
  — Exclusive doubleword.
  — Acquire/Release.
  — Acquire/Release Exclusive.
  — Acquire/Release Exclusive doubleword.

These instructions are:

• LDR.W, LDRB.W, LDRH.W, LDRD, LDRSB.W, LDRSH.W (immediate, not literal).
• LDRT, LDRBT, LDRHT, LDRSBT, LDRSHT (immediate).
• LDREX, LDREXB, LDREXH, LDA, LDAB, LDAH, LDAEX, LDAEXB, LDAEXH.
• LDREXD, LDAEXD.
• STR.W, STRB.W, STRH.W, STRD (immediate).
• STRT, STRBT, STRHT (immediate).
• STREX, STREXB, STREXH, STL, STLH, STLEX, STLEXB, STLEXH.
• STREXD, STLEXD.

Move to general-purpose register

These instructions are:

• MOVW, MOVT (immediate).

System instructions, Send Event, NOP, and Clear Exclusive

The System instructions are Cache maintenance instructions, TLB maintenance instructions, and Address translation instructions. These are encoded in the (coproc == 0b1111) System register encoding space.

These instructions are:

• ICIALLU, ICIALLUIS, ICIMVAU.
• DCCIMVAC, DCCISW, DCCMVCAC, DCCMVAU, DCCSW, DCIMVAC, DCISW.
• TLBIALLLH, TLBIALLLHS, TLBIALLLHIS, TLBIALLNSH, TLBIALLNSHIS, TLBIALSID, TLBIALSIDIS, TLBIIPAS2, TLBIIPAS2IS, TLBIIPAS2L, TLBIIPAS2LIS, TLBIMVA, TLBIMVAA, TLBIMVAIS, TLBIMVAAIS, TLBIMVAAAL, TLBIMVAAALIS, TLBIMVAHL, TLBIMVAAHIS, TLBIMVAHIS, TLBIMVAH, TLBIMVAAHIS, TLBIMVAAAL, TLBIMVAAALIS, TLBIMVAHLIS, TLBIMVAHL.
• ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, ATS12NSOUW, ATS1CPR, ATS1CPW, ATS1CUR, ATS1CUW, ATS1HR, ATS1HW.
• BPIALL, BPIALLIS, BPIMVA.
• SEV.W, SEVL.W.
• NOP.W.
• CLREX.
**T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state**

This subsection describes all instruction not listed in either:

- T32 instructions that are changed in Debug state on page H2-6435.
- T32 instructions that are unchanged in Debug state on page H2-6436.

These instructions are CONSTRAINED UNPREDICTABLE in Debug state. In general, the permissible behaviors are:

- The instruction generates an Undefined Instruction exception.
- The instruction executes as a NOP.
- If the instruction reads the PC or PSTATE, it uses an UNKNOWN value.
- If the instruction modifies the PC or PSTATE, other than by advancing the PC to the sequentially next instruction, it sets DLR and DSPSR to unknown values.
- If the instruction is similar to a Debug state instruction, it executes as that Debug state instruction.
- The instruction has the same behavior as in Non-debug state.

The following list shows the permissible behaviors for T32 instruction in Debug state. An instruction might appear multiple times in the list, in which case the choice of permissible behaviors is any of those listed.

### Exception-generating instructions

These instructions are:

- SVC.
- HVC.
- SMC.
- UDF.
- BKPT.
- HLT.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- SVC behaves as DCPS1.
- HVC behaves as DCPS2.
- SMC behaves as DCPS3.
- They generate the exception the instruction would generate in Non-debug state. The exception is taken as described in Exceptions in Debug state on page H2-6448

---

**Note**

SMC must not generate a Secure Monitor Call exception from Non-secure state if EDSR.SDD is set to 1.

---

### Instructions that explicitly write to the PC (branches)

These instructions are:

- B, B (conditional), CBZ, CBNZ BL.
- BX, BLX (register or immediate).
- BXJ, TBB, TBH.
- MOV pc and related instructions.
- LDR pc, LDM (with a register list includes the PC), POP (with a register list that includes the PC).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
• They execute as in Non-debug state without branching and set DSPSR and DLR to UNKNOWN values.

**Exception return and related instructions, other than ERET**

These instructions are:

- SRS, RFE, SUBS pc, 1r, and related instructions.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching, setting DLR and DSPSR to UNKNOWN values, and either:
  - Execute the DRPS operation instead of performing an exception return, using UNKNOWN SPSR values.
  - Not changing Exception level or PE mode.

**Instructions that request entry to a low-power state**

These instructions are:

- WFE, WFI.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They generate a synchronous exception if the corresponding instruction would be trapped in Non-debug state. See *Configurable instruction enables and disables, and trap controls* on page G1-5322.
- A WFE instruction is permitted to clear the Event register if it is set.

**Note**

This means that these instructions must not suspend execution.

**Instructions that read the PC**

These instructions are:

- LDR (literal), LDRB (literal), LDRH (literal), LDRSB (literal), LDRSH (literal).
- ADR, ADRL, ADRH.
- PLD (literal), PLI (literal).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state using an UNKNOWN value for the PC operand.

**Instructions that explicitly modify PSTATE, other than DCPS and ERET**

These instructions are:

- CMP, TST, TEQ, CNM.
- <opc>S.
- MRC p14, 0, APSR_nzcv, c0, c1, 0 (accessing DBGDSR.int).
- CPS, SETEND, IT.
- MSR CPSR (immediate), MSR APSR (register), MSR APSR (immediate), MSR APSR (register).
- VMRS APSR_nzcv, FPSCR.
- QADD, QDADD, QSUB, QDSUB.
- SMLABB, SMLABT, SMLATB, SMLATT, SMLAD, SMLAWB, SMLAWT, SMLSD, SMUAD.
- SSAT, SSAT16, USAT, USAT16.
• SADD, SADD8, SADD16, SASX, SSAX, SSUB, SSUB8, SSUB16.
• UADD, UADD8, UADD16, UASX, USAX, USAUB, USUN8, USUB16.
• When ARMv8.1-PAN is implemented, SETPAN.

These instructions behave in one of the following ways:
• They are UNDEFINED.
• They execute as a NOP.
• They execute as in Non-debug state, setting DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

Instructions that read PSTATE.{N, Z, C, V} or other PSTATE fields

These instructions are:
• SEL, VSEL.
• ADC, SBC, all instructions with an RRX shift.
• MRS CPSR.

These instructions behave in one of the following ways:
• They are UNDEFINED.
• They execute as a NOP.
• They execute as in Non-debug state:
  — For the conditional operations and those using the PSTATE.C flag as an input, these instructions use an UNKNOWN value for the Condition flag.
  — For the MRS instruction, they return an UNKNOWN value.

All other instructions

These instructions behave in one of the following ways:
• They are UNDEFINED.
• They execute as a NOP.
• They have the same behavior as in Non-debug state.

—— Note ———
This includes instructions defined as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state. These instructions are CONSTRAINED UNPREDICTABLE in Debug state. This includes some T32 instructions that specify R15 as a destination or source register.

Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors describes the CONSTRAINED UNPREDICTABLE behavior for these instructions. In Debug state these CONSTRAINED UNPREDICTABLE choices are further restricted:
• Instructions that specify R15 as a destination register:
  — Are not permitted to branch, because the architecture does not define a branch operation in Debug state.
  — Might set DLR and DSPSR to UNKNOWN values.
  — Might have any of the other permitted behaviors.
• Instructions that specify R15 as a source operand:
  — Cannot use PC + offset, because there is no architecturally-defined PC in Debug state.
  — Might have any of the other permitted behaviors, including using an UNKNOWN value.

H2.4.3 Decode tables

The syntax in the tables is defined as follows:

1 The bit has a fixed value of 1.
0 The bit has a fixed value of 0.
The field has any value other than the value or values specified. The field might be an encoding field in the instruction whose value is supplied by the debugger.

---

**Note**

The instruction encodings in Chapter C6 A64 Base Instruction Descriptions and Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions might show these bits as (0) or (1). A debugger must set these bits to 0 or 1, as appropriate.

Any other value indicates an encoding field in the instruction whose value is supplied by the debugger. Some values might be reserved or undefined, in which case the instruction is UNDEFINED or CONSTRAINED UNPREDICTABLE in Debug state, as it is in Non-debug state.

For more information about the instruction encodings, see:
- Chapter C6 A64 Base Instruction Descriptions.
- Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions.

For information about the syntax used in Table H2-2, Table H2-3, Table H2-4, and Table H2-5 on page H2-6442, see:
- Common syntax terms on page C1-151.
- Assembler symbols on page F2-3657.

Table H2-2 shows the A64 instructions that are modified in Debug state. For details of how these are packed in the EDITR see the register description.

H2.4.4 Security in Debug state

If EL3 is implemented or the implemented Security state is Secure state, security in Debug state is governed by the Secure debug disabled flag, EDSCR.SDD.

On entry to Debug state

If entering in Secure state, EDSCR.SDD is set to 0. Otherwise EDSCR.SDD is set to the inverse of ExternalSecureInvasiveDebugEnabled(). That is:

- If ExternalSecureInvasiveDebugEnabled() == TRUE, EDSCR.SDD is set to 0.
- If ExternalSecureInvasiveDebugEnabled() == FALSE, EDSCR.SDD is set to 1.

Note

Normally, if ExternalSecureInvasiveDebugEnabled() == FALSE then halting is prohibited and it is not possible to enter Debug state from Secure state. However, because changes to the authentication signals require a Context synchronization event to guarantee their effect, there is a period during which the PE might halt even though the authentication signals prohibit halting.

In Debug state

The value of EDSCR.SDD does not change, even if ExternalSecureInvasiveDebugEnabled() changes.

Note

- DBGAUTHSTATUS_EL1.{SNID, SID, NSNID, NSID} are not frozen in Debug state.
- If EDSCR.SDD set to 1 in Debug state, then there is no means to enter Secure state from Non-secure state. In this case it is impossible for the PE to be in Secure state. This is a general principle of behavior in Debug state.

In Non-debug state

EDSCR.SDD returns the inverse of ExternalSecureInvasiveDebugEnabled(). If the authentication signals that control ExternalSecureInvasiveDebugEnabled() change, a Context synchronization event is required to guarantee their effect.

Note

- In Non-debug state, EDSCR.SDD is unaffected by the Security state of the PE.
- A Context synchronization event is also required to guarantee that changes in the authentication signals are visible in DBGAUTHSTATUS_EL1.{SNID, SID, NSNID, NSID}.

If EL3 is not implemented and the implemented Security state is Non-Secure state, EDSCR.SDD is RES1.
H2.4.5 Privilege in Debug state

The only additional privileges offered to Debug state are:

- The privilege to execute Debug state operations, DCPS, DRPS, MRS, MSR.
- The privilege to execute DTR access instructions regardless of the Exception level and traps.

The DTR access instructions can be executed at any Exception level, including EL0, regardless of any control register settings that might force these instructions to be undefined or trapped in Non-debug state. These instruction are:

- The MRS and MSR instructions that access DBGDTR_EL0, DBGDTRTX_EL0, and DBGDTRRX_EL0 in AArch64 state.
- The MRC and MCR instructions that access DBGDTRTXint and DBGDTRRXint in AArch32 state.

All other instructions operate with the privilege determined by the current Exception level and security state. This applies to all Special-purpose and System registers accesses, memory accesses, and undefined instructions, and includes generating exceptions when the System registers trap or disable an instruction.

H2.4.6 Debug state operations, DCPS, DRPS, MRS, MSR

ARMv8 defines operations to change between Exception levels in Debug state. These operations can also change the mode at the current Exception level.

DCPS<n>

Executing a DCPS<n> instruction in Debug state moves the PE to a higher Exception level or to a specific mode at the current Exception level.

If the DCPS<n> instruction is executed in AArch32 state and the target Exception level is using AArch64:

- The current instruction set switches from T32 to A64.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for system calls in Non-debug state. See Execution state on page D1-2137.

Otherwise, the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE might change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- In AArch64 state the current endianness is determined by the value of SCTLR_ELx.EE for the target Exception level.
- In AArch32 state the current endianness is determined by the value of SCTLR.EE or HSCTLR.EE for the target Exception level.

The DCPS<n> instructions are:

In AArch64 state

- DCP51
- DCP52
- DCP53

In AArch32 state, in the T32 instruction set only

- T1 variant
- T1 variant
- T1 variant

The DCPS instructions are undefined in Non-debug state.
Table H2-6 shows the target of the instruction. In Table H2-6 the entries have the following meaning:

**EL1h/Svc**

This means that the target is:
- EL1h if EL1 is using AArch64.
- EL1 and Supervisor mode if EL1 is using AArch32.

**EL2h/Hyp**

This means that the target is:
- EL2h if EL2 is using AArch64.
- EL2 and Hyp mode if EL2 is using AArch32.

**EL3h/Monitor**

This means that the target is:
- EL3h if EL3 is using AArch64.
- EL3 and Monitor mode if EL3 is using AArch32.

**Svc**

Secure Supervisor mode, in EL3 using AArch32.

**Monitor**

Secure Monitor mode, in EL3 using AArch32.

### Table H2-6 Target for DCPS instructions in Debug state

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Target when DCPS instruction executed at stated Exception level:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EL0</td>
</tr>
<tr>
<td>DCPS1</td>
<td>EL1h/Svc</td>
</tr>
<tr>
<td>DCPS2</td>
<td>EL2h/Hyp</td>
</tr>
<tr>
<td>DCPS3</td>
<td>EL3h/Monitor</td>
</tr>
</tbody>
</table>

In AArch32 Monitor mode, DCPS1 and DCPS3 clear SCR.NS to 0.

**Note**

In AArch64 state, at EL3, DCPS<in> does not change SCR_EL3.NS.

However:

- **DCPS1** is undefined at EL0 if either:
  - EL2 is implemented and enabled in the current Security state, and is using AArch64 and HCR_EL2.TGE == 1.
  - In Non-secure state, EL2 is implemented and using AArch32 and HCR.TGE == 1.

- **DCPS2** is undefined at all Exception levels if EL2 is not implemented.

- **DCPS2** is undefined at the following Exception levels if EL2 is implemented:
  - At EL0 and EL1 in Secure state if EL2 is disabled in the current Security state.
  - At EL3 if EL3 is using AArch32.

- **DCPS3** is undefined at all Exception levels if either:
  - EDSCR.SDD == 1.
  - EL3 is not implemented.
Note

The references to DCPS1, DCPS2, and DCPS3 in this section link to the descriptions of the instructions in the A64 instruction set. The DCPS<n> instructions are also defined in the T32 instruction set, see DCPS1 on page F5-3922, DCPS2 on page F5-3924 and DCPS3 on page F5-3926. These instructions are not defined in the A32 instruction set, because A32 instructions cannot be executed in Debug state.

On executing a DCPS instruction:

- If the target Exception level is using AArch64:
  - ELR_ELx of the target Exception level becomes UNKNOWN.
  - SPSR_ELx of the target Exception level becomes UNKNOWN.
  - ESR_ELx of the target Exception level becomes UNKNOWN.
  - DLR_EL0 and DSPSR_EL0 become UNKNOWN.

- If the target Exception level is using AArch32 DLR and DSPSR become UNKNOWN and:
  - If the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.
  - If the target Exception level is EL2, then ELR_hyp, SPSR_hyp, and HSR become UNKNOWN.

If the target Exception level is using AArch32, and the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become unknown.

The DCPSInstruction() function is described in Chapter J1 ARMv8 Pseudocode.

DRPS

Executing the DRPS operation in Debug state moves the PE to a lower Exception level, or to another PE mode at the current Exception level, by copying the current SPSR to PSTATE.

If DRPS is executed in AArch64 state and the target Exception level is using AArch32:

- The current instruction set switches from A64 to T32.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for exception returns in Non-debug state. See Execution state on page D1-2137.

Otherwise the instruction set does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE might change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- If targeting an Exception level using AArch64, current endianness is set according to SCTLR_ELx.EE, or SCTLR_EL1.E0E for the target Exception level.
- If targeting an Exception level using AArch32, current endianness is set by SPSR.E as appropriate.

The DRPS instructions are:

In AArch64 state

- DRPS

In AArch32 state, in the T32 instruction set only

- ERET

If the SPSR specifies an illegal exception return, then PSTATE. {M, nRW, EL, SP} are unchanged and PSTATE.IL is set to 1. For further information on illegal exception returns, see Illegal return events from AArch64 state on page D1-2168.

PSTATE. {N, Z, C, V, Q, GE, IT, T, SS, D, A, I, F} are ignored in Debug state. This means that the effect of the DRPS operation on these fields is to set them to an UNKNOWN value that might be the value from the SPSR. For more information see Process state (PSTATE) in Debug state on page H2-6429.
All other PSTATE fields are copied from SPSR.

**DRPS** is undefined at EL0 and in Non-debug state.

--- **Note** ---

Unlike an exception return, the DRPS operation has no architecturally-defined effect on the Event Register and Exclusives monitors. DRPS might set the Event Register or clear the Exclusives monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

---

On executing a DRPS instruction:

- If the target Exception level is using AArch64:
  - DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- If the target Exception level is using AArch32:
  - DLR and DSPSR become UNKNOWN.

The DRPSInstruction() function is described in Chapter J1 *ARMv8 Pseudocode*.

### MRS and MSR

The other Debug state instructions are used to read or write DLR_EL0 and DSPSR_EL0. These instructions are:

#### In AArch64 state

- MRS
- MSR (register)

#### In AArch32 state

- MRC
- MCR

MRS <Xt>, DLR_EL0 ; Copy DLR_EL0 to <Xt>
MRS <Xt>, DSPSR_EL0 ; Copy DSPSR_EL0 to <Xt>
MSR DLR_EL0, <Xt> ; Copy <Xt> to DLR_EL0
MSR DSPSR_EL0, <Xt> ; Copy <Xt> to DSPSR_EL0

These instructions can be executed at any Exception level when in Debug state, including EL0. They are undefined in Non-debug state.

### H2.4.7 Exceptions in Debug state

The following sections describe how exceptions are handled in Debug state:

- **Generating exceptions when in Debug state.**
- **Taking exceptions when in Debug state** on page H2-6449.
- **Reset in Debug state** on page H2-6450.

#### Generating exceptions when in Debug state

In Debug state:

- Instruction Abort exceptions cannot happen because instructions are not fetched from memory.
- Interrupts, including SError and virtual interrupts are ignored and remain pending:
  - The pending interrupt remains visible in ISR.
- Debug exceptions and debug events are ignored.
- **SCR.EA** is treated as if it were set to 0, regardless of its actual state, other than for the purpose of reading the bit.
• Any attempt to execute an instruction bit pattern that is an allocated instruction at the current Exception level, but is listed in Executing instructions in Debug state on page H2-6430 as undefined in Debug state, generates an exception, that is taken to the current Exception level, or to EL1 if executing at EL0.

Note

If the exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception.

The priority and syndrome for these exceptions is the same as for executing an encoding that does not have an allocated instruction.

• Instructions executed at EL2, EL1 and EL0 that are configured by EL3 control registers to trap to EL3:
  — When the value of EDSCR.SDD is 0, generate the appropriate trap exception that is taken to EL3.
  — When the value of EDSCR.SDD is 1, are treated as UNDEFINED and generate an exception that is taken to the current Exception level, or to EL1 if the instruction is executed at EL0. If the exception is taken to an Exception level that is using AArch32 it is taken as an Undefined Instruction exception. If the exception is taken to an Exception level using AArch64 or to AArch32 Hyp mode, then it is reported with an EC value of 0x00.

Otherwise configurable traps, enables, and disables for instructions are unaffected by Debug state, and executing an affected instruction generates the appropriate exception.

Otherwise, synchronous exceptions, including Data Aborts, are generated as they would be in Non-debug state and taken to the appropriate Exception level in Debug state.

Note

If EDSCR.SDD == 1 then an exception from Non-secure state is never taken to Secure state. See Security in Debug state on page H2-6444.

Taking exceptions when in Debug state

When the PE is in Debug state, all exceptions are synchronous. When an exception is generated, it is taken to Debug state. This means that:

• The target Exception level is as defined for the exception in Non-debug state.

• If the target Exception level is using AArch32 then the target PE mode is as defined for the exception in Non-debug state.

• The exception syndrome is reported as defined for the exception in Non-debug state, except for the case described in Data Aborts in Memory access mode on page H4-6488 for which the reporting requirements are relaxed.

The exception syndrome is reported using the syndrome register or registers for the target Exception level. In AArch64 state, these are ESR_ELx, and FAR_ELx. In AArch32 state, these are DFSR, DFAR, HSR, HDFAR, and HPFAR. For example:

— If a Data Abort exception is taken to Abort mode at EL1 or EL3 and the exception is taken from AArch32 state and using the Short-descriptor translation table format, the DFSR reports the exception using the Short-descriptor format fault encoding. For exceptions other than Data Abort exceptions taken to Abort mode, DFSR is not updated.

— If an instruction is trapped to an Exception level using AArch64 due to a configurable trap, disable, or enable, the exception code reported is the same as it would be in Non-debug state.

The effect on auxiliary syndrome registers, such as AFSR, is IMPLEMENTATION DEFINED.

Note

Generally, the AArch32 Fault Address Registers (FARs) and Fault Status Registers (FSRs) are not described as syndrome registers, although the term is appropriate to their function.
• The PE remains in Debug state and changes to the target mode.
• If EL3 is using AArch32 and the exception is taken from Monitor mode, SCR.NS is cleared to 0.
• If the exception is taken to an Exception level using AArch32, the PE continues to execute T32 instructions, regardless of the TE bit in the System register for the target Exception level.
• The endianness switches to that indicated by the EE bit of the System register for the target Exception level.
• The SPSR for the target Exception level or mode is corrupted and becomes UNKNOWN.
• If the target Exception level is using AArch64, ELR_ELx for the target Exception level becomes unknown.
• If the target Exception level is EL2 using AArch32, ELR_hyp becomes unknown.
• If the target Exception level is EL1 or EL3 using AArch32, LR_<mode> for the target mode becomes unknown.
• DLR and DSPSR become UNKNOWN.
• The cumulative error flag, EDSCR.ERR, is set to 1. See Cumulative error flag on page H4-6492.
• PSTATE.IL is cleared to 0.
• PSTATE.{IT, T, SS, D, A, I, F} are set to UNKNOWN values, and PSTATE.{N, Z, C, V, Q, GE} are unchanged. However, these fields are ignored and are not observable in Debug state. For more information see Process state (PSTATE) in Debug state on page H2-6429.

The debugger must save any state that can be corrupted by an exception before executing an instruction that might generate another exception.

Pseudocode description of taking exceptions in Debug state

The pseudocode function AArch64.TakeException() shows the behavior when the PE takes an exception to an Exception level using AArch64 in Non-debug state. In Debug state, this is replaced with the function AArch64.TakeExceptionInDebugState().

The pseudocode functions AArch32.EnterMode(), AArch32.EnterHypMode(), and AArch32.EnterMonitorMode() show the behavior when the PE takes an exception to an Exception level using AArch32 in Non-debug state. In Debug state:
• AArch32.EnterMode() is replaced with the function AArch32.EnterModeInDebugState().
• AArch32.EnterHypMode() is replaced with the function AArch32.EnterHypModeInDebugState().
• AArch32.EnterMonitorMode() is replaced with AArch32.EnterMonitorModeInDebugState().

Reset in Debug state

If the PE is reset when in Debug state, it exits Debug state and enters Non-debug reset state. When the PE is in reset state, EDSCR.STATUS == 0b000010 and writes to EDITR are ignored.

Note

If EDECR.RCE == 1, meaning that a Reset Catch debug event is programmed, and if halting is allowed on exiting reset state, then on exiting reset state the PE halts and re-enters Debug state. See Reset Catch debug events on page H3-6477. All PE registers have taken their reset values, which might be UNKNOWN.

H2.4.8 Accessing registers in Debug state

Register accesses are unchanged in Debug state. The view of each register is determined by either the current Exception level or the mode, or both, and accesses might be disabled or trapped by controls at a higher Exception level.
General-purpose register access, other than AArch64 state SP access

A single general-purpose register can be read by issuing an MSR instruction through the ITR to write DBGDTR_EL0 in AArch64 state, or an MCR instruction through the ITR to write DBGDTRTXint in AArch32 state. The debugger can then read the DTR register or registers through the external debug interface. The reverse sequence writes to a general-purpose register.

Figure H2-1 shows the reading and writing of general-purpose registers, other than SP, in Debug state in AArch64 state.

![Flowchart](image)

**Figure H2-1 Reading and writing general-purpose registers, other than SP, in Debug state in AArch64 state**

Figure H2-2 on page H2-6452 shows the reading and writing of general-purpose registers in Debug state in AArch32 state.
SIMD and floating-point register, System register, and AArch64 state SP accesses

To read a SIMD and floating-point register or a System register, the debugger must first copy the value into a general-purpose register using:

- An FMOV instruction in AArch64 state or a VMOV instruction in AArch32 state for floating-point transfers to SIMD and FP registers.
- A UMOV instruction in AArch64 state or a VMOV instruction in AArch32 state for SIMD transfers to SIMD and FP registers.
- An MRS instruction in AArch64 state or an MRC instruction in AArch32 state for System registers.
- A MOV Xd,SP instruction for the SP register in AArch64 state.

The debugger can then read out the particular general-purpose register. The reverse sequence writes a register.

PC and PSTATE access

The debugger reads the program counter and PSTATE of the process being debugged through the DLR_EL0 and DSPSR_EL0 System registers. The actual values of PC and PSTATE cannot be directly observed in Debug state:

- Instructions that are used for direct reads and writes of PC and PSTATE in Non-debug state are UNDEFINED in Debug state.
- On taking an exception, ELR_ELx and SPSR_ELx at the target Exception level are UNKNOWN. They do not record the PC and PSTATE.

PSTATE. {IL, E, M, nRW, EL, SP} are indirectly read by instructions executed in Debug state, but all other PSTATE fields are ignored and cannot be observed. See also:

- Process state (PSTATE) in Debug state on page H2-6429.
- Executing instructions in Debug state on page H2-6430.
- Exceptions in Debug state on page H2-6448.
H2.4.9 Accessing memory in Debug state

How the PE accesses memory is unchanged in Debug state. This includes:

• The operation of the MMU, including address translation, tagged address handling, access permissions, memory attribute determination, and the operation of any TLBs.

• The operation of any caches and coherency mechanisms.

• Alignment support.

• Endianness support.

• The Memory order model.

Simple memory transfers

Simple memory accesses can be performed in Debug state by issuing memory access instructions through the ITR and passing data through the DTR registers. *Executing instructions in Debug state* on page H2-6430 lists the memory access instructions that are supported in Debug state.

Bulk memory transfers

Memory access mode can accelerate bulk memory transfers in Debug state. See *DCC and ITR access modes* on page H4-6486.
H2.5 Exiting Debug state

The PE exits Debug state when it receives a Restart request trigger event. If EDSCR.ITE == 0 the behavior of any instruction issued through the ITR in Normal access mode or an operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state after the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Note

- Implementations can set EDSCR.ITE to 1 to indicate that further instructions can be accepted by ITR before the previous instructions have completed. If any previous instruction has not completed and EDSCR.ITE == 1, then the PE must complete these instructions in Debug state before executing the restart sequence. EDSCR.ITE == 0 indicates that the PE is not ready to restart.
- A debugger must observe that any instructions issued through EDITR that might generate a synchronous exception, as complete, before issuing a restart request. It can do this by observing the completion of a later instruction, as synchronous exceptions must occur in program order. For example, a debugger can observe that an instruction that reads or writes a DTR register is complete because of its effect on the EDSCR.{TXfull, RXfull} flags.

On exiting Debug state, the PE sets the program counter to the address in DLR, where:

- If exiting to AArch32 state:
  - Bits[31:1] of the PC are set to the value of bits[31:1] of DLR.
  - Bit[0] of the PC is set to a CONSTRAINED UNPREDICTABLE choice of 0 or the value of bit[0] in DLR.
- If exiting to AArch64 state:
  - Bits[63:56] of DLR_EL0 might be ignored as part of tagged address handling. See Address tagging in AArch64 state on page D5-2374.
  - Otherwise the PC is set from DLR_EL0.

Note

Bits[63:32] of DLR_EL0 are ignored when exiting to AArch32 state.

Exit from Debug state can give rise to a PC alignment fault exception when the program counter is used. Unlike an exception return, this might also happen when returning to AArch32 state. For more information, see PC alignment checking on page D1-2152.

On exiting Debug state, PSTATE is set from DSPSR in the same way that an exception return sets PSTATE from SPSR_ELx:

- The same illegal exception return checks that apply to an exception return also apply to exiting Debug state. If the return from Debug state is an illegal exception return then the effect on PSTATE and the PC is the same as for any other illegal exception return. See Exception return on page D1-2167 and Exception return to an Exception level using AArch32 on page G1-5269.
- The checks on the PSTATE.IT bits that apply to exiting Debug state into AArch32 state are the same as those that apply to an exception return. See Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.
- PSTATE.SS is copied from DSPSR.SS if all of the following hold:
  - MDSCR_EL1.SS == 1.
  - The debug target Exception level is using AArch64.
  - Software step exceptions from the restart Exception level are enabled.
  - Otherwise PSTATE.SS is set to 0.
Note

Unlike a return using ERET, PSTATE.SS must be restored from DSPSR.SS because otherwise it is UNKNOWN.

However, if OSDLR.DLK == 1 and DBGPRCR.CORENPDQ == 0, meaning the OS Double Lock is implemented and locked in Non-debug state and therefore Software Step exceptions are disabled, but otherwise Software Step exceptions would be enabled from the restart Exception level, it is CONSTRAINED UNPREDICTABLE whether PSTATE.SS is copied from DSPSR.SS.

- If ARMv8.1-PAN is implemented, PSTATE.PAN is copied from DSPSR_EL0.PAN.
- If ARMv8.2-UAO is implemented, PSTATE.UAO is copied from DSPSR_EL0.UAO.
- If ARMv8.4-DIT is implemented, on exit from Debug state to AArch64 state, DSPSR_EL0.DIT is copied to PSTATE.DIT.
- If ARMv8.4-DIT is implemented, on exit from Debug state to AArch32 state, DSPSR.DIT is copied to CPSR.DIT.

Note

- One important difference between Debug state exit and an exception return is that the PE can exit Debug state at EL0. Despite this, the behavior of an exit from Debug state is similar to an exception return. For example, PSTATE.{D, A, I, F} is updated regardless of the value of SCTLR_EL1.UMA.
- Exit from Debug state has no architecturally-defined effect on the Event Register and Exclusives monitors. An exit from Debug state might set the Event Register or clear the Exclusives monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

The ExitDebugState() function is described in Chapter J1 ARMv8 Pseudocode.
H2 Debug State
H2.5 Exiting Debug state
Chapter H3
Halting Debug Events

This chapter describes a particular class of debug events. It contains the following sections:

- Introduction to Halting debug events on page H3-6458.
- Halting Step debug events on page H3-6460.
- Halt Instruction debug event on page H3-6470.
- Exception Catch debug event on page H3-6471.
- External Debug Request debug event on page H3-6475.
- OS Unlock Catch debug event on page H3-6476.
- Reset Catch debug events on page H3-6477.
- Software Access debug event on page H3-6478.
- Synchronization and Halting debug events on page H3-6479.

--- Note ---
Table K13-1 on page K13-7390 disambiguates the general register references used in this chapter.
H3.1 Introduction to Halting debug events

External debug defines Halting debug events. The following Halting debug events are available in ARMv8:

- Halting Step debug event on page H3-6460.
- Halt Instruction debug event on page H3-6470.
- Exception Catch debug event on page H3-6471.
- External Debug Request debug event on page H3-6475.
- OS Unlock Catch debug event on page H3-6476.
- Reset Catch debug events on page H3-6477.
- Software Access debug event on page H3-6478.

If halting is allowed, a Halting debug event halts the PE. The PE enters Debug state.

In addition, breakpoints and watchpoints might halt the PE if halting is allowed. See Breakpoint and Watchpoint debug events on page H2-6420. Because breakpoints and watchpoints can generate an exception or halt the PE, Breakpoint and Watchpoint debug events are not classified as Halting debug events.

For a definition of Debug state, see Chapter H2 Debug State. For a definition of halting allowed, see Halting allowed and halting prohibited on page H2-6419.

Debug state entry and debug event prioritization on page H2-6421 describes the behavior when multiple debug events are generated by an instruction.

See also Synchronization and Halting debug events on page H3-6479.

Table H3-1 shows the behavior of Breakpoint, Watchpoint, and Halting debug events.

H3.2 Halting Step debug events

Halting Step is a debug resource that a debugger can use to make the PE step through code one instruction at a time. This section describes the Halting Step debug events. It is divided into the following sections:

- Overview of a Halting Step debug event.
- The Halting Step state machine.
- Using Halting Step on page H3-6463.
- Detailed Halting Step state machine behavior on page H3-6463.
- Synchronization and the Halting Step state machine on page H3-6466.
- Stepping T32 IT instructions on page H3-6467.
- Disabling interrupts while stepping on page H3-6468.
- Syndrome information on Halting Step on page H3-6468.
- Pseudocode description of Halting Step debug events on page H3-6469.

The architecture describes the behavior as a simple Halting Step state machine. See The Halting Step state machine.

H3.2.1 Overview of a Halting Step debug event

The behavior of Halting Step is defined by a state machine, shown in Figure H3-1 on page H3-6462. A Halting Step debug event executes a single instruction and then returns control to the debugger. When the debugger software wants to execute a Halting Step:

1. With the PE in Debug state, the debugger activates Halting Step.
2. The debugger signals the PE to exit Debug state and return to the instruction that is to be stepped.
3. The PE executes that single instruction.
4. The PE enters Debug state before executing the next instruction.

However, an exception might be generated while the instruction is being stepped. That is either:

- A synchronous exception generated by the instruction being stepped.
- An asynchronous exception taken before or after the instruction being stepped.

Halting Step has its own enable control bit, EDECR.SS and EDESR.SS.

--- Note ---

Because the Halting Step state machine states occur as a result of normal PE operation, the states can be described as both:

- PE states.
- Halting Step states.

H3.2.2 The Halting Step state machine

The state machine states are:

**Inactive**

Halting Step is inactive. No Halting Step debug events can be generated, therefore execution is not affected by Halting Step. The PE is in this state whenever either of the following is true:

- Halting Step is disabled. That is, EDECR.SS is set to 0 and EDESR.SS is set to 0.
- Halting is prohibited. See Halting the PE on debug events on page H2-6419. In this state, if EDECR.SS is set to 1 then a Halting Step debug event is pending.

In Figure H3-1 on page H3-6462 this state is shown in red.

**Active-not-pending**

Halting Step is enabled and active. This is the state in which the PE steps an instruction. EDECR.SS == 1 and EDESR.SS == 0. Software must not set EDECR.SS to 1 unless the PE is in Debug state, otherwise behavior is CONSTRAINED UNPREDICTABLE, as described in Changing the value of EDECR.SS when not in Debug state on page H3-6467.

In Figure H3-1 on page H3-6462 this state is shown in green.
Active-pending

Halting Step is enabled and active. The step has completed, and the PE enters Debug state. 
EDESR.SS == 1.

In Figure H3-1 on page H3-6462 this state is shown in green.

Whenever Halting Step is enabled and active, whether the state machine is in the active-not-pending state or in the active-pending state depends on EDESR.SS. Halting Step state machine states on page H3-6463 shows this.

In the simple sequential execution of the program the PE executes the Halting Step state machine, as follows:
1. Initially, Halting Step is inactive.
2. After exiting Debug state, Halting Step is active-not-pending.
3. The PE executes an instruction and Halting Step is active-pending.
4. The pending Debug state entry is taken on the next instruction and the step is complete.

Exceptions and other changes to the PE context can interrupt this sequence.

Figure H3-1 on page H3-6462 shows a Halting Step state machine.
Halting step is disabled

Halting step is enabled

Execution within Secure state

Execution within Secure state

a. Step completed occurs when:
   • A debug event, other than a Halting Step debug event, causes entry into Debug state.

b. Step completed occurs when:
   • An instruction is executed without taking an exception.
   • An exception is taken to a state where halting is allowed.
   • A reset.

c. Step completed occurs when:
   • An SMC exception is taken to Secure state where halting is prohibited.

d. An asynchronous exception taken to a state where halting is allowed.

e. An asynchronous exception taken to Secure state where halting is prohibited.

Figure H3-1 Halting Step state machine
The following bits control the state machine, as shown in Table H3-3:

• EDECR.SS. This is the Halting Step enable bit.

Note

— The EDECR value is preserved over powerdown, meaning that the step active state is maintained over a powerdown event.
— A debugger must only change the value of EDECR.SS when the PE is in Debug state, otherwise behavior is CONSTRAINED UNPREDICTABLE as described in Changing the value of EDECR.SS when not in Debug state on page H3-6467.

• EDESR.SS. This is the Halting Step debug event pending bit.

Table H3-3 shows the Halting Step state machine states. The letter X in a register column means that the relevant bit can be set to either zero or one.

H3.2.3 Using Halting Step

To step a single instruction the PE must be in Debug state:

1. The debugger sets EDECR.SS to 1 to enable Halting step.
2. The debugger signals the PE to exit Debug state with DLR set to the address of the instruction being stepped. The PE clears EDESR.SS to 0 and the Halting Step state machine enter the active-not-pending state.
3. The PE executes the instruction being stepped. If an exception is taken to a state where halting is prohibited, then EDESR.SS is always correct for the preferred return address of the exception.
4. The PE enters Debug state before executing the next instruction and the step is complete.

H3.2.4 Detailed Halting Step state machine behavior

The behavior of the Halting Step state machine is described in the following sections:

• Entering the active-not-pending state on page H3-6464.
• PE behavior in the active-not-pending state on page H3-6464.
• Entering the active-pending state on page H3-6465.
• PE behavior in the active-pending state on page H3-6465
• PE behavior in the inactive state when in Non-debug state on page H3-6466.
• PE behavior in Debug state on page H3-6466.
**Entering the active-not-pending state**

The PE enters the active-not-pending state:

- By exiting Debug state with **EDECR.SS == 1**.
- By an exception return from a state where halting is prohibited to a state where halting is allowed with **EDECR.SS == 1** and **EDESR.SS == 0**.
- As described in *Synchronization and the Halting Step state machine* on page H3-6466.

**PE behavior in the active-not-pending state**

When the PE is in the active-not-pending state it does one of the following:

- It executes one instruction and does one of the following:
  - Completes it without generating a synchronous exception.
  - Generates a synchronous exception.
  - Generates a debug event that causes entry to Debug state.
- It takes an asynchronous exception without executing any instruction.
- It takes an asynchronous debug event into Debug state.

**If no exception or debug event is generated**

If no exception or debug event is generated the PE sets **EDESR.SS** to 1. This means that the Halting Step state machine advances to the active-pending state.

**If an exception or debug event is generated**

The PE sets **EDESR.SS** according to all of the following:

- The type of exception.
- The target Exception level of the exception.
- If the exception is taken to Secure state, whether halting is prohibited in Secure state.
  - This is determined by the result of **ExternalSecureInvasiveDebugEnabled()**.

If an exception or debug event is generated, the PE sets **EDESR.SS** to 1 if one of the following applies:

- A synchronous exception is generated by the instruction and one of the following applies:
  - The exception is taken to EL1 or EL2.
  - The exception is taken to EL3, it is not an SMC exception, and **ExternalSecureInvasiveDebugEnabled() == TRUE**.
  - The exception is an SMC exception.
- An asynchronous exception is generated before executing an instruction and this is either:
  - Taken to EL1 or EL2.
  - Taken to EL3 and **ExternalSecureInvasiveDebugEnabled() == TRUE**.
- A PE reset occurs.

Otherwise **EDESR.SS** is unchanged. This happens when:

- No instruction is executed because either:
  - An asynchronous exception is taken to EL3 and **ExternalSecureInvasiveDebugEnabled() == FALSE**.
  - An asynchronous debug event causes entry to Debug state.
- An instruction is executed and either:
  - Generates a synchronous exception other than an SMC exception which is taken to EL3, and **ExternalSecureInvasiveDebugEnabled() == FALSE**.
  - Generates a synchronous debug event and causes entry to Debug state.
If halting is prohibited after taking the exception or debug event, then the Halting Step state machine advances to the inactive state. Otherwise the Halting Step state machine advances to the active-pending state.

--- Note ---

The underlying criteria for the value of **EDESR.SS** on an exception are:

- Whether halting is allowed at the target of the exception. If halting is allowed, the PE must step into the exception. If halting is prohibited, the PE must step over the exception.
- Whether the preferred return address of the exception is the instruction itself or the next instruction, if the PE steps over the exception.

---

Table H3-4 shows the behavior of the active-not-pending state. The letter X indicates that `ExternalSecureInvasiveDebugEnabled()` can be either TRUE or FALSE.

### Table H3-4 Summary of active-not-pending state behavior

### Entering the active-pending state

The PE enters the active-pending state by one of the following:

- From the active-not-pending state by:
  - Executing an instruction without taking an exception.
  - Taking an exception so that the PE remains in a state where halting is allowed.

- An exception return from a state where halting is prohibited when **EDESR.SS** == 1.

--- Note ---

That is, an exception return from Secure state with `ExternalSecureInvasiveDebugEnabled()` == FALSE to Non-secure state with `ExternalInvasiveDebugEnabled()` == TRUE.

---

- A reset when the value of **EDECR.SS** == 1, regardless of the state the PE was in before the reset occurred.
- From the active-pending state by taking an asynchronous exception to a state where halting is allowed.
- Following the description in *Synchronization and the Halting Step state machine* on page H3-6466.

### PE behavior in the active-pending state

When the PE is in the active-pending state, it enters Debug state before executing an instruction.
The entry into Debug state has higher priority than all other types of synchronous debug event and synchronous exception. However, the architecture does not define the prioritization of this Debug state entry with respect to any unmasked pending asynchronous exception. If an asynchronous exception is prioritized over the entry to Debug state, then EDESR.SS is unchanged.

For more information on the prioritization of debug events, see Debug state entry and debug event prioritization on page H2-6421.

**PE behavior in the inactive state when in Non-debug state**

EDESR.SS is not updated by the execution of an instruction or the taking of an exception when Halting Step is inactive. This means that EDESR.SS is not changed by an exception handled in a state where halting is prohibited.

On return to a state where halting is allowed, the Halting Step state machine is restored either to the active-pending state or the active-not-pending state, depending on the value of EDESR.SS. The return to a state where halting is allowed is normally by an exception return, which is a Context synchronization event.

See also Synchronization and the Halting Step state machine.

**PE behavior in Debug state**

Halting Step is inactive in Debug state because halting is prohibited, see Halting allowed and halting prohibited on page H2-6419.

Entry to Debug state does not change EDESR.SS.

EDESR.SS is cleared to 0 on exiting Debug state as the result of a restart request. If EDECR.SS == 1, Halting Step enters the active-not-pending state.

**Note**

This means that EDESR.SS is never cleared to 0 by the execution of an instruction in Debug state, or by taking an exception when in Debug state as described in PE behavior in the active-not-pending state on page H3-6464, because the Halting Step state machine is not in the active-not-pending state. EDESR.SS can be cleared by a write to EDESR, see the register description.

However, if the PE exits Debug state as the result of a PE reset and EDECR.SS == 1, then Halting Step immediately enters the active-pending state, as EDESR.SS is set to the value of EDECR.SS.

**H3.2.5 Synchronization and the Halting Step state machine**

The Halting Step state machine also changes state if:

- Halting becomes allowed or prohibited other than by exit from Debug state, an exception return, or taking an exception. This means that halting becomes allowed or prohibited because:
  - The security state changes without an exception return. See State and mode changes without explicit context synchronization events on page G2-5420.
  - The external authentication interface changes.
  - The OS Double Lock is implemented and the status, DoubleLockStatus(), changes.

- A write to EDECR when the PE is in Non-debug state changes the value of EDECR.SS.

**Note**

Behavior is CONSTRAINED UNPREDICTABLE if the value of EDECR.SS is changed when the PE is in Non-debug state, see Changing the value of EDECR.SS when not in Debug state on page H3-6467.

- A write to EDESR when the PE is in Non-debug state clears EDESR.SS to 0.

These operations are guaranteed to take effect only after a Context synchronization event. If the instruction being stepped generates a Context synchronization event, then the PE might use the old or new state.
The PE must perform the required behavior of the new state before or immediately following the next Context synchronization event, but it is not required to do so immediately. This means that the PE can perform the required behavior of the old state before the next Context synchronization event. This is illustrated in Example H3-1 and Example H3-2.

Example H3-1 Synchronization requirements 1

**EDECR.SS** is set to 1 in Debug state, requesting the active-not-pending state on exit from Debug state. On exit from Debug state the PE immediately takes an exception to Secure state. `ExternalSecureInvasiveDebugEnabled()` == FALSE, meaning that halting is prohibited in Secure state. The PE does not step any instructions but executes the software in Secure state as normal. **EDES.R.SS** remains set to 0. If `ExternalSecureInvasiveDebugEnabled()` subsequently becomes TRUE, meaning that halting is now allowed, the PE must perform the required behavior of the active-not-pending state before or immediately following the next Context synchronization event, but it is not required to do so immediately.

Example H3-2 Synchronization requirements 2

**EDECR.SS** is set to 1 in Debug state. On exit from Debug state the PE executes an MSR instruction that sets `OSDLR_EL1.DLK` to 1 and `DoubleLockStatus()` becomes TRUE. This change requires a Context synchronization event to guarantee its effect, meaning it is CONSTRAINED UNPREDICTABLE whether:

- Halting is allowed:
  - The PE enters Debug state on the next instruction.
- Halting is prohibited:
  - The PE does not enter Debug state.

The value in **EDES.R.SS** depends on whether halting was allowed or prohibited when the write to `OSDLR_EL1.DLK` completed, and so it might be 0 or 1. If a second MSR instruction clears `OSDLR_EL1.DLK` to 0, the PE must perform the required behavior of the state indicated by **EDES.R.SS** before or immediately following the next Context synchronization event, but it is not required to do so immediately.

See also *Synchronization and Halting debug events on page H3-6479.*

**Changing the value of EDECR.SS when not in Debug state**

If software changes the value of **EDECR.SS** when the PE is not in Debug state then behavior is CONSTRAINED UNPREDICTABLE, and one or more of the following behaviors occurs:

- The value of **EDECR.SS** becomes UNKNOWN.
- The state of the Halting Step state machine becomes UNKNOWN.
- On a reset of the PE, the value of **EDECR.SS** and the state of the Halting Step state machine are UNKNOWN.

**H3.2.6 Stepping T32 IT instructions**

In an implementation that supports the ITD control, the architecture permits a combination of one T32 IT instruction and another 16-bit T32 instruction to be treated as a single 32-bit instruction when the value of the ITD field that applies to the current Exception level is 1.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

- The PE considers such a pair of instructions to be one instruction.
- The PE considers such a pair of instructions be two instructions.
It is IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD bit. For example:

- The debug logic might consider such a pair of instructions as one instruction, regardless of the state of the applicable ITD field.
- The debug logic might consider such a pair of instructions as two instructions, regardless of the state of the applicable ITD field.
- The debug logic might consider such a pair of instructions as one instruction when the value of the applicable ITD field is 1, and as two instructions when the value of the ITD field is 0.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

The ITD control fields are:

- **HSCTLR.ITD** Applies to execution at EL2 when EL2 is using AArch32.
- **SCTLR.ITD** Applies to execution at EL0 or EL1 when EL1 is using AArch32.
- **SCTLR_EL1.ITD** Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

### H3.2.7 Disabling interrupts while stepping

When using Halting Step, the sequence of entering Debug state, interacting with the debugger, and then exiting Debug state for each instruction reduces the rate at which the PE executes instructions. However, the rate at which certain interrupts, such as timer interrupts, are generated might be fixed by the system. This means it might be necessary to disable interrupts while using Halting Step by setting EDSCR.INTdis, to allow the code being debugged to make forward progress.

### H3.2.8 Syndrome information on Halting Step

Three EDSCR.STATUS encodings record different scenarios for entering Debug state on a Halting Step debug event:

- **Halting Step, normal**
  - An instruction other than a Load-Exclusive instruction was stepped.

- **Halting Step, exclusive**
  - A Load-Exclusive instruction was stepped.

- **Halting Step, no syndrome**
  - The syndrome data is not available.

If the PE enters Debug state due to a Halting Step debug event immediately after stepping an instruction in the active-not-pending state, EDSCR.STATUS is set to either:

- Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
- Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.

If the stepped instruction was a conditional Load-Exclusive instruction that failed its Condition code check, EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, normal, or Halting Step, exclusive.

Otherwise the PE enters Debug state without stepping an instruction. This means that the Halting Step state machine enters the active-pending state directly from the inactive state, without going through active-not-pending state. In this case, EDSCR.STATUS is set to Halting Step, no syndrome. This happens when:

- The PE enters directly into the active-pending state on an exception return to Non-secure state from EL3 when Halting is prohibited in Secure state.
- The active-pending state is entered for other reasons. See Synchronization and the Halting Step state machine on page H3-6466
In addition, `EDSCR.STATUS` is set to one of a `CONSTRAINED UNPREDICTABLE` choice if:

- The instruction being stepped generated a synchronous exception, or a pending asynchronous exception was taken before the instruction was executed.
  In this case `EDSCR.STATUS` is set to a `CONSTRAINED UNPREDICTABLE` choice of:
  - Halting Step, no syndrome, or Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
  - Halting Step, no syndrome, or Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.
- The instruction that was stepped was an exception return instruction or an ISB. As these instructions are not in the Load-Exclusive instructions, `EDSCR.STATUS` is set to a `CONSTRAINED UNPREDICTABLE` choice of Halting Step, no syndrome or Halting Step, normal.
- The PE enters directly into the active-pending state on reset because `EDECR.SS` is set to 1. `EDSCR.STATUS` is set to a `CONSTRAINED UNPREDICTABLE` choice of Halting Step, no syndrome or Halting Step, normal.

In all cases, if `EDSCR.STATUS` is not set to Halting Step, no syndrome, then it must indicate whether the stepped instruction was a Load-Exclusive instruction by setting `EDSCR.STATUS` to Halting Step, normal or Halting Step, exclusive.

---

**Note**

In an implementation that always sets `EDSCR.STATUS` to Halting Step, no syndrome is not compliant.

---

**H3.9 Pseudocode description of Halting Step debug events**

There are two pseudocode functions for Halting Step debug events:

- `RunHaltingStep()`. This is called after an instruction has executed and any exception generated by the instruction is taken. It is also called after taking a reset before executing any instructions. That is, reset is treated like an asynchronous exception, even if `EDECR.RCE == 1`. `RunHaltingStep()` affects the next instruction.
- `CheckHaltingStep()`. This is called before the next instruction is executed. If a step is pending, it generates the debug event.
H3.3 Halt Instruction debug event

A Halt Instruction debug event is generated when EDSCR.HDE == 1, halting is allowed, and the PE executes the Halt instruction, HLT.

The pseudocode for Halt Instruction debug events is described in HLT on page C6-823 for A64 and HLT on page F5-3947 for A32 and T32.

HLT never generates a debug exception. It is treated as UNDEFINED if EDSCR.HDE == 0, or if halting is prohibited.

Note A debugger can replace a program instruction with a Halt instruction to generate a Halt Instruction debug event. Debuggers that use the HLT instruction must be aware of the ARMv8-A rules for concurrent modification of executable code, CMODX. The rules for concurrent modification and execution of instructions do not allow one thread of execution or an external debugger to replace an instruction with an HLT instruction when these same instructions are being executed by a different thread of execution. See Concurrent modification and execution of instructions on page B2-94.

The T32 HLT instruction is unconditionally executed inside an IT block, even when it is treated as undefined. The A32 HLT instruction is CONSTRAINED UNPREDICTABLE if the Condition code field is not 0b1110, with the set of behaviors the same as for BKPT. See Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.

Note The HLT instruction is part of the external debug solution for ARMv8-A. As such, the presence of the HLT instruction is not indicated in the ID registers. In particular, the AArch32 System register ID_ISAR0. Debug does not indicate the presence of the HLT instruction.

H3.3.1 HLT instructions as the first instruction in a T32 IT block

In an implementation that supports the ITD control, the architecture permits a combination of one T32 IT instruction and certain other 16-bit T32 instruction to be treated as a single 32-bit instruction when the value of the ITD field that applies to the current Exception level is 1.

The T32 HLT instruction cannot be combined with an IT instruction in this way. In an implementation that supports the ITD control, if the first instruction in an IT block is an HLT instruction, then the behavior of the instruction depends on the value of the applicable ITD field:

- If the value of the ITD field is 1, then the combination is treated as undefined and an Undefined Instruction exception is generated either by the IT instruction or by the HLT instruction.
- If the value of the ITD field is 0, then the HLT instruction unconditionally executed.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

To set an Halt Instruction debug event on the first instruction of an IT block, debuggers must replace the IT instruction with an HLT instruction to ensure consistent behavior.

The ITD control fields are:
- HSCTLR.ITD Applies to execution at EL2 when EL2 is using AArch32.
- SCTLR.ITD Applies to execution at EL0 or EL1 when EL1 is using AArch32.
- SCTLR_EL1.ITD Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

Note An HLT instruction is always unconditional, even within an IT block.
**H3.4 Exception Catch debug event**

Exception Catch debug events:

- Are generated when the corresponding bit in the Exception Catch Control Register, EDECCR, is set to 1 on all entries to a given Exception level. This means:
  - Exceptions taken to the Exception level.
  - Exception returns to the Exception level.
- Are taken synchronously, after entry to the Exception level.
- Ignore the Execution state of the target Exception level.
- Are ignored if halting is prohibited.

From ARMv8.2 the definition is extended to include generation of Exception Catch debug events on reset entry, see *Exception Catch debug events from ARMv8.2* on page H3-6473.

The EDECCR contains two sets of fields:

- One set for Non-secure state.
- One set for Secure state.

Each set of fields control generation of Exception Catch debug events:

- On exception entry and, from ARMv8.2, on reset entry.
- On exception return.

Each field within each set contains one bit for each Exception level in that state. Bits corresponding to Exception levels that are not implemented are RES0. For more information see the EDECCR description.

--- Note  

- EDECCR does not replace DBGVCR:
  - DBGVCR is retained in AArch32 state for backwards compatibility.
  - DBGVCR is ignored in AArch64 state and never generates entries to Debug state.
  - DBGVCR cannot be accessed by the external debug interface.
- EDECCR is only visible as OSECCR_EL1 by System register instructions in AArch64 state, and as DBGOSECCR by System register access instructions in AArch32 state, when the OS Lock is locked to allow software to save and restore it over a powerdown.
- Exception Catch debug events are not disabled when the OS Lock is locked.

---

For an Exception Catch debug event generated after taking an exception to a trapped Exception level:

- The PE must not fetch instructions from the vector address before entering Debug state, if address translation is disabled in the translation regime at the target Exception level.
- On entering Debug state:
  - The current Exception level is the target Exception level of the exception.
  - The ELR, SPSR, ESR, and other syndrome registers contain information about the exception.
  - DLR contains the exception vector address or, from ARMv8.2, the reset address.

**H3.4.1 Prioritization of Exception Catch debug events**

The following rules define the prioritization of Exception Catch debug events:

- It is IMPLEMENTATION DEFINED whether Exception Catch debug events are higher or lower priority than each of Software Step exceptions and Halting Step debug events.
Exception Catch debug events are higher priority than all synchronous exceptions other than Software Step exceptions.

Exception Catch debug events are lower priority than Reset Catch debug events.

--- Note ---

As described in Synchronous exception prioritization for exceptions taken to AArch64 state on page D1-2179, an exception trapping form of a Vector Catch debug event might generate a second debug exception as part of the exception entry, before the Exception Catch debug event is taken. See Vector Catch exceptions on page D2-2316 or Vector Catch exceptions on page G2-5413.

A second unmasked asynchronous exception can be taken before the PE enters Debug state. If this second exception does not generate an Exception Catch debug event, the exception handler executed at the higher Exception level later returns to the trapped Exception level, causing the Exception Catch debug event to be generated again.

See also Debug state entry and debug event prioritization on page H2-6421.

From ARMv8.2, when an Exception Catch debug event is generated on exception entry, the PE must enter Debug state as part of the exception entry:

- After the exception entry has updated the program counter, PSTATE and syndrome registers for the exception.
- Before the first instruction at the handler is executed.
- Before any asynchronous or lower priority synchronous exception or debug event is taken at the first instruction in the exception handler.

From ARMv8.2, when an Exception Catch debug event is generated on exception return, the PE must enter Debug state:

- After the exception return has updated the program counter and PSTATE.
- Before the execution of the first instruction at the return address is completed.

--- Note ---

From ARMv8.2, there is no prioritization between asynchronous exceptions, asynchronous debug events, and an Exception Catch debug event generated on an exception return.

--- H3.4.2 CONstrained UNPREDICTABLE generation of Exception Catch debug events ---

When ARMv8.2-Debug is not implemented, the PE is executing code at a given Exception level, and the corresponding EDECCR bit is 1, it is CONSTRAINED UNPREDICTABLE whether an Exception Catch debug event is generated.

--- Note ---

It is possible to generate Exception Catch debug events:

- As a trap on all instruction fetches from the trapped Exception level as part of an instruction fetch.
- On entry to the Exception level, as described in Detailed Halting Step state machine behavior on page H3-6463.

This is similar to the implementation options allowed for Vector Catch debug events. The architecture does not require that the event is generated following an ISB operation executed at the Exception level.

Examples of this are:

- If the debugger writes to EDECCR so that the current Exception level is trapped.
- If the OS restore code writes to OSECCR so that the current Exception level is trapped.
H3.4 Exception Catch debug event

From ARMv8.2, the definition of Exception Catch debug events is extended so that Exception Catch debug events can be generated from:

- Exception entry.
- Reset entry.
- Exception return.

It is IMPLEMENTATION DEFINED whether a reset into an Exception level generates an Exception Catch debug event.

Exception catch debug events are taken synchronously, after the exception or reset entry or the exception return has been processed by the PE.

For exception returns, the final Exception level of the exception return determines whether an Exception Catch debug event is generated. On an illegal exception return an Exception Catch debug event is generated only if EDECCR is programmed to generate an Exception Catch debug event for an exception return to the current Exception level.

The NSR and SR fields in EDECCR determine whether Exception Catch debug events can be generated from reset entry. Table H3-5 shows how exception entry and exception return Exception Catch debug events are enabled by a combination of the fields NSR, SR, NSE and SE in EDECCR.

### Table H3-5 Summary of Exception Catch debug event control

<table>

H3.4.4 Examples of Exception Catch debug events

If EDECCR == 0x20, meaning that the Exception Catch debug event is enabled for Non-secure EL1, then the following exceptions generate Exception Catch debug events:

- An exception taken from Non-secure EL0 to Non-secure EL1.
- An exception return from EL2 to Non-secure EL1.
- An exception return from EL3 to Non-secure EL1.

For example, on taking a Data Abort exception from Non-secure EL0 to Non-secure EL1, using AArch64:

- ELR_EL1 and SPSR_EL1 are written with the preferred return address and PE state for a return to EL0.
- ESR_EL1 and FAR_EL1 are written with the syndrome information for the exception.
- DLR_EL0 is set to VBAR_EL1 + 0x400, the synchronous exception vector.
- DSPSR_EL0 is written with the PE state for an exit to EL1.

The following do not generate Exception Catch debug events:

- An exception taken from EL0 to EL2, if enabled in the current Security state, or EL3.
H3.4 Exception Catch debug event

- An exception return from EL2, if enabled in the current Security state, to EL0.
- An exception taken from Secure EL0 to Secure EL1.
- An exception return from EL3 to Secure EL1.

H3.4.5 Pseudocode description of Exception Catch debug events

The pseudocode function `CheckExceptionCatch()` is described in Chapter J1 ARMv8 Pseudocode.
H3.5  **External Debug Request debug event**

External Debug Request debug events are asynchronous debug events.

An External Debug Request debug event is generated when signaled by the embedded cross-trigger. See Chapter H5 *The Embedded Cross-Trigger Interface*.

--- **Note**

ARMv8-A requires the implementation of an embedded cross-trigger.

An implementation might also support IMPLEMENTATION DEFINED ways of generating an External Debug Request debug event.

---

H3.5.1  **Synchronization and External Debug Request debug events**

An External Debug Request debug event that is asserted before a *Context synchronization event* is taken and the PE enters Debug state before the first instruction following the *Context synchronization event* completes its execution, provided that halting is allowed after completion of the *Context synchronization event*.

An External Debug Request debug event that is being asserted when the PE comes out of reset is taken, and the PE enters Debug state before the first instruction after the reset completes its execution, provided that halting is allowed when the PE exits reset state.

If the first instruction after the *Context synchronization event* or after coming out of reset generates a synchronous exception then the architecture does not define the order in which the debug event and the exception or exceptions are taken.

Otherwise, when halting is allowed, External Debug Request debug events must be taken in finite time, without requiring the synchronization of any necessary change to the external authentication interface.

--- **Note**

These rules are based on the rules that apply when taking asynchronous exceptions. See *Asynchronous exception types, routing, masking and priorities* on page D1-2186.

---

If an unmasked External Debug Request debug event was pending but is changed to not pending before it is taken, then the architecture permits the External Debug Request debug event to be taken, but does not require this to happen. If the External Debug Request debug event is taken then it must be taken before the first *Context synchronization event* after the External Debug Request debug event was changed to not pending.

Example H3-3 shows an example of the synchronization requirements.

---

**Example H3-3 Synchronization requirements**

Secure software locks up in a tight loop, so it executes indefinitely without any synchronization operations. An External debug request must be able to break the PE out of that loop. This is a requirement even if DBGEN or SPIDEN or both are LOW on entry to the loop, meaning that halting is prohibited, and are only asserted HIGH later.

---

H3.5.2  **Pseudocode description of External Debug Request debug events**

The `ExternalDebugRequest()` function is described in *Chapter J1 ARMv8 Pseudocode*. 
H3.6 OS Unlock Catch debug event

An OS Unlock Catch debug event is generated when EDECR.OSUCE == 1 and the state of the OS Lock changes from locked to unlocked.

When the OS Lock is unlocked, the PE sets EDESR.OSUC to 1 if EDECR.OUCE is set to 1 and the PE is in Non-debug state, meaning the OS Unlock Catch debug event becomes pending. However, this is an indirect write to EDESR.OSUC, meaning the OS Unlock Catch debug event is not guaranteed to be taken before a subsequent context synchronization event. If the PE enters Debug state or EDECR.OSUCE is cleared to 0 before EDESR.OSUC becomes set to 1, then EDESR.OSUC might not be set.

OS Unlock Catch debug events are not generated if the OS Lock is unlocked when the PE is in Debug state. See also:

- Synchronization and Halting debug events on page H3-6479.
- The EDECR and EDESR register descriptions.

EDESR.OSUC is cleared to 0 on a Warm reset and on exiting Debug state.

H3.6.1 Using the OS Unlock Catch debug event

If the debugger attempts to access a debug register when the Core power down domain is completely off or in a low-power state in which the core power domain registers cannot be accessed, and that access returns an error, then the debugger must retry the access. However, if the Core power domain is regularly powered down, this can lead to unreliable debugger behavior.

The debugger can program a Reset Catch debug event to halt the PE when it has powered up, and can program the debug registers from Debug state. However, if the PE boot software restores the debug registers, as described in Debug OS Save and Restore sequences on page H6-6527, then newly written values are overwritten by the restore sequence.

The debugger can program an OS Unlock Catch debug event to halt the PE after the restore sequence has completed, and program the debug registers from Debug state.

H3.6.2 Pseudocode description of OS Unlock Catch debug event

The CheckOSUnlockCatch() function is called when the OS Lock is unlocked.

The CheckPendingOSUnlockCatch() function is called before an instruction is executed. If an OS Unlock Catch is pending, it generates the debug event.
H3.7  Reset Catch debug events

A Reset Catch debug event is generated when EDECR.RCE == 1 and the PE exits reset state. When the Reset Catch debug event is generated, it is recorded by setting EDESR.RC to 1.

If halting is allowed when the event is generated, the Reset Catch debug event is taken immediately and synchronously. On entering Debug state, DLR has the address of the reset vector. The PE must not fetch any instructions from memory.

Otherwise, the Reset Catch debug event is pended and taken when halting is allowed. See also:
- Synchronization and Halting debug events on page H3-6479.
- The EDECR and EDESR register descriptions.

This means that EDESR.RC is set to the value of EDECR.RCE on a Warm reset. EDESR.RC is cleared to 0 on exiting Debug state.

H3.7.1  Pseudocode description of Reset Catch debug event

The CheckResetCatch() function is called after reset before executing any instruction.

The CheckPendingResetCatch() function is called before an instruction is executed. If a Reset Catch is pending, it generates the Reset Catch debug event.
H3.8 Software Access debug event

When the value of EDSCR.TDA is 1, software access to the following AArch64 and AArch32 debug System registers generate a Software Access debug event:

- The Breakpoint Value Registers, DBGBVR.
- The Breakpoint Control Registers, DBGBCR.
- The Watchpoint Value Registers, DBGWVR.
- The Watchpoint Control Registers, DBGWCR.

However, EDSCR.TDA is ignored if any of the following applies:

- The value of OSLSR.OSLK == 1, meaning that the OS Lock is locked.
- Halting is prohibited. See Halting allowed and halting prohibited on page H2-6419.
- The register access generates an exception.

Note

- The only accesses to the specified registers that generate a Software Access debug event are:
  - Accesses to System registers in AArch64 state.
  - Accesses to System registers in the \( \text{coproc} \equiv 0b1110 \) encoding space in AArch32 state.
- Accesses by a PE using the external debug interface never generate a Software Access debug event.

H3.8.1 Pseudocode description of Software Access debug event

The CheckSoftwareAccessToDebugRegisters() function is described in Chapter J1 ARMv8 Pseudocode.
H3.9  Synchronization and Halting debug events

The behavior of external debug depends on:

- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special-purpose registers.
- The state of the external authentication interface.

For some registers, all read and write accesses that update the register occur in program order, without any additional synchronization, but others require an explicit Context synchronization event. For more information on the synchronization of register updates see:

- Synchronization requirements for AArch64 System registers on page D12-2663.
- Synchronization of changes to the external debug registers on page H8-6540.
- State and mode changes without explicit context synchronization events on page G2-5420.

Changes to the external authentication interface do not require explicit synchronization to affect External Debug Request debug events. See Synchronization and External Debug Request debug events on page H3-6475.

For changes that require explicit synchronization, it is CONSTRAINED UNPREDICTABLE whether instructions between the change and the Context synchronization event observe the old state or the new state.

This means that any change to these registers or the external authentication interface requires explicit synchronization by a Context synchronization event before the change takes effect. This ensures that for instructions appearing in program order after the change, the change affects the following:

- The generation and behavior of Breakpoint and Watchpoint debug events. See Synchronization and debug exceptions on page D2-2330 for exceptions taken from AArch64 state, or Synchronization and debug exceptions on page G2-5420 for exceptions taken from AArch32 state.
- The generation of all Halting debug events by instructions.
- Taking a pending Halting debug event or other asynchronous Debug event. See:
  - Pending Halting debug events.
  - Synchronization and External Debug Request debug events on page H3-6475.
- The behavior of the Halting Step state machine. See Synchronization and the Halting Step state machine on page H3-6466.

H3.9.1  Pending Halting debug events

A Halting debug event might be pending:

1. If Halting Step of an instruction sets EDESR.SS is set to 1, and halting is prohibited following the step, then the Halting Step state machine is inactive but a Halting Step debug event is pending.
2. If a Reset Catch debug event sets EDESR.RC to 1, and halting is prohibited following reset, then a Reset Catch debug event is pending.
3. If an OS Unlock Catch debug event sets EDESR.OSUC to 1, then an OS Unlock Catch debug event is pending.

Pending Halting debug events are discarded by a Cold reset. The debugger can also force a pending event to be dropped by writing to EDESR.

Any Halting debug event that is observed as pending in the EDESR before a Context synchronization event is taken and the PE enters Debug state before the first instruction following the Context synchronization event completes its execution. This is only possible if halting is allowed after completion of the Context synchronization event.
If the first instruction after the Context synchronization event generates a synchronous exception then the architecture does not define the order in which the debug event and the exception or exceptions are taken, unless both:

- A Halting Step debug event is pending. EDESR.SS == 1.
- The Context synchronization event is an exception return from a state where halting is prohibited to a state where halting is allowed.

--- Note ---

This applies to an exception return from Secure state with ExternalSecureInvasiveDebugEnabled() == FALSE to Non-secure state with ExternalInvasiveDebugEnabled() == TRUE.

---

In this case the order in which the debug events are handled is specified to avoid a double-step. See Entering the active-pending state on page H3-6465.

If an asynchronous exception is also pending after the Context synchronization event then the architecture does not define the order in which the debug event and the exception or exceptions are taken.

--- Note ---

These rules are based on the rules that apply to taking asynchronous exceptions. See Asynchronous exception types, routing, masking and priorities on page D1-2186.
Chapter H4
The Debug Communication Channel and Instruction Transfer Register

This chapter describes communication between a debugger and the implemented debug logic, using the Debug Communications Channel (DCC) and the Instruction Transfer Register (ITR), and associated control flags. It contains the following sections:

• Introduction on page H4-6482.
• DCC and ITR registers on page H4-6483.
• DCC and ITR access modes on page H4-6486.
• Flow control of the DCC and ITR registers on page H4-6490.
• Synchronization of DCC and ITR accesses on page H4-6494.
• Interrupt-driven use of the DCC on page H4-6500.
• Pseudocode description of the operation of the DCC and ITR registers on page H4-6501.

Note
Where necessary Table K13-1 on page K13-7390 disambiguates the general register references used in this chapter.
H4  The Debug Communication Channel and Instruction Transfer Register

H4.1 Introduction

The Debug Communications Channel, DCC, is a channel for passing data between the PE and an external agent, such as a debugger. The DCC provides a communications channel between:

• An external debugger, described as the debug host.
• The debug implementation on the PE, described as the debug target.

The DCC can be used:

• As a 32-bit full-duplex channel.
• As a 64-bit half-duplex channel.

The DCC is an essential part of Debug state operation and can also be used in Non-debug state.

The Instruction Transfer Register, ITR, passes instructions to the PE to execute in Debug state.

The PE includes flow-control mechanisms for both the DCC and ITR.
H4.2 DCC and ITR registers

The DCC comprises data transfer registers, the DTRs, and associated flow-control flags. The data transfer registers are DTRRX and DTRTX.

The ITR comprises a single register, EDITR, and associated flow-control flags.

In AArch64 state, software can access the data transfer registers as:

- A receive and transmit pair for 32-bit full duplex operation:
  - The write-only DBGDTRTX_EL0 register to transmit data.
  - The read-only DBGDTRRX_EL0 register to receive data.
- A single 64-bit read/write register, DBGDTR_EL0, for 64-bit half-duplex operation.
- The read/write OSDTRTX_EL1 and OSDTRRX_EL1 registers for save and restore.

In AArch32 state, software can only access the data transfer registers as:

- A receive and transmit pair, for 32-bit full duplex operation:
  - The write-only DBGDTRTXint register to transmit data.
  - The read-only DBGDTRRXint register to receive data.
- The read/write DBGDTRTXext and DBGDTRRXext registers for save and restore.

The data transfer registers are also accessible by the external debug interface as a pair of 32-bit registers, DBGDTRRX_EL0 and DBGDTRTX_EL0. Both registers are read/write, allowing both 32-bit full-duplex and 64-bit half-duplex operation.

The DCC flow-control flags are EDSCR. {RXfull, TXfull, RXO, TXU}:

- The RXfull and TXfull ready flags are used for flow-control and are visible to software in the Debug system registers in DCCSR.
- The RX overrun flag, RXO, and the TX underrun flag, TXU, report flow-control errors.
- The flow-control flags are also accessible by software as simple read/write bits for saving and restoring over a powerdown when the OS Lock is locked in DSCR.
- The flow-control flags are accessible from the external debug interface in EDSCR.

Figure H4-1 on page H4-6484 shows the System register and external debug interface views of the EDSCR and DTR registers in both AArch64 state and AArch32 state. These figures do not include the save and restore views.
H4.2 DCC and ITR registers

EDITR and the ITR flow-control flags, EDSCR.ITE, ITO} are accessible only by the external debug interface:
- The EDITR specifies an instruction to execute in Debug state.
- The ITR empty flag, ITE, is used for flow-control.
- The ITR overrun flag, ITO, reports flow-control errors.

The sticky overflow flag, EDSCR.ERR, is used by both the DCC and ITR to report flow-control errors.

To save and restore the DCC registers for an external debugger over powerdown, software uses:
- The MDSCR_EL1, OSDTRTX_EL1, and OSDTRRX_EL1 registers in AArch64 state.
The DBGDSCRext, DBGDTRTXext, and DBGDTRRXext registers in AArch32 state.

--- Note ---
There is no save and restore mechanism for the ITR registers as the ITR is only used in Debug state.

---

Figure H4-3 System register views of EDSR and DTR registers for save and restore
H4.3 DCC and ITR access modes

The DCC and ITR support two access modes:

<table>
<thead>
<tr>
<th>DCC and ITR access mode, links to description</th>
<th>Applies when:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal access mode</td>
<td>EDSCR.MA == 0 or the PE is in Non-debug state</td>
</tr>
<tr>
<td>Memory access mode on page H4-6487</td>
<td>EDSCR.MA == 1 and the PE is in Debug state</td>
</tr>
</tbody>
</table>

H4.3.1 Normal access mode

The Normal access mode allows use of the DCC as a communications channel between target and host. It also allows the use of the ITR for issuing instructions to the PE in Debug state.

In Normal access mode, if there is no overrun or underrun, the following occurs:

For accesses by software:

- Direct writes to DBGDTRTX update the value in DTRTX and indirectly write 1 to TXfull.
- Direct reads from DBGDTRRX return the value in DTRRX and indirectly write 0 to RXfull.
- In AArch64 state, direct writes to DBGDTR_EL0 update both DTRTX and DTRRX, indirectly write 1 to TXfull, and do not change RXfull:
  - DTRTX is set from bits[31:0] of the transfer register.
  - DTRRX is set from bits[63:32] of the transfer register.
- In AArch64 state, direct reads from DBGDTR_EL0 return the concatenation of DTRRX and DTRTX, indirectly write 0 to RXfull, and do not change TXfull:
  - Bits[31:0] of the transfer register are set from DTRRX.
  - Bits[63:32] of the transfer register are set from DTRTX.

**Note**

For DBGDTR_EL0, the word order is reversed for reads with respect to writes.

Software reads TXfull and RXfull using DCCSR.

For accesses by the external debug interface:

- Writes to EDITR trigger the instruction to be executed if the PE is in Debug state:
  - If the PE is in AArch64 state, this is an A64 instruction.
  - If the PE is in AArch32 state, this is a T32 instruction. The T32 instruction is a pair of halfwords where the first halfword is taken from the lower 16-bits, and the second halfword is taken from the upper 16-bits.
- Reads of DBGDTRTX_EL0 return the value in DTRTX and indirectly write 0 to TXfull.
- Writes to DBGDTRTX_EL0 update the value in DTRTX and do not change TXfull.
- Reads of DBGDTRRX_EL0 return the value in DTRRX and do not change RXfull.
- Writes to DBGDTRRX_EL0 update the value in DTRRX and indirectly write 1 to RXfull.

TXfull and RXfull are visible to the external debug interface in EDSCR.

The PE detects overrun and underrun by the external debug interface, and records errors in EDSCR.[TXU, RXO, ITO, ERR]. See Flow control of the DCC and ITR registers on page H4-6490.

See also Synchronization of DCC and ITR accesses on page H4-6494.
H4.3.2 Memory access mode

When the PE is in Debug state, Memory access mode can be selected to accelerate word-aligned block reads or writes of memory by an external debugger. Memory access mode can only be enabled in Debug state, and no instructions can be issued directly by the debugger when in Memory access mode.

If there is no overrun or underrun when in Memory access mode, an access by the external debug interface results in the following:

- **External reads from DBGDTRTX_EL0 cause:**
  1. The existing value in DTRTX to be returned. This clears EDSCR.TXfull to 0.
  2. The equivalent of LDR W1,[X0],#4, if in AArch64 state, or LDR R1,[R0],#4, if in AArch32 state, to be executed.
  3. The equivalent of the MSR DBGDTRX_EL0,X1 instruction, if in AArch64 state, or the MCR p14,0,R1,c0,c5,0 instruction, if in AArch32 state, to be executed.
  4. EDSCR.{TXfull, ITE} to be set to {1,1}, and X1 or R1 to be set to an UNKNOWN value.

- **External writes to DBGDTRRX_EL0 cause:**
  1. The value in DTRRX to be updated. This sets EDSCR.RXfull to 1.
  2. The equivalent of the instruction MRS X1,DBGDTRRX_EL0, if in AArch64 state, or MRC p14,0,R1,c0,c5,0 if in AArch32 state, to be executed.
  3. The equivalent of the instruction STR W1,[X0],#4, if in AArch64 state, or STR R1,[R0],#4, if in AArch32 state, to be executed.
  4. EDSCR.{RXfull, ITE} to be set to {0,1}, and X1 or R1 to be set to an UNKNOWN value.

- **External reads from DBGDTRTX_EL0 return the last value written to DTRRX.**
- **External writes to EDITR generate an overrun error.**

During these accesses, EDSCR.{TXfull, RXfull, ITE} are used for flow control.

--- Note ---

An overrun or underrun might result in EDSCR.ERR being set to 1 asynchronously to the sequence of operations that are outlined in this section. As this is timing-dependent, it is UNPREDICTABLE when the EDSCR.ERR flag affects the instructions and therefore whether neither instruction, only the first instruction, or both instructions are executed. If the second instruction is executed, then the first instruction must have been executed. However, in each case X1 or R1 is set to an UNKNOWN value. This means that:

- In both cases, if the memory access instruction is not executed, then the base register X0 or R0 is not updated, meaning the debugger can determine the last accessed location.
- In the list describing External reads from DBGDTRTX_EL0, DTRTX and EDSCR.TXfull get set to UNKNOWN values. If the load was executed, then the value that was read by the PE is lost. This means the operation might need to be repeated by the debugger, and it is not advisable to use Memory access mode to read from read-sensitive locations using the underrun and overrun detection for flow control.
- In the list describing External writes to DBGDTRRX_EL0, EDSCR.RXfull is set to an UNKNOWN value. A Data Abort from the memory access can also set EDSCR.ERR to 1. See Data Aborts in Memory access mode on page H4-6488.

---

The architecture does not require precisely when these flags are set or cleared by the sequence of operations outlined in this section. For example, in the case of an external write to DBGDTRRX_EL0, in AArch64 state, RXfull might be cleared after step 2, or it might not be cleared until after step 3, as an implementation is free to fuse these steps into a single operation. The architecture does require that the flags are set as at step 4 when the PE is ready to accept a further read or write without causing an overrun error or an underrun error.

The process outlined in this section represents a simple sequential execution model of Memory access mode. An implementation is free to pipeline, buffer, and re-order instructions and transactions, as long as the following remain true:

- Data items are transferred into and out of the DTR in order and without loss of data, other than as a result of an overrun or an underrun.
• Data Aborts occur in order.

• The constraints of the memory type are met.

• In the list describing External reads from DBGDTRTX_EL0 on page H4-6487:
  — The MSR equivalent operation at step 3 of the sequence reads the value loaded by step 2.
  — If the list is performed in a loop, for all but the first iteration of this list, the value read by step 1 returns the values written by the MSR equivalent operation at the previous iteration of step 3.

• In the list describing External writes to DBGDTRRX_EL0 on page H4-6487:
  — The MSR equivalent operation at step 2 of the sequence returns the value written at step 1.
  — The STR equivalent at step 3 of the sequence writes the value read at step 2.

• If the PE cannot accept a read or write, as applicable, during the sequence, then the flags are updated to indicate an overrun or underrun.

See Flow control of the DCC and ITR registers on page H4-6490 for more information on overrun and underrun.

Ordering, access sizes and effect on Exclusives monitors

For the purposes of memory ordering, access sizes, and effect on the Exclusives monitor, accesses in Memory access mode are consistent with Load/Store word instructions executed by the PE.

The simple sequential access model of Memory-access mode, as stated in Memory access mode on page H4-6487, must also be ordered with respect to instructions executed as a result of explicit writes to EDITR in Normal mode both before and after accesses to the DTR registers in Memory-access mode.

Data Aborts in Memory access mode

If a memory access generates a Data Abort, then:

• The Data Abort exception is taken. See Exceptions in Debug state on page H2-6448:
  — This means EDSCR.ERR is set to 1, see Cumulative error flag on page H4-6492.
  — If the Data Abort occurs on stage 2 of an address translation, then the values returned in the ISV field and in bits[23:14] of the ISS are UNKNOWN.
    If this Data Abort is taken to EL2 using AArch64, the ISS is returned by ESR_EL2. ISS encoding for an exception from a Data Abort on page D12-2781 describes the usual encoding of this ISS.
    If EL2 is using AArch32 and this Data Abort is taken to Hyp mode, the ISS is returned by HSR. ISS encoding for an exception from a Data Abort on page G8-5829 describes the usual encoding of this ISS.

• Register R0 retains the address that generated the abort.

• Register R1 is set to an UNKNOWN value.

• EDSCR.TXfull, for a load, or EDSCR.RXfull, for a store, is set to an UNKNOWN value.

• DTRTX, for a load, or DTRRX, for a store, is set to an UNKNOWN value.

• EDSCR.ITE is set to 1.

Illegal Execution state exception

If PSTATE.IL is set to 1 when EDSCR.MA == 1, then on an external write access to DBGDTRRX_EL0 or an external read from DBGDTRTX_EL0, it is CONSTRAINED UNPREDICTABLE whether the PE:

• Takes an Illegal Execution state exception without performing any operations. In this case:
  — EDSCR.ERR is set to 1, see Cumulative error flag on page H4-6492.
  — Register R0 is unchanged.
  — Register R1 is set to an UNKNOWN value.
H4 The Debug Communication Channel and Instruction Transfer Register

H4.3 DCC and ITR access modes

— EDSCR.TXfull or EDSCR.RXfull, as applicable, is set to an UNKNOWN value.
— DTRTX or DTRRX, as applicable, is set an UNKNOWN value.
— EDSCR.ITE is set to 1.

See also Exceptions in Debug state on page H2-6448.

• Ignores PSTATE.IL.

——— Note ————

The typical usage model for Memory access mode involves executing instructions in Normal access mode to set up X0 before setting EDSCR.MA to 1. These instructions generate an Illegal state exception if PSTATE.IL is set to 1.

Alignment constraints

If the address in R0 is not aligned to a multiple of four, the behavior is as follows:

• For each external DTR access a CONSTRAINED UNPREDICTABLE choice of:
  1. The PE makes an unaligned memory access to R0. If alignment checking is enabled for the memory access, this generates an Alignment fault.
  2. The PE makes a memory access to Align(X[0],4) in AArch64 state, or Align(R[0],4) in AArch32 state.
  3. The PE generates an Alignment fault, regardless of whether alignment checking is enabled.
  4. The PE does nothing.

• Following each memory access, if there is no Data Abort, R0 is updated with an UNKNOWN value.

• For external writes to DBGDTRRX_EL0, if the PE writes to memory, an UNKNOWN value is written.

• For external reads of DBGDTRTX_EL0 an UNKNOWN value is returned.

• The RXfull and TXfull flags are left in an UNKNOWN state, meaning that a DBGDTRTX_EL0 read can trigger a TX underrun, and a DBGDTRTX_EL0 write can trigger an RX overrun.

H4.3.3 Memory-mapped accesses to the DCC and ITR

Writes to the flags in EDSCR by external debug interface accesses to the DCC and the ITR registers are indirect writes, because they are a side-effect of the access. The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see Register access permissions for memory-mapped accesses on page H8-6544.
H4.4 Flow control of the DCC and ITR registers

- Ready flags.
- Buffering writes to EDITR.
- Overrun and underrun flags.
- Cumulative error flag on page H4-6492.

H4.4.1 Ready flags

In Normal access mode:

- For the DTR registers there are two ready flags:
  - EDSCR.RXfull == 1 indicates that DBGDTRRX_EL0 contains a valid value that has been written by the external debugger and not yet read by software running on the target.
  - EDSCR.TXfull == 1 indicates that DBGDTRTX_EL0 contains a valid value that has been written by software running on the target and not yet read by an external debugger.

- For the ITR register there is a single ready flag:
  - EDSCR.ITE == 1 indicates that the PE is ready to accept an instruction to the ITR.

  Note
  The architecture permits a PE to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, as long as those instructions are discarded if EDSCR.ERR is set, either by an underrun or overrun or by any of the other error conditions described in this architecture, such as an instruction generating an abort.

In Memory access mode:

- EDSCR.{RXfull, ITE} == {0,1} indicates that DBGDTRRX_EL0 is empty and the PE is ready to accept a word external write to DBGDTRRX_EL0.

- EDSCR.{TXfull, ITE} == {1,1} indicates that DBGDTRTX_EL0 is full and the PE is ready to accept a word external read from DBGDTRTX_EL0.

All other values indicate that the PE is not ready, and result in a DTR overrun or underrun error, an ITR overrun error, or both, as defined in Overrun and underrun flags.

EDSCR.{ITE, RXfull, TXfull} shows the status of the ITR and DCC registers. It ignores the question of whether a read or write cannot be accepted because, for example, EDSCR.ERR is set or the OPTIONAL Software Lock is locked for memory-mapped accesses (EDLSR.SLK == 1).

H4.4.2 Buffering writes to EDITR

The architecture permits a processor to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, provided that:

- Those instructions are discarded if EDSCR.ERR is set to 1, either by an underrun or an overrun, or by any other error conditions described in this architecture, such as an instruction generating an abort.

- The PE maintains the simple sequential execution model with the order of instructions determined by the order in which the PE accepts the EDITR writes. In particular, the buffered instructions must be executed in the Execution state consistent with a simple sequential execution of the instructions, even if one of the previous instructions is a state changing operation, such as DCPS or DRPS.

H4.4.3 Overrun and underrun flags

Each of the ready flags has a corresponding overrun or a corresponding underrun flag. These are sticky status flags that are set if the register is accessed using the external debug interface when the corresponding ready flag is not in the ready state.
If the PE is in Debug state and Memory access mode, the corresponding error flag is also set if the PE is not ready to accept an operation because a previous load or store is still in progress. The sticky status flag remains set until cleared by writing 1 to EDRCR.CSE.

——Note——
The architecture permits a PE to continue to accept and buffer data to write to memory in Memory access mode.

Table H4-1 shows DCC and ITR ready flags and the overrun and underrun flags associated with them.

Table H4-1 DCC and ITR ready flags and the associated overrun/underrun flags

<table>
<thead>
<tr>
<th>External debug interface access</th>
<th>Overrun/Underrun condition</th>
<th>ESCR flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>Write DBGDTRRX_EL0</td>
<td>ESCR.RXfull == ‘1’</td>
<td></td>
</tr>
<tr>
<td>Read DBGDTRTX_EL0</td>
<td>ESCR.TXfull == ‘0’</td>
<td></td>
</tr>
<tr>
<td>Write EDITR</td>
<td>Halted() &amp;&amp; (ESCR.ITE == ‘0’</td>
<td></td>
</tr>
</tbody>
</table>

When an overrun or underrun flag is set to 1, the cumulative error flag, ESCR.ERR, described in Cumulative error flag on page H4-6492, is also set to 1.

In the event of an external write to DBGDTRRX_EL0 or EDITR generating an overrun, or an external read from DBGDTRTX_EL0 generating an underrun:

- For a write, the written value is ignored.
- For a read, an UNKNOWN value is returned.
- ESCR.TXfull, ESCR.RXfull or ESCR.ITE, as applicable, are not updated.

There is no overrun or underrun detection on external reads of DBGDTRRX_EL0 or external writes of DBGDTRTX_EL0.

There is no overrun or underrun detection of direct reads and direct writes of the DTR System registers by software:

- If RXfull == 0, a direct read of DBGDTRRX or DBGDTR_EL0 returns UNKNOWN.
- If TXfull == 1, a direct write of:
  - DBGDTRTX sets DTRTX to UNKNOWN.
  - DBGDTR_EL0 sets DTRRX and DTRTX to UNKNOWN.

See DCC accesses in Non-debug state on page H4-6495 for more information.

Accessing 64-bit data

In AArch64 state, a software access to the DBGDTR_EL0 register and an external debugger access to both DBGDTRRX_EL0 and DBGDTRTX_EL0 can perform a 64-bit half-duplex operation.

However, there is only overrun and underrun detection on one of the external debug registers. That is:

- If software directly writes a 64-bit value to DBGDTR_EL0, only TXfull is set to 1, meaning:
  - A subsequent external write to DBGDTRRX_EL0 would not be detected as an overrun.
  - If the external debugger reads DBGDTRTX_EL0 first, software might observe MDCCSR_EL0.TXfull == 0 and send a second value before the external debugger reads DBGDTRTX_EL0, leading to an undetected overrun.
  - On external writes to both DBGDTRRX_EL0 and DBGDTRTX_EL0 only RXfull is set to 1, meaning:
    - A subsequent direct write of DBGDTRTX_EL0 would not be detected as an overrun.
--- If the external debugger writes to DBGDTRRX_EL0 first, software might observe MDCCSR_EL0.RXfull == 1 and read a full 64-bit value, before the external debugger writes to DBGDTRTX_EL0, leading to an undetected underrun.

To avoid this, debuggers need to be aware of the data size used by software for transfers and ensure that 64-bit data is read or written in the correct order. If the PE is in Non-debug state, this order is as follows:

- The external debugger must check EDSCR.{RXfull, TXfull} before each transfer.
- To receive a 64-bit value from the target, the external debugger must read DBGDTRRX_EL0 before reading DBGDTRTX_EL0.
- To send a 64-bit value to the target, the external debugger must write to DBGDTRTX_EL0 before writing DBGDTRRX_EL0.

Because three accesses are required to transfer 64 bits of data, 64-bit transfers are not recommended for regular communication between host and target. The use of underrun and overrun detection means that only one access is required for 32 bits of data when using 32-bit transfers.

In Debug state, the debugger controls the instructions executed by the PE, so these limitations do not apply. 64-bit transfers provide a means to transfer a 64-bit general register between the host and the target in Debug state.

### H4.4.4 Cumulative error flag

The cumulative error flag, EDSCR.ERR, is set to 1:

- On taking an exception from Debug state.
- On any signalled overrun or underrun in the DCC or ITR.

When EDSCR.ERR == 1:

- External reads of DBGDTRTX_EL0 do not have any side-effects.
- External writes to DBGDTRRX_EL0 are ignored.
- External writes to EDITR are ignored.
- No further instructions can be issued in Debug state. This includes any instructions previously accepted as external writes to EDITR that occur in program order after the instruction or access that caused the error.

This allows a debugger to stream data, or, in Debug state, instructions, to the target without having to:

- Check EDSCR.{RXfull, TXfull, ITE} before each access.
- Check EDSCR.{ITO, RXO, TXU} following each access, for overrun or underrun.
- Check PSTATE or other syndrome registers, or both, for an exception following each instruction executed in Debug state that might generate a synchronous exception.

The cumulative error flag remains set until cleared to 0 by writing 1 to EDRCR.CSE. However, the effect of writing 1 to EDRCR.CSE to clear EDSCR.ERR is CONSTRAINED UNPREDICTABLE when both of the following apply:

- The PE is in Debug state.
- The value of EDSCR.ITE is 0.

When these conditions apply and a value of 1 is written to EDRCR.CSE, either or both of the following might occur:

- EDSCR.ERR is not cleared to 0.
- Any instructions in EDITR that have not been executed might be executed subsequently, rather than being ignored.

--- Note

This means that a debugger must poll EDSCR.ITE until it has the value 1, indicating that EDITR is empty, before writing to EDRCR.CSE to clear the EDSCR.ERR flag to 0.

---

For overruns and underruns, EDSCR.{ITO, RXO, TXU} record the error type.
Pseudocode description of clearing the error flag

The ClearStickyErrors() pseudocode function is described in Chapter J1 ARMv8 Pseudocode.
H4.5 Synchronization of DCC and ITR accesses

In addition to the standard synchronization requirements for register accesses, the following subsections describe additional requirements that apply for the DCC and ITR registers:

- **Summary of System register accesses to the DCC.**
- **DCC accesses in Non-debug state on page H4-6495.**
- **Synchronization of DCC interrupt request signals on page H4-6498.**
- **DCC and ITR access in Debug state on page H4-6498.**

In these sections, accesses by the external debug interface are referred to as external reads and external writes. Accesses to System registers are referred to as direct reads, direct writes, indirect reads, and indirect writes.

---

**Note**

In *Synchronization requirements for AArch64 System registers* on page D12-2663 external reads and external writes are described as forms of indirect access. This whole section uses more explicit terminology.

---

The DTR registers and the DCC flags, TXfull and RXfull, form a communication channel, with one end operating asynchronously to the other. Implementations must respect the ordering of accesses to these registers in order to maintain the correct behavior of the channel.

External reads of, and external writes to DBGDTRRX_EL0 and DBGDTRTX_EL0 are asynchronous to direct reads of, and direct writes to, DBGDTRRX, DBGDTRTX, and in AArch64 state DBGDTR_EL0, made by software using System register access instructions. The direct reads and direct writes indirectly write to the DCC flags. The external reads and external writes indirectly read the DCC flags to check for underrun and overrun.

H4.5.1 Summary of System register accesses to the DCC

System register accesses to the DTR registers are direct reads and writes of those registers, as shown in Table H4-2 on page H4-6495. Several of these instructions access the same registers using different encodings.

With the exception of the read and write bits, DBGDTRRX and DBGDTRTX are the same encoding, with exception of the read/write bits, but use different registers. The Armv8 architecture governs the order of these instructions, as described in *Synchronization requirements for AArch64 System registers* on page D12-2663. For more details, see the description of the individual register in the relevant chapter, Chapter D12 AArch64 System Register Descriptions or Chapter G8 AArch32 System Register Descriptions.
Table H4-2 shows a summary of System register accesses to the DCC.

H4.5.2 DCC accesses in Non-debug state

In Non-debug state DCC accesses are as described in Normal access mode on page H4-6486:

- If a direct read of DCCSR returns RXfull == 1, then a following direct read of DBGDTRRX, or in AArch64 state of DBGDTR_EL0, returns valid data and indirectly writes 0 to DCCSR.RXfull as a side-effect.
- If a direct read of DCCSR returns TXfull == 0, then a following direct write to DBGDTRTX, or in AArch64 state to DBGDTR_EL0, writes the intended value, and indirectly writes 1 to DCCSR.TXfull as a side-effect.

No Context synchronization event is required between these two instructions. Overrun and underrun detection prevents intervening external reads and external writes affecting the outcome of the second instruction.

The indirect write to the DCC flags as part of the DTR access instruction is made atomically with the DTR access. Because a direct read of DBGDTRRX is an indirect write to DCCSR.RXfull, it must occur in program order with respect to the direct read of DCCSR, meaning it must not return a speculative value for DTRRX that predates the RXfull flag returned by the read of DCCSR. The direct write to DBGDTRTX must not be executed speculatively.

Direct reads of DBGDTRRX, or in AArch64 state DBGDTR_EL0, and DCCSR, must occur in program order with respect to other direct reads of the same register using the same encoding.

The following accesses have an implied order within the atomic access:

- In the simple sequential execution of the program the indirect write of the DCC flags occurs immediately after the direct DTR access.

--- Note ---

For an access to DBGDTR_EL0, this means the indirect write happens after both DBGDTRRX_EL0 and DBGDTRTX_EL0 have been accessed.
In the simple sequential execution model, for an external read of DBGDTRTX_EL0 or an external write of DBGDTRRX_EL0:

- The check of the DCC flags for overrun or underrun occurs immediately before the access.
- If there is no underrun or overrun, the update of the DCC flags occurs immediately after the access.
- If there is underrun or overrun, the update of the DCC underrun or overrun flags occurs immediately after the access.

All observers must observe the same order for accesses.

--- Note ---

These requirements do not create order where order does not otherwise exist. It applies only for ordered accesses.

Without explicit synchronization following external writes and external reads:

- The value written by the external write to DBGDTRRX_EL0 that does not overrun, must be observable to direct reads of DBGDTRRX and DBGDTR_EL0 in finite time.

- The DCC flags that are updated as a side-effect of the external write or external read must be observable:
  - To subsequent external reads of EDSCR.
  - To subsequent external reads of DBGDTRRX_EL0 when checking for underrun.
  - To subsequent external writes to DBGDTRTX_EL0 when checking for overrun.
  - To direct reads of DCCSR in finite time.

However, explicit synchronization is required to guarantee that a direct read of DCCSR returns up-to-date DCC flags. This means that if a signal is received from another agent that indicates that DCCSR must be read, an ISB is required to ensure that the direct read of DCCSR occurs after the signal has been received. This also synchronizes the value in DBGDTRRX, if applicable. However, if that signal is an interrupt exception triggered by COMMIRQ, COMMTX, or COMMRX, the exception entry is sufficient synchronization. See Synchronization of DCC interrupt request signals on page H4-6498.

Explicit synchronization is required following a direct read or direct write:

- To ensure that a value directly written to DBGDTRTX is observable to external reads of DBGDTRTX_EL0.

- To ensure that a value directly written to DBGDTR_EL0 is observable to external reads of DBGDTRTX_EL0 and DBGDTRRX_EL0.

- To guarantee that the indirect writes to the DCC flags that were a side-effect of the direct read or direct write have occurred, and therefore that the updated values are:
  - Observable to external reads of EDSCR.
  - Observable to external reads of DBGDTRRX_EL0 when checking for underrun.
  - Observable to external writes of DBGDTRTX_EL0 when checking for overrun.
  - Returned by a following direct read of DCCSR.

See also Memory-mapped accesses to the DCC and ITR on page H4-6489 and Synchronization of changes to the external debug registers on page H8-6540.

--- Note ---

These ordering rules mean that software:

- Must not read DBGDTRRX without first checking DCCSR.RXfull or if the previously-read value of DCCSR.RXfull is 0.
  It is not sufficient to read both registers and then later decide whether to discard the read value, as there might be an intervening write from the external debug interface.

- Must not write DBGDTRTX without first checking DCCSR.TXfull or if the previously-read value of DCCSR.TXfull is 1.
  The write to DBGDTRTX overwrites the value in DTRTX, and the external debugger might or might not have read this value.
• Must ensure there is an explicit *Context synchronization event* following a DTR access, even if not immediately returning to read DCCSR again. This synchronization operation can be an exception return.

**Derived requirements**

The rules for DCC accesses in Non-debug state are as follows:

- Following a direct read of **DBGDTRRX** when RXfull is 1:
  - If an external write to **DBGDTRRX** checks the RXfull flag for overrun and observes that the value of RXfull is 0, the value returned by the previous direct read must not be affected by the external write.
  - If an external read of **EDSCR** returns a RXfull value of 0, then the value returned by the previous direct read must not be affected by a following external write to **DBGDTRRX**, and the following external write does not overrun.

- Following a direct read of **DBGDTR_EL0**, when RXfull is 1:
  - If an external write to **DBGDTRRX** checks the RXfull flag for overrun and observes that the value of RXfull is 0, the value returned by the previous direct read must not be affected by the external write nor by a following direct write to **DBGDTR_TX**.
  - If an external read of **EDSCR** returns a RXfull value of 0, then the value returned by the previous direct read must not be affected by subsequent external writes to **DBGDTRRX** and **DBGDTR_TX** in any order, and the following external write of **DBGDTRRX** will not overrun.

- Following a direct write to **DBGDTR_TX**, when TXfull is 0:
  - If an external read of **DBGDTRTX** checks the TXfull flag for underrun and observes that the value of TXfull is 1, the value returned by the external read must be the value written by the previous direct write.
  - If an external read of **EDSCR** returns a TXfull value of 1, then the value returned by a following external read of **DBGDTRRX** must be the value written by the previous direct read, and the subsequent external read will not underrun.

- Following a direct write to **DBGDTR_EL0**, when TXfull is 0:
  - If an external read of **DBGDTRTX** checks the TXfull flag for underrun and observes that the value of TXfull is 1, the values returned by the external read and by a subsequent external read of **DBGDTRRX** must be the value written by the previous direct write.
  - If an external read of **EDSCR** returns a TXfull value of 1, then the value returned by subsequent external reads of **DBGDTRRX** and **DBGDTR_TX**, in any order, must be the value written by the previous direct read, and the subsequent external read of **DBGDTRTX** does not underrun.

- Following an external read of **DBGDTR_TX** that does not underrun, if a direct read of **DCCSR** returns a TXfull value of 0, then the value returned by the external read must not be affected by a following direct write to **DBGDTR_TX**.

- Following a first external read **DBGDTRRX** and a following second external read of **DBGDTR_TX** that does not underrun, if a direct read of **DCCSR** returns a TXfull value of 0, then the values returned by the external reads must not be affected by a following direct write to **DBGDTR_EL0**.

- Following an external write to **DBGDTRRX** that does not overrun, if a direct read of **DCCSR** returns an RXfull value of 1, then the value returned by a following direct read of **DBGDTRRX** or **DBGDTR_EL0** must be the value written by the previous external write.

- Following a first external write to **DBGDTRRX** and a following second external write to **DBGDTR_TX** that does not overrun, if a direct read of **DCCSR** returns an RXfull value of 1, then the value returned by a subsequent direct read of **DBGDTR_EL0** must return the values written by the previous external writes.
H4.5.3 Synchronization of DCC interrupt request signals

Following an external read or external write access to the DTR registers, the interrupt request signals, COMMIRQ, COMMTX, and COMMRX, must be updated in finite time without explicit synchronization.

The updated values must be observable to a direct read of DCCSR or DBGDTRRX, or a direct write of DBGDTRTX executed after taking an interrupt exception generated by the interrupt request. The updated values must also be observable to a direct write of DBGDTRTX executed after taking an interrupt exception generated by the interrupt request.

Note

The requirement that indirect writes to registers are observable to direct reads in finite time does not imply that all observers will observe the indirect write at the same time. For more information, see Synchronization requirements for AArch64 System registers on page D12-2663 and Synchronization of changes to AArch32 System registers on page G8-5640.

Following a direct read of DBGDTRRX or a direct write to DBGDTRRX, software must execute a Context synchronization event to guarantee the interrupt request signals have been updated in finite time. This synchronization operation can be an exception return.

H4.5.4 DCC and ITR access in Debug state

In Debug state, stricter observability rules apply for instructions issued through the ITR, to maintain communication between a debugger and the PE, without requiring excessive explicit synchronization.

In Normal access mode, without explicit synchronization:

• A direct read or direct write of the DTR registers by an instruction written to EDITR must be observable to an external write or an external read in finite time:
  — A direct read of DBGDTRRX must be observable to an external write of DBGDTRRX_EL0.
  — A direct read of DBGDTR_EL0 must be observable to an external write of DBGDTRRX_EL0 and DBGDTRTX_EL0.
  — A direct write of DBGDTRTX must be observable to an external read of DBGDTRTX_EL0.
  — A direct write of DBGDTR_EL0 must be observable to an external read of DBGDTRRX_EL0 and DBGDTRTX_EL0.

This includes the indirect write to the DCC flags that occurs atomically with the access as described in DCC accesses in Non-debug state on page H4-6495.

The subsequent external write or external read must observe either the old or the new values of both the DTR contents and DCC flags. If the old values are observed, this typically results in overrun or underrun, assuming the old values of the DCC flags indicate an overrun or underrun condition, as would normally be the case. This means the debugger can observe the direct read or direct write without explicit synchronization and without explicitly testing the DCC flags in EDSCR, because it can rely on overrun and underrun tests.

• External reads of DBGDTRTX_EL0 that do not underrun and external writes to DBGDTRRX_EL0 that do not overrun must be observable to an instruction subsequently written to EDITR on completion of the first external access. This includes the indirect write to the DCC flags.

This means that without explicit synchronization and without the need to first check the DCC flags in DCCSR:
  — If the instruction is a direct read of DBGDTRRX, it observes the external write.
  — If the instruction is a direct write of DBGDTRTX, it observes the external read.

• Writes to EDITR that do not overrun commit an instruction for execution immediately. The instruction must complete execution in finite time without requiring any further operation by the debugger.

• After an external write to the EDITR, the ITR flags that are updated as a side effect of that write must be observable by:
  — An external read of the EDSCR that follows the external write to the EDITR.
  — When checking for overrun, another external write to the EDITR that follows the original external write to the EDITR.
In Memory access mode, these requirements shift to the instructions implicitly executed by external reads and external writes of the DTR registers, as described in Memory access mode on page H4-6487.
H4.6 Interrupt-driven use of the DCC

Arm recommends implementations provide a level-sensitive DCC interrupt request through the IMPLEMENTATION DEFINED interrupt controller as a private peripheral interrupt for the originating PE.

--- Note ---
- In addition to connection to the interrupt controller Arm also recommends COMMIRQ, COMMTX, and COMMRX signals that might be implemented for use by any legacy system peripherals.
- GICv3 reserves a private peripheral interrupt number for the COMMIRQ interrupt.

The DCCINT register provides a first level of interrupt masking within the PE, meaning only a single interrupt source, COMMIRQ, is needed at the interrupt controller.

See also Synchronization of DCC interrupt request signals on page H4-6498.
H4.7 Pseudocode description of the operation of the DCC and ITR registers

The basic operation of the DCC and ITR registers is shown by the following pseudocode functions. These functions do not cover the behavior when OSLSR.OSLK == 1, meaning that the OS Lock is locked:

- `DBGDTR_EL0[]`
- `DBGDTRRX_EL0[]`
- `DBGDTRTX_EL0[]`
- `EDITR[]`
- `CheckForDCCInterrupts()`

For the definition of the DTR Registers, see `shared/debug/dccanditr/DTR` on page J1-7089.
H4 The Debug Communication Channel and Instruction Transfer Register
H4.7 Pseudocode description of the operation of the DCC and ITR registers
Chapter H5
The Embedded Cross-Trigger Interface

This chapter describes the embedded cross-trigger interface. It contains the following sections:

- About the Embedded Cross-Trigger (ECT) on page H5-6504.
- Basic operation on the ECT on page H5-6506.
- Cross-triggers on a PE in an ARMv8 implementation on page H5-6510.
- Description and allocation of CTI triggers on page H5-6511.
- CTI registers programmers’ model on page H5-6515.
- Examples on page H5-6516.
H5.1 About the Embedded Cross-Trigger (ECT)

The **Embedded Cross-Trigger**, ECT, allows a debugger to:

- Send trigger events to a PE. For example, this might be done to halt the PE.
- Send a trigger event to one or more PEs, or other system components, when a trigger event occurs on another PE or system component. For example, this might be done to halt all PEs when one individual PE halts.

Figure H5-1 shows the logical structure of an ECT.

![Figure H5-1 Structure of an embedded cross-trigger](image)

The ECT can deliver many types of trigger events, which are described in the following sections:

- [Debug request trigger event on page H5-6511](#).
- [Restart request trigger event on page H5-6512](#).
- [Cross-halt trigger event on page H5-6512](#).
- [Performance Monitors overflow trigger event on page H5-6512](#).
- [Generic trace external input trigger events on page H5-6513](#).
- [Generic trace external output trigger events on page H5-6513](#).
- [Generic CTI interrupt trigger event on page H5-6513](#).

An ARMv8-A implementation must:

- Include a cross-trigger interface, CTI.
- Implement at least the input and output triggers defined in this architecture.

In addition, see [Cross-triggers on a PE in an ARMv8 implementation on page H5-6510](#).

ARM recommends that this cross-trigger interface includes:

- The ability to route trigger events between Trace Units, which typically have advanced event triggering logic.
- An output trigger to the interrupt controller.

Also, ARM recommends that the Embedded Cross-Trigger includes the capability to send and receive implementation defined system trigger events to and from other system components, including a system counter, using a system CTI. See [Halt-on-debug on page I2-6720](#).
Note

The ECT and CTI must only signal trigger events for external debugging. They must not route software events, such as interrupts. For example, the Performance Monitors overflow input trigger is provided to allow entry to Debug state on a counter overflow, and the output trigger to the interrupt controller is provided to generally allow events from the external debug sub-system to be routed to a software agent. However, the combination of the two must not be used as a mechanism to route Performance Monitors overflows to an interrupt controller.

H5.1.1 Implementation with a CoreSight CTI

For details of the recommended connections in an ARMv8-A implementation, see Appendix K2 Recommended External Debug Interface. See also CoreSight™ SoC Technical Reference Manual.
H5.2 Basic operation on the ECT

The ECT comprises a Cross-Trigger Matrix, CTM, and one Cross-Trigger Interface, CTI, for each PE. The ECT might also include other CTIs for other system components. The CTM passes events between the CTI blocks over channels. The CTM can have a maximum of 32 channels.

The main interfaces of the cross-trigger interface, CTI, are:
- The input triggers:
  - These are trigger event inputs from the PE to the CTI.
- The output triggers:
  - These are trigger event outputs from the CTI to the PE.
- The input channels:
  - These are channel event inputs from the cross-trigger matrix, CTM, to the CTI.
- The output channels:
  - These are channel event outputs from the CTI to the CTM.

Each CTI block has:
- Up to 32 input triggers that come from the PE:
  - The input triggers are numbered 0-31.
- Up to 32 output triggers that go to the PE:
  - The output triggers are numbered 0-31.

Figure H5-2 on page H5-6507 shows the logical internal structure of a CTI.
Figure H5-2 Structure of a cross-trigger interface

**Note**

- The number of triggers in IMPLEMENTATION DEFINED. Figure H5-2 shows eight input and eight output triggers.
- The number of channels is IMPLEMENTATION DEFINED. Figure H5-2 shows four channels.
- In Figure H5-2 the input channel gate function is a CTIv2 feature.

When the CTI receives an input trigger event, this generates channel events on one or more internal channels, according to the mapping function defined by the Input trigger→output channel mapping registers, CTIINEN[n].

The CTI also contains an application trigger and channel pulse to allow a debugger to create channel events directly on internal channels by writing to the CTI control registers.
Channel events on each internal channel are passed to a corresponding output channel that is controlled by a channel gate. The channel gate can block propagation of channel events from an internal channel to an output channel.

The output channels from a CTI are combined, using a logical OR function, with the output channels from all other CTIs to form the input channels on other CTIs. The input channels of this CTI are the logical OR of the output channels on all other CTIs. This is the cross-trigger matrix, CTM. Therefore, the number of input channels must equal the number of output channels.

--- Note ---
The number of input triggers and output triggers is not required to be the same.

---

The internal channels form an internal cross-trigger matrix within the CTI. This delivers events directly from the input triggers to the output triggers. Therefore the number of internal channels is the same as the number of input and output channels on the external CTM, and there is a direct mapping between the two.

Channel events received on each input channel are passed to the corresponding internal channel. It is IMPLEMENTATION DEFINED whether the cross-trigger gate also blocks propagation of channel events from input channels to internal channels.

When the CTI receives a channel event on an internal channel this generates trigger events on one or more output triggers, according to the mapping function defined by the Input channel → output trigger mapping registers, CTIOUTEN<n>.

The CTI contains the input and output trigger interfaces to the PE and the interface of the cross-trigger matrix. The architecture does not define the signal protocol used on the trigger interfaces, and:

- It is IMPLEMENTATION DEFINED whether the CTI supports multicycle input trigger events.
- It is IMPLEMENTATION DEFINED whether the CTM supports multicycle channel events.

See Multicycle events.

However, an output trigger is asserted until acknowledged. The output trigger can be:

- Self-acknowledging. This means that no further action is required from the debugger.
- Acknowledged by the debugger writing 1 to the corresponding bit of CTIINTACK.

The time taken to propagate a trigger event from the first PE, through its CTI, across the CTM to another CTI, and thereby to a second PE is IMPLEMENTATION DEFINED.

--- Note ---
ARM recommends that this path is not longer than the shortest software communication path between those PEs. This is because if the first PE halts, the Cross-halt trigger event can propagate through the ECT and halt the second PE without causing software on the second PE to malfunction because the first PE is in Debug state and is not responding.

H5.2.1 Multicycle events

A multicycle event is one with a continuous state that might persist over many cycles, as opposed to a discrete event. A typical implementation of a multicycle event is a level-based signal interface, whereas a discrete event might be implemented as a pulse signal or message.

CTI support for multicycle trigger events is IMPLEMENTATION DEFINED. Use of multicycle trigger events is deprecated. Of the architecturally defined input trigger events, the Performance Monitors overflow trigger event and Generic trace external output trigger events can be multicycle input triggers.

CTM support for multicycle channel events is IMPLEMENTATION DEFINED. A CTM that does not support multicycle channel events cannot propagate a multicycle trigger event between CTIs.

--- Note ---
A full ECT might comprise a mix of CTIs, some of which can support multicycle trigger events. In bridging these components, multicycle channel events become single channel events at the boundary between the CTIs.
An ECT that supports multicycle trigger events

When an ECT supports multicycle trigger events, an input trigger event to the CTI continuously asserts channel events on all output channels mapped to it until either:

- The input trigger event is removed.
- The channel mapping function is disabled.

This means that an input trigger that is asserted for multiple cycles causes any channels that are mapped to it to become active for multiple cycles. Consequently, any output triggers mapped from that channel are asserted for multiple cycles.

Note

The output trigger remains asserted for at least as long as the channel remains active. This means that even if the output trigger is acknowledged, it remains asserted until the channel deactivates.

The CTI does not guarantee that these events have precisely the same duration, as the triggers and channels can cross between clock domains.

CTIAPPSET and CTIAPPCLEAR can set a channel active for multiple cycles. CTIAPPULSE generates a single channel event. CTICHINSTATUS and CTICHOUTSTATUS can report whether a channel is active.

An ECT that does not support multicycle trigger events

When an ECT does not support multicycle trigger events, an input trigger event to the CTI generates a single channel event on all output channels mapped to it, regardless of how long the input trigger event is asserted.

This means that an input trigger event that is asserted for multiple cycles generates a single channel event on any channels mapped to it. Consequently any self-acknowledging output triggers mapped from those channels are single trigger events.

Note

A single event is typically a single cycle, but there is no guarantee that this is always the case.

CTIAPPSET and CTIAPPCLEAR can only generate a single channel event. CTIAPPULSE generates a single channel event. If the ECT does not support multicycle channel events, use of CTIAPPSET and CTIAPPCLEAR is deprecated, and the debugger must only use CTIAPPULSE. CTICHINSTATUS and CTICHOUTSTATUS must be treated as UNKNOWN.
H5.3 Cross-triggers on a PE in an ARMv8 implementation

An Armv8 PE must include a cross-trigger interface, and the implementation must include at least the input and output triggers defined in this architecture. The number of channels in the cross-trigger matrix is IMPLEMENTATION DEFINED, but there must be a minimum of three. Software can read CTIDEVID.NUMCHAN to discover the number of implemented channels.

The CTM must connect to all PEs in the same Inner Shareability domain as the Armv8-A PE, but can also connect to additional PEs. ARM strongly recommends that the CTM connects all PEs implementing a CTI in the system. This includes ARMv7-A PEs and other PEs that can be connected using a CoreSight CTI module.

--- Note ---

In a uniprocessor system the CTM is OPTIONAL. The CTM might be connected other CTI modules for non-PEs, such as triggers for system visibility components. ARM recommends that the CTM is implemented.

---

Any CTI connected to a PE that is not an Armv8-A PE must implement at least:

- The Debug request trigger event.
- The Restart trigger event.
- The Cross-halt trigger event.

For more information about the CTI, see the CoreSight™ SoC Technical Reference Manual. Armv8-A refines the generic CTI by defining roles for each of the implemented input and output triggers.
H5.4 Description and allocation of CTI triggers

Table H5-1 shows the output trigger events defined by the architecture and the related trigger numbers.

**Note**
Input triggers to the CTI are outputs from other blocks.

Table H5-1 and Table H5-2 show the minimum set of trigger events defined by the architecture. However:

- The Generic trace external input and output trigger events are only required if the OPTIONAL PE Trace Unit is implemented. If the OPTIONAL PE Trace Unit is not implemented, these trigger events are reserved.

- Support for the generic CTI interrupt trigger event is IMPLEMENTATION DEFINED because details of interrupt handling in the system, including any interrupt controllers, are IMPLEMENTATION DEFINED. Details regarding how the CTI interrupt is connected to an interrupt controller and its allocated interrupt number lie outside the scope of the architecture. ARM strongly recommends that implementations provide a means to generate interrupts based on external debug events.

- The other trigger events are required by the architecture.

An Armv8-A implementation can extend the CTI with additional triggers. These start with the number eight.

### H5.4.1 Debug request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to force the PE into Debug state. The trigger event is asserted until acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to CTIINTACK[0].
A debugger must poll CTITRIGOUTSTATUS[0] until it reads as 0, to confirm that the output trigger has been
deasserted before generating any event that must be ordered after the write to CTIINTACK, such as a write to
CTIAPPnPULSE to activate another trigger.

If the PE is already in Debug state, the PE ignores the trigger event, but the CTI continues to assert it until it is
removed by the debugger. See also External Debug Request debug event on page H3-6475.

H5.4.2 Restart request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to request the
PE to exit Debug state. If the PE is in Non-debug state, the request is ignored by the PE.

If a Restart request trigger event is received at or about the same time as the PE enters Debug state, it is
CONstrained UNpredictable whether:
• The request is ignored by the PE. In this case the PE enters Debug state and remains in Debug state.
• The PE enters Debug state and then immediately restarts.

Debuggers must program the CTI to send Restart request trigger events only to PEs that are halted. To enable the
PE to disambiguate discrete Restart request trigger events, after sending a Restart request trigger event, the debugger
must confirm that the PE has restarted and halted before sending another Restart request trigger event. Debuggers
can use EDPRSR.{SDR, HALTED} to determine the Execution state of the PE.

Before generating a Restart request trigger event for a PE, a debugger must ensure any Debug request trigger event
targeting that PE is cleared. Debug request trigger event on page H5-6511 describes how to do this.

The trigger event is self-acknowledging, meaning that the debugger requires no further action to remove the trigger
event. The trigger event is acknowledged even if the request is ignored by the PE. See also Exiting Debug state on
page H2-6454.

H5.4.3 Cross-halt trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted by a PE when it is entering
Debug state.

To reduce the latency of halting, ARM recommends that an implementation issues the Cross-halt trigger event early
in the committed process of entering Debug state. This means that there is no requirement to wait until all aspects
of entry to Debug state have completed before issuing the trigger event. Speculative emission of Cross-halt trigger
events is not allowed. The Cross-halt trigger event must not be issued early enough for a subsequent Debug request
trigger event, that might be derived from the Cross-halt trigger event, to be recorded in the EDSCR.STATUS field.
This applies to Debug request trigger events that are acting as inputs to the PE.

H5.4.4 Performance Monitors overflow trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted each time the PE asserts
a new Performance Monitors counter overflow interrupt request. See Chapter D6 The Performance Monitors
Extension.

If the CTI supports multicycle trigger events, then the trigger event remains asserted until the overflow is cleared
by a write to PMOVSCLR_EL0. Otherwise, the trigger event is asserted when the value of PMOVSCLR_EL0
changes from zero to a non-zero value.
--- Note ---

- This does not replace the recommended connection of Performance Monitors overflow trigger event to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI.

- Events can be counted when `ExternalNoninvasiveDebugEnabled()` == FALSE, and, in Secure state, when `ExternalSecureNoninvasiveDebugEnabled()` == FALSE. Secure software must be aware that overflow trigger events are nevertheless visible to the CTI.

### H5.4.5 Statistical Profiling Extension sample trigger event

If the Statistical Profiling Extension is implemented, and a sample record is written to memory, CTI input trigger 2 is asserted. This trigger might also be directly connected to other IMPLEMENTATION DEFINED debug features.

For more information see Chapter D8 The Statistical Profiling Extension.

### H5.4.6 Generic trace external input trigger events

These are output trigger events from the CTI, and input trigger events to the OPTIONAL PE Trace Unit, that are used in conjunction with the Generic trace external output trigger events to pass trigger events between:

- The PE and the OPTIONAL PE Trace Unit.
- The OPTIONAL PE Trace Unit and any other component attached to the CTM, including other Trace Units.

There are four Generic trace external input trigger events.

The trigger events are self-acknowledging. This means that the debugger does not have to take any further action to remove the events.

### H5.4.7 Generic trace external output trigger events

These are input trigger events to the CTI, and output trigger events from the OPTIONAL PE Trace Unit, used in conjunction with the Generic trace external input trigger events to pass trigger events between:

- The PE and the OPTIONAL PE Trace Unit.
- The OPTIONAL PE Trace Unit and any other component attached to the CTM, including other Trace Units.

There are four Generic trace external output trigger events.

### H5.4.8 Generic CTI interrupt trigger event

This is an output trigger event from the CTI, and an input to an IMPLEMENTATION DEFINED interrupt controller, and can transfer trigger events from the PE, PE Trace Units, or any other component attached to the CTI and CTM to software as an interrupt. The Generic CTI interrupt trigger event must be connected to the interrupt controller as an interrupt that can target the originating PE.

--- Note ---

- ARM recommends that the Generic CTI interrupt trigger event is a private peripheral interrupt, but implementations might instead make this trigger event available as a shared peripheral interrupt or a local peripheral interrupt.

- GICv3 reserves a private peripheral interrupt number for this interrupt.

It is IMPLEMENTATION DEFINED whether this trigger event is:

- Self-acknowledging. This means that the debugger is not required to take any further action, and that the interrupt controller must treat the trigger event as a pulse or edge-sensitive interrupt.
• Acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to
  `CTINTACK[2]`. This means that the interrupt controller must treat the trigger event as a level-sensitive
  interrupt.

  ARM recommends that the Generic CTI interrupt trigger event is a self-acknowledging trigger event.
H5.5 CTI registers programmers’ model

The CTI registers programmers’ model is described in Chapter H8 About the External Debug Registers. The following sections contain information specific to the CTI:

• External debug register resets on page H8-6558.
• External debug interface register access permissions on page H8-6547.
• Cross-trigger interface registers on page H8-6556.
• The individual register descriptions in Cross-Trigger Interface registers on page H9-6665.

See also Memory-mapped accesses to the external debug interface on page H8-6544.

H5.5.1 CTI reset

An External Debug reset resets the CTI. See External debug register resets on page H8-6558 for details of CTI register resets. All CTI output triggers and output channels are deasserted on an External Debug reset.

——— Note ————

An indirect read of an output trigger might not observe the deasserted state until the processor is Cold reset. For more information, see Synchronization of changes to the external debug registers on page H8-6540.

H5.5.2 CTI authentication

The CTI ignores the state of the IMPLEMENTATION DEFINED authentication interface. This means that:

• CTITRIGINSTATUS shows the status of the input triggers and CTICHINSTATUS shows the status of the input channels, regardless of the value of ExternalNoninvasiveDebugEnabled().

——— Note ————

The PE does not generate the Cross-halt trigger event and the PE Trace Unit does not generate Generic trace external output trigger events when ExternalNoninvasiveDebugEnabled() == FALSE. However, the PE can generate Performance Monitors overflow trigger events.

———

• The CTI can generate external triggers regardless of the value of ExternalInvasiveDebugEnabled().

——— Note ————

The PE ignores Debug request and Restart request trigger events when ExternalInvasiveDebugEnabled() == FALSE. The PE Trace Unit ignores Generic trace external input trigger events when ExternalNoninvasiveDebugEnabled() == FALSE. The behavior of Generic CTI interrupt requests is part of the IMPLEMENTATION DEFINED handling of these interrupts, but it is permissible for an interrupt controller to receive these requests even when ExternalInvasiveDebugEnabled() == FALSE.
H5.6 Examples

The CTI is fully programmable and allows for flexible cross-triggering of events within a PE and between PEs in a multiprocessor system. For example:

- The Cross-halt trigger event and the Debug request trigger event can be used for cross-triggering in a multiprocessor system.
- The Cross-halt trigger event and the Generic interrupt trigger event can be used for event-driven debugging in a multiprocessor system.
- The Performance Monitors overflow trigger event and the Debug request trigger event can force entry to Debug state on overflow of a Performance Monitors event counter, for event-driven profiling.

**Note**

This does not replace the recommended connection of Performance Monitors overflow trigger events to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI. ARM recommends that the Performance Monitors overflow signal is directly available as a local interrupt source.

- The Generic trace external input and Generic trace external output trigger events can pass trace events into and out of the event logic of the PE Trace Unit. They can do this:
  - To pass trace events between Trace Units.
  - In conjunction with the Performance Monitors overflow trigger event, to couple the Performance Monitors to the PE Trace Unit.
  - In conjunction with the Debug request trigger event, to trigger entry to Debug state on a trace event.
  - In conjunction with other CTIs, to signal a trace trigger event onto a CoreSight trace interconnect.

The following sections describe some examples in more detail:

- **Halting a single PE.**
- **Halting all PEs in a group when any one PE halts** on page H5-6517.
- **Synchronously restarting a group of PEs** on page H5-6517.
- **Halting a single PE on Performance Monitors overflow** on page H5-6517.

**Example H5-1 Halting a single PE**

To halt a single PE, set:

1. **CTIGATE[0]** to 0, so that the CTI does not pass channel events on internal channel 0 to the CTM.
2. **CTIOUTEN0[0]** to 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 0.

**Note**

The Cross-halt trigger event is input trigger 0, meaning it is controlled by the instance of **CTIOUTEN<n>** for which <n> is 0.

3. **CTIAPPPULSE[0]** to 1, to generate a channel event on channel 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to **CTIINTACK[0]**, before restarting the PE.
Example H5-2 Halting all PEs in a group when any one PE halts

To program a group of PEs so that when one PE in the group halts, all of the PEs in that group halt, set the following registers for each PE in the group:

1. **CTIGATE[2]** to 1, so that each CTI passes channel events on internal channel 2 to the CTM.
2. **CTIINEN0[2]** to 1, so that each CTI generates a channel event on channel 2 in response to a Cross-halt trigger event.
3. **CTIOUTEN0[2]** to 1, so that each CTI generates a Debug request trigger event in response to a channel event on channel 2.

--- Note ---
The Cross-halt trigger event is input trigger 0, meaning it is controlled by the instances of **CTIINEN<n>** and **CTIOUTEN<n>** for which <n> is 0.

When a PE has halted, clear the Debug request trigger event by writing a value of 1 to **CTIINTACK[0]**, before restarting the PE.

Example H5-3 Synchronously restarting a group of PEs

To restart a group of PEs, for each PE in the group:

1. If the PE was halted because of a Debug request trigger event, the debugger must ensure the trigger event is deasserted. It can do this by:
   a. Writing 1 to **CTIINTACK[0]** to clear the Debug request trigger event.
   b. Polling **CTITRIGOUTSTATUS[0]**, until it reads as 0, to confirm that the trigger event has been deasserted.
2. Set **CTIGATE[1]** to 1, so that each CTI passes channel events on internal channel 1 to the CTM.
3. Set **CTIOUTEN1[1]** to 1, so that each CTI generates a Restart request trigger event in response to a channel event on channel 1.

--- Note ---
This example must use the instance of **CTIOUTEN<n>** for which <n> is 1.

4. Set **CTIAPPULSE[1]** to 1 on any one PE in the group, to generate a channel event on channel 1.

Example H5-4 Halting a single PE on Performance Monitors overflow

To halt a single PE on a Performance Monitors overflow set:

1. **CTIGATE[3]** to 0, so that the CTI does not pass channel events on internal channel 3 to the CTM.
2. **CTIINEN1[3]** to 1, so that the CTI generates a channel event on channel 3 in response to a Performance Monitors overflow trigger event.

--- Note ---
This step of this example must use the instance of **CTIINEN<n>** for which <n> is 1.

3. **CTIOUTEN0[3]** to 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 3.
--- Note ---

This step of this example must use the instance of CTIOUTEN<n> for which <n> is 0.

---

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to CTIINTACK[0], before restarting the PE. Clear the overflow status by writing to PMOVSCLR_EL0.
