LES-PRE-20349

In this document, where the term Arm is used to refer to the company it means “Arm or any of its subsidiaries as appropriate”.

—— Note ———
• The term Arm can refer to versions of the Arm architecture, for example Armv8 refers to version 8 of the Arm architecture. The context makes it clear when the term is used in this way.
• This document describes only the Armv8-A architecture profile. For the behaviors required by the previous version of this architecture profile, ARMv7-A, see the ARM Architecture Reference Manual, ARMv7-A and ARMv7-R edition.

Confidentiality Status
This document is Non-Confidential. The right to use, copy and disclose this document may be subject to license restrictions in accordance with the terms of the agreement entered into by Arm and the party that Arm delivered this document to.

Product Status
The information in this document is final, that is for a developed product.

Limitations of this issue
This issue of the Armv8 Architecture Reference Manual contains many improvements and corrections. Validation of this document has identified the following issues that Arm will address in future issues:
• PE state on reset to AArch64 state on page D1-2290 and PE state on reset into AArch32 state on page G1-5559 require further update. Since the reset information is present in the register descriptions, this does not affect the quality status of the release.
• The descriptions of read-only registers incorrectly mention reset information and will be fixed in a future release. The correct information is present in the register XML.
• Appendix K13 Arm Pseudocode Definition requires further review and update. Since this appendix is informative, rather than being part of the architecture specification, this does not affect the quality status of this release.
Contents
Arm Architecture Reference Manual Armv8, for Armv8-A architecture profile

Preface
About this manual ................................................................. xviii
Using this manual ................................................................ xx
Conventions .......................................................................... xxvi
Additional reading ................................................................. xxviii
Feedback ................................................................................ xxx

Part A Armv8 Architecture Introduction and Overview

Chapter A1 Introduction to the Armv8 Architecture
A1.1 About the Arm architecture ........................................... A1-34
A1.2 Architecture profiles ..................................................... A1-36
A1.3 Armv8 architectural concepts ........................................ A1-38
A1.4 Supported data types .................................................... A1-41
A1.5 Advanced SIMD and floating-point support................... A1-51
A1.6 The Arm memory model ............................................... A1-57

Chapter A2 Armv8-A Architecture Extensions
A2.1 Armv8 architecture extensions ..................................... A2-60
A2.2 Architectural features within Armv8.0 architecture ......... A2-63
A2.3 The Armv8 Cryptographic Extension ............................. A2-66
A2.4 The Armv8.1 architecture extension ............................... A2-67
A2.5 The Armv8.2 architecture extension ............................... A2-70
A2.6 The Armv8.3 architecture extension ............................... A2-78
A2.7 The Armv8.4 architecture extension ............................... A2-81
A2.8 The Armv8.5 architecture extension ............................... A2-86
A2.9 The Reliability, Availability, and Serviceability Extension (RAS Extension) .......... A2-90
A2.10 The Statistical Profiling Extension (SPE) ............................................................. A2-91
A2.11 The Scalable Vector Extension (SVE) ................................................................... A2-92
A2.12 The Activity Monitors Extension ........................................................................ A2-93
A2.13 The Memory Partitioning and Monitoring (MPAM) Extension ............................. A2-94

Part B The AArch64 Application Level Architecture

Chapter B1 The AArch64 Application Level Programmers’ Model
B1.1 About the Application level programmers’ model ................................................ B1-98
B1.2 Registers in AArch64 Execution state ................................................................. B1-99
B1.3 Software control features and EL0 ................................................................. B1-104

Chapter B2 The AArch64 Application Level Memory Model
B2.1 About the Arm memory model ........................................................................ B2-108
B2.2 Atomicity in the Arm architecture .......................................................... B2-110
B2.3 Definition of the Armv8 memory model .................................................. B2-115
B2.4 Caches and memory hierarchy ................................................................ B2-133
B2.5 Alignment support .............................................................................. B2-138
B2.6 Endian support ............................................................................... B2-140
B2.7 Memory types and attributes .............................................................. B2-143
B2.8 Mismatched memory attributes ......................................................... B2-153
B2.9 Synchronization and semaphores .......................................................... B2-156

Part C The AArch64 Instruction Set

Chapter C1 The A64 Instruction Set
C1.1 About the A64 instruction set ........................................................................ C1-170
C1.2 Structure of the A64 assembler language .................................................. C1-171
C1.3 Address generation ................................................................................ C1-177
C1.4 Instruction aliases .................................................................................. C1-180

Chapter C2 About the A64 Instruction Descriptions
C2.1 Understanding the A64 instruction descriptions ........................................ C2-182
C2.2 General information about the A64 instruction descriptions ....................... C2-185

Chapter C3 A64 Instruction Set Overview
C3.1 Branches, Exception generating, and System instructions ..................... C3-190
C3.2 Loads and stores .................................................................................. C3-197
C3.3 Data processing - immediate .............................................................. C3-214
C3.4 Data processing - register ................................................................ C3-219
C3.5 Data processing - SIMD and floating-point ............................................. C3-227

Chapter C4 A64 Instruction Set Encoding
C4.1 A64 instruction set encoding ................................................................ C4-252

Chapter C5 The A64 System Instruction Class
C5.1 The System instruction class encoding space ........................................ C5-362
C5.2 Special-purpose registers ......................................................................... C5-374
C5.3 A64 System instructions for cache maintenance ..................................... C5-459
C5.4 A64 System instructions for address translation ....................................... C5-520
C5.5 A64 System instructions for TLB maintenance ......................................... C5-543
C5.6 A64 System instructions for prediction restriction ................................... C5-739
Chapter D5  The AArch64 Virtual Memory System Architecture
D5.1 About the Virtual Memory System Architecture (VMSA) ........................................ D5-2504
D5.2 The VMSAv8-64 address translation system .............................................................. D5-2512
D5.3 VMSAv8-64 translation table format descriptors .......................................................... D5-2565
D5.4 Memory access control ............................................................................................... D5-2577
D5.5 Memory region attributes ........................................................................................... D5-2599
D5.6 Virtualization Host Extensions .................................................................................... D5-2609
D5.7 Nested virtualization .................................................................................................. D5-2615
D5.8 VMSAv8-64 memory aborts ......................................................................................... D5-2622
D5.9 Translation Lookaside Buffers (TLBs) ......................................................................... D5-2632
D5.10 TLB maintenance requirements and the TLB maintenance instructions ................. D5-2638
D5.11 Caches in a VMSAv8-64 implementation .................................................................. D5-2655

Chapter D6  Armv8.5 Memory Tagging Extension
D6.1 Introduction .................................................................................................................. D6-2660
D6.2 Allocation Tags ............................................................................................................. D6-2661
D6.3 Tag checking ................................................................................................................ D6-2662
D6.4 Tagged and Untagged Addresses ................................................................................. D6-2663
D6.5 PE access to Allocation Tags ........................................................................................ D6-2664
D6.6 Enabling the Memory Tagging Extension ..................................................................... D6-2665
D6.7 PE handling of Tag Check failure ................................................................................ D6-2666
D6.8 PE generation of Tag Checked and Tag UncHECKed accesses .................................... D6-2667

Chapter D7  The Performance Monitors Extension
D7.1 About the Performance Monitors ................................................................................. D7-2670
D7.2 Accuracy of the Performance Monitors ....................................................................... D7-2673
D7.3 Behavior on overflow ................................................................................................... D7-2675
D7.4 Attributability ............................................................................................................... D7-2677
D7.5 Effect of EL3 and EL2 ................................................................................................ D7-2679
D7.6 Event filtering .............................................................................................................. D7-2682
D7.7 Performance Monitors and Debug state ..................................................................... D7-2684
D7.8 Counter enables .......................................................................................................... D7-2685
D7.9 Counter access ............................................................................................................ D7-2687
D7.10 PMU events and event numbers ................................................................................. D7-2689
D7.11 Performance Monitors Extension registers .............................................................. D7-2723

Chapter D8  The Activity Monitors Extension
D8.1 About the Activity Monitors Extension ....................................................................... D8-2726
D8.2 Properties and behavior of the activity monitors .......................................................... D8-2727
D8.3 AMU events and event numbers .................................................................................. D8-2729

Chapter D9  The Statistical Profiling Extension
D9.1 About the Statistical Profiling Extension ...................................................................... D9-2732
D9.2 Defining the sample population ................................................................................... D9-2734
D9.3 Controlling when an operation is sampled ................................................................... D9-2736
D9.4 Enabling profiling ........................................................................................................ D9-2739
D9.5 Filtering sample records .............................................................................................. D9-2741
D9.6 The profiling data ........................................................................................................ D9-2742
D9.7 The Profiling Buffer ..................................................................................................... D9-2750
D9.8 Profiling Buffer management ...................................................................................... D9-2754
D9.9 Synchronization and Statistical Profiling ..................................................................... D9-2758
Chapter D10  Statistical Profiling Extension Sample Record Specification
  D10.1 About the Statistical Profiling Extension Sample Records .................... D10-2762
  D10.2 Alphabetical list of Statistical Profiling Extension packets .................. D10-2765

Chapter D11  The Generic Timer in AArch64 state
  D11.1 About the Generic Timer ................................................................. D11-2790
  D11.2 The AArch64 view of the Generic Timer ........................................... D11-2794

Chapter D12  AArch64 System Register Encoding
  D12.1 The System register encoding space .................................................. D12-2800
  D12.2 op0==0b10, Moves to and from debug and trace System registers .......... D12-2801
  D12.3 op0==0b11, Moves to and from non-debug System registers, Special-purpose registers D12-2803

Chapter D13  AArch64 System Register Descriptions
  D13.1 About the AArch64 System registers ................................................ D13-2818
  D13.2 General system control registers ...................................................... D13-2826
  D13.3 Debug registers ................................................................................ D13-3429
  D13.4 Performance Monitors registers ....................................................... D13-3526
  D13.5 Activity Monitors registers .............................................................. D13-3584
  D13.6 Statistical Profiling Extension registers ............................................ D13-3609
  D13.7 RAS registers .................................................................................. D13-3647
  D13.8 Generic Timer registers ................................................................... D13-3685

Part E  The AArch32 Application Level Architecture

Chapter E1  The AArch32 Application Level Programmers’ Model
  E1.1 About the Application level programmers’ model .................................... E1-3782
  E1.2 The Application level programmers’ model in AArch32 state ................... E1-3783
  E1.3 Advanced SIMD and floating-point instructions ................................. E1-3794
  E1.4 About the AArch32 System register interface ....................................... E1-3805
  E1.5 Exceptions ....................................................................................... E1-3806

Chapter E2  The AArch32 Application Level Memory Model
  E2.1 About the Arm memory model ............................................................ E2-3808
  E2.2 Atomicity in the Arm architecture ....................................................... E2-3810
  E2.3 Definition of the Armv8 memory model .............................................. E2-3814
  E2.4 Caches and memory hierarchy ......................................................... E2-3829
  E2.5 Alignment support ............................................................................ E2-3834
  E2.6 Endian support ................................................................................ E2-3836
  E2.7 Memory types and attributes ............................................................. E2-3840
  E2.8 Mismatched memory attributes ....................................................... E2-3850
  E2.9 Synchronization and semaphores .................................................... E2-3853

Part F  The AArch32 Instruction Sets

Chapter F1  The AArch32 Instruction Sets Overview
  F1.1 Support for instructions in different versions of the Arm architecture .......... F1-3866
  F1.2 Unified Assembler Language .................................................................. F1-3887
  F1.3 Branch instructions ............................................................................ F1-3889
  F1.4 Data-processing instructions .................................................................. F1-3870
  F1.5 PSTATE and banked register access instructions .................................. F1-3878
  F1.6 Load/store instructions ........................................................................ F1-3879
  F1.7 Load/store multiple instructions .......................................................... F1-3882
  F1.8 Miscellaneous instructions ................................................................... F1-3883
  F1.9 Exception-generating and exception-handling instructions .................... F1-3885
Chapter G2  
AArch32 Self-hosted Debug  
G2.1 About self-hosted debug ................................................................. G2-5612  
G2.2 The debug exception enable controls .............................................. G2-5616  
G2.3 Routing debug exceptions ............................................................. G2-5617  
G2.4 Enabling debug exceptions from the current Privilege level and Security state G2-5619  
G2.5 The effect of powerdown on debug exceptions .............................. G2-5621  
G2.6 Summary of permitted routing and enabling of debug exceptions ...... G2-5622  
G2.7 Pseudocode description of debug exceptions ................................. G2-5624  
G2.8 Breakpoint Instruction exceptions .................................................. G2-5625  
G2.9 Breakpoint exceptions .................................................................. G2-5628  
G2.10 Watchpoint exceptions ................................................................. G2-5632  
G2.11 Vector Catch exceptions ............................................................. G2-5653  
G2.12 Synchronization and debug exceptions ........................................... G2-5667  

Chapter G3  
AArch32 Self-hosted Trace  
G3.1 About self-hosted trace ................................................................. G3-5678  
G3.2 Prohibited regions in self-hosted trace .............................................. G3-5679  
G3.3 Self-hosted trace timestamps ......................................................... G3-5680  
G3.4 Synchronization in self-hosted trace ................................................ G3-5681  

Chapter G4  
The AArch32 System Level Memory Model  
G4.1 About the memory system architecture .......................................... G4-5684  
G4.2 Address space ................................................................................ G4-5685  
G4.3 Mixed-endian support ..................................................................... G4-5686  
G4.4 AArch32 cache and branch predictor support ................................... G4-5687  
G4.5 System register support for IMPLEMENTATION DEFINED memory features G4-5711  
G4.6 External aborts ................................................................................ G4-5712  
G4.7 Memory barrier instructions .......................................................... G4-5714  
G4.8 Pseudocode description of general memory System instructions .......... G4-5715  

Chapter G5  
The AArch32 Virtual Memory System Architecture  
G5.1 About VMSAv8-32 ......................................................................... G5-5720  
G5.2 The effects of disabling address translation stages on VMSAv8-32 behavior G5-5728  
G5.3 Translation tables ........................................................................... G5-5732  
G5.4 The VMSAv8-32 Short-descriptor translation table format .................. G5-5737  
G5.5 The VMSAv8-32 Long-descriptor translation table format ................... G5-5746  
G5.6 Memory access control ................................................................. G5-5766  
G5.7 Memory region attributes ............................................................... G5-5777  
G5.8 Translation Lookaside Buffers (TLBs) .............................................. G5-5789  
G5.9 TLB maintenance requirements ...................................................... G5-5793  
G5.10 Caches in VMSAv8-32 ................................................................. G5-5807  
G5.11 VMSAv8-32 memory aborts ......................................................... G5-5810  
G5.12 Exception reporting in a VMSAv8-32 implementation ...................... G5-5822  
G5.13 Address translation instructions .................................................... G5-5841  
G5.14 Pseudocode description of VMSAv8-32 memory system operations ...... G5-5848  
G5.15 About the System registers for VMSAv8-32 .................................... G5-5850  
G5.16 Functional grouping of VMSAv8-32 System registers ....................... G5-5856  

Chapter G6  
The Generic Timer in AArch32 state  
G6.1 About the Generic Timer in AArch32 state ....................................... G6-5858  
G6.2 The AArch32 view of the Generic Timer ........................................... G6-5862  

Chapter G7  
AArch32 System Register Encoding  
G7.1 The AArch32 System register encoding space .................................. G7-5870  
G7.2 VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space G7-5871  
G7.3 VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space G7-5874
Chapter H7  The PC Sample-based Profiling Extension
H7.1 About the PC Sample-based Profiling Extension ........................................ H7-6822

Chapter H8  About the External Debug Registers
H8.1 Relationship between external debug and System registers ................. H8-6826
H8.2 Endianness and supported access sizes ............................................. H8-6827
H8.3 Synchronization of changes to the external debug registers .......... H8-6828
H8.4 Memory-mapped accesses to the external debug interface ........... H8-6832
H8.5 External debug interface register access permissions ............... H8-6835
H8.6 External debug interface registers .................................................. H8-6839
H8.7 Cross-trigger interface registers ..................................................... H8-6845
H8.8 External debug register resets ....................................................... H8-6847

Chapter H9  External Debug Register Descriptions
H9.1 About the debug registers .......................................................... H9-6852
H9.2 External debug registers .............................................................. H9-6853
H9.3 Cross-Trigger Interface registers ................................................ H9-6960

Part I  Memory-mapped Components of the Armv8 Architecture

Chapter I1  Requirements for Memory-mapped Components
I1.1 Supported access sizes .......................................................... I1-7008
I1.2 Synchronization of memory-mapped registers .......................... I1-7010
I1.3 Access requirements for reserved and unallocated registers ........ I1-7012

Chapter I2  System Level Implementation of the Generic Timer
I2.1 About the Generic Timer specification ........................................ I2-7014
I2.2 Memory-mapped counter module ................................................ I2-7016
I2.3 Memory-mapped timer components ............................................ I2-7020

Chapter I3  Recommended External Interface to the Performance Monitors
I3.1 About the external interface to the Performance Monitors registers ....... I3-7026

Chapter I4  Recommended External Interface to the Activity Monitors
I4.1 About the external interface to the Activity Monitors Extension registers .......... I4-7032

Chapter I5  External System Control Register Descriptions
I5.1 About the external system control register descriptions ................ I5-7034
I5.2 External Performance Monitors registers summary ..................... I5-7036
I5.3 Performance Monitors external register descriptions ............... I5-7039
I5.4 External Activity Monitors Extension registers summary ........... I5-7113
I5.5 Activity Monitors external register descriptions ..................... I5-7115
I5.6 Generic Timer memory-mapped registers overview ................. I5-7150
I5.7 Generic Timer memory-mapped register descriptions ............... I5-7151
I5.8 RAS Registers ................................................................. I5-7199

Part J  Architectural Pseudocode

Chapter J1  Armv8 Pseudocode
J1.1 Pseudocode for AArch64 operations ........................................... J1-7300
J1.2 Pseudocode for AArch32 operation .......................................... J1-7415
J1.3 Shared pseudocode ................................................................. J1-7493
Part K  Appendixes

Appendix K1  Architectural Constraints on UNPREDICTABLE behaviors
  K1.1  AArch32 CONSTRAINED UNPREDICTABLE behaviors ........................................ K1-7606
  K1.2  AArch64 CONSTRAINED UNPREDICTABLE behaviors ........................................ K1-7630

Appendix K2  Recommended External Debug Interface
  K2.1  About the recommended external debug interface ........................................... K2-7648
  K2.2  PMUEVENT bus ......................................................................................... K2-7652
  K2.3  Recommended authentication interface ...................................................... K2-7653
  K2.4  Management registers and CoreSight compliance .......................................... K2-7655

Appendix K3  Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events
  K3.1  Arm recommendations for IMPLEMENTATION DEFINED event numbers ......... K3-7666
  K3.2  Summary of events for exceptions taken to an Exception level using AArch64 K3-7681

Appendix K4  Recommendations for reporting memory attributes on an interconnect
  K4.1  Arm recommendations for reporting memory attributes on an interconnect ... K4-7684

Appendix K5  Additional Information for Implementations of the Generic Timer
  K5.1  Providing a complete set of features in a system level implementation .......... K5-7686
  K5.2  Gray-count scheme for timer distribution scheme ......................................... K5-7688

Appendix K6  Legacy Instruction Syntax for AArch32 Instruction Sets
  K6.1  Legacy Instruction Syntax ........................................................................... K6-7690

Appendix K7  Address translation examples
  K7.1  AArch64 Address translation examples ..................................................... K7-7698
  K7.2  AArch32 Address translation examples ..................................................... K7-7710

Appendix K8  Example OS Save and Restore Sequences
  K8.1  Save Debug registers .................................................................................. K8-7720
  K8.2  Restore Debug registers ............................................................................ K8-7722

Appendix K9  Recommended Upload and Download Processes for External Debug
  K9.1  Using memory access mode in AArch64 state ............................................. K9-7726

Appendix K10  Software Usage Examples
  K10.1  Use of the Advanced SIMD complex number instructions ......................... K10-7730
  K10.2  Use of the Armv8.2 extensions to the Cryptographic Extension .................. K10-7732

Appendix K11  Barrier Litmus Tests
  K11.1  Introduction ............................................................................................. K11-7740
  K11.2  Load-Acquire, Store-Release and barriers ................................................ K11-7743
  K11.3  Load-Acquire Exclusive, Store-Release Exclusive and barriers .................. K11-7747
  K11.4  Using a mailbox to send an interrupt ...................................................... K11-7752
  K11.5  Cache and TLB maintenance instructions and barriers ............................ K11-7753
  K11.6  Armv7 compatible approaches for ordering, using DMB and DSB barriers .. K11-7765

Appendix K12  Random Number Generation
  K12.1  Properties of the generated random number ............................................. K12-7780

Appendix K13  Arm Pseudocode Definition
  K13.1  About the Arm pseudocode ..................................................................... K13-7782
Appendix K14 Registers Index

K14.1 Introduction and register disambiguation .................................................. K14-7810
K14.2 Alphabetical index of AArch64 registers and System instructions .......... K14-7815
K14.3 Functional index of AArch64 registers and System instructions ............ K14-7830
K14.4 Alphabetical index of AArch32 registers and System instructions .......... K14-7845
K14.5 Functional index of AArch32 registers and System instructions ............ K14-7855
K14.6 Alphabetical index of memory-mapped registers .................................. K14-7867
K14.7 Functional index of memory-mapped registers ..................................... K14-7874

Glossary
Preface

This preface introduces the *Arm Architecture Reference Manual, Armv8, for Armv8-A architecture profile*. It contains the following sections:

- *About this manual* on page xviii.
- *Using this manual* on page xx.
- *Conventions* on page xxvi.
- *Additional reading* on page xxviii.
- *Feedback* on page xxx.
About this manual

This manual describes the Arm® architecture v8, Armv8. The architecture describes the operation of an Armv8-A Processing element (PE), and this manual includes descriptions of:

- The two Execution states, AArch64 and AArch32.
- The instruction sets:
  - In AArch32 state, the A32 and T32 instruction sets, that are compatible with earlier versions of the Arm architecture.
  - In AArch64 state, the A64 instruction set.
- The states that determine how a PE operates, including the current Exception level and Security state, and in AArch32 state the PE mode.
- The Exception model.
- The interprocessing model, that supports transitioning between AArch64 state and AArch32 state.
- The memory model, that defines memory ordering and memory management. This manual covers a single architecture profile, Armv8-A, that defines a Virtual Memory System Architecture (VMSA).
- The programmers’ model, and its interfaces to System registers that control most PE and memory system features, and provide status information.
- The Advanced SIMD and floating-point instructions, that provide high-performance:
  - Single-precision, half-precision, and double-precision floating-point operations.
  - Conversions between double-precision, single-precision, and half-precision floating-point values.
  - Integer, single-precision floating-point, half-precision floating-point, and in A64, double-precision vector operations in all instruction sets.
  - Single-precision, half-precision, and double-precision floating-point vector operations in the A64 instruction set.
- The security model, that provides two security states to support secure applications.
- The virtualization model, that support the virtualization of Non-secure operation.
- The Debug architecture, that provides software access to debug features.

This manual gives the assembler syntax for the instructions it describes, meaning that it describes instructions in textual form. However, this manual is not a tutorial for Arm assembler language, nor does it describe Arm assembler language, except at a very basic level. To make effective use of Arm assembler language, read the documentation supplied with the assembler being used.

This manual is organized into parts:

Part A Provides an introduction to the Armv8-A architecture, and an overview of the AArch64 and AArch32 Execution states.

Part B Describes the application level view of the AArch64 Execution state, meaning the view from EL0. It describes the application level view of the programmers’ model and the memory model.

Part C Describes the A64 instruction set, that is available in the AArch64 Execution state. The descriptions for each instruction also include the precise effects of each instruction when executed at EL0, described as unprivileged execution, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate Arm machine code.

Part D Describes the system level view of the AArch64 Execution state. It includes details of the System registers, most of which are not accessible from EL0, and the system level view of the programmers’ model and the memory model. This part includes the description of self-hosted debug.
Part E  Describes the application level view of the AArch32 Execution state, meaning the view from the EL0. It describes the application level view of the programmers’ model and the memory model.

———  Note  ————
In AArch32 state, execution at EL0 is execution in User mode.

Part F  Describes the T32 and A32 instruction sets, that are available in the AArch32 Execution state. These instruction sets are backwards-compatible with earlier versions of the Arm architecture. This part describes the precise effects of each instruction when executed in User mode, described as unprivileged execution or execution at EL0, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate Arm machine code.

———  Note  ————
User mode is the only mode where software execution is unprivileged.

Part G  Describes the system level view of the AArch32 Execution state, that is generally compatible with earlier versions of the Arm architecture. This part includes details of the System registers, most of which are not accessible from EL0, and the instruction interface to those registers. It also describes the system level view of the programmers’ model and the memory model.

Part H  Describes the Debug architecture for external debug. This provides configuration, breakpoint and watchpoint support, and a Debug Communications Channel (DCC) to a debug host.

Part I  Describes additional features of the architecture that are not closely coupled to a processing element (PE), and therefore are accessed through memory-mapped interfaces. Some of these features are optional.

Part J  Provides pseudocode that describes various features of the Armv8 architecture.

Part K, Appendixes  Provide additional information. Some appendixes give information that is not part of the Armv8 architectural requirements. The cover page of each appendix indicates its status.

Glossary  Defines terms used in this document that have a specialized meaning.

———  Note  ————
Terms that are generally well understood in the microelectronics industry are not included in the Glossary.
Using this manual

The information in this manual is organized into parts, as described in this section.

Part A, Introduction and Architecture Overview

Part A gives an overview of the Armv8-A architecture profile, including its relationship to the other Arm PE architectures. It introduces the terminology used to describe the architecture, and gives an overview of the Executions states, AArch64 and AArch32. It contains the following chapter:

Chapter A1 Introduction to the Armv8 Architecture
Read this for an introduction to the Armv8 architecture.

Part B, The AArch64 Application Level Architecture

Part B describes the AArch64 state application level view of the architecture. It contains the following chapters:

Chapter B1 The AArch64 Application Level Programmers’ Model
Read this for an application level description of the programmers’ model for software executing in AArch64 state. It describes execution at EL0 when EL0 is using AArch64 state.

Chapter B2 The AArch64 Application Level Memory Model
Read this for an application level description of the memory model for software executing in AArch64 state. It describes the memory model for execution in EL0 when EL0 is using AArch64 state. It includes information about Arm memory types, attributes, and memory access controls.

Part C, The A64 Instruction Set

Part C describes the A64 instruction set, that is used in AArch64 state. It contains the following chapters:

Chapter C1 The A64 Instruction Set
Read this for a description of the A64 instruction set and common instruction operation details.

Chapter C2 About the A64 Instruction Descriptions
Read this to understand the format of the A64 instruction descriptions.

Chapter C3 A64 Instruction Set Overview
Read this for an overview of the individual A64 instructions, that are divided into five functional groups.

Chapter C4 A64 Instruction Set Encoding
Read this for a description of the A64 instruction set encoding.

Chapter C5 The A64 System Instruction Class
Read this for a description of the AArch64 System instructions and register descriptions, and the System instruction class encoding space.

Chapter C6 A64 Base Instruction Descriptions
Read this for information on key aspects of the A64 base instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions
Read this for information on key aspects of the A64 Advanced SIMD and floating-point instructions and for descriptions of the individual instructions, which are listed in alphabetical order.
Part D, The AArch64 System Level Architecture

Part D describes the AArch64 state system level view of the architecture. It contains the following chapters:

**Chapter D1 The AArch64 System Level Programmers’ Model**
Read this for a description of the AArch64 state system level view of the programmers’ model.

**Chapter D2 AArch64 Self-hosted Debug**
Read this for an introduction to, and a description of, self-hosted debug in AArch64 state.

**Chapter D3 AArch64 Self-hosted Trace**
Read this for an introduction to, and a description of, self-hosted trace in AArch64 state.

**Chapter D4 The AArch64 System Level Memory Model**
Read this for a description of the AArch64 state system level view of the general features of the memory system.

**Chapter D5 The AArch64 Virtual Memory System Architecture**
Read this for a system level view of the AArch64 Virtual Memory System Architecture (VMSA), the memory system architecture of an Armv8 implementation that is executing in AArch64 state.

**Chapter D7 The Performance Monitors Extension**
Read this for a description of an implementation of the Arm Performance Monitors, that are an optional non-invasive debug component.

**Chapter D8 The Activity Monitors Extension**
Read this for a description of an implementation of the Arm Activity Monitors, an optional non-invasive component.

**Chapter D9 The Statistical Profiling Extension**
Read this for a description of an implementation of the Statistical Profiling Extension, that is an optional AArch64 state non-invasive debug component.

**Chapter D10 Statistical Profiling Extension Sample Record Specification**
Read this for a description the sample records generated by the Statistical Profiling Extension.

**Chapter D11 The Generic Timer in AArch64 state**
Read this for a description of the AArch64 view of an implementation of the Arm Generic Timer.

**Chapter D12 AArch64 System Register Encoding**
Read this for a description of the description of the encoding of the AArch64 System registers, and the other uses of the AArch64 System registers encoding space.

**Chapter D13 AArch64 System Register Descriptions**
Read this for an introduction to, and description of, each of the AArch64 System registers.

Part E, The AArch32 Application Level Architecture

Part E describes the AArch32 state application level view of the architecture. It contains the following chapters:

**Chapter E1 The AArch32 Application Level Programmers’ Model**
Read this for an application level description of the programmers’ model for software executing in AArch32 state. It describes execution at EL0 when EL0 is using AArch32 state.

**Chapter E2 The AArch32 Application Level Memory Model**
Read this for an application level description of the memory model for software executing in AArch32 state. It describes the memory model for execution in EL0 when EL0 is using AArch32 state. It includes information about Arm memory types, attributes, and memory access controls.
Part F, The AArch32 Instruction Sets

Part F describes the T32 and A32 instruction sets, that are used in AArch32 state. It contains the following chapters:

Chapter F1 The AArch32 Instruction Sets Overview
Read this for an overview of the T32 and A32 instruction sets.

Chapter F2 About the T32 and A32 Instruction Descriptions
Read this to understand the format of the T32 and A32 instruction descriptions.

Chapter F3 T32 Instruction Set Encoding
Read this for a description of the T32 instruction set encoding. This includes the T32 encoding of the Advanced SIMD and floating-point instructions.

Chapter F4 A32 Instruction Set Encoding
Read this for a description of the A32 instruction set encoding. This includes the A32 encoding of the Advanced SIMD and floating-point instructions.

Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions
Read this for a description of each of the T32 and A32 base instructions.

Chapter F6 T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions
Read this for a description of each of the T32 and A32 Advanced SIMD and floating-point instructions.

Part G, The AArch32 System Level Architecture

Part G describes the AArch32 state system level view of the architecture. It contains the following chapters:

Chapter G1 The AArch32 System Level Programmers’ Model
Read this for a description of the AArch32 state system level view of the programmers’ model for execution in an Exception level that is using AArch32.

Chapter G2 AArch32 Self-hosted Debug
Read this for an introduction to, and a description of, self-hosted debug in AArch64 state.

Chapter G3 AArch32 Self-hosted Trace
Read this for an introduction to, and a description of, self-hosted trace in AArch64 state.

Chapter G4 The AArch32 System Level Memory Model
Read this for a system level view of the general features of the memory system.

Chapter G5 The AArch32 Virtual Memory System Architecture
Read this for a description of the AArch32 Virtual Memory System Architecture (VMSA).

Chapter G6 The Generic Timer in AArch32 state
Read this for a description of the AArch32 view of an implementation of the Arm Generic Timer.

Chapter G7 AArch32 System Register Encoding
Read this for a description of the description of the encoding of the AArch32 System registers, including the System instructions that are part of the AArch32 System registers encoding space.

Chapter G8 AArch32 System Register Descriptions
Read this for a description of each of the AArch32 System registers.
Part H, External Debug

Part H describes the architecture for external debug. It contains the following chapters:

**Chapter H1 About External Debug**
Read this for an introduction to external debug, and a definition of the scope of this part of the manual.

**Chapter H2 Debug State**
Read this for a description of debug state, which the PE might enter as the result of a Halting debug event.

**Chapter H3 Halting Debug Events**
Read this for a description of the external debug events referred to as Halting debug events.

**Chapter H4 The Debug Communication Channel and Instruction Transfer Register**
Read this for a description of the communication between a debugger and the PE debug logic using the Debug Communications Channel and the Instruction Transfer register.

**Chapter H5 The Embedded Cross-Trigger Interface**
Read this for a description of the embedded cross-trigger interface.

**Chapter H6 Debug Reset and Powerdown Support**
Read this for a description of reset and powerdown support in the Debug architecture.

**Chapter H7 The PC Sample-based Profiling Extension**
Read this for a description of the PC Sample-based Profiling Extension that is an OPTIONAL extension to an Armv8 implementation.

**Chapter H8 About the External Debug Registers**
Read this for some additional information about the external debug registers.

**Chapter H9 External Debug Register Descriptions**
Read this for a description of each external debug register.

Part I, Memory-mapped Components of the Armv8 Architecture

Part I describes the memory-mapped components in the architecture. It contains the following chapters:

**Chapter I1 Requirements for Memory-mapped Components**
Read this for descriptions of some general requirements for memory-mapped components within a system that complies with the Armv8 Architecture.

**Chapter I2 System Level Implementation of the Generic Timer**
Read this for a definition of a system level implementation of the Generic Timer.

**Chapter I3 Recommended External Interface to the Performance Monitors**
Read this for a description of the recommended memory-mapped and external debug interfaces to the Performance Monitors.

**Chapter I4 Recommended External Interface to the Activity Monitors**
Read this for a description of the recommended memory-mapped interface to the Activity Monitors.

**Chapter I5 External System Control Register Descriptions**
Read this for a description of each memory-mapped system control register.
Part J, Architectural Pseudocode

Part J contains pseudocode that describes various features of the Arm architecture. It contains the following chapter:

Chapter J1 Armv8 Pseudocode

Read this for the pseudocode definitions that describe various features of the Armv8 architecture, for operation in AArch64 state and in AArch32 state.

Part K, Appendixes

This manual contains the following appendixes:

Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors

Read this for a description of the architecturally-required constraints on UNPREDICTABLE behaviors in the Armv8 architecture, including AArch32 behaviors that were UNPREDICTABLE in previous versions of the architecture.

Appendix K2 Recommended External Debug Interface

Read this for a description of the recommended external debug interface.

Note

This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events

Read this for a description of Arm recommendations for the use of the IMPLEMENTATION DEFINED event numbers.

Note

This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix K4 Recommendations for reporting memory attributes on an interconnect

Read this for the Arm recommendations about how the architectural memory attributes are reported on an interconnect.

Appendix K5 Additional Information for Implementations of the Generic Timer

Read this for additional information about implementations of the Arm Generic Timer. This information does not form part of the architectural definition of the Generic Timer.

Appendix K6 Legacy Instruction Syntax for AArch32 Instruction Sets

Read this for information about the pre-UAL syntax of the AArch32 instruction sets, which can still be valid for the A32 instruction set.

Appendix K7 Address translation examples

Read this for examples of translation table lookups using the translation regimes described in Chapter D5 The AArch64 Virtual Memory System Architecture and Chapter G5 The AArch32 Virtual Memory System Architecture.

Appendix K8 Example OS Save and Restore Sequences

Read this for software examples that perform the OS Save and Restore sequences for an Armv8 debug implementation.
Using this manual

Chapter H6 *Debug Reset and Powerdown Support* describes the OS Save and Restore mechanism.

**Appendix K9 Recommended Upload and Download Processes for External Debug**

Read this for information about implementing and using the Arm architecture.

**Note**

This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

**Appendix K10 Software Usage Examples**

Read this for software examples that help understanding of some aspects of the Arm architecture.

**Note**

This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

**Appendix K11 Barrier Litmus Tests**

Read this for examples of the use of barrier instructions provided by the Armv8 architecture.

**Note**

This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

**Appendix K13 Arm Pseudocode Definition**

Read this for definitions of the AArch32 pseudocode.

**Appendix K14 Registers Index**

Read this for an alphabetic and functional index of AArch32 and AArch64 registers, and memory-mapped registers.

**Glossary**

Defines terms used in this document that have a specialized meaning.

**Note**

Terms that are generally well understood in the microelectronics industry are not included in the Glossary.
Conventions

The following sections describe conventions that this book can use:

- **Typographic conventions.**
- **Signals on page xxvii.**
- **Numbers on page xxvii.**
- **Pseudocode descriptions on page xxvii.**
- **Assembler syntax descriptions on page xxvii.**

**Typographic conventions**

The typographical conventions are:

- **italic** Introduces special terminology, and denotes citations.
- **bold** Denotes signal names, and is used for terms in descriptive lists, where appropriate.
- **monospace** Used for assembler syntax descriptions, pseudocode, and source code examples.
  Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.

**SMALL CAPITALS**

Used in body text for a few terms that have specific technical meanings, and are defined in the *Glossary*.

**Colored text** Indicates a link. This can be:

- A URL, for example [http://infocenter.arm.com](http://infocenter.arm.com).
- A cross-reference, that includes the page number of the referenced information if it is not on the current page, for example, *Assembler syntax descriptions on page xxvii.*
- A link, to a chapter or appendix, or to a glossary entry, or to the section of the document that defines the colored term, for example *Simple sequential execution* or *SCTRL*.

**{ and }** Braces, { and }, have two distinct uses:

**Optional items**

In syntax descriptions braces enclose optional items. In the following example they indicate that the <shift> parameter is optional:

```
ADD <id|WSP>, <dn|WSP>, #<imm>{, <shift>}
```

Similarly they can be used in generalized field descriptions, for example `TCR_ELx.{I}PS` refers to a field in the `TCR_ELx` registers that is called either `IPS` or `PS`.

**Sets of items**

Braces can be used to enclose sets. For example, `HCR_EL2.{E2H, TGE}` refers to a set of two register fields, `HCR_EL2.E2H` and `HCR_EL2.TGE`.

**Notes** Notes are formatted as:

```markdown
Note
```

This is a Note.

In this Manual, Notes are used only to provide additional information, usually to help understanding of the text. While a Note may repeat architectural information given elsewhere in the Manual, a Note never provides any part of the definition of the architecture.
Signals

In general this specification does not define hardware signals, but it does include some signal examples and recommendations. The signal conventions are:

**Signal level**

The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:

- HIGH for active-HIGH signals.
- LOW for active-LOW signals.

**Lower-case n**

At the start or end of a signal name denotes an active-LOW signal.

Numbers

Numbers are normally written in decimal. Binary numbers are preceded by `0b`, and hexadecimal numbers by `0x`. In both cases, the prefix and the associated value are written in a monospace font, for example `0xFFFF0000`. To improve readability, long numbers can be written with an underscore separator between every four characters, for example `0xFFFF_0000_0000_0000`. Ignore any underscores when interpreting the value of a number.

Pseudocode descriptions

This manual uses a form of pseudocode to provide precise descriptions of the specified functionality. This pseudocode is written in monospace font, and is described in Appendix K13 Arm Pseudocode Definition.

Assembler syntax descriptions

This manual contains numerous syntax descriptions for assembler instructions and for components of assembler instructions. These are shown in a monospace font, and use the conventions described in Structure of the A64 assembler language on page C1-171, Appendix K13 Arm Pseudocode Definition, and Pseudocode operators and keywords on page K12-5648.
Additional reading

This section lists relevant publications from Arm and third parties.

See the Infocenter, http://infocenter.arm.com, for access to Arm documentation.

Arm publications

- ARM® Architecture Reference Manual Supplement, ARMv8, for the ARMv8-R AArch32 architecture profile (ARM DDI 0568).
- ARM® Debug Interface Architecture Specification, ADIv6.0 (ARM IHI 0074).
- ARM® Debug Interface Architecture Specification, ADIv5.0 to ADIv5.2 (ARM IHI 0031).
- ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0 (ARM IHI 0069).
- ARM® CoreSight™ Architecture Specification (ARM IHI 0029).
- ARM® Procedure Call Standard for the ARM 64-bit Architecture (ARM IHI 0055).
- ARM® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile (ARM DDI 0587).

Other publications

The following publications are referred to in this manual, or provide more information:

- SM3 Cryptographic Hash Algorithm, China Internet Network Information Center (CNNIC).
- SM4 Block Cipher Algorithm, China Internet Network Information Center (CNNIC).
- The QARMA Block Cipher Family, Roberto Avanzi, Qualcomm Product Security Initiative.
Feedback

Arm welcomes feedback on its documentation.

Feedback on this manual

If you have comments on the content of this manual, send e-mail to errata@arm.com. Give:

• The title.
• The number, ARM DDI 0487E.a.
• The page numbers to which your comments refer.
• A concise explanation of your comments.

Arm also welcomes general suggestions for additions and improvements.

Arm tests PDFs only in Adobe Acrobat and Acrobat Reader, and cannot guarantee the appearance or behavior of any document when viewed with any other PDF reader.
Part A

Armv8 Architecture Introduction and Overview
Chapter A1
Introduction to the Armv8 Architecture

This chapter introduces the Arm architecture. It contains the following sections:

- *About the Arm architecture* on page A1-34.
- *Supported data types* on page A1-41.
A1.1 About the Arm architecture

The Arm architecture described in this Architecture Reference Manual defines the behavior of an abstract machine, referred to as a *processing element*, often abbreviated to *PE*. Implementations compliant with the Arm architecture must conform to the described behavior of the processing element. It is not intended to describe how to build an implementation of the PE, nor to limit the scope of such implementations beyond the defined behaviors.

Except where the architecture specifies differently, the programmer-visible behavior of an implementation that is compliant with the Arm architecture must be the same as a simple sequential execution of the program on the processing element. This programmer-visible behavior does not include the execution time of the program.

The Arm Architecture Reference Manual also describes rules for software to use the processing element.

The Arm architecture includes definitions of:

- An associated debug architecture, see:
  - Chapter D2 AArch64 Self-hosted Debug.
  - Chapter G2 AArch32 Self-hosted Debug.
  - Part H of this manual, External Debug on page 6697.

- Associated trace architectures that define PE Trace Units that implementers can implement with the associated processor hardware. For more information, see:
  - The *Embedded Trace Macrocell Architecture Specification*.
  - Chapter D3 AArch64 Self-hosted Trace.
  - Chapter G3 AArch32 Self-hosted Trace.

**Note**

A PE Trace Unit may be named a trace macrocell in other documentation.

The Arm architecture is a *Reduced Instruction Set Computer* (RISC) architecture with the following RISC architecture features:

- A large uniform register file.
- A *load/store* architecture, where data-processing operations only operate on register contents, not directly on memory contents.
- Simple addressing modes, with all load/store addresses determined from register contents and instruction fields only.

The architecture defines the interaction of the PE with memory, including caches, and includes a memory translation system. It also describes how multiple PEs interact with each other and with other observers in a system.

This document defines the Armv8-A architecture profile. See *Architecture profiles* on page A1-36 for more information.

The Arm architecture supports implementations across a wide range of performance points. Implementation size, performance, and very low power consumption are key attributes of the Arm architecture.

An important feature of the Armv8 architecture is backwards compatibility, combined with the freedom for optimal implementation in a wide range of standard and more specialized use cases. The Armv8 architecture supports:

- A 64-bit Execution state, AArch64.
- A 32-bit Execution state, AArch32, that is compatible with previous versions of the Arm architecture.

**Note**

The AArch32 Execution state is compatible with the Armv7-A architecture profile, and enhances that profile to support some features included in the AArch64 Execution state.

Features that are optional are explicitly defined as such in this Manual.
Note
The presence of an ID register field for a feature does not imply that the feature is optional.

Both Execution states support SIMD and floating-point instructions:

- **AArch32 state provides:**
  - SIMD instructions in the base instruction sets that operate on the 32-bit general-purpose registers.
  - Advanced SIMD instructions that operate on registers in the *SIMD and floating-point register (SIMD&FP register)* file.
  - Floating-point instructions that operate on registers in the SIMD&FP register file.
- **AArch64 state provides:**
  - Advanced SIMD instructions that operate on registers in the SIMD&FP register file.
  - Floating-point instructions that operate on registers in the SIMD&FP register file.

Note
See *Conventions on page xxvi* for information about conventions used in this manual, including the use of SMALL CAPITALS for particular terms that have Arm-specific meanings that are defined in the *Glossary.*
A1.2 Architecture profiles

The Arm architecture has evolved significantly since its introduction, and Arm continues to develop it. Eight major versions of the architecture have been defined to date, denoted by the version numbers 1 to 8. Of these, the first three versions are now obsolete.

The generic names AArch64 and AArch32 describe the 64-bit and 32-bit Execution states:

**AArch64**  
Is the 64-bit Execution state, meaning addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

**AArch32**  
Is the 32-bit Execution state, meaning addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets.

--- Note ---

The Base instruction set comprises the supported instructions other than the Advanced SIMD and floating-point instructions.

---

Arm defines three architecture profiles:

**A**  
Application profile, described in this manual:

- Supports a Virtual Memory System Architecture (VMSA) based on a Memory Management Unit (MMU).

--- Note ---

An Armv8-A implementation can be called an AArchv8-A implementation.

---

- Supports the A64, A32, and T32 instruction sets.

**R**  
Real-time profile:

- Supports a Protected Memory System Architecture (PMSA) based on a Memory Protection Unit (MPU).
- Supports the A32 and T32 instruction sets.

**M**  
Microcontroller profile:

- Implements a programmers' model designed for low-latency interrupt processing, with hardware stacking of registers and support for writing interrupt handlers in high-level languages.
- Implements a variant of the R-profile PMSA.
- Supports a variant of the T32 instruction set.

--- Note ---

This Architecture Reference Manual describes only the Armv8-A profile.

---

For information about the R and M architecture profiles, and earlier Arm architecture versions see:

- The ARM® Architecture Reference Manual Supplement, ARMv8, for the ARMv8-R AArch32 architecture profile.
A1.2.1 Debug architecture version

The Arm Debug architecture is fully integrated with the architecture, and does not have a separate version number.
A1.3 Armv8 architectural concepts

Armv8 introduces major changes to the Arm architecture, while maintaining a high level of consistency with previous versions of the architecture. The Armv8 Architecture Reference Manual includes significant changes in the terminology used to describe the architecture, and this section introduces both the Armv8 architectural concepts and the associated terminology.

The following subsections describe key Armv8 architectural concepts. Each section introduces the corresponding terms that are used to describe the architecture:

- Execution state

A1.3.1 Execution state

The Execution state defines the PE execution environment, including:

- The supported register widths.
- The supported instruction sets.
- Significant aspects of:
  - The exception model.
  - The Virtual Memory System Architecture (VMSA).
  - The programmers’ model.

The Execution states are:

AArch64

The 64-bit Execution state. This Execution state:

- Provides 31 64-bit general-purpose registers, of which X30 is used as the procedure link register.
- Provides a 64-bit program counter (PC), stack pointers (SPs), and exception link registers (ELRs).
- Provides 32 128-bit registers for SIMD vector and scalar floating-point support.
- Provides a single instruction set, A64. For more information, see The Armv8 instruction sets on page A1-39.
- Defines the Armv8 Exception model, with up to four Exception levels, EL0 - EL3, that provide an execution privilege hierarchy, see Exception levels on page D1-2268.
- Provides support for 64-bit virtual addressing. For more information, including the limits on address ranges, see Chapter D5 The AArch64 Virtual Memory System Architecture.
- Defines a number of Process state (PSTATE) elements that hold PE state. The A64 instruction set includes instructions that operate directly on various PSTATE elements.
- Names each System register using a suffix that indicates the lowest Exception level at which the register can be accessed.

AArch32

The 32-bit Execution state. This Execution state:

- Provides 13 32-bit general-purpose registers, and a 32-bit PC, SP, and link register (LR). The LR is used as both an ELR and a procedure link register. Some of these registers have multiple banked instances for use in different PE modes.
- Provides a single ELR, for exception returns from Hyp mode.
- Provides 32 64-bit registers for Advanced SIMD vector and scalar floating-point support.
- Provides two instruction sets, A32 and T32. For more information, see The Armv8 instruction sets on page A1-39.
- Supports the Armv7-A exception model, based on PE modes, and maps this onto the Armv8 Exception model, that is based on the Exception levels.
- Provides support for 32-bit virtual addressing.
• Defines a number of Process state (PSTATE) elements that hold PE state. The A32 and T32 instruction sets include instructions that operate directly on various PSTATE elements, and instructions that access PSTATE by using the Application Program Status Register (APSR) or the Current Program Status Register (CPSR).

Later subsections give more information about the different properties of the Execution states.

Transferring control between the AArch64 and AArch32 Execution states is known as interprocessing. The PE can move between Execution states only on a change of Exception level, and subject to the rules given in Interprocessing on page D1-2380. This means different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.

A1.3.2   The Armv8 instruction sets

In Armv8 the possible instruction sets depend on the Execution state:

AArch64   AArch64 state supports only a single instruction set, called A64. This is a fixed-length instruction set that uses 32-bit instruction encodings.

For information on the A64 instruction set, see Chapter C3 A64 Instruction Set Overview.

AArch32   AArch32 state supports the following instruction sets:

A32      This is a fixed-length instruction set that uses 32-bit instruction encodings.

T32      This is a variable-length instruction set that uses both 16-bit and 32-bit instruction encodings.

In previous documentation, these instruction sets were called the ARM and Thumb instruction sets. Armv8 extends each of these instruction sets. In AArch32 state, the Instruction set state determines the instruction set that the PE executes.

For information on the A32 and T32 instruction sets, see Chapter F1 The AArch32 Instruction Sets Overview.

The Armv8 instruction sets support SIMD and scalar floating-point instructions. See Advanced SIMD and floating-point support on page A1-51.

A1.3.3   System registers

System registers provide control and status information of architected features.

The System registers use a standard naming format: <register_name>.<bit_field_name> to identify specific registers as well as control and status bits within a register.

Bits can also be described by their numerical position in the form <register_name>[x:y] or the generic form bits[x:y].

In addition, in AArch64 state, most register names include the lowest Exception level that can access the register as a suffix to the register name:

• <register_name>_ELx, where x is 0, 1, 2, or 3.

For information about Exception levels, see Exception levels on page D1-2268.

The System registers comprise:

• The following registers that are described in this manual:
  — General system control registers.
  — Debug registers.
  — Generic Timer registers.
  — Optionally, Performance Monitor registers.
  — Optionally, the Activity Monitors registers.
Optionally, one or more of the following groups of registers that are defined in other Arm architecture specifications:

- Trace System registers, as defined in the Embedded Trace Macrocell Architecture Specification, ETMv4.
- Scalable Vector Extension System registers, as defined in the Arm® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for Armv8-A.
- Generic Interrupt Controller (GIC) System registers, see The Arm Generic Interrupt Controller System registers.

RAS Extension System registers, as defined in the Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile. The RAS Extension is a mandatory extension to the Armv8.2 architecture, and an optional extension to the Armv8.0 and Armv8.1 architectures.

For information about the AArch64 System registers, see Chapter D13 AArch64 System Register Descriptions.

For information about the AArch32 System registers, see Chapter G8 AArch32 System Register Descriptions.

### The Arm Generic Interrupt Controller System registers

From version 3 of the Arm Generic Interrupt Controller architecture, GICv3, the GIC architecture specification defines a System register interface to some of its functionality. The System register summaries in this manual include these registers, see:

- About the GIC System registers on page D12-2815, for more information about the AArch64 GIC System registers.
- About the GIC System registers on page G7-5888, for more information about the AArch32 GIC System registers.

These sections give only short overviews of the GIC System registers. For more information, including descriptions of the registers, see the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0 (ARM IHI 0069).

Note

The programmers’ model for earlier versions of the GIC architecture is wholly memory-mapped.

### A1.3.4 Armv8 Debug

Armv8 supports the following:

**Self-hosted debug**

In this model, the PE generates debug exceptions. Debug exceptions are part of the Armv8 Exception model.

**External debug**

In this model, debug events cause the PE to enter Debug state. In Debug state, the PE is controlled by an external debugger.

All Armv8 implementations support both models. The model chosen by a particular user depends on the debug requirements during different stages of the design and development life cycle of the product. For example, external debug might be used during debugging of the hardware implementation and OS bring-up, and self-hosted debug might be used during application development.

For more information about self-hosted debug:

- In AArch64 state, see Chapter D2 AArch64 Self-hosted Debug.
- In AArch32 state, see Chapter G2 AArch32 Self-hosted Debug.

For more information about external debug, see Part H External Debug on page 6697.
A1.4 Supported data types

The Armv8 architecture supports the following integer data types:

<table>
<thead>
<tr>
<th>Type</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte</td>
<td>8 bits</td>
</tr>
<tr>
<td>Halfword</td>
<td>16 bits</td>
</tr>
<tr>
<td>Word</td>
<td>32 bits</td>
</tr>
<tr>
<td>Doubleword</td>
<td>64 bits</td>
</tr>
<tr>
<td>Quadword</td>
<td>128 bits</td>
</tr>
</tbody>
</table>

The architecture also supports the following floating-point data types:

- Double-precision, see *Double-precision floating-point format* on page A1-48 for details.

It also supports:

- Fixed-point interpretation of words and doublewords. See *Fixed-point format* on page A1-49.
- Vectors, where a register holds multiple elements, each of the same data type. See *Vector formats* on page A1-42 for details.

The Armv8 architecture provides two register files:

- A general-purpose register file.
- A SIMD&FP register file.

In each of these, the possible register widths depend on the Execution state.

In AArch64 state:

- A general-purpose register file contains 64-bit registers:
  - Many instructions can access these registers as 64-bit registers or as 32-bit registers, using only the bottom 32 bits.
- A SIMD&FP register file contains 128-bit registers:
  - The quadword integer data types only apply to the SIMD&FP register file.
  - The floating-point data types only apply to the SIMD&FP register file.
  - While the AArch64 vector registers support 128-bit vectors, the effective vector length can be 64-bits or 128-bits depending on the A64 instruction encoding used, see *Instruction Mnemonics* on page C1-173.

For more information on the register files in AArch64 state, see *Registers in AArch64 Execution state* on page B1-99.

In AArch32 state:

- A general-purpose register file contains 32-bit registers:
  - Two 32-bit registers can support a doubleword.
  - Vector formatting is supported, see *Figure A1-4 on page A1-45*.
- A SIMD&FP register file contains 64-bit registers:
  - AArch32 state does not support quadword integer or floating-point data types.

  **Note**
  Two consecutive 64-bit registers can be used as a 128-bit register.

For more information on the register files in AArch32 state, see *The general-purpose registers, and the PC, in AArch32 state* on page E1-3785.
A1.4.1 Vector formats

In an implementation that includes the SIMD instructions that operate on the SIMD&FP register file, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant end of the vector.

Vector formats in AArch64 state

In AArch64 state, the SIMD&FP registers can be referred to as Vn, where n is a value from 0 to 31.

The SIMD&FP registers support three data formats for loads, stores, and data-processing operations:

- A single, scalar, element in the least significant bits of the register.
- A 64-bit vector of byte, halfword, or word elements.
- A 128-bit vector of byte, halfword, word, or doubleword elements.

The element sizes are defined in Table A1-1 with the vector format described as:

- For a 128-bit vector: Vn{.2D, .4S, .8H, .16B}.
- For a 64-bit vector: Vn{.1D, .2S, .4H, .8B}.

Table A1-1 SIMD elements in AArch64 state

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>8 bits</td>
</tr>
<tr>
<td>H</td>
<td>16 bits</td>
</tr>
<tr>
<td>S</td>
<td>32 bits</td>
</tr>
<tr>
<td>D</td>
<td>64 bits</td>
</tr>
</tbody>
</table>

Figure A1-1 on page A1-43 shows the SIMD vectors in AArch64 state.
Vector formats in AArch32 state

Table A1-2 shows the available formats. Each instruction description specifies the data types that the instruction supports.

<table>
<thead>
<tr>
<th>Data type specifier</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>.&lt;size&gt;</td>
<td>Any element of <code>&lt;size&gt;</code> bits</td>
</tr>
<tr>
<td>.F&lt;size&gt;</td>
<td>Floating-point number of <code>&lt;size&gt;</code> bits</td>
</tr>
<tr>
<td>.I&lt;size&gt;</td>
<td>Signed or unsigned integer of <code>&lt;size&gt;</code> bits</td>
</tr>
<tr>
<td>.P&lt;size&gt;</td>
<td>Polynomial over {0, 1} of degree less than <code>&lt;size&gt;</code></td>
</tr>
<tr>
<td>.S&lt;size&gt;</td>
<td>Signed integer of <code>&lt;size&gt;</code> bits</td>
</tr>
<tr>
<td>.U&lt;size&gt;</td>
<td>Unsigned integer of <code>&lt;size&gt;</code> bits</td>
</tr>
</tbody>
</table>

Polynomial arithmetic over \{0, 1\} on page A1-50 describes the polynomial data type.

The .F16 data type is the half-precision data type selected by the FPSCR.AHP bit, see Half-precision floating-point formats on page A1-45.

The .F32 data type is the Arm standard single-precision floating-point data type, see Single-precision floating-point format on page A1-47.
The instruction definitions use a data type specifier to define the data types appropriate to the operation. Figure A1-2 shows the hierarchy of the Advanced SIMD data types.

![Advanced SIMD data type hierarchy in AArch32 state](image)

† Output format only. See VMULL instruction description.
‡ Available only if the Cryptographic Extension is implemented. See VMULL instruction description.

**Figure A1-2 Advanced SIMD data type hierarchy in AArch32 state**

For example, a multiply instruction must distinguish between integer and floating-point data types.

An integer multiply instruction that generates a double-width (long) result must specify the input data types as signed or unsigned. However, some integer multiply instructions use modulo arithmetic, and therefore do not have to distinguish between signed and unsigned inputs.

Figure A1-3 on page A1-45 shows the Advanced SIMD vectors in AArch32 state.

--- **Note** ---

In AArch32 state, a pair of even and following odd numbered doubleword registers can be concatenated and treated as a single quadword register.
The AArch32 general-purpose registers support vectors formats for use by the SIMD instructions in the Base instruction set. Figure A1-4 shows these formats, that means that a general-purpose register can be treated as either 2 halfwords or 4 bytes.

### A1.4.2 Half-precision floating-point formats

Armv8 supports two half-precision floating-point formats:

- IEEE half-precision, as described in the IEEE 754-2008 standard.
- Arm alternative half-precision format.

Both formats can be used for conversions to and from other floating-point formats. FPCR.AHP controls the format in AArch64 state and FPSCR.AHP controls the format in AArch32 state. ARMv8.2-FP16 adds half-precision data-processing instructions, which always use the IEEE format. These instructions ignore the value of the relevant AHP field, and behave as if it has an Effective value of 0.
The description of IEEE half-precision includes Arm-specific details that are left open by the standard, and is only an introduction to the formats and to the values they can contain. For more information, especially on the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

For both half-precision floating-point formats, the layout of the 16-bit format is the same. The format is:

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>10</th>
<th>9</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>exponent</td>
<td>fraction</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The interpretation of the format depends on the value of the exponent field, bits[14:10] and on which half-precision format is being used.

\[ 0 < \text{exponent} < 0x1F \]

- The value is a normalized number and is equal to:
  \[ (-1)^S \times 2^{(\text{exponent}-15)} \times (1.\text{fraction}) \]

  The minimum positive normalized number is \(2^{-14}\), or approximately \(6.104 \times 10^{-5}\).

  The maximum positive normalized number is \((2 - 2^{-10}) \times 2^{15}\), or 65504.

  Larger normalized numbers can be expressed using the alternative format when the exponent == 0x1F.

\[ \text{exponent} == 0 \]

- The value is either a zero or a denormalized number, depending on the fraction bits:
  
  \[ \text{fraction} == 0 \]

    - The value is a zero. There are two distinct zeros:
      \[ +0 \] when \(S==0\)
      \[ -0 \] when \(S==1\).
  
  \[ \text{fraction} != 0 \]

    - The value is a denormalized number and is equal to:
      \[ (-1)^S \times 2^{-14} \times (0.\text{fraction}) \]

      The minimum positive denormalized number is \(2^{-24}\), or approximately \(5.960 \times 10^{-8}\).

      Half-precision denormalized numbers are not flushed to zero by default. When ARMv8.2-FP16 is implemented, the FPCR.FZ16 bit controls whether Flush-to-Zero mode is enabled for half-precision data-processing instructions. For details, see Flush-to-zero on page A1-54.

\[ \text{exponent} == 0x1F \]

- The value depends on which half-precision format is being used:

  **IEEE half-precision**

  The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

  \[ \text{fraction} == 0 \]

    - The value is an infinity. There are two distinct infinities:
      \[ +\infty \] when \(S==0\). This represents all positive numbers that are too big to be represented accurately as a normalized number.
      \[ -\infty \] when \(S==1\). This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

  \[ \text{fraction} != 0 \]

    - The value is a NaN, and is either a quiet NaN or a signaling NaN.

      The two types of NaN are distinguished by their most significant fraction bit, bit[9]:

      \[ \text{bit}[9] == 0 \] The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.
The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

**Alternative half-precision**
The value is a normalized number and is equal to:
\[-1^S \times 2^{16} \times (1.fraction)\]
The maximum positive normalized number is \((2^{-10}) \times 2^{16}\) or 131008.

### A1.4.3 Single-precision floating-point format

The single-precision floating-point format is as defined by the IEEE 754 standard.

This description includes Arm-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

A single-precision value is a 32-bit word with the format:

<table>
<thead>
<tr>
<th>31 30</th>
<th>23 22</th>
<th></th>
<th></th>
<th></th>
<th></th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>exponent</td>
<td>fraction</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The interpretation of the format depends on the value of the exponent field, bits[30:23]:

- **0 < exponent < 0xFF**
  - The value is a *normalized number* and is equal to:
    \[-1^S \times 2^{(exponent - 127)} \times (1.fraction)\]
  - The minimum positive normalized number is \(2^{-126}\), or approximately \(1.175 \times 10^{-38}\).
  - The maximum positive normalized number is \((2 - 2^{-23}) \times 2^{127}\), or approximately \(3.403 \times 10^{38}\).

- **exponent == 0**
  - The value is either a zero or a *denormalized number*, depending on the fraction bits:
    - **fraction == 0**
      - The value is a zero. There are two distinct zeros:
        - +0 When \(S==0\).
        - –0 When \(S==1\).
        - These usually behave identically. In particular, the result is *equal if +0 and –0 are compared as floating-point numbers*. However, they yield different results in some circumstances. For example, the sign of the infinity produced as the result of dividing by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer comparison of the two words.
    - **fraction != 0**
      - The value is a denormalized number and is equal to:
        \[-1^S \times 2^{-126} \times (0.fraction)\]
      - The minimum positive denormalized number is \(2^{-149}\), or approximately \(1.401 \times 10^{-45}\).

- **exponent == 0xFF**
  - The value is either an *infinity* or a *Not a Number* (NaN), depending on the fraction bits:
    - **fraction == 0**
      - The value is an infinity. There are two distinct infinities:
        - +infinity When \(S==0\). This represents all positive numbers that are too big to be represented accurately as a normalized number.
-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a quiet NaN or a signaling NaN.

The two types of NaN are distinguished by their most significant fraction bit, bit[22]:

bit[22] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[22] == 1

The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

For details of the default NaN, see NaN handling and the Default NaN on page A1-55.

Note

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as unordered with everything, including itself.

A1.4.4 Double-precision floating-point format

The double-precision floating-point format is as defined by the IEEE 754 standard. Double-precision floating-point is supported by both SIMD and floating-point instructions in AArch64 state, and only by floating-point instructions in AArch32 state.

This description includes implementation-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

A double-precision value is a 64-bit doubleword, with the format:

<table>
<thead>
<tr>
<th>63 62</th>
<th>52 51</th>
<th>32 31</th>
<th></th>
<th></th>
<th></th>
<th></th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>exponent</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>fraction</td>
</tr>
</tbody>
</table>

Double-precision values represent numbers, infinities, and NaNs in a similar way to single-precision values, with the interpretation of the format depending on the value of the exponent:

0 < exponent < 0x7FF

The value is a normalized number and is equal to:

\((-1)^S \times 2^{(exponent-1023)} \times (1.\text{fraction})\)

The minimum positive normalized number is 2⁻¹⁰²², or approximately 2.225 × 10⁻³⁰⁸.

The maximum positive normalized number is \((2 – 2⁻⁵²) \times 2¹⁰²³\), or approximately 1.798 × 10³⁰⁸.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros that behave in the same way as the two single-precision zeros:

+0 when S==0

-0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

\((-1)^S \times 2⁻¹⁰²² \times (0.\text{fraction})\)
The minimum positive denormalized number is $2^{-1074}$, or approximately $4.941 \times 10^{-324}$. Optionally, denormalized numbers are flushed to zero in floating-point calculations. For details, see *Flush-to-zero* on page A1-54.

exponent == 0x7FF

The value is either an infinity or a NaN, depending on the fraction bits:

fraction == 0

The value is an infinity. As for single-precision, there are two infinities:

+infinity When S==0.

-infinity When S==1.

fraction != 0

The value is a NaN, and is either a quiet NaN or a signaling NaN.

The two types of NaN are distinguished by their most significant fraction bit, bit[51] of the doubleword:

bit[51] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[51] == 1

The NaN is a quiet NaN. The sign bit and the remaining fraction bits can take any value.

For details of the default NaN, see *NaN handling and the Default NaN* on page A1-55.

Note

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as unordered with everything, including itself.

### A1.4.5 Fixed-point format

Fixed-point formats are used only for conversions between floating-point and fixed-point values. They apply to general-purpose registers.

Fixed-point values can be signed or unsigned, and can be 16-bit or 32-bit. Conversion instructions take an argument that specifies the number of fraction bits in the fixed-point number. That is, it specifies the position of the binary point.

### A1.4.6 Conversion between floating-point and fixed-point values

Armv8 supports the conversion of a scalar floating-point to or from a signed or unsigned fixed-point value in a general-purpose register.

The instruction argument #fbits indicates that the general-purpose register holds a fixed-point number with fbits bits after the binary point, where fbits is in the range 1 to 64 for a 64-bit general-purpose register, or 1 to 32 for a 32-bit general-purpose register.

More specifically:

- For a 64-bit register Xd:
  - The integer part is Xd[63:#fbits].
  - The fractional part is Xd[#fbits-1]:0.
- For a 32-bit register Wd or Rd:
  - The integer part is Wd[31:#fbits] or Rd[31:#fbits].
  - The fractional part is Wd[#fbits-1]:0 or Rd[#fbits-1]:0.
These instructions can cause the following floating-point exceptions:

**Invalid Operation**  
When the floating-point input is NaN or Infinity or when a numerical value cannot be represented within the destination register.

**Inexact**  
When the numeric result differs from the input value.

**Input Denormal**  
When Flush-to-zero mode is enabled and the denormal input is replaced by a zero.

--- Note -----
An out of range fixed-point result is saturated to the destination size.

For more information, see *Floating-point exceptions and exception traps* on page D1-2313.

### A1.4.7 Polynomial arithmetic over \{0, 1\}

Some SIMD instructions that operate on SIMD&FP registers can operate on polynomials over \{0, 1\}, see *Supported data types* on page A1-41. The polynomial data type represents a polynomial in x of the form \(b_{n-1}x^{n-1} + \ldots + b_1x + b_0\) where \(b_k\) is bit\([k]\) of the value.

The coefficients 0 and 1 are manipulated using the rules of Boolean arithmetic:
- \(0 + 0 = 1 + 1 = 0\)
- \(0 + 1 = 1 + 0 = 1\)
- \(0 \times 0 = 0 \times 1 = 1 \times 0 = 0\)
- \(1 \times 1 = 1\).

That is:
- Adding two polynomials over \{0, 1\} is the same as a bitwise exclusive OR.
- Multiplying two polynomials over \{0, 1\} is the same as integer multiplication except that partial products are exclusive-ORed instead of being added.

A64, A32, and T32 provide instructions for performing polynomial multiplication of 8-bit values.
- For AArch32, see *VMUL (integer and polynomial)* on page F6-5165 and *VMULL (integer and polynomial)* on page F6-5171.
- For AArch64, see *PMUL* on page C7-1849 and *PMULL, PMULL2* on page C7-1851.

The Cryptographic Extension adds the ability to perform long polynomial multiplies of 64-bit values. See *PMULL, PMULL2* on page C7-1851.

#### Pseudocode description of polynomial multiplication

In pseudocode, polynomial addition is described by the EOR operation on bitstrings.

Polynomial multiplication is described by the `PolynomialMult()` function defined in Chapter J1 *Armv8 Pseudocode.*
A1.5  Advanced SIMD and floating-point support

Note
In AArch32 state, the SIMD instructions that operate on SIMD&FP registers are always described as the Advanced SIMD instructions, to distinguish them from the SIMD instructions in the base instruction sets, that operate on the 32-bit general-purpose registers. The A64 instruction set does not provide any SIMD instructions that operate on the general-purpose registers, and therefore some AArch64 state descriptions use SIMD as a synonym for Advanced SIMD. Unless the context clearly indicates otherwise, this section describes the support for SIMD instructions that operate on SIMD&FP registers.

Armv8 can support the following levels of support for Advanced SIMD and floating-point instructions:

• Full SIMD and floating-point support without exception trapping.
• Full SIMD and floating-point support with exception trapping.
• No floating-point or SIMD support. This option is licensed only for implementations targeting specialized markets.

Note
All systems that support standard operating systems with rich application environments provide hardware support for Advanced SIMD and floating-point. It is a requirement of the ARM Procedure Call Standard for AArch64, see Procedure Call Standard for the Arm 64-bit Architecture.

Armv8 supports single-precision (32-bit) and double-precision (64-bit) floating-point data types and arithmetic as defined by the IEEE 754 floating-point standard. It also supports the half-precision (16-bit) floating-point data type for data storage, by supporting conversions between single-precision and half-precision data types and double-precision and half-precision data types. When ARMv8.2-FP16 is implemented, it also supports the half-precision floating-point data type for data-processing operations.

The SIMD instructions provide packed Single Instruction Multiple Data (SIMD) and single-element scalar operations, and support:

• Single-precision and double-precision arithmetic in AArch64 state.
• Single-precision arithmetic only in AArch32 state.
• When ARMv8.2-FP16 is implemented, half-precision arithmetic is supported in AArch64 and AArch32 states.

Floating-point support in AArch64 state SIMD is IEEE 754-2008 compliant with:

• Configurable rounding modes.
• Configurable Default NaN behavior.
• Configurable Flush-to-zero behavior.

Floating-point computation using AArch32 Advanced SIMD instructions remains unchanged from Armv7. A32 and T32 Advanced SIMD floating-point always uses Arm standard floating-point arithmetic and performs IEEE 754 floating-point arithmetic with the following restrictions:

• Denormalized numbers are flushed to zero, see Flush-to-zero on page A1-54.
• Only default NaNs are supported, see NaN handling and the Default NaN on page A1-55.
• The Round to Nearest rounding mode is used.
• Untrapped floating-point exception handling is used for all floating-point exceptions.

If floating-point exception trapping is supported, floating-point exceptions, such as Overflow or Divide by Zero, can be handled without trapping. This applies to both SIMD and floating-point operations. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation. For more information about floating-point exceptions, see Floating-point exceptions and exception traps on page D1-2313.
In AArch64 state, the following registers control floating-point operation and return floating-point status information:

- The Floating-Point Control Register, FPCR, controls:
  - The half-precision format where applicable, FPCR.AHP bit.
  - Default NaN behavior, FPCR.DN bit.
  - Flush-to-zero behavior, FPCR.{FZ, FZ16} bits. If ARMv8.2-FP16 is not implemented, FPCR.FZ16 is RES0.
  - Rounding mode support, FPCR.Rmode field.
  - Len and Stride fields associated with execution in AArch32 state, and only supported for a context save and restore from AArch64 state. These fields are obsolete in Armv8 and can be implemented as RAZ/WI. If they are implemented as RW and are programmed to a nonzero value, they make some AArch32 floating-point instructions UNDEFINED.
  - Floating-point exception trap controls, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits, see Floating-point exceptions and exception traps on page D1-2313.

- The Floating-Point Status Register, FPSR, provides:
  - Cumulative floating-point exceptions flags, FPSR.{IDC, IXC, UFC, OFC, DZC, IOC and QC}.
  - The AArch32 floating-point comparison flags {N,Z,C,V}. These bits are RES0 if AArch32 floating-point is not implemented.

- **Note**

  In AArch64 state, the process state flags, PSTATE.{N,Z,C,V} are used for all data-processing compares and any associated conditional execution.

  If ARMv8.5-CondM is implemented, the instructions AXFLAG and XAFLAG convert between the Arm condition flag format and an alternative format shown in Relationship between ARM format and alternative format PSTATE condition flags on page C6-752.

AArch32 state provides a single Floating-Point Status and Control Register, FPSCR, combining the FPCR and FPSR fields.

For system level information about the SIMD and floating-point support, see Advanced SIMD and floating-point support on page G1-5570.

### A1.5.1 Instruction support

The Advanced SIMD and floating-point instructions support:

- Load and store for single elements and vectors of multiple elements.

  - **Note**

    Single elements are also referred to as scalar elements.

- Data processing on single and multiple elements for both integer and floating-point data types.
- When ARMv8.3-CompNum is implemented, complex number arithmetic.
- Floating-point conversion between different levels of precision.
- Conversion between floating-point, fixed-point integer, and integer data types.
- Floating-point rounding.

For more information on the SIMD and floating-point instructions in AArch64 state, see Chapter C3 A64 Instruction Set Overview.

For more information on the Advanced SIMD and floating-point instructions in AArch32 state, see Chapter F1 The AArch32 Instruction Sets Overview.
A1.5.2 Floating-point standards, and terminology

The Arm includes support for all the required features of ANSI/IEEE Std 754-2008, *IEEE Standard for Binary Floating-Point Arithmetic*, referred to as IEEE 754-2008. However, some terms in this manual are based on the 1985 version of this standard, referred to as IEEE 754-1985:

- Arm floating-point terminology generally uses the IEEE 754-1985 terms. This section summarizes how IEEE 754-2008 changes these terms.
- References to IEEE 754 that do not include the issue year apply to either issue of the standard.

Table A1-3 shows how the terminology in this manual differs from that used in IEEE 754-2008.

Table A1-3 Floating-point terminology

a. Normalized number is used in preference to normal number, because of the other specific uses of normal in this manual.

A1.5.3 Arm standard floating-point input and output values

Armv8 provides full IEEE 754 floating-point arithmetic support. In AArch32 state, floating-point operations performed using Advanced SIMD instructions are limited to Arm standard floating-point operation, regardless of the selected rounding mode in the FPSCR. Unlike AArch32, AArch64 SIMD floating point arithmetic is performed using the rounding mode selected by the FPCR.

Arm standard floating-point arithmetic supports the following input formats defined by the IEEE 754 floating-point standard:

- Zeros.
- Normalized numbers.
- Denormalized numbers are flushed to 0 before floating-point operations, see Flush-to-zero on page A1-54.
- NaNs.
- Infinities.

Arm standard floating-point arithmetic supports the Round to Nearest (roundTiesToEven) rounding mode defined by the IEEE 754 standard.

Arm standard floating-point arithmetic supports the following output result formats defined by the IEEE 754 standard:

- Zeros.
- Normalized numbers.
- Results that are less than the minimum normalized number are flushed to zero, see Flush-to-zero on page A1-54.
• NaNs produced in floating-point operations are always the default NaN, see *NaN handling and the Default NaN* on page A1-55.

• Infinities.

### A1.5.4 Flush-to-zero

The performance of floating-point processing can be reduced when doing calculations involving denormalized numbers and Underflow exceptions. In many algorithms, this performance can be recovered, without significantly affecting the accuracy of the final result, by replacing the denormalized operands and intermediate results with zeros. To permit this optimization, Arm floating-point implementations allow a Flush-to-zero mode to be used for different floating-point formats as follows:

For AArch64:

- If FPCR.FZ==1, then Flush-to-Zero mode is used for all Single-Precision and Double-Precision inputs and outputs of all instructions.
- If FPCR.FZ16==1, then Flush-to-Zero mode is used for all Half-Precision inputs and outputs of floating-point instructions, other than:
  - Conversions between Half-Precision and Single-Precision numbers.
  - Conversions between Half-Precision and Double-Precision numbers.

For AArch32:

- If FPSCR.FZ==0, then Flush-to-Zero mode is used for all Single-Precision and Double-Precision inputs and outputs of all Advanced SIMD floating-point instructions.
- If FPSCR.FZ==1, then Flush-to-Zero mode is used for all Single-Precision and Double-Precision inputs and outputs of all instructions.
- If FPSCR.FZ16==1, then Flush-to-Zero mode is used for all Half-Precision inputs and outputs of floating-point instructions, other than:
  - Conversions between Half-Precision and Single-Precision numbers.
  - Conversions between Half-Precision and Double-Precision numbers.

If Flush-To-Zero mode is used on an Single-precision or Double-precision input:

- All inputs to floating-point operations that are denormalized numbers in their represented precision are treated as though they were zero with the same sign as the input, and an Input Denormal floating-point exception is generated.

**Note**

The Input Denormal floating-point exception occurs only in Flush-to-zero mode.

- In AArch32 state, the FPSCR contains a cumulative exception bit FPSCR.IDC and optional trap enable bit FPSCR.IDE corresponding to the Input Denormal floating-point exception.
- In AArch64 state, the FPSR contains a cumulative exception bit FPSR.IDC and optional trap enable bit FPCR.IDE corresponding to the Input Denormal floating-point exception.
- The occurrence of all floating-point exceptions except Input Denormal is determined using the input values that are treated as zero by this mechanism.

If Flush-To-Zero mode is used on a Half-precision input:

- All inputs to floating-point operations that are denormalized numbers in their represented precision are treated as though they were zero with the same sign as the input.

**Note**

When ARMv8.2-FP16 is implemented, when in Flush-to-zero mode, a half-precision floating-point number...
that is flushed to zero does not generate an Input Denormal floating-point exception. This is because this situation is much less exceptional than for double-precision or single-precision denormalized numbers.

• The occurrence of all floating-point exceptions is determined using the input values that are treated as zero by this mechanism.

If Flush-To-Zero mode is used on any output of an instruction:

• The output is returned as zero, with the same sign bit as the result, if the result before rounding of the operation specified by the instruction satisfies the condition:

\[ 0 < \text{Abs(result)} < \text{MinNorm}, \]

where:

- MinNorm is \(2^{-14}\) for half-precision.
- MinNorm is \(2^{-126}\) for single-precision.
- MinNorm is \(2^{-1022}\) for double-precision.

If this occurs, then:

- An Underflow Exception is generated, but in all implementations, the Underflow Exception is not trapped even if the AArch32 FPSCR.UFE==1 or the AArch64 FPCR.UFE==1.
- An Inexact Exception is not generated.

Note
 Flush-to-zero mode is incompatible with the IEEE 754 standard, and must not be used when IEEE 754 compatibility is a requirement. Flush-to-zero mode must be used with care. Although it can improve performance on some algorithms, there are significant limitations on its use. These are application dependent:

• On many algorithms, it has no noticeable effect, because the algorithm does not normally use denormalized numbers.

• On other algorithms, it can cause exceptions to occur or seriously reduce the accuracy of the results of the algorithm.

A1.5.5 NaN handling and the Default NaN

The IEEE 754 standard specifies that:

• An operation that causes an Invalid Operation floating-point exception generates a quiet NaN as its result if that exception is untrapped.

• An operation involving a quiet NaN operand, but not a signaling NaN operand, returns an input NaN as its result.

The floating-point processing behavior when Default NaN mode is disabled adheres to this, with the following additions:

• If an untrapped Invalid Operation floating-point exception occurs, the quiet NaN result is derived from:
  - The first signaling NaN operand, if the exception occurs because at least one of the operands is a signaling NaN.
  - Otherwise, the default NaN.

• If an untrapped Invalid Operation floating-point exception does not occur, but at least one of the operands is a quiet NaN, the result is derived from the first quiet NaN operand.

Depending on the operation, the exact value of a derived quiet NaN result may differ in both sign and number of fraction bits from its source. For a quiet NaN result derived from signaling NaN operand, the most-significant fraction bit is set to 1.
Note

• In these descriptions, first operand relates to the left-to-right ordering of the arguments to the pseudocode function that describes the operation.

• The IEEE 754 standard specifies that the sign bit of a NaN has no significance.

The SIMD and floating-point processing behavior when Default NaN mode is enabled is that the Default NaN is the result of all floating-point operations that either:

• Cause untrapped Invalid Operation floating-point exceptions.
• Have one or more quiet NaN inputs, but no signaling NaN inputs.

Table A1-4 shows the format of the default NaN for Arm floating-point operations.

Default NaN mode is selected for the floating-point processing by setting the FPCR.DN bit to 1.

Other aspects of the functionality of the Invalid Operation floating-point exception are not affected by Default NaN mode. These are that:

• If untrapped, it causes the FPSR.IOC bit to be set to 1.
• If trapped, it causes a user trap handler to be invoked.

A1.6 The Arm memory model

The Arm memory model supports:

- Generating an exception on an unaligned memory access.
- Restricting access by applications to specified areas of memory.
- Translating virtual addresses (VAs) provided by executing instructions to physical addresses (PAs).
- Altering the interpretation of multi-byte data between big-endian and little-endian.
- Controlling the order of accesses to memory.
- Controlling caches and address translation structures.
- Synchronizing access to shared memory by multiple PEs.
- Barriers that control and prevent speculative access to memory.

VA support depends on the Execution state, as follows:

AArch64 state

Supports 64-bit virtual addressing, with the Translation Control Register determining the supported VA range. Execution at EL1 and EL0 supports two independent VA ranges, each with its own translation controls.

AArch32 state

Supports 32-bit virtual addressing, with the Translation Control Register determining the supported VA range. For execution at EL1 and EL0, system software can split the VA range into two subranges, each with its own translation controls.

The supported PA space is IMPLEMENTATION DEFINED, and can be discovered by system software.

Regardless of the Execution state, the Virtual Memory System Architecture (VMSA) can translate VAs to blocks or pages of memory anywhere within the supported PA space.

For more information, see:

For execution in AArch64 state

- Chapter B2 The AArch64 Application Level Memory Model.
- Chapter D4 The AArch64 System Level Memory Model.
- Chapter D5 The AArch64 Virtual Memory System Architecture.

For execution in AArch32 state

- Chapter E2 The AArch32 Application Level Memory Model.
- Chapter G4 The AArch32 System Level Memory Model.
- Chapter G5 The AArch32 Virtual Memory System Architecture.
Chapter A2
Armv8-A Architecture Extensions

This chapter introduces the Arm architecture versions and extensions. It contains the following sections:

- Armv8 architecture extensions on page A2-60.
- Architectural features within Armv8.0 architecture on page A2-63.
- The Armv8 Cryptographic Extension on page A2-66.
- The Armv8.1 architecture extension on page A2-67.
- The Armv8.2 architecture extension on page A2-70.
- The Armv8.3 architecture extension on page A2-78.
- The Armv8.4 architecture extension on page A2-81.
- The Armv8.5 architecture extension on page A2-86.
- The Reliability, Availability, and Serviceability Extension (RAS Extension) on page A2-90.
- The Statistical Profiling Extension (SPE) on page A2-91.
- The Scalable Vector Extension (SVE) on page A2-92.
- The Activity Monitors Extension on page A2-93.
- The Memory Partitioning and Monitoring (MPAM) Extension on page A2-94.
A2.1 Armv8 architecture extensions

The original Armv8-A architecture is called Armv8.0. The following sections of this manual describe or summarize permitted extensions to Armv8.0:

- The Armv8 Cryptographic Extension on page A2-66.
- The Reliability, Availability, and Serviceability Extension (RAS Extension) on page A2-90.
- Event monitors on page D1-2379.
- The IVIPT Extension on page D5-2657.
- Chapter H7 The PC Sample-based Profiling Extension.

In addition to describing Armv8.0, this manual describes the following architectural extensions:

Features added to Armv8.0 in later releases

Architectural features and architectural requirements have been added to the original Armv8-A architecture. For more information, see:

- Additional functionality added to Armv8.0 in later releases on page A2-63.
- Architectural requirements within Armv8.0 architecture on page A2-65.

For more information, see Architectural features within Armv8.0 architecture on page A2-63.

The Armv8.1 architectural extension

The Armv8.1 architecture extension adds both:

- Architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.
- Architectural requirements. These are mandatory.

An implementation is Armv8.1 compliant when all of the following apply:

- It includes all of the Armv8.1 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.1 compliant implementation includes the optional architecture component or extension. See Architectural features added by Armv8.1 on page A2-67 for all of the Armv8.1 architectural features.
- It includes all of the Armv8.1 architectural requirements. Additional requirements of Armv8.1 on page A2-69 lists these requirements.

For more information, see The Armv8.1 architecture extension on page A2-67.

The Armv8.2 architectural extension

The Armv8.2 architecture extension is an extension to Armv8.1. It adds both:

- Architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.
- Architectural requirements. These are mandatory.

An implementation is Armv8.2 compliant if all of the following apply:

- It is Armv8.1 compliant.
- It includes all of the Armv8.2 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.2 compliant implementation includes the optional architecture component or extension. The features are listed at:
  - Architectural features added by Armv8.2 on page A2-70, which lists the original Armv8.2 architectural features.
  - Features added to the Armv8.2 extension in later releases on page A2-76, which lists additional Armv8.2 architectural features.
- It includes all of the Armv8.2 architectural requirements. Additional requirements of Armv8.2 on page A2-76 lists these requirements.

For more information, see The Armv8.2 architecture extension on page A2-70.
The Armv8.3 architectural extension

The Armv8.3 architecture extension is an extension to Armv8.2. It adds both:

- Architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.
- Architectural requirements. These are mandatory.

An implementation is Armv8.3 compliant if all of the following apply:

- It is Armv8.2 compliant.
- It includes all of the Armv8.3 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.3 compliant implementation includes the optional architecture component or extension. The features are listed at:
  - Architectural features added by Armv8.3 on page A2-78, which lists the original Armv8.3 architectural features.
  - Features added to the Armv8.3 extension in later releases on page A2-80, which lists additional Armv8.3 architectural features.
- It includes all of the Armv8.3 architectural requirements. Additional requirements of Armv8.3 on page A2-80 lists these requirements.

For more information, see The Armv8.3 architecture extension on page A2-78.

The Armv8.4 architectural extension

The Armv8.4 architecture extension is an extension to Armv8.3. It adds architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.

An implementation is Armv8.4 compliant if all of the following apply:

- It is Armv8.3 compliant.
- It includes all of the Armv8.4 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.4 compliant implementation includes the optional architecture component or extension. See Architectural features added by Armv8.4 on page A2-81 for all of the Armv8.4 architectural features.

For more information, see The Armv8.4 architecture extension on page A2-81.

The Armv8.5 architectural extension

The Armv8.5 architecture extension is an extension to Armv8.4. It adds architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.

An implementation is Armv8.5 compliant if all of the following apply:

- It is Armv8.4 compliant.
- It includes all of the Armv8.5 architectural features that are mandatory. This includes all architectural features of an optional architecture component or extension that are defined as mandatory, if the Armv8.5 compliant implementation includes the optional architecture component or extension. See Architectural features added by Armv8.5 on page A2-86 for all of the Armv8.5 architectural features.
- It includes all of the Armv8.3 architectural requirements. Additional requirements of Armv8.5 on page A2-88 lists these requirements.

For more information, see The Armv8.5 architecture extension on page A2-86.

The Statistical Profiling Extension (SPE)

SPE is an optional extension to Armv8.2. That is, SPE requires the implementation of Armv8.2.

For more information, see The Statistical Profiling Extension (SPE) on page A2-91.

The Scalable Vector Extension (SVE)

SVE is an optional extension to Armv8.2. That is, SVE requires the implementation of Armv8.2.
For more information, see *The Scalable Vector Extension (SVE)* on page A2-92.

**The Activity Monitors Extension (AMU)**

AMU is an optional extension to Armv8.4. That is, AMU requires the implementation of Armv8.4.

For more information, see *The Activity Monitors Extension* on page A2-93.

**The Memory Partitioning and Monitoring Extension (MPAM)**

MPAM is an optional extension to Armv8.2. That is, MPAM requires the implementation of Armv8.2.

For more information, see *The Memory Partitioning and Monitoring (MPAM) Extension* on page A2-94.

See also *Permitted implementation of subsets of Armv8.x and Armv8.(x+1) architectural features*.

### A2.1.1 Permitted implementation of subsets of Armv8.x and Armv8.(x+1) architectural features

An Armv8.x compliant implementation can include any arbitrary subset of the architectural features of Armv8.(x+1), subject only to those constraints that require that certain features be implemented together.

An Armv8.x compliant implementation cannot include any features of Armv8.(x+2).

———— Note —————

The addition of Armv8.(x+1) features to an Armv8.x compliant implementation is only permitted if the implementer has a licence to Armv8.(x+1) in addition to the licence to Armv8.x.
A2.2 Architectural features within Armv8.0 architecture

This includes architectural features and architectural requirements that have been added to the Armv8.0 architecture since the initial release, that were not part of the original Armv8-A architecture, see:

- Additional functionality added to Armv8.0 in later releases
- Architectural requirements within Armv8.0 architecture on page A2-65

A2.2.1 Additional functionality added to Armv8.0 in later releases

An implementation of Armv8.0 can include any or all of the features that this section describes.

The Armv8.0 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

ARMv8.0-SB, Armv8.0 Speculation Barrier

ARMv8.0-SB introduces a barrier to control speculation.

This instruction is introduced to both AArch64 and AArch32 states.

This feature is optional in Armv8.0 implementations, and mandatory in Armv8.5 implementations.

The following fields identify the presence of ARMv8.0-SB:

- ID_AA64ISAR1_EL1.SB
- ID_ISAR6_EL1.SB
- ID_ISAR6.SB

For more information, see:

- Speculation Barrier (SB) on page B2-126.
- Barriers and CLREX instructions on page C3-193.
- Speculation Barrier (SB) on page E2-3825.
- Miscellaneous instructions on page F1-3883.

ARMv8.0-SSBS, Armv8.0 Speculative Store Bypass Safe

ARMv8.0-SSBS allows software to indicate whether hardware is permitted to load or store speculatively in a manner that could give rise to a cache timing side channel, which in turn could be used to derive an address from values loaded to a register from memory. To do this, the software sets the PSTATE.SSBS bit.

This feature is supported in both AArch64 and AArch32 states.

This feature is optional in Armv8.0 implementations, and mandatory in Armv8.5 implementations.

The following fields identify the presence of ARMv8.0-SSBS:

- ID_AA64PFR0_EL1.SSBS
- ID_PFR0_EL1.SSBS
- ID_PFR0.SSBS

For more information, see:

- Speculative Store Bypass Safe (SSBS) on page B2-123.
- Speculative Store Bypass Safe (SSBS) on page E2-3822.

ARMv8.0-CSV2, Armv8.0 Cache Speculation Variant 2

Armv8.0-CSV2 adds a mechanism to identify if hardware cannot disclose information about whether branch targets trained in one hardware described context can affect speculative execution in a different hardware described context. In AArch64 state, this feature also adds the SCXTNUM_EL0, SCXTNUM_EL1, SCXTNUM_EL2 and SCXTNUM_EL3 registers, which provide a number that can be used to separate out different context numbers within their respective Exception levels for the purpose of protecting against side-channels using branch prediction and similar resources.

This feature is supported in both AArch64 and AArch32 states. The SCXTNUM_ELx registers are only supported in AArch64 state.
This feature is mandatory in Armv8.0 implementations.
The following fields identify the presence of ARMv8.0-CSV2:
- ID_AA64PFR0_EL1.CSV2
- ID_PFR0_EL1.CSV2
- ID_PFR0.CSV2

For more information, see:
- Restrictions on the effects of speculation on page B2-123.
- Restrictions on the effects of speculation on page E2-3821.

ARMv8.0-CSV3, Armv8.0 Cache Speculation Variant 3

Armv8.0-CSV3 adds a mechanism to identify if hardware cannot disclose information about
whether data loaded under speculation with a permission or domain fault can be used to form an
address, generate condition codes, or generate SVE predicate values, to be used by instructions
newer than the load in the speculative sequence.

This feature is supported in both AArch64 and AArch32 states.
This feature is mandatory in Armv8.0 implementations.
The following fields identify the presence of ARMv8.0-CSV3:
- ID_AA64PFR0_EL1.CSV3
- ID_PFR2_EL1.CSV3
- ID_PFR2.CSV3

ARMv8.0-PredInv, Armv8.0 Prediction Invalidation

ARMv8.0-PredInv adds the CFP RCTX, CPP RCTX, DVP RCTX, CFPRCTX, CPPRCTX, and
DVP RCTX System instructions. These instructions prevent predictions based on information
gathered from earlier execution within a particular execution context from affecting the later
speculative execution within that context, to the extent that the speculative execution is observable
through side channels.

This feature is supported in both AArch64 and AArch32 states.
This feature is optional in Armv8.0 implementations, and mandatory in Armv8.5 implementations.
The following fields identify the presence of ARMv8.0-PredInv:
- ID_AA64ISAR1_EL1.SPECRES
- ID_ISAR6_EL1.SPECRES
- ID_ISAR6.SPECRES

For more information, see:
- Prediction restriction instructions on page C5-368.
- Execution and data prediction restriction System instructions on page D4-2494.
- Execution and data prediction restriction System instructions on page G4-5708.

ARMv8.0-CP15SDISABLE2, Armv8.0 CP15SDISABLE2

ARMv8.0-CP15SDISABLE2 provides an implementation-defined mechanism, the
CP15SDISABLE2 signal, which when asserted HIGH prevents writes to a set of Secure CP15
registers. This signal is analogous to the existing CP15SDISABLE signal.

This feature is only supported when EL3 is executing in AArch32 state.
This feature is optional in Armv8.0 implementations.
For more information, see:
- The CP15SDISABLE and CP15SDISABLE2 input signals on page G5-5854.

ARMv8.0-DoubleLock, Armv8.0 Double Lock

The ARMv8.0-DoubleLock feature is the mnemonic used for the OS Double Lock.
If ARMv8.3-DoPD is not implemented, this feature is optional if ARMv8.2-Debug is
implemented and mandatory if ARMv8.2-Debug is not implemented.
If ARMv8.3-DoPD is implemented, this feature is not implemented.

The ID_AA64DFR0_EL1.DoubleLock field identifies that the OS Double Lock has been implemented.

A2.2.2 Architectural requirements within Armv8.0 architecture

The Armv8.0 architecture includes some mandatory changes that have been added to the architecture at a later date that are not associated with a feature. These are:

Prefetch speculation protection

When substituting a direct branch with another direct branch, or a \texttt{NOP} with a direct branch, by the modified PE, at around the time that the executing PE is executing the software being modified, prefetch speculation protection prevents the old instructions from accidentally being fetched to the executing PE. For further information on implementation of these requirements, see:

- Ordering of instruction fetches on page B2-122.
- Ordering of instruction fetches on page E2-3820.

An implementation of the Armv8.0 architecture must comply with all of the additional requirements. When combined with the mandatory architectural features that have been added to the Armv8.0 architecture, such an implementation is also called an implementation of the Armv8.0 architecture.
A2.3 The Armv8 Cryptographic Extension

The Armv8 Cryptographic Extension provides instructions for the acceleration of encryption and decryption, and includes the following features:

- **ARMv8.0-AES**, which includes **AESD** and **AESE** instructions.
- **ARMv8.0-SHA**, which includes the **SHA1** and **SHA256** instructions.

The presence of the Cryptographic Extension in an implementation is subject to export license controls. The Cryptographic Extension is an extension of the SIMD support and operates on the vector register file.

The Cryptographic Extension also provides multiply instructions that operate on long polynomials.

The Cryptographic Extension provides this functionality in AArch64 state and AArch32 state, and an implementation that supports both AArch64 state and AArch32 state provides the same Cryptographic Extension functionality in both states.

For more information, see *The Cryptographic Extension* on page C3-247 or *The Cryptographic Extension in AArch32 state* on page F1-3899.

A2.3.1 Armv8.2 extensions to the Cryptographic Extension

From Armv8.2, an implementation of the Armv8.0 Cryptographic Extension can include either or both of:

- The AES functionality, including support for multiplication of 64-bit polynomials. The **ID_AA64ISAR0_EL1.AES** field indicates whether this functionality is supported.
- The SHA1 and SHA2-256 functionality. The **ID_AA64ISAR0_EL1.{SHA2, SHA1}** fields indicate whether this functionality is supported.

In addition, Armv8.2 adds two optional extensions to the Armv8 Cryptographic Extension, that provide cryptographic functionality in AArch64 state only. These two optional features are:

**ARMv8.2-SHA, SHA2-512 and SHA3 functionality**

In the A64 instruction set only, Armv8.2-SHA adds Advanced SIMD instructions that support:

- SHA2-512 (SHA512).
- SHA3.

Implementation of ARMv8.2-SHA requires implementation of the Armv8.0 Cryptographic Extension SHA-1 and SHA256 functionality.

The **ID_AA64ISAR0_EL1.{SHA2, SHA3}** fields identify the presence of Armv8.2-SHA.

For more information see *Armv8.2-SHA, SHA2-512 and SHA3* on page C3-248.

**ARMv8.2-SM, SM3 and SM4 functionality**

In the A64 instruction set only, Armv8.2-SM adds Advanced SIMD instructions that support the Chinese cryptography algorithms SM3 and SM4.

Implementation of ARMv8.2-SM is independent of the implementation of any SHA functionality.

The **ID_AA64ISAR0_EL1.{SM3, SM4}** fields identify the presence of ARMv8.2-SM.

--- **Note**

This means Armv8.2-SM can be implemented without any other Cryptographic Extension features.

For more information see *Armv8.2-SM, SM3 and SM4* on page C3-249.
A2.4 The Armv8.1 architecture extension

The Armv8.1 architecture extension adds both architectural features and architectural requirements, see:

- Architectural features added by Armv8.1.
- Additional requirements of Armv8.1 on page A2-69.

A2.4.1 Architectural features added by Armv8.1

An implementation of the Armv8.1 extension must include all of the features that this section describes as mandatory. Such an implementation, when combined with the additional requirements of Armv8.1, is also called an implementation of the Armv8.1 architecture.

The Armv8.1 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

**ARMv8.1-LSE, Armv8.1 Large System Extensions**

ARMv8.1-LSE introduces a set of atomic instructions:

- Compare and Swap instructions, CAS and CASP.
- Atomic memory operation instructions, LD<OP> and ST<OP>, where <OP> is one of ADD, CLR, EOR, SET, SMAX, SMIN, UMAX, and UMIN.
- Swap instruction, SWP.

These instructions are only added to the A64 instruction set.

This feature is mandatory in Armv8.1 implementations.

Implementations of Armv8.1-VHE require the implementation of Armv8.1-LSE.

The ID_AA64ISAR0_EL1.Atomic field identifies the presence of ARMv8.1-LSE.

For more information, see:

- Compare and Swap on page C3-209.
- Atomic memory operations on page C3-210.
- Swap on page C3-212.

**ARMv8.1-RDMA, Armv8.1 Advanced SIMD instructions**

ARMv8.1-RDMA introduces Rounding Double Multiply Add/Subtract Advanced SIMD instructions. For more information, see:

For the A64 instruction set

- SQRDMLAH (by element) on page C7-2009.
- SQRDMLAH (vector) on page C7-2012.
- SQRDMLSH (by element) on page C7-2014.

For the T32 and A32 instruction sets

- VQRDMLAH on page F6-5247.
- VQRDMLSH on page F6-5251.

This feature is mandatory in Armv8.1 implementations.

The following fields identify the presence of Armv8.1-RDMA:

- ID_AA64ISAR0_EL1.RDM.
- ID_ISAR5_EL1.RDM.
- ID_ISAR5.RDM.

**ARMv8.1-LOR, Limited ordering regions**

Limited ordering regions allow large systems to perform special load-acquire and store-release instructions that provide order between the memory accesses to a region of the PA map as observed by a limited set of observers.

This feature is supported in AArch64 state only.
This feature is mandatory in Armv8.1 implementations.
The ID_AA64MMFR1_EL1.RO field identifies the support for ARMv8.1-LOR.
For more information, see:
• Limited ordering regions on page B2-131.

ARMv8.1-HPD, Hierarchical permission disables
ARMv8.1-HPD introduces the facility to disable the hierarchical attributes, APTable, PXNTable, and UXNTable, in the translation tables. This disable has no effect on the NSTable bit.
This feature is mandatory in Armv8.1 implementations.
This feature is added only to the VMSAv8-64 translation regimes. Armv8.2 extends this to the AArch32 translation regimes, see ARMv8.2-AA32HPD.
The ID_AA64MMFR1_EL1.HPDS field identifies the support for ARMv8.1-HPD.

ARMv8.1-TTHM, Hardware management of the Access flag and dirty state
In Armv8.0, all updates to the translation tables are performed by software. From Armv8.1, for the VMSAv8-64 translation regimes only, hardware can perform updates to the translation tables in two contexts:
• Hardware management of the Access flag.
• Hardware management of dirty state, with updates to a dirty state in the translation tables.
The dirty state is introduced in Armv8.1.
Hardware management of dirty state can only be enabled when hardware management of the Access flag is also enabled.
This feature is optional in Armv8.1 implementations. It is IMPLEMENTATION DEFINED whether this is implemented.
The ID_AA64MMFR1_EL1.HAFDBS field identifies the support for ARMv8.1-TTHM.
For more information, see:
• The dirty state on page D5-2589.
• Hardware management of the Access flag and dirty state on page D5-2590.

ARMv8.1-PAN, Privileged access never
ARMv8.1-PAN adds a bit to PSTATE. When the value of this PAN state bit is 1, any privileged data access from EL1, or EL2 when HCR_EL2.E2H is 1, to a virtual memory address that is accessible at EL0, generates a Permission fault.
This feature is mandatory in Armv8.1 implementations.
This feature is supported in AArch64 and AArch32 states.
The following fields identify the support for ARMv8.1-PAN:
• ID_AA64MMFR1_EL1.PAN.
• ID_MMFR3_EL1.PAN.
• ID_MMFR3.PAN.
For more information, see:
• About PSTATE.PAN on page D5-2578.
• About the PAN bit on page G5-5769.

ARMv8.1-VMID16, 16-bit VMID
In an Armv8.1 implementation, when EL2 is using AArch64, the VMID size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits.
This feature is optional in Armv8.1 implementations. It is IMPLEMENTATION DEFINED whether this is implemented.
When implemented, this feature is supported only when EL2 is using AArch64.
The ID_AA64MMFR1_EL1.VMIDBits field identifies the supported VMID size.
ARMv8.1-VHE, Virtualization Host Extensions

Armv8.1 introduces the Virtualization Host Extensions (VHE) that provide enhanced support for Type 2 hypervisors in Non-secure state.

This feature is mandatory in Armv8.1 implementations.

An implementation that includes ARMv8.1-VHE requires ARMv8.1-LSE to be implemented.

The ID_AA64MMFR1_EL1.VH field identifies the support for ARMv8.1-VHE.

The following fields indicate the presence of the Virtualization Host Extensions for debug, including the changes for the PC Sample-based Profiling Extension and the Performance Monitors Extension:

- ID_AA64DFR0_EL1.DebugVer.
- ID_DFR0_EL1.{CopSDbg, CopDbg}.

For more information, see:

- Virtualization Host Extensions on page D5-2609.

ARMv8.1-PMU, Armv8.1 PMU Extension

Armv8.1 makes the following enhancements to the Performance Monitors Extension:

- The event number space is extended to 16 bits to allow additional IMPLEMENTATION DEFINED event types, and the reserved space for future additions to the architecturally-defined event types is extended.
- The HPMD bit is added to MDCR_EL2. This bit disables event counting at EL2.
- The STALL_FRONTEND and STALL_BACKEND events are required to be implemented.

For more information, see Required events on page D7-2720.

The Performance Monitors Extension is an OPTIONAL feature, but if it is implemented, an Armv8.1 implementation must include ARMv8.1-PMU.

The following fields identify the ARMv8.1-PMU:

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.

A2.4.2 Additional requirements of Armv8.1

The Armv8.1 architecture includes some mandatory changes that are not associated with a feature. These are:

Changes to CRC32 instructions

- All implementations of the Armv8.1 architecture are required to implement the CRC32* instructions. These are optional in Armv8.0.

The following fields identify the support for the CRC32* instructions:

- ID_AA64ISAR0_EL1.CRC32.
- ID_ISAR5_EL1.CRC32.
- ID_ISAR5.CRC32.

An implementation of the Armv8.1 extension must comply with all of the additional requirements. Such an implementation, when combined with the mandatory architectural features of Armv8.1, is also called an implementation of the Armv8.1 architecture.
A2.5 The Armv8.2 architecture extension

The Armv8.2 architecture extension adds both architectural features and architectural requirements, see:

- Architectural features added by Armv8.2.
- Additional requirements of Armv8.2 on page A2-76.
- Features added to the Armv8.2 extension in later releases on page A2-76.

The Armv8.2 architecture extension also adds functionality to the Cryptographic Extension, see Armv8.2 extensions to the Cryptographic Extension on page A2-66.

A2.5.1 Architectural features added by Armv82

An implementation of the Armv8.2 extension must include all of the features that this section describes as mandatory. Such an implementation, when combined with the additional requirements of Armv8.2, is also called an implementation of the Armv8.2 architecture.

The Armv8.2 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

**ARMv8.2-A64ISA, Armv8.2 changes to the A64 ISA**

ARMv8.2-A64ISA adds the BFC instruction to the A64 instruction set as an alias of BFM. It also requires that the BFC instruction and the A64 pseudo-instruction REV64 are implemented by assemblers.

Note

- In Armv8.0 and Armv8.1, the A64 pseudo-instruction REV64 is optional.
- Because this feature relates to support for an instruction alias and for a pseudo-instruction, there are no corresponding feature ID register fields.

This change to the instruction set and assembler requirements is mandatory in an Armv8.2 implementation.

For more information, see:

- **BFC** on page C6-800.
- **REV64** on page C6-1155.

**ARMv8.2-ATS1E1, AT S1E1R and AT S1E1W instruction variants, taking account of PSTATE.PAN**

ARMv8.2-ATS1E1 adds variants of the AArch64 AT S1E1R and AT S1E1W instructions and the AArch32 ATS1CPR and ATS1CPW instructions. These instructions factor in the PSTATE.PAN bit when determining whether or not the location will generate a permission fault for a privileged access, as is reported in the PAR. For more information, see:

For the AArch64 System instructions

- **AT S1E1RP, Address Translate Stage 1 EL1 Read PAN** on page C5-533.
- **AT S1E1WP, Address Translate Stage 1 EL1 Write PAN** on page C5-537.

For the AArch32 System instructions

- **ATS1CPRP, Address Translate Stage 1 Current state PL1 Read PAN** on page G8-5930.
- **ATS1CPWP, Address Translate Stage 1 Current state PL1 Write PAN** on page G8-5932.

This feature is mandatory in Armv8.2 implementations.

These instructions are added to the A64 and A32/T32 instruction sets.

The following fields identify the presence of ARMv8.2-ATS1E1:

- **ID_AA64MMFR1_EL1.PAN**.
- **ID_MMFR3_EL1.PAN**.
- **ID_MMFR3.PAN**.
For more information, see:
- Address translation instructions on page D5-2561.
- ATSIC**, Address translation stage 1, current security state on page G5-5842.
- Encoding and availability of the address translation instructions on page G5-5843.

**ARMv8.2-FP16, Half-precision floating-point data processing**

ARMv8.2-FP16 supports:
- Half-precision data-processing instructions for Advanced SIMD and floating-point in both AArch64 and AArch32 states.
- The FPCR.FZ16 and FPSCR.FZ16 bits, that enable a Flush-to-zero mode for half-precision data-processing instructions.

This feature is optional in Armv8.2 implementations, unless The Scalable Vector Extension (SVE) is implemented, in which case ARMv8.2-FP16 is mandatory. When this feature is implemented it is implemented in both Advanced SIMD and floating-point, and in AArch64 and AArch32 states.

The following fields identify the presence of ARMv8.2-FP16:
- \texttt{ID\_AA64PFR0\_EL1.\{FP, AdvSIMD\}}.
- \texttt{MVFR1\_EL1.\{FHP, SIMDHP\}}.
- \texttt{MVFR1.\{FHP, SIMDHP\}}.

For more information, see:
- Modified immediate constants in A64 instructions on page C2-186.

**ARMv8.2-DotProd, SIMD Dot Product**

ARMv8.2-DotProd provides instructions to perform the dot product of two 32-bit vectors, accumulating the result in a third 32-bit vector. This can be performed using signed or unsigned arithmetic.

This feature is optional in Armv8.2 implementations, and mandatory in Armv8.4 implementations. These instructions are added to the A64 and A32/T32 instruction sets.

The following fields identify the presence of ARMv8.2-DotProd:
- \texttt{ID\_AA64ISAR0\_EL1.DP}.
- \texttt{ID\_ISAR6\_EL1.DP}.
- \texttt{ID\_ISAR6.DP}.

For more information, see:
- SIMD dot product on page C3-246.
- Advanced SIMD dot product instructions on page F1-3897.

**ARMv8.2-FHM, Floating-point multiplication variant**

ARMv8.2-FHM adds floating-point multiplication instructions. These instructions are added to the A64 and A32/T32 instruction sets.

This feature is optional in Armv8.2 implementations, and can only be implemented when ARMv8.2-FP16 is implemented. This feature is mandatory in Armv8.4 implementations when ARMv8.2-FP16 is implemented. This feature is not implemented in Armv8.4 implementations when ARMv8.2-FP16 is not implemented.

The following fields identify the presence of ARMv8.2-FHM:
- \texttt{ID\_AA64ISAR0\_EL1.FHM}.
- \texttt{ID\_ISAR6\_EL1.FHM}.
- \texttt{ID\_ISAR6.FHM}.

For more information, see:
- SIMD arithmetic on page C3-234.
- SIMD by element arithmetic on page C3-240.
ARMv8.2-LSMAOC, Load/Store Multiple atomicity and ordering controls

ARMv8.2-LSMAOC adds controls that disable legacy behavior of AArch32 Load Multiple and Store Multiple instructions, and provide a trap of one aspect of this legacy behavior.

Implementation of ARMv8.2-LSMAOC is optional. When implemented it provides:

- LSMAOE fields in the SCTLR_EL1, SCTLR_EL2, HSCTLR, and SCTLR registers. These fields can have the following effects on the behavior of AArch32 Load Multiple and Store Multiple instructions:
  - An interrupt can be taken between two memory accesses made by a single Load Multiple or Store Multiple instruction.
  - The memory accesses made by a single Load Multiple or Store Multiple instruction to Device memory with the non-Reordering attribute can be reordered.

- nTLSMD fields in the SCTLR_EL1, SCTLR_EL2, HSCTLR, and SCTLR registers. These fields can cause an access to Device-nGRE, Device-nGnRE, or Device-nGnRnE memory by an AArch32 Load Multiple and Store Multiple instruction to generate an Alignment fault.

Note

Armv8.2 deprecates software dependence on the legacy behavior of AArch32 Load Multiple and Store Multiple instructions, and these fields disable this behavior.

The following fields identify the support for ARMv8.2-LSMAOC:

- ID_AA64MMFR2_EL1.LSM
- ID_MMFR4_EL1.LSM
- ID_MMFR4.LSM.

For more information, see the register field descriptions and:

- Generation of Alignment faults by Load/store multiple accesses to Device memory on page E2-3835.
- Multi-register loads and stores that access Device memory on page E2-3848.
- Taking an interrupt or other exception during a multiple-register load or store on page G1-5535.

ARMv8.2-UAO, PSTATE override of Unprivileged Load/Store

Armv8.2 adds a bit to PSTATE. When the value of PSTATE.UAO is 1, and when executed at EL1 or at EL2 with HCR_EL2.E2H, TGE \( \{1, 1\} \), the memory accesses made by the Load/Store unprivileged instructions behave as if they were made by the Load/Store register instructions. See Load/Store unprivileged on page C3-201 and Load/Store register on page C3-197.

This feature is mandatory in Armv8.2 implementations.

This feature is supported in AArch64 state only.

The ID_AA64MMFR2_EL1.UAO field identifies the support for ARMv8.2-UAO.

For more information, see About PSTATE.UAO on page D5-2579.

ARMv8.2-DCPoP, Data cache clean to Point of Persistence

ARMv8.2-DCPoP introduces a mechanism to identify and manage persistent memory locations in a shared memory hierarchy, including adding the DC CVAP instruction.

This feature is mandatory in Armv8.2 implementations.

This feature is supported in AArch64 state only.

The ID_AA64ISAR1_EL1.DPB field identifies the support for ARMv8.2-DCPoP.

For more information about ARMv8.2-DCPoP, see Memory hierarchy on page B2-133.
ARMv8.2-VPIPT, VMID-aware PIPT instruction cache

ARMv8.2-VPIPT supports a instruction cache type, described as the VMID-aware PIPT (VPIPT) instruction cache.

--- Note ---
ARMv8.2 adds VPIPT to the set of supported cache types, meaning an Armv8.2 implementation is permitted to implement VPIPT caches, but is not required to do so.

This feature is supported in AArch64 and AArch32 states.
The CTR_EL0.L1Ip and CTR.L1Ip fields identify the support for ARMv8.2-VPIPT.
For more information, see:
• VPIPT (VMID-aware PIPT) instruction caches on page D5-2656.
• VPIPT (VMID-aware PIPT) instruction caches on page G5-5808.

ARMv8.2-AA32HPD, AArch32 Hierarchical permission disables

ARMv8.1-HPD introduced the ability to disable the hierarchical attributes, APTable, PXNTable, and UXNTable, in the VMSAv8-64 translation regimes. ARMv8.2-AA32HPD extends this functionality to the VMSAv8-32 translation regimes when those regimes are using the Long descriptor translation table format.

This feature is optional in Armv8.2 implementations. It is IMPLEMENTATION DEFINED whether this is implemented.
The ID_MMFR4_EL1.HPDS and ID MMFR4.HPDS fields identify the support for ARMv8.2-AA32HPD.
For more information, see Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5750.

ARMv8.2-TTPBHA, Translation table page-based hardware attributes

Armv8.2 provides a mechanism to allow operating systems or hypervisors to make up to four bits of translation table final-level descriptors available for IMPLEMENTATION DEFINED hardware use.

This functionality is available for all translation regimes in AArch64 state and for stages of translation in AArch32 state that use the Long descriptor translation table format.

ARMv8.2-TTPBHA is optional in Armv8.2 implementations, but implementation of ARMv8.2-TTPBHA requires implementation of both:
• ARMv8.1-HPD.
• ARMv8.2-AA32HPD, if any Exception level higher than EL0 can use AArch32.

--- Note ---
For stage 1 translations, page-based hardware attributes can only be used for a stage of translation for which the Hierarchical permission disables field has a value of 1.

The following fields identify the support for ARMv8.2-TTPBHA:
• ID_AA64MMFR1_EL1.HPDS
• ID MMFR4_EL1.HPDS
• ID MMFR4.HPDS.

For more information, see:
• Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D5-2570.
• Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors on page G5-5750.
ARMv8.2-LPA, Large PA and IPA support

ARMv8.2-LPA:
- Allows a larger intermediate physical address (IPA) and PA space of up to 52 bits when using the 64KB translation granule.
- Allows a level 1 block size where the block covers a 4TB address range for the 64KB translation granule if the implementation support 52 bits of PA.

This is an optional feature in Armv8.2 implementations. It is IMPLEMENTATION DEFINED whether it is implemented.

This feature is supported in AArch64 state only.

The ID_AA64MMFR0_EL1.PARange field identifies the support for ARMv8.2-LPA.

For more information about ARMv8.2-LPA, see:
- VMSA address types and address spaces on page D5-2505.
- Address size configuration on page D5-2519.
- Extending addressing above 48 bits on page D5-2524.
- VMSA v8-64 translation table level 0, level 1, and level 2 descriptor formats on page D5-2565.
- Armv8 translation table level 3 descriptor formats on page D5-2568.

ARMv8.2-LVA, Large VA support

ARMv8.2-LVA supports a larger VA space for each translation table base register of up to 52 bits when using the 64KB translation granule.

This feature is supported in AArch64 state only.

This is an optional feature in Armv8.2 implementations. It is IMPLEMENTATION DEFINED whether it is implemented.

If ARMv8.2-LVA is implemented, then any implemented trace macrocell must be at least ETMv4.2.

The ID_AA64MMFR2_EL1.VARange field identifies the support for ARMv8.2-LVA.

For more information about ARMv8.2-LVA, see:
- VMSA address types and address spaces on page D5-2505.
- Address size configuration on page D5-2519.
- Extending addressing above 48 bits on page D5-2524.
- VMSA v8-64 translation table level 0, level 1, and level 2 descriptor formats on page D5-2565.
- Armv8 translation table level 3 descriptor formats on page D5-2568.

ARMv8.2-TTCNP, Translation table Common not private translations

ARMv8.2-TTCNP permits multiple PEs in the same Inner Shareable domain to use the same translation tables for a given stage of address translation.

This feature is mandatory in Armv8.2 implementations.

This facility is available for all VMSA v8-64 translation regimes and for VMSA v8-32 translation stages that use the Long descriptor translation table format.

The following fields identify the support for ARMv8.2-TTCNP:
- ID_AA64MMFR2_EL1.CnP
- ID_MMFR4_EL1.CnP
- ID_MMFR4.CnP

For more information, see:
- Common not private translations on page D5-2633.
- Common not private translations in VMSA v8-32 on page G5-5797.
ARMv8.2-TTS2UXN, Translation table stage 2 Unprivileged Execute-never

ARMv8.2-TTS2UXN extends the stage 2 translation table access permissions to provide control of whether memory is executable at EL0 independent of whether it is executable at EL1.

This feature is mandatory in Armv8.2 implementations.

This facility is available for stage 2 translation stages in VMSAv8-64 and VMSAv8-32.

The following fields identify the support for ARMv8.2-TTS2UXN:

- ID_AA64MMFR1_EL1.XNX.
- ID_MMFR4_EL1.XNX.
- ID_MMFR4.XNX.

For more information, see:

- Access permissions for instruction execution on page D5-2583.
- Access permissions for instruction execution on page G5-5770.

ARMv8.2-Debug, Armv8.2 Debug

ARMv8.2-Debug covers a selection of mandatory changes, including:

- If the Core power domain is powered up and DoubleLockStatus() == TRUE, EDPRSR.{DLK,SPD,PU} is only permitted to read {UNKNOWN, 0, 0}.
- The definition of Exception Catch debug events is extended to include reset entry.
- All CONSTRAINED UNPREDICTABLE cases that generate Exception Catch debug events are removed.
- Controls are added to EDECCR to control Exception Catch debug event generation on exception return.
- All IMPLEMENTATION DEFINED control of external debug accesses to OSLAR_EL1 is removed.
- ExternalSecureNoninvasiveDebugEnabled() cannot override software controls of counting attributable events in Secure state.

If ARMv8.2-Debug is implemented, ARMv8.0-DoubleLock is OPTIONAL.

The fields that identify the support for ARMv8.2-Debug are:

- ID_AA64DFR0_EL1.DebugVer and DBGDIDR.Version.
- ID_DFR0_EL1.{CopSDbg, CopDbg} and ID_DFR0.{CopSDbg, CopDbg}.
- EDDEVARCH.ARCHID.

For more information, see:

- Exception Catch debug events from Armv8.2 on page H3-6759.
- EDPRSR.{DLK, SPD, PU} and the Core power domain on page H6-6813.
- Interaction with EL3 on page D7-2679.
- External access disabled on page H8-6835.

ARMv8.2-PCSample, PC Sample-based Profiling

In Armv8.2, the control and implementation of the OPTIONAL PC Sample-based Profiling extension is moved from ED*SR Debug registers to PM*SR registers in the Performance Monitors address space. See Chapter H7 The PC Sample-based Profiling Extension.

This is an optional feature in Armv8.2 implementations. It is IMPLEMENTATION DEFINED whether it is implemented.

The following fields identify the support for ARMv8.2-PCSample:

- EDDEVID.PCSample.
- DBGDEVID.PCSample.
- EDDEVID1.PCSROffset.
- DBGDEVID1.PCSROffset.
- PMDEVID.PCSample.
ARMv8.2-IESB, Implicit error synchronization event

ARMv8.2-IESB adds an implicit error synchronization event at exception entry and return, controlled by the added SCTLR_ELx.IESB fields. An IESB field is added to the ESR_ELx syndrome registers.

The implicit error synchronization events affect the same synchronizable asynchronous events that are synchronized by the ESB instruction, see The Reliability, Availability, and Serviceability Extension (RAS Extension) on page A2-90.

This feature is optional in Armv8.2 implementations.

This feature is supported in AArch64 state only.

The ID_AA64MMFR2_EL1.IESB field identifies the support for ARMv8.2-IESB.

For more information, see the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the Armv8-A architecture profile.

Extensions to the Arm Cryptographic Extensions

See the description of the ARMv8.2-SHA and ARMv8.2-SM features in Armv8.2 extensions to the Cryptographic Extension on page A2-66.

A2.5.2 Additional requirements of Armv8.2

The Armv8.2 architecture includes some mandatory changes that are not associated with a feature. These are:

Changes to ACTLR2 and HCTLR2 registers

In AArch32 state, the ACTLR2 and HACTLR2 registers become mandatory.

Implementation of RAS Extension

The RAS Extension must be implemented, see The Reliability, Availability, and Serviceability Extension (RAS Extension) on page A2-90.

An implementation of the Armv8.2 extension must comply with all of the additional requirements. Such an implementation, when combined with the mandatory architectural features of Armv8.2, is also called an implementation of the Armv8.2 architecture.

If PMUv3 is implemented, the feature ARMv8.4-PMU is optional in Armv8.2 implementations.

A2.5.3 Features added to the Armv8.2 extension in later releases

ARMv8.2-EVT, Armv8.2 Enhanced Virtualization Traps

ARMv8.2-EVT introduces additional traps for EL1 and EL0 Cache controls. These traps are independent of existing controls.

This feature is supported in AArch64 and AArch32 states.

This feature is optional in Armv8.2 implementations and is mandatory in Armv8.5.

ID_AA64MMFR2_EL1.EVT identifies the support for the AArch64 traps controls.

ID_MMFR4_EL1.EVT and ID_MMFR4.EVT identify support for the AArch32 traps.

For more information, see:

• HCR_EL2. {TTLBIS, TTLBOS, TICAB, TOCU, TID4}.
• HCR2. {TTLBIS, TICAB, TOCU, TID4}.

ARMv8.2-DCCVADP, Armv8.2 Cache clean to Point of Deep Persistence

ARMv8.2-DCCVADP allows two levels of cache clean to the Point of Persistence by:

• Redefining Point of Persistence, which changes the scope of DC CVAP.
• Defining a Point of Deep Persistence.
• Adding the DC CVADP System instruction.

This feature is supported in AArch64 state only.
This feature is optional in Armv8.2 implementations, and is mandatory in Armv8.5 implementations.

The ID_AA64ISAR1_EL1.DPB identifies the support for ARMv8.2-DCCVADP.

For further information, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page D4-2479.
A2.6 The Armv8.3 architecture extension

The Armv8.3 architecture extension adds both architectural features and additional requirements, see:

- Architectural features added by Armv8.3.
- Additional requirements of Armv8.3 on page A2-80.
- Features added to the Armv8.3 extension in later releases on page A2-80.

A2.6.1 Architectural features added by Armv8.3

An implementation of the Armv8.3 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.3 architecture.

The Armv8.3 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

ARMv8.3-CompNum, SIMD complex number support

ARMv8.3-CompNum introduces instructions for floating-point multiplication and addition of complex numbers.

These instructions are added to the A64 and A32/T32 instruction sets.

This feature is mandatory in Armv8.3 implementations.

The half-precision versions of these instructions are implemented only if ARMv8.2-FP16 is implemented. Otherwise they are UNDEFINED.

The fields that identify the presence of ARMv8.3-CompNum are:

- ID_AA64ISAR1_EL1.FCMA.
- ID_ISAR5_EL1.VCMA.
- ID_ISAR5.VCMA.

For more information, see:

- SIMD complex number arithmetic on page C3-246.
- Advanced SIMD complex number arithmetic instructions on page F1-3897.

ARMv8.3-JSConv, Javascript conversion instructions

ARMv8.3-JSConv introduces instructions that perform a conversion from a double-precision floating point value to a signed 32-bit integer, with rounding to zero. For more information, see:

For the A64 instruction set

- FJCVTZS on page C7-1584.

For the A32/T32 instruction set

- VJCVT on page F6-5015.

These instructions are added to the A64 and A32/T32 instruction sets.

The feature is mandatory in Armv8.3 implementations.

The fields that identify the presence of ARMv8.3-JSConv are:

- ID_AA64ISAR1_EL1.JSCVT
- ID_ISAR6_EL1.JSCVT
- ID_ISAR6.JSCVT.

For more information, see:

- Floating-point conversion on page C3-229.
- About the A64 SIMD and floating-point instructions on page C7-1372.
- Advanced SIMD and floating-point instructions on page E1-3794.
- Floating-point data-processing instructions on page F1-3901.

ARMv8.3-RCPC, Weaker release consistency
ARMv8.3-RCPC introduces three instructions to support the weaker *Release Consistency processor consistent* (RCpc) model that enables the reordering of a Store-Release followed by a Load-Acquire to a different address:

- **LDAPR** on page C6-920.
- **LDAPRB** on page C6-922.
- **LDAPRH** on page C6-924.

These instructions are added to the A64 instruction set.

The feature is mandatory in Armv8.3 implementations.

The **ID_AA64ISAR1_EL1.LRCPC** field identifies the presence of ARMv8.3-RCPC.

For more information, see:
- **Load-Acquire/Store-Release** on page C3-202.

**ARMv8.3-NV, Nested Virtualization**

ARMv8.3-NV provides support for a Guest Hypervisor to run in Non-secure EL1 and ensures that the Guest Hypervisor is unaware that it is running at that Exception level. A Guest Hypervisor is supported regardless of the value of **HCR_EL2.E2H**.

This feature is supported in AArch64 state only. The feature is optional in Armv8.3 implementations. This feature must be implemented if **ARMv8.4-NV** is implemented.

The **ID_AA64MMFR2_EL1.NV** field identifies the support for ARMv8.3-NV.

For more information, see **Nested virtualization** on page D5-2615.

**ARMv8.3-CCIDX, Cache extended number of sets**

ARMv8.3-CCIDX introduces the following registers to allow caches to be described with greater numbers of sets and greater associativity:

- A 64-bit format of **CCSIDR_EL1**.
- **CCSIDR2_EL1**.
- **CCSIDR2**.

This feature is supported in AArch64 and AArch32 states. This feature is optional in Armv8.3 implementations.

The following fields identify the support for ARMv8.3-CCIDX:

- **ID_AA64MMFR2_EL1.CCIDX**
- **ID_MMFR4_EL1.CCIDX**.
- **ID_MMFR4.CCIDX**.

For more information, see:
- **Possible formats of the Cache Size Identification Register, CCSIDR_EL1** on page D4-2473.
- **Possible formats of the Cache Size Identification Registers, CCSIDR and CCSIDR2** on page G4-5689.

**ARMv8.3-PAuth, Pointer Authentication**

ARMv8.3-PAuth adds functionality that supports address authentication of the contents of a register before that register is used as the target of an indirect branch, or as a load.

This feature is supported only in AArch64 state. This feature is mandatory in Armv8.3 implementations.

The fields **ID_AA64ISAR1_EL1.{GPI, GPA, API, APA}** identify the presence for ARMv8.3-PAuth.

For more information, see **Pointer authentication in AArch64 state** on page D5-2508.
A2.6.2 Additional requirements of Armv8.3

If PMUv3 is implemented, the feature ARMv8.4-PMU is optional in Armv8.3 implementations.

A2.6.3 Features added to the Armv8.3 extension in later releases

ARMv8.3-SPE, Armv8.3 Statistical Profiling Extensions

The ARMv8.3-SPE adds an Alignment Flag in the Events packet and filtering on this event using PMSEVFR_EL1, together with support for the profiling of Scalable Vector Extension operations. This feature is only supported in AArch64.

This feature is optional in Armv8.3 implementations. When ARMv8.3-SPE is implemented the Statistical Profiling Extension must be implemented.

The fields in ID_AA64DFR0_EL1.PMSVer identify the support for ARMv8.3-SPE.

For more information see Chapter D9 The Statistical Profiling Extension and Chapter D10 Statistical Profiling Extension Sample Record Specification.

ARMv8.3-DoPD, Armv8.3 Debug over Powerdown

The ARMv8.3-DoPD provides a debug programmers’ model where all debug and PMU registers are in the Core power domain, all CTI registers are in the Debug power domain. Power control is provided by a CoreSight Granular Power requestor (GPR) component.

When the OPTIONAL powerup mechanism is implemented and this feature is implemented, the debugger makes power control requests for the Core power domain using a CoreSight Class 0x9 ROM Table block, instead of using EDRCR.COREPURQ. EDRCR.COREPURQ is not implemented. Refer to the ARM® CoreSight Architecture Specification for more information.

This feature is optional in Armv8.3 implementations.

When ARMv8.3-DoPD is implemented:

- ARMv8.0-DoubleLock is not implemented.
- ARMv8.2-Debug must be implemented.
- If an ETMv4 PE Trace Unit is implemented, the ETM must implement:
  - ETMv4.5 or later.
  - The Unified Power Domain Model.

The fields that identify the presence of ARMv8.3-DoPD are:

- EDDEVID.DebugPower.
- CTIDEV ARCH.REVISION.

For more information see Chapter H6 Debug Reset and Powerdown Support.
A2.7 The Armv8.4 architecture extension

The Armv8.4 architecture extension adds architectural features, see Architectural features added by Armv8.4. It also adds features to earlier architecture extensions, see Features added to earlier extensions on page A2-85.

A2.7.1 Architectural features added by Armv8.4

An implementation of the Armv8.4 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.4 architecture.

The Armv8.4 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

ARMv8.4-DIT, Data Independent Timing instructions
ARMv8.4-DIT provides independent timing for data processing instructions with the addition of the PSTATE.DIT and CPSR.DIT fields.
This feature is supported in AArch64 and AArch32 states.
This feature is mandatory in Armv8.4 implementations.
The following fields identify the support for ARMv8.4-DIT:
- ID_AA64PFR0_EL1.DIT.
- ID_PFR0_EL1.DIT.
- ID_PFR0.DIT.
For more information, see:
- About PSTATE.DIT on page B1-105.
- About the DIT bit on page E1-3793.

ARMv8.4-CondM, Condition flag Manipulation
ARMv8.4-CondM provides instructions which manipulate the PSTATE.{N,Z,C,V} flags.
These instructions are added to the A64 instruction set only.
This feature is mandatory in Armv8.4 implementations.
The ID_AA64ISAR0_EL1.TS field identifies the presence of ARMv8.4-CondM.
For more information, see Flag manipulation instructions on page C3-221.

ARMv8.4-RCPC, Armv8.4 enhancements to weaker release consistency
ARMv8.4-RCPC provides versions of the LDAPR and STLR with a 9-bit unscaled signed immediate offset.
These instructions are added to the A64 instruction set only.
This feature is mandatory in Armv8.4 implementations.
The ID_AA64ISAR1_EL1.LRCPC field identifies the presence of ARMv8.4-RCPC.
For more information, see:
- Changes to single-copy atomicity in Armv8.4 on page B2-111.
- Non-exclusive Load-Acquire and Store-Release instructions on page C3-203.
- A64 instructions that are changed in Debug state on page H2-6715.

ARMv8.4-LSE, Large System Extensions
ARMv8.4-LSE introduces changes to single-copy atomicity requirements for loads and stores, and changes to alignment requirements for loads and stores.
This feature is supported in AArch64 state only.
This feature is mandatory in Armv8.4 implementations.
The ID_AA64MMFR2_EL1.AT field identifies the support for ARMv8.4-LSE.
For more information, see:
- Requirements for single-copy atomicity on page B2-110.
ARMv8.4-TLBI, TLB maintenance and TLB range instructions

ARMv8.4-TLBI provides TLBI maintenance instructions that extend to the Outer Shareable domain and TLBI invalidation instructions that apply to a range of input addresses.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations.

The field ID_AA64ISAR0_EL1.TLB identifies the presence of ARMv8.4-TLBI.

For more information, see:
- TLB maintenance instruction syntax on page D5-2641.
- TLB range maintenance instructions on page D5-2649.

ARMv8.4-TTL, Translation Table Level

ARMv8.4-TTL provides the TTL field to indicate the level of translation table walk holding the leaf entry for the address that is being invalidated. This field is provided in all TLB maintenance instructions that take a VA or an IPA argument.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations.

The field ID_AA64MMFR2_EL1.TTL identifies the presence of ARMv8.4-TTL.

For more information, see:
- TLB maintenance instruction syntax on page D5-2641.
- TLB range maintenance instructions on page D5-2649.

ARMv8.4-S2FWB, Stage 2 forced Write-Back

ARMv8.4-S2FWB reduces the requirement of additional cache maintenance instructions in systems where the data Cacheability attributes used by the Guest operating system are different from those expected by the Hypervisor.

This feature is supported in AArch64 state.

This feature is mandatory in Armv8.4 implementations.

The ID_AA64MMFR2_EL1.FWB field identifies the support for ARMv8.4-S2FWB.

For more information, see:
- Memory region attributes on page D5-2599.
- The stage 2 memory region attributes, EL1&0 translation regime on page D5-2601.

ARMv8.4-TTST, Small Translation tables

ARMv8.4-TTST relaxes the lower limit on the size of translation tables, by increasing the maximum permitted value of the T1SZ and T0SZ fields in TCR_EL1, TCR_EL2, TCR_EL3, VTCR_EL2 and VSTCR_EL2.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations or if ARMv8.4-SecEL2 is implemented.

This feature is optional if ARMv8.4-SecEL2 is not implemented.

The ID_AA64MMFR2_EL1.ST field identifies the support for ARMv8.4-TTST.

For more information, see:
- Input address size on page D5-2521.
- Overview of the VMSAv8-64 address translation stages on page D5-2536.

ARMv8.4-TTRem, Change in size of translation table mappings

ARMv8.4-TTRem provides support to identify the requirements of hardware to have break-before-make sequences when changing between block size for a translation.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations.
The ID_AA64MMFR2_EL1.BBM field identifies the support for ARMv8.4-TTRem.
For more information, see:
- Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D5-2570.
- Support levels for changing block size on page D5-2640.

**ARMv8.4-SecEL2, Secure EL2**
ARMv8.4-SecEL2 permits EL2 to be implemented in Secure state. When Secure EL2 is enabled, a translation regime is introduced that follows the same format as the other Secure translation regimes.
This feature is not supported if EL2 is using AArch32.
This feature is mandatory in Armv8.4 implementations which implement both EL2 and Secure state.
The ID_AA64PFR0_EL1.SEL2 field identifies the support for ARMv8.4-SecEL2.
For more information, see:
- Virtualization on page D1-2274.
- The VMSAv8-64 address translation system on page D5-2512.

**ARMv8.4-NV, Enhanced support for Nested Virtualization**
ARMv8.4 supports nested virtualization by redirecting register accesses that would be trapped to EL1 and EL2 to access memory instead. The address of the memory access depends on information held in introduced register, VNCR_EL2.
This feature is supported in AArch64 state only.
This feature is optional in Armv8.4 implementations.
The ID_AA64MMFR2_EL1.NV field identifies the support for ARMv8.4-NV.
For more information, see Enhanced support for nested virtualization on page D5-2617.

**ARMv8.4-IDST, ID Space Trap handling**
ARMv8.4-IDST causes all AArch64 read accesses to the feature ID register space when exceptions are generated, to be reported in ESR_ELx using the EC code 0x18.
This feature is supported in AArch64 state only.
This feature is mandatory in Armv8.4 implementations.
The ID_AA64MMFR2_EL1.IDS field identifies the support for ARMv8.4-IDST.

**ARMv8.4-CNTSC, Generic Counter Scaling**
ARMv8.4-CNTSC adds a scaling register to the memory-mapped counter module that allows the frequency of the counter that is generated to be scaled from the basic frequency reported in the counter ID mechanisms.
This feature is supported in AArch64 and AArch32 states.
This feature is optional in Armv8.4 implementations.
The CNTID.CNTSC field identifies the support for ARMv8.4-CNTSC.
For more information, see:
- CNTCR, Counter Control Register on page I5-7154.

**ARMv8.4-Debug, Armv8.4 Debug relaxations and extensions**
ARMv8.4-Debug covers a selection of mandatory changes, including:
- The fields MDCR_EL3. {EPMAD, EDAD} control Non-secure access to the debug and PMU registers. The bus master is responsible for other debug authentication.
- The feature ARMv8.0-DoubleLock has been introduced. See Features added to earlier extensions on page A2-85.
- The Software Lock is obsolete.
• Non-invasive Debug controls are relaxed.
• Secure and Non-secure views of the debug registers are enabled.

The fields that identify the support for ARMv8.4-Debug are:
• ID_AA64DFR0_EL1.DebugVer
• DBGIDR.Version
• ID_DFR0_EL1.{CopSDbg, CopDbg}
• ID_DFR0.{CopSDbg, CopDbg}
• EDDEV ARCH.ARCHID

For more information, see:
• Definition and constraints of a debugger in the context of external debug on page H1-6700
• External debug interface register access permissions on page H8-6835

ARMv8.4-Trace, Armv8.4 Self-hosted Trace Extensions

ARMv8.4-Trace adds controls of trace in a self-hosted system through System registers.
The feature provides:
• Control of Exception levels and Security states where trace generation is prohibited.
• Control of whether an offset is used for the timestamp recorded with trace information.
• A context synchronization instruction TSB CSYNC which can be used to prevent reordering of trace operation accesses with respect to other accesses of the same System registers.

If an ETM Architecture PE Trace Unit is implemented, this feature is mandatory, and the ETM PE Trace Unit must implement System register access to its control registers. If a different PE Trace Unit is implemented, this feature is optional.
The reset state of the PE has prohibited regions controlled by the feature and not the external authentication signals. An external trace controller must override the internal controls before enabling trace, including trace from reset. This is a change from previous trace architectures and is not backwards-compatible.
The fields that identify the support for ARMv8.4-Trace are:
• ID_AA64DFR0_EL1.TraceFilt,
• ID_DFR0_EL1.TraceFilt
• ID_DFR0.TraceFilt
• EDDFR.TraceVer
• ID_AA64DFR0_EL1.TraceVer

For more information, see:
• Chapter D3 AArch64 Self-hosted Trace.
• Chapter G3 AArch32 Self-hosted Trace.

ARMv8.4-PMU, Armv8.4 PMU Extensions

ARMv8.4-PMU introduces the PMMIR_EL1 and PMMIR registers.
This feature is supported in AArch64 and AArch32 states.
The Performance Monitors Extension is an optional feature, but if it is implemented, an Armv8.4 implementation must include ARMv8.4-PMU.
The fields that identify the support for ARMv8.4-PMU are:
• ID_AA64DFR0_EL1.PMUVer.
• ID_DFR0_EL1.Perfmon.
• ID_DFR0.Perfmon.
• EDDFR.PMUVer,

For more information, see PMU events and event numbers on page D7-2689.
ARMv8.4-RAS, Armv8.4 RAS Extension

ARMv8.4-RAS implements RAS System Architecture v1.1 and adds support for:
- ARMv8.4-DFE.
- Simplifications to ERR<n>STATUS.
- Additional ERR<n>MISC<m> registers.
- The optional RAS Common Fault Injection Model Extension.

This feature is supported in AArch64 and AArch32 states.

This feature is mandatory in Armv8.4 implementations.

The following fields identify the support or partial support for ARMv8.4-RAS:
- ID_AA64PFR0_EL1.RAS.
- ID_AA64PFR1_EL1.RAS_frac.
- ID_PFR0_EL1.RAS.
- ID_PFR2_EL1.RAS_frac.
- ID_PFR2.RAS.
- ID_PFR2.RAS_frac.

For more information, see:
- The Reliability, Availability, and Serviceability Extension (RAS Extension) on page A2-90.
- ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

ARMv8.4-DFE, Armv8.4 Double Fault Extension

ARMv8.4-DFE provides two controls:
- SCR_EL3.EASE.
- SCR_EL3.NMEA.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.4 implementations if EL3 is implemented and EL3 uses AArch64. Otherwise, it is not implemented.

This feature is implemented if ID_AA64PFR0_EL1.RAS \( \geq \) 0b0010 and the implementation includes EL3 using AArch64.

For more information, see:
- The Reliability, Availability, and Serviceability Extension (RAS Extension) on page A2-90.
- ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

A2.7.2 Features added to earlier extensions

The existing functionality of OS Double Lock is added as a feature mnemonic in Armv8.0, see ARMv8.0-DoubleLock on page A2-64.
A2.8 The Armv8.5 architecture extension

The Armv8.5 architecture extension adds architectural features and additional requirements, see:

- Architectural features added by Armv8.5.
- Additional requirements of Armv8.5 on page A2-88.

Features are also added to earlier architecture extensions, see Features added to earlier extensions on page A2-89.

A2.8.1 Architectural features added by Armv8.5

An implementation of the Armv8.5 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the Armv8.5 architecture.

The Armv8.5 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

**ARMv8.5-CondM, Armv8.5 Condition flag manipulation**

ARMv8.5-CondM provides instructions that convert between the PSTATE condition flag format used by the FCMP instruction and an alternative format described in Relationship between ARM format and alternative format PSTATE condition flags on page C6-752.

These instructions are added to the A64 instruction set only.

This feature is mandatory in Armv8.5 implementations.

The ID_AA64ISAR0_EL1.TS field identifies the presence of ARMv8.5-CondM.

For more information, see:

- Flag manipulation instructions on page C3-221.
- Relationship between ARM format and alternative format PSTATE condition flags on page C6-752.

**ARMv8.5-FRINT, Armv8.5 Floating-point to integer**

ARMv8.5-FRINT provides instructions that round a floating-point number to an integral valued floating point number that fits in a 32-bit or 64-bit integer number range.

These instructions are added to the A64 instruction set only.

This feature requires SIMD&FP, and is mandatory in Armv8.5 implementations when SIMD&FP is implemented.

The ID_AA64ISAR1_EL1.FRINTTS identifies the presence of ARMv8.5-FRINT.

For more information see Floating-point round to integral value on page C3-230.

**ARMv8.5-CSEH, Armv8.5 Context synchronization and exception handling**

ARMv8.5-CSEH provides a mechanism to control whether exception entry and exception return are context synchronization events. Fields in the SCTLR_ELx registers enable and disable context synchronization at exception entry and return at an Exception level.

This feature is supported in AArch64 state only.

This feature is optional in Armv8.5 implementations.

The ID_AA64MMFR0_EL1.ExS identifies the presence of ARMv8.5-CSEH.

For more information see:

- SCTLR_EL1, System Control Register (EL1) on page D13-3258, SCTLR_EL2 and SCTLR_EL3.
- Context synchronization event on page Glossary-7884

**ARMv8.5-GTG, Armv8.5 Guest translation granule size**

ARMv8.5-GTG allows a hypervisor to support different granule sizes for Stage 2 and Stage 1 translation, and allows a nested hypervisor to determine what stage 2 granule sizes are available.

This feature is supported in AArch64 state only.
This feature is mandatory in Armv8.5 implementations.

The ID_AA64MMFR0_EL1.{TGran16_2, TGran64_2, TGran4_2} fields identify whether each of the granule sizes is supported for Stage 2 translation. The ID_AA64MMFR0_EL1.{TGran16, TGran64, TGran4} fields identify whether each of the granule sizes is supported for Stage 1 translations.

For more information, see Memory translation granule size on page D5-2526.

ARMv8.5-BTI, Armv8.5 Branch target identification

ARMv8.5-BTI allows memory pages to be guarded against the execution of instructions that are not the intended target of a branch. To do this, it introduces:

- The GP field, which denotes the blocks and pages in stage 1 translation tables that are guarded pages,
- The PSTATE.BTYPE field, which is used to determine whether an access to a guarded memory region will generate a Branch Target exception,
- The BTI instruction, which is used to guard against the execution of instructions that are not the intended target of a branch.

This feature is supported in AArch64 state only.

This feature is mandatory in Armv8.5 implementations.

The ID_AA64PFR1_EL1.BT field identifies the presence of ARMv8.5-BTI.

For more information, see:
- Exception entry on page D1-2293.
- Synchronous exception types, routing and priorities on page D1-2307.
- VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats on page D5-2565.
- About PSTATE.BTYPE on page D5-2579.
- Effect of entering Debug state on PSTATE on page H2-6713.

ARMv8.5-E0PD, Armv8.5 Preventing EL0 access to halves of address maps

ARMv8.5-E0PD prevents access at EL0 to half of the addresses in the memory map.

This feature is supported in AArch64 state only. When EL1 is using AArch64 state, this feature affects access to EL0, in either execution state.

This feature is mandatory in Armv8.5 implementations.

The ID_AA64MMFR2_EL1.E0PD field identifies support for ARMv8.5-E0PD.

For more information see:
- Preventing EL0 access to halves of the address map on page D5-2581.
- TCR_EL1.{E0PD0, E0PD1}.
- TCR_EL2.{E0PD0, E0PD1}.

ARMv8.5-RNG, Armv8.5 Random number generator

ARMv8.5-RNG introduces the RNDR and RNDRRS registers. Reads to these registers return a 64-bit random number. A read to RNDRRS will cause a reseeding of the random number before the generation of the random number that is returned.

This feature is supported in AArch64 state only.

This feature is optional in Armv8.5 implementations.

The ID_AA64ISAR0_EL1.RNDR field identifies support for ARMv8.5-RNG.

For more information see:
- Effect of random number generation instructions on Condition flags on page C6-752.
- Appendix K12 Random Number Generation.
ARMv8.5-MemTag, Armv8.5 Memory Tagging Extension

ARMv8.5-MemTag provides architectural support for run-time, always-on detection of various classes of memory error to aid with software debugging to eliminate vulnerabilities arising from memory-unsafe languages.

This feature is supported in AArch64 state only.
This feature is optional in Armv8.5 implementations.

The field that identifies the support for ARMv8.5-MemTag is ID_AA64PFR1_EL1.MTE.

For more information, see:
- Chapter D6 Armv8.5 Memory Tagging Extension.
- Chapter B2 The AArch64 Application Level Memory Model.
- PMU events and event numbers on page D7-2689.
- Chapter D9 The Statistical Profiling Extension.
- Chapter H2 Debug State.

ARMv8.5-PMU, Armv8.5 PMU Extensions

ARMv8.5-PMU extends event counters to 64-bit event counters, and adds mechanisms to disable the cycle counter in Secure state and in EL2.

ARMv8.5-PMU relaxes the behavior of PMCR.{IMP, IDCODE}, and deprecates use of these fields.

This feature is supported in AArch64 and AArch32 states.

The Performance Monitors Extension is an optional feature, but if it is implemented, an Armv8.5 implementation must include ARMv8.5-PMU.

The fields that identify the support for ARMv8.5-PMU are:
- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.Perfmon.
- ID_DFR0.Perfmon.
- EDDFR.PMUVer,

For more information, see:
- Behavior on overflow on page D7-2675
- Prohibiting event counting on page D7-2679.
- PMU events and event numbers on page D7-2689.

A2.8.2 Additional requirements of Armv8.5

The Armv8.5 architecture includes some mandatory changes that are not associated with a feature. These are:

Restrictions on effects of speculation

Further restrictions are placed on execution for:
- Execution prediction instructions that predict addresses or register values
- Data loaded under speculation with a permission or domain fault.
- Any System register read under speculation to a register that is not architecturally accessible from the current Exception level.

For more information, see:
- Restrictions on the effects of speculation on page B2-123.
- Restrictions on the effects of speculation on page E2-3821.

Changes to CTIDEVARCH, CTIDEVAFF0, and CTIDEVAFF1

CTIDEVARCH, CTIDEVAFF0, and CTIDEVAFF1 must be implemented.

Changes to the input channel gate function
If the Cross-Trigger Matrix (CTM) is implemented, the input channel gate function must be implemented.

**Deprecation of EDPRCR.CWRR**

EDPRCR.CWRR is deprecated.

Mandatory changes are also made to earlier architectural extensions, see *Architectural requirements added to earlier extensions*.

### A2.8.3 Features added to earlier extensions

The features that have been added to earlier architectural extensions are:

- ARMv8.0-SB on page A2-63.
- ARMv8.0-SSBS on page A2-63.
- ARMv8.0-CSV2 on page A2-63.
- ARMv8.0-CSV3 on page A2-64.
- ARMv8.0-PredInv on page A2-64.
- ARMv8.0-CP15SDISABLE2 on page A2-64.
- ARMv8.2-EVT on page A2-76.
- ARMv8.2-DCCVADP on page A2-76.
- ARMv8.3-SPE on page A2-80.
- ARMv8.3-DoPD on page A2-80.

### A2.8.4 Architectural requirements added to earlier extensions

The additional architectural requirement that has been added to earlier extensions is *Prefetch speculation protection* on page A2-65.
A2.9 The Reliability, Availability, and Serviceability Extension (RAS Extension)

The RAS Extension is a mandatory extension to the Armv8.2 architecture, and an optional extension to the Armv8.0 and the Armv8.1 architectures.

The RAS Extension improves the dependability of a system by providing:
• Reliability, that is, the continuity of correct service.
• Availability, that is, the readiness for correct service.
• Serviceability, that is, the ability to undergo modifications and repairs.

ID_AA64FR0_EL1.RAS in AArch64 state, and ID_PFR0.RAS in AArch32 state, indicate whether the RAS Extension is implemented.

The RAS Extension introduces a barrier instruction, the Error Synchronization Barrier (ESB), to the A32, T32, and A64 instruction sets.

System registers introduced by the RAS Extension are described in:
• For AArch64, RAS registers on page D13-3647.
• For AArch32, RAS registers on page G8-6579.

In addition, the RAS Extension introduces a number of memory-mapped registers. These are described in the ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile.

Armv8.2 introduces the following architectural features to the RAS Extension:
• ARMv8.2-IESB.

Armv8.4 introduces the following architectural features to the RAS Extension:
• ARMv8.4-RAS.
• ARMv8.4-DFE.
A2.10 The Statistical Profiling Extension (SPE)

The Statistical Profiling Extension is an optional extension introduced by the Armv8.2 architecture. Implementation of the Statistical Profiling Extension requires implementation of at least Armv8.1 of the Armv8-A architecture profile. The Statistical Profiling Extension is only supported in AArch64 state.

The Statistical Profiling Extension provides a non-invasive method of sampling software and hardware using randomized sampling of either architectural instructions, as defined by the instruction set architecture, or by microarchitectural operations.

ID_AA64DFR0_EL1.PMSVer indicates whether the Statistical Profiling Extension is implemented.

For more information see Chapter D9 The Statistical Profiling Extension.
A2.11 The Scalable Vector Extension (SVE)

The Scalable Vector Extension is an optional extension introduced by the Armv8.2 architecture. SVE is supported in AArch64 state only.

The Scalable Vector Extension provides vector instructions that, primarily, support wider vectors than the Arm Advanced SIMD instruction set. The *ARM® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for ARMv8-A* describes the SVE.

**ID_AA64PFR0_EL1.SVE** indicates whether the Scalable Vector Extension is implemented.

The Scalable Vector Extension affects some AArch64 System registers, and those register changes are included in this issue of this Manual, where they are identified as SVE features. SVE also introduces AArch64 System registers, however these do not appear in this manual. For more information about the System registers introduced by SVE, please see the *ARM® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for ARMv8-A*.

The Scalable Vector Extension introduces the following System registers:
- **ID_AA64PFR0_EL1**.
- **ZCR_EL1**, and an EL2 alias of this register, **ZCR_EL12**.
- **ZCR_EL2**.
- **ZCR_EL3**.

The Scalable Vector Extension modifies the following existing System registers:
- **CPACR_EL1**.
- **CPTR_EL2**.
- **CPTR_EL3**.
- **ESR_ELx**.
- **ID_AA64PFR0_EL1**.
- **TCR_EL1**.
- **TCR_EL2**.
A2.12 The Activity Monitors Extension

The Activity Monitors Extension is an optional extension introduced by the Armv8.4 architecture. AMU is supported in AArch64 and AArch32 states.

The Activity Monitors Extension implements version 1 of the Activity Monitors architecture, AMUv1, which provides a function similar to a subset of the existing Performance Monitors Extension functionality, intended for system management use rather than debugging and profiling.

The Activity Monitors Extension implements a System register interface to the Activity Monitors registers, and also supports an optional external memory-mapped interface.

The fields that identify the presence of the Activity Monitors Extension are:

- ID_AA64PFR0_EL1.AMU.
- ID_PFR0_EL1.AMU.
- ID_PFR0.AMU.
- EDPFR.AMU.

For more information, see Chapter D8 The Activity Monitors Extension.
A2.13 The Memory Partitioning and Monitoring (MPAM) Extension

The Memory Partitioning and Monitoring Extension is an optional extension introduced by the Armv8.4 architecture and requires implementation of at least Armv8.2 of the Armv8-A architecture profile. MPAM is supported in AArch64 state only.

The MPAM Extension provides a framework for memory-system component controls that partition one or more of the performance resources of the component.

The fields that identify the presence of the MPAM Extension are:

- ID_AA64PFR0_EL1.MPAM.
- EDPFR.MPAM.

For more information, see ARM® Architecture Reference Manual Supplement, Memory System Resource Partitioning and Monitoring (MPAM), for ARMv8-A.
Part B

The AArch64 Application Level Architecture
Chapter B1
The AArch64 Application Level Programmers’ Model

• About the Application level programmers’ model on page B1-98.
• Registers in AArch64 Execution state on page B1-99.
• Software control features and EL0 on page B1-104.
B1.1  About the Application level programmers’ model

This chapter contains the programmers’ model information required for application development.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of the system information is needed to put the Application level programmers' model into context.

Depending on the implementation choices, the architecture supports multiple levels of execution privilege, indicated by different Exception levels that number upwards from EL0 to EL3. EL0 corresponds to the lowest privilege level and is often described as unprivileged. The Application level programmers’ model is the programmers’ model for software executing at EL0. For more information see Exception levels on page D1-2268.

System software determines the Exception level, and therefore the level of privilege, at which software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged at EL0. This:

• Permits the operating system to allocate system resources to an application in a unique or shared manner.
• Provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some system level understanding is necessary, and where relevant it gives a reference to the system level description.

Execution at any Exception level above EL0 is often referred to as privileged execution.

For more information on the system level view of the architecture refer to Chapter D1 The AArch64 System Level Programmers’ Model.
B1.2 Registers in AArch64 Execution state

This section describes the registers and process state visible at EL0 when executing in the AArch64 state. It includes the following:

- Registers in AArch64 state
- Process state, PSTATE on page B1-100
- System registers on page B1-102

B1.2.1 Registers in AArch64 state

In the AArch64 application level view, an Arm processing element has:

**R0-R30**

31 general-purpose registers, R0 to R30. Each register can be accessed as:

- A 64-bit general-purpose register named X0 to X30.
- A 32-bit general-purpose register named W0 to W30.

See the register name mapping in Figure B1-1.

![Figure B1-1 General-purpose register naming](image)

The X30 general-purpose register is used as the procedure call link register.

--- Note ---

In instruction encodings, the value 0b11111 (31) is used to indicate the ZR (zero register). This indicates that the argument takes the value zero, but does not indicate that the ZR is implemented as a physical register.

---

**SP**

A 64-bit dedicated Stack Pointer register. The least significant 32 bits of the stack-pointer can be accessed via the register name WSP.

The use of SP as an operand in an instruction, indicates the use of the current stack pointer.

--- Note ---

Stack pointer alignment to a 16-byte boundary is configurable at EL1. For more information see the Procedure Call Standard for the Arm 64-bit Architecture.

---

**PC**

A 64-bit Program Counter holding the address of the current instruction.

Software cannot write directly to the PC. It can only be updated on a branch, exception entry or exception return.

--- Note ---

Attempting to execute an A64 instruction that is not word-aligned generates a PC alignment fault, see PC alignment checking on page D1-2287.

---

**V0-V31**

32 SIMD&FP registers, V0 to V31. Each register can be accessed as:

- A 128-bit register named Q0 to Q31.
- A 64-bit register named D0 to D31.
- A 32-bit register named S0 to S31.
- A 16-bit register named H0 to H31.
- An 8-bit register named B0 to B31.
- A 128-bit vector of elements.
• A 64-bit vector of elements.

Where the number of bits described by a register name does not occupy an entire SIMD&FP register, it refers to the least significant bits. See Figure B1-2.

Figure B1-2 SIMD and floating-point register naming

For more information about data types and vector formats, see Supported data types on page A1-41.

FPCR, FPSR Two SIMD and floating-point control and status registers, FPCR and FPSR.

See Registers for instruction processing and exception handling on page D1-2277 for more information on the registers.

Pseudocode description of registers in AArch64 state

In the pseudocode functions that access registers:

• The assignment form is used for register writes.
• The non-assignment for register reads.

The uses of the X[] function are:

• Reading or writing X0-X30, using n to index the required register.
• Reading the zero register ZR, accessed as X[31].

Note

The pseudocode use of X[31] to represent the zero register does not indicate that hardware must implement this register.

The AArch64 SP[] function is used to read or write the current SP.

The AArch64 PC[] function is used to read the PC.

The AArch64 V[] function is used to read or write the Advanced SIMD and floating-point registers V0-V31, using a parameter n to index the required register.

The AArch64 Vpart[] function is used to read or write a part of one of V0-V31, using a parameter n to index the required register, and a parameter part to indicate the required part of the register, see the function description for more information.

The SP[], PC[], V[], and Vpart[] functions are defined in Chapter J1 Armv8 Pseudocode.

B1.2.2 Process state, PSTATE

Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.
The following PSTATE information is accessible at EL0:

The Condition flags

Flag-setting instructions set these. They are:

- **N** Negative Condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to:
  - 1 if the result is negative.
  - 0 if the result is positive or zero.

- **Z** Zero Condition flag. Set to:
  - 1 if the result of the instruction is zero.
  - 0 otherwise.

  A result of zero often indicates an equal result from a comparison.

- **C** Carry Condition flag. Set to:
  - 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition.
  - 0 otherwise.

- **V** Overflow Condition flag. Set to:
  - 1 if the instruction results in an overflow condition, for example a signed overflow that is the result of an addition.
  - 0 otherwise.

Conditional instructions test the N, Z, C and V Condition flags, combining them with the Condition code for the instruction to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution, see Condition flags and related instructions on page C6-751.

The exception masking bits

- **D** Debug exception mask bit. When EL0 is enabled to modify the mask bits, this bit is visible and can be modified. However, this bit is architecturally ignored at EL0.

- **A** SError interrupt mask bit.

- **I** IRQ interrupt mask bit.

- **F** FIQ interrupt mask bit.

For each bit, the values are:

- 0 Exception not masked.
- 1 Exception masked.

Access at EL0 using AArch64 state depends on SCTLR_EL1.UMA. See Traps to EL1 of EL0 accesses to the PSTATE, (D, A, I, F) interrupt masks on page D1-2330.

See Process state, PSTATE on page D1-2284 for the system level view of PSTATE.
Accessing PSTATE fields at EL0

At EL0 using AArch64 state, PSTATE fields can be accessed using Special-purpose registers that can be directly read using the MRS instruction and directly written using the MSR (register) instructions. Table B1-1 shows the Special-purpose registers that access the PSTATE fields that hold AArch64 state when the PE is at EL0 using AArch64. All other PSTATE fields do not have direct read and write access at EL0.

<table>
<thead>
<tr>
<th>Special-purpose register</th>
<th>PSTATE fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>NZCV</td>
<td>N, Z, C, V</td>
</tr>
<tr>
<td>DAIF</td>
<td>D, A, I, F</td>
</tr>
</tbody>
</table>

Software can also use the MSR (immediate) instruction to directly write to PSTATE.\{D, A, I, F\}. Table B1-2 shows the MSR (immediate) operands that can directly write to PSTATE.\{D, A, I, F\} when the PE is at EL0 using AArch64 state.

<table>
<thead>
<tr>
<th>Operand</th>
<th>PSTATE fields</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAIFSet</td>
<td>D, A, I, F</td>
<td>Directly sets any of the PSTATE.{D, A, I, F} bits to 1</td>
</tr>
<tr>
<td>DAIFClr</td>
<td>D, A, I, F</td>
<td>Directly clears any of the PSTATE.{D, A, I, F} bits to 0</td>
</tr>
</tbody>
</table>

However, access to the PSTATE.\{D, A, I, F\} fields at EL0 using AArch64 state depends on SCTLR_EL1.UMA. Traps to EL1 of EL0 accesses to the PSTATE.\{D, A, I, F\} interrupt masks on page D1-2330.

Writes to the PSTATE fields have side-effects on various aspects of the PE operation. All of these side-effects, are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

B1.2.3  System registers

System registers provide support for execution control, status and general system configuration. The majority of the System registers are not accessible at EL0.

However, some System registers can be configured to allow access from software executing at EL0. Any access from EL0 to a System register with the access right disabled causes the instruction to behave as UNDEFINED. The registers that can be accessed from EL0 are:

- **Cache ID registers**
  The CTR_EL0 and DCZID_EL0 registers provide implementation parameters for EL0 cache management support.

- **Debug registers**
  A debug communications channel is supported by the MDCCSR_EL0, DBGDTR_EL0, DBGDTRRX_EL0 and DBGDTRTX_EL0 registers.

- **Performance Monitors registers**
  The Performance Monitors Extension provides counters and configuration registers. Software executing at EL1 or a higher Exception level can configure some of these registers to be accessible at EL0.

  For more details, see Chapter D7 The Performance Monitors Extension.

- **Activity Monitors registers**
  The Activity Monitors Extension provides counters and configuration registers. Software executing at EL1 or a higher Exception level can configure these registers to be accessible at EL0.
For more details, see Chapter D8 *The Activity Monitors Extension*.

**Thread ID registers**  
The `TPIDR_EL0` and `TPIDRRO_EL0` registers are two thread ID registers with different access rights.

**Timer registers**  
In Armv8 the following operations are performed:

- Read access to the system counter clock frequency using `CNTFRQ_EL0`.
- Physical and virtual timer count registers, `CNTPCT_EL0` and `CNTVCT_EL0`.
- Physical up-count comparison, down-count value and timer control registers, `CNTP_CVAL_EL0`, `CNTP_TVAL_EL0`, and `CNTP_CTL_EL0`.
- Virtual up-count comparison, down-count value and timer control registers, `CNTV_CVAL_EL0`, `CNTV_TVAL_EL0`, and `CNTV_CTL_EL0`. 
B1.3 Software control features and EL0

The following sections describe the EL0 view of the Armv8 software control features:

- Exception handling
- Wait for Interrupt and Wait for Event
- The YIELD instruction
- Application level cache management on page B1-105
- Instructions relating to Debug on page B1-105

B1.3.1 Exception handling

In the Arm architecture, an exception causes a change of program flow. Execution of an exception handler starts, at an Exception level higher than EL0, from a defined vector that relates to the exception taken.

Exceptions include:

- Interrupts.
- Memory system aborts.
- Exceptions generated by attempting to execute an instruction that is UNDEFINED.
- System calls.
- Secure monitor or Hypervisor traps.
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in Chapter D1 The AArch64 System Level Programmers’ Model.

The SVC instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a system call to an operating system.

The BRK instruction generates a Breakpoint Instruction exception. This provides a mechanism for debugging software using debugger executing on the same PE, see Breakpoint Instruction exceptions on page D2-2411.

--- Note ---

The BRK instruction is supported only in the A64 instruction set. The equivalent instruction in the T32 and A32 instruction sets is BKPT.

B1.3.2 Wait for Interrupt and Wait for Event

Issuing a WFI instruction indicates that no further execution is required until a WFI wake-up event occurs, see Wait For Interrupt on page D1-2375. This permits entry to a low-power state.

Issuing a WFE instruction indicates that no further execution is required until a WFE wake-up event occurs, see Wait for Event mechanism and Send event on page D1-2372. This permits entry to a low-power state.

B1.3.3 The YIELD instruction

The YIELD instruction provides a hint that the task performed by a thread is of low importance so that it could yield, see YIELD on page C6-1370. This mechanism can be used to improve overall performance in a Symmetric Multithreading (SMT) or Symmetric Multiprocessing (SMP) system.

Examples of when the YIELD instruction might be used include a thread that is sitting in a spin-lock, or where the arbitration priority of the snoop bit in an SMP system is modified. The YIELD instruction permits binary compatibility between SMT and SMP systems.

The YIELD instruction is a NOP hint instruction.

The YIELD instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use for future migration to a multiprocessor or multithreading system. Operating systems can use YIELD in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.
B1.3.4 Application level cache management

A small number of cache management instructions can be enabled at EL0 from higher levels of privilege using the SCTLR_EL1 System register. Any access from EL0 to an operation with the access right disabled causes the instruction to behave as UNDEFINED.

About the available operations, see Application level access to functionality related to caches on page B2-134.

B1.3.5 Instructions relating to Debug

Exception handling on page B1-104 refers to the BRK instruction, which generates a Breakpoint Instruction exception. In addition, in both AArch64 state and AArch32 state, the HLT instruction causes the PE to halt execution and enter Debug state. This provides a mechanism for debugging software using a debugger that is external to the PE, see Chapter H1 About External Debug.

—— Note ———

In AArch32 state, previous versions of the architecture defined the DBG instruction, that could provide a hint to the debug system. In Armv8, this instruction executes as a NOP. Arm deprecates the use of the DBG instruction.

B1.3.6 About PSTATE.DIT

When the value of PSTATE.DIT is 1:

• The instructions listed in DIT are required to have;
  — Timing which is independent of the values of the data supplied in any of its registers, and the values of the NZCV flags.
  — Responses to asynchronous exceptions which do not vary based on the values supplied in any of their registers, or the values of the NZCV flags.

• All loads and stores must have their timing insensitive to the value of the data being loaded or stored.

—— Note ———

• Arm recommends that the ARMv8.3-PAuth instructions do not have their timing dependent on the key value used in the pointer authentication, regardless of the PSTATE.DIT bit.

• When the value of PSTATE.DIT is 0, the architecture makes no statement about the timing properties of any instructions. However, it is likely that these instructions have timing that is invariant of the data in many situations.

A corresponding DIT bit is added to PSTATE in AArch64 state, and to CPSR in AArch32 state.

On an exception that is taken from AArch64 state to AArch64 state, PSTATE.DIT is copied to SPSR_ELx.DIT.

On an exception that is taken from AArch32 state to AArch64 state, CPSR.DIT is copied to SPSR_ELx.DIT.

On an exception return from AArch64 state:

• SPSR_ELx.DIT is copied to PSTATE.DIT, when the target Exception level is in AArch64 state.
• SPSR_ELx.DIT is copied to CPSR.DIT, when the target Exception level is in AArch32 state.

PSTATE.DIT can be written and read at all exception levels.

—— Note ———

• PSTATE.DIT is unchanged on entry into Debug state.
• PSTATE.DIT is not guaranteed to have any effect in Debug state.
Chapter B2
The AArch64 Application Level Memory Model

This chapter gives an application level view of the memory model. It contains the following sections:

- About the Arm memory model on page B2-108.
- Atomicity in the Arm architecture on page B2-110.
- Definition of the Armv8 memory model on page B2-115.
- Caches and memory hierarchy on page B2-133.
- Endian support on page B2-140.
- Memory types and attributes on page B2-143.
- Synchronization and semaphores on page B2-156.

Note
In this chapter, System register names usually link to the description of the register in Chapter D13 AArch64 System Register Descriptions, for example SCTLR_EL1.
B2.1  About the Arm memory model

The Arm architecture is a weakly ordered memory architecture that permits the observation and completion of
memory accesses in a different order from the program order. The following sections of this chapter provide the
complete definition of the Armv8 memory model, this introduction is not intended to contradict the definition found
in those sections. In general, the basic principles of the Armv8 memory model are:

• To provide a memory model that has similar weaknesses to those found in the memory models used by
high-level programming languages such as C or Java. For example, by permitting independent memory
accesses to be reordered as seen by other observers.

• To avoid the requirement for multi-copy atomicity in the majority of memory types.

• The provision of instructions and memory barriers to compensate for the lack of multi-copy atomicity in the
cases where it would be needed.

• The use of address, data, and control dependencies in the creation of order so as to avoid having excessive
numbers of barriers or other explicit instructions in common situations where some order is required by the
programmer or the compiler.

• If ARMv8.5-MemTag is implemented and enabled the definitions of the memory model which apply to data
accesses and data apply to Allocation Tag accesses and Allocation tags, unless otherwise specified in
Chapter D6 Armv8.5 Memory Tagging Extension.

This section contains:

• Address space.

• Memory type overview.

B2.1.1  Address space

Address calculations are performed using 64-bit registers. However, supervisory software can configure the top
eight address bits for use as a tag, as described in Address tagging in AArch64 state on page D5-2506. If this is done,
address bits[63:56]:

• Are not considered when determining whether the address is valid.

• Are never propagated to the program counter.

Supervisory software determines the valid address range. Attempting to access an address that is not valid generates
an MMU fault.

Simple sequential execution of instructions might overflow the valid address range. For more information, see
Virtual address space overflow on page D4-2469.

Memory accesses use the Mem[] function. This function makes an access of the required type. If supervisory software
configures the top eight address bits for use as a tag, the top eight address bits are ignored.

The AccType{} enumeration defines the different access types.

Note

• Chapter D4 The AArch64 System Level Memory Model and Chapter D5 The AArch64 Virtual Memory System
Architecture include descriptions of memory system features that are transparent to the application, including
memory access, address translation, memory maintenance instructions, and alignment checking and the
associated fault handling. These chapters also include pseudocode descriptions of these operations.

• For information on the pseudocode that relates to memory accesses, see Basic memory access on
page D4-2499, Unaligned memory access on page D4-2500, and Aligned memory access on page D4-2500.

B2.1.2  Memory type overview

Armv8 provides the following mutually-exclusive memory types:

Normal  This is generally used for bulk memory operations, both read/write and read-only operations.
Device

The Arm architecture forbids *Speculative* reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive Locations. Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.

Device memory has additional attributes that have the following effects:

- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See *Gathering* on page B2-149.
- They preserve the access order and synchronization requirements for accesses to a single peripheral. See *Reordering* on page B2-150.
- They indicate whether a write can be acknowledged other than at the end point. See *Early Write Acknowledgement* on page B2-151.

For more information on Normal memory and Device memory, see *Memory types and attributes* on page B2-143.

---

**Note**

Earlier versions of the Arm architecture defined a single Device memory type and a Strongly-ordered memory type. A *Note* in *Device memory* on page B2-147 describes how these memory types map onto the Armv8 memory types.
B2.2 Atomicity in the Arm architecture

Atomicity is a feature of memory accesses, described as atomic accesses. The Arm architecture description refers to two types of atomicity, single-copy atomicity and multi-copy atomicity. In the Armv8 architecture, the atomicity requirements for memory accesses depend on the memory type, and whether the access is explicit or implicit. For more information, see:

- Requirements for single-copy atomicity.
- Properties of single-copy atomic accesses on page B2-112.
- Multi-copy atomicity on page B2-112.
- Requirements for multi-copy atomicity on page B2-112.
- Concurrent modification and execution of instructions on page B2-112.

For more information about the memory types, see Memory type overview on page B2-108.

B2.2.1 Requirements for single-copy atomicity

For explicit memory accesses generated from an Exception level the following rules apply:

- A read that is generated by a load instruction that loads a single general-purpose register and is aligned to the size of the read in the instruction is single-copy atomic.
- A write that is generated by a store instruction that stores a single general-purpose register and is aligned to the size of the write in the instruction is single-copy atomic.
- Reads that are generated by a Load Pair instruction that loads two general-purpose registers and are aligned to the size of the load to each register are treated as two single-copy atomic reads, one for each register being loaded.
- Writes that are generated by a Store pair instruction that stores two general-purpose registers and are aligned to the size of the store of each register are treated as two single-copy atomic writes, one for each register being stored.
- Load-Exclusive Pair instructions of two 32-bit quantities and Store-Exclusive Pair instructions of 32-bit quantities are single-copy atomic.
- When the Store-Exclusive of a Load-Exclusive/Store-Exclusive pair instruction using two 64-bit quantities succeeds, it causes a single-copy atomic update of the entire memory location being updated.

Note

To atomically load two 64-bit quantities, perform a Load-Exclusive pair/Store-Exclusive pair sequence of reading and writing the same value for which the Store-Exclusive pair succeeds, and use the read values from the Load-Exclusive pair.

- Where translation table walks generate a read of a translation table entry, this read is single-copy atomic.
- For the atomicity of instruction fetches, see Concurrent modification and execution of instructions on page B2-112.
- Reads to SIMD and floating-point registers of a single 64-bit or smaller quantity that is aligned to the size of the quantity being loaded are treated as single-copy atomic reads.
- Writes from SIMD and floating-point registers of a single 64-bit or smaller quantity that is aligned to the size of the quantity being stored are treated as single-copy atomic writes.
- Element or Structure Reads to SIMD and floating-point registers of 64-bit or smaller elements, where each element is aligned to the size of the element being loaded, have each element treated as a single-copy atomic read.
- Element or Structure Writes from SIMD and floating-point registers of 64-bit or smaller elements, where each element is aligned to the size of the element being stored, have each element treated as a single-copy atomic store.
• Reads to SIMD and floating-point registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit reads.

• Writes from SIMD and floating-point registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit writes.

• For unaligned memory accesses, the single-copy atomicity is described in Alignment of data accesses on page B2-138.

• The reads and writes of the two words or two double-words accessed by CASP instructions are single-copy atomic at the size of the two words or double-words.

All other memory accesses are regarded as streams of accesses to bytes, and no atomicity between accesses to different bytes is ensured by the architecture.

All accesses to any byte are single-copy atomic.

——— Note ————
In AArch64 state, no memory accesses from a DC ZVA have single-copy atomicity of any quantity greater than individual bytes.

If, according to these rules, an instruction is executed as a sequence of accesses, exceptions, including interrupts, can be taken during that sequence, regardless of the memory type being accessed. If any of these exceptions are returned from using their preferred return address, the instruction that generated the sequence of accesses is re-executed, and so any access performed before the exception was taken is repeated. See also Taking an interrupt or other exception during a multiple-register load or store on page D1-2325.

——— Note ————
The exception behavior for these multiple access instructions means that they are not suitable for use for writes to memory for the purpose of software synchronization.

Changes to single-copy atomicity in Armv8.4
Instructions that are introduced in ARMv8.4-RCPC are single-copy atomic when the following conditions are true:

• All bytes being accessed are within the same 16-byte quantity aligned to 16 bytes.
• Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

Otherwise it is IMPLEMENTATION DEFINED whether they are single-copy atomic.

If ARMv8.4-LSE is implemented, all loads and stores are single-copy atomic when the following conditions are true:

• Accesses are unaligned to their data size but are aligned within a 16-byte quantity that is aligned to 16 bytes.
• Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

Otherwise it is IMPLEMENTATION DEFINED whether loads and stores are single-copy atomic.

If ARMv8.4-LSE is implemented, LDP, LDNP, and STP instructions that load or store two 64-bit registers are single-copy atomic when the following conditions are true:

• The overall memory access is aligned to 16 bytes.
• Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

If ARMv8.4-LSE is implemented, LDP, LDNP, and STP instructions that access fewer than 16 bytes are single-copy atomic when the following conditions are true:

• All bytes being accessed are within a 16-byte quantity aligned to 16 bytes.
• Accesses are to Inner Write-Back, Outer Write-Back Normal cacheable memory.

Otherwise it is IMPLEMENTATION DEFINED whether LDP, LDNP, or STP instructions that access fewer than 16 bytes are single-copy atomic.
B2.2.2       Properties of single-copy atomic accesses

A memory access instruction that is single-copy atomic has the following properties:

1. For a pair of overlapping single-copy atomic store instructions, all of the overlapping writes generated by one of the stores are Coherence-after the corresponding overlapping writes generated by the other store.

2. For a single-copy atomic load instruction L1 that overlaps a single-copy atomic store instruction S2, if one of the overlapping reads generated by L1 Reads-from one of the overlapping writes generated by S2, then none of the overlapping writes generated by S2 are Coherence-after the corresponding overlapping reads generated by L1.

For more information, see *Definition of the Armv8 memory model* on page B2-115.

B2.2.3       Multi-copy atomicity

In a multiprocessing system, writes to a memory location are *multi-copy atomic* if the following conditions are both true:

- All writes to the same location are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

**Note**
Writes that are not coherent are not multi-copy atomic.

B2.2.4       Requirements for multi-copy atomicity

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory, writes are not required to be multi-copy atomic.

The Armv8 memory model is *Other-multi-copy atomic*. For more information, see *Ordering constraints* on page B2-119.

B2.2.5       Concurrent modification and execution of instructions

The Armv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where each of the instruction before modification and the instruction after modification is one of a B, BL, BRK, HVC, ISB, NOP, SMC, or SVC instruction.

For the B, BL, BRK, HVC, ISB, NOP, SMC, and SVC instructions the architecture guarantees that, after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.

For all other instructions, to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.

2. To ensure that the modified instructions are observable, a PE that is writing the instructions must issue the following sequence of instructions and operations:

```asm
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; enter this code with <Wt> containing a new 32-bit instruction, 
; to be held in Cacheable space at a location pointed to by Xn.
```

For more information, see *Definition of the Armv8 memory model* on page B2-115.
STR wt, [Xn]
DC CVAU, Xn ; Clean data cache by VA to point of unification (PoU)
DSB ISH ; Ensure visibility of the data cleaned from cache
IC IVAU, Xn ; Invalidate instruction cache by VA to PoU
DSB ISH

Note

• The DC CVAU operation is not required if the area of memory is either Non-cacheable or Write-Through Cacheable.

• If the contents of physical memory differ between the mappings, changing the mapping of VAs to PAs can cause the instructions to be concurrently modified by one PE and executed by another PE. If the modifications affect instructions other than those listed as being acceptable for modification, synchronization must be used to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.

3. In a multiprocessor system, the IC IVAU is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. However, when the modified instructions are observable, each PE that is executing the modified instructions must issue the following instruction to ensure execution of the modified instructions:
   ISB ; Synchronize fetched instruction stream

For more information about the required synchronization operation, see Synchronization and coherency issues between data and instruction accesses on page B2-136.

For information about memory accesses caused by instruction fetches, see Ordering relations on page B2-118.

B2.2.6 Possible implementation restrictions on using atomic instructions

In some implementations, and for some memory types, the properties of atomicity can be met only by functionality outside the PE. Some system implementations might not support atomic instructions for all regions of the memory. In particular, this can apply to:

• Any type of memory in the system that does not support hardware cache coherency.

• Device, Non-cacheable memory, or memory that is treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such implementations, it is defined by the system:

• Whether the atomic instructions are atomic in regard to other agents that access memory.

• If the atomic instructions are atomic in regard to other agents that access memory, which address ranges or memory types this applies to.

An implementation can choose which memory type is treated as Non-cacheable.

The memory types for which it is architecturally guaranteed that the atomic instructions will be atomic are:

• Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

• Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

If the atomic instructions are not atomic in regard to other agents that access memory, then performing an atomic instruction to such a location can have one or more of the following effects:

• The instruction generates a synchronous External abort.

• The instruction generates a System Error interrupt.

• The instruction generates an IMPLEMENTATION DEFINED MMU fault reported using the Data Abort Fault status code of ESR_ELx.DFSC = 110101.
For the EL1&0 translation regime, if the atomic instruction is not supported because of the memory type that is defined in the first stage of translation, or the second stage of translation is not enabled, then this exception is a first stage abort and is taken to EL1. Otherwise, the exception is a second stage abort and is taken to EL2.

- The instruction is treated as a NOP.
- The instructions are performed, but there is no guarantee that the memory accesses were performed atomically in regard to other agents that access memory. In this case, the instruction might also generate a System Error interrupt.
B2.3 Definition of the Armv8 memory model

This section describes observation and ordering in the Armv8 memory model. It contains the following subsections:

- Locations
- Ordering and observability
- Ordering constraints
- Completion and endpoint ordering
- Ordering of instruction fetches
- Restrictions on the effects of speculation
- Memory barriers
- Limited ordering regions

For more information about endpoint ordering of memory accesses, see Reordering on page B2-150.

In the Armv8 memory model, the Shareability memory attribute indicates the degree to which hardware must ensure memory coherency between a set of observers, see Memory types and attributes on page B2-143.

The Armv8 architecture defines additional memory attributes and associated behaviors, which are defined in the system level section of this manual. See:

- Chapter D4 The AArch64 System Level Memory Model
- Chapter D5 The AArch64 Virtual Memory System Architecture

See also Mismatched memory attributes on page B2-153.

B2.3.1 Locations

The Armv8 memory model provides a set of definitions that are used to constrain the permitted sequences of accesses to memory. The Armv8 memory model defines:

- The ordering of observation of memory accesses between different observers.
- The ordering of arrival of memory accesses arriving at an endpoint.
- The mechanisms to control the ordering of observation of memory accesses and the arrival of memory accesses at an endpoint.

Locations, Memory effects, and Observers

The Armv8 memory model provides the following definition of a Location in memory:

Location

A Location refers to a single byte in memory.

As part of its execution an instruction might generate a Memory effect. Observers in the system might observe the Memory effects of that instruction on a Location. The Armv8 memory model provides the following definitions of a Memory effect and an Observer:

Memory effect

The Memory effects of an instruction are the read, write, or barrier effects of that instruction. For an instruction that accesses memory:

- A read effect is generated for each Location that is read by the instruction.
- A write effect is generated for each Location that is written by the instruction.

An instruction can generate both read and write effects.

The Memory effects of instruction $I_1$ are said to appear in program order before the Memory effects of instruction $I_2$ if and only if $I_1$ occurs before $I_2$ in program order.
For the purposes of describing the Armv8 memory model, all read and write effects access only Normal memory locations in a Common Shareability Domain, and excludes the situations described in Mismatched memory attributes on page B2-153. Where this section refers to a read, write, or memory barrier without any qualification, then it is referring to the corresponding Memory effect.

Observer

An Observer refers to either a processing element, or some other memory accessing agent that can generate reads from or writes to memory.

Common Shareability Domain

A Common Shareability Domain for a program is the smallest Shareability domain that contains all of the active Observers of the Memory effects generated by a program.

B2.3.2 Ordering and observability

The Armv8 memory model permits reordering of memory accesses. This section defines the constraints placed on the reordering of memory accesses using the following:

• Register value dependencies to establish order between instructions on a PE.
• Ordering constraints to establish order between accesses to a Location.

Register value dependencies

The Armv8 memory model defines the following dependencies between instructions:

Register dependency

A Register dependency from a first data value V1 to a second data value V2 exists within a PE if and only if either:

• The register, excluding the AArch64 zero register (XZR or WZR), that is used to hold V1 is used in the calculation of V2.
• There is a Register dependency from V1 to a third data value V3 and there is a register dependency from V3 to V2.

Register data dependency

A Register data dependency from a first data value V1 to a second data value V2 exists within a PE if and only if either:

• The register, excluding the AArch64 zero register (XZR or WZR) and the AArch32 PC, that is used to hold V1 and is used in the calculation of V2, and the calculation between V1 and the V2 does not consist of either:
  — A conditional branch whose condition is determined by V1.
  — A conditional selection, move, or computation whose condition is determined by V1, where the input data values for the selection, move, or computation do not have a data dependency on V1.
• There is a Register data dependency from V1 to a third data value V3, and there is a Register data dependency from V3 to V2.

Address dependency

An Address dependency from a read R1 to a subsequent read R2 exists if and only if there is a Register data dependency from the data value that is returned by R1 to the address used by R2.

An Address dependency from a read R1 to a subsequent write W2 exists if and only if there is a Register dependency from the data value that is returned by R1 to the address used by W2.
Data dependency

A Data dependency from a read R₁ to a subsequent write W₂ exists if and only if there is a Register dependency from the data value returned by R₁ to the data value written by W₂.

Control dependency

A Control dependency from a read R₁ to a subsequent instruction I₂ exists if and only if either:

• There is a Register dependency from the data value returned by R₁ to the data value used in the evaluation of a conditional branch, and I₂ is only executed as a result of one of the possible outcomes of that conditional branch.

• There is a Register dependency from the data value returned by R₁ to the data value used in the determination of a synchronous exception on an instruction I₃, and I₂ appears in program order after I₃.

Ordering and observability at a Location

Memory effects on a Location are related by the following relations:

Reads-from

A Reads-from relation that couples reads and writes to the same Location such that each read is paired with a single write in the program. A read R₂ of a Location Reads-from a write W₁ to the same Location if and only if R₂ takes its data from W₁.

Note

The Reads-from relation represents a read being satisfied by a write and then returning the written data.

Coherence order

A Coherence order relation for each Location in the program that provides a total order on all writes from all coherent Observers to that Location, starting with a notional write of the initial value.

Note

The Coherence order of a Location represents the order in which writes to the Location arrive at memory.

Coherence-after

A write W₂ to a Location is Coherence-after another write W₁ to the same Location if and only if W₂ is sequenced after W₁ in the Coherence order of the Location.

A write W₂ to a Location is Coherence-after a read R₁ of the same location if and only if R₁ Reads-from a write W₃ to the same Location and W₂ is Coherence-after W₃.

Overlapping accesses

Two Memory effect overlap if and only if they access the same Location. Two instructions overlap if and only if one or more of their generated Memory effects overlap.

Observed-by

A read or a write RW₁ from an Observer is Observed-by a write W₂ from a different Observer if and only if W₂ is coherence-after RW₁.

A write W₁ from an Observer is Observed-by a read R₂ from a different Observer if and only if R₂ Reads-from W₁.

Note

The Observed-by relation only relates accesses generated by different Observers.
DMB FULL

A DMB FULL is a DMB with neither the LD or the ST qualifier.

Where this section refers to DMB without any qualification, then it is referring to all types of DMB.

Unless a specific shareability domain is defined, a DMB applies to the Common Shareability Domain.

All properties that apply to DMB also apply to the corresponding DSB.

Ordering relations

In addition to the ordering relations for a single Location, the Armv8 memory model also provides ordering relations to describe the ordering of Memory effects to multiple Locations. These are as follows:

Dependency-ordered-before

A dependency creates externally-visible order between a read and another Memory effect generated by the same Observer. A read R1 is Dependency-ordered-before a read or write RW2 from the same Observer if and only if R1 appears in program order before RW2 and any of the following cases apply:

• There is an Address dependency or a Data dependency from R1 to RW2.
• RW2 is a write W2 and there is a Control dependency from R1 to W2.
• RW2 is a read R2 generated by an instruction appearing in program order after an instruction I3 that generates a Context synchronization event, and there is a Control dependency from R1 to I3.
• RW2 is a write W2 appearing in program order after a read or a write RW3 and there is an Address dependency from R1 to RW3.
• RW2 is a write W2 that is Coherence-after a write W3 and there is a Control dependency or a Data dependency from R1 to W3.
• RW2 is a read R2 that Reads-from a write W3 and there is an Address dependency or a Data dependency from R1 to W3.

Atomic-ordered-before

Load-Exclusive and Store-Exclusive instructions provide some ordering guarantees, even in the absence of dependencies. A read or a write RW1 is Atomic-ordered-before a read or a write RW2 from the same Observer if and only if RW1 appears in program order before RW2 and either of the following cases apply:

• RW1 is a read R1 and RW2 is a write W2 such that R1 and W2 are generated by an atomic instruction or a successful Load-Exclusive/Store-Exclusive instruction pair to the same Location.
• RW1 is a write W1 generated by an atomic instruction or a successful Store-Exclusive instruction and RW2 is a read R2 generated by an instruction with Acquire or AcquirePC semantics such that R2 Reads-from W1.

For more information, see Synchronization and semaphores on page B2-156.

Barrier-ordered-before

Barrier instructions order prior Memory effects before subsequent Memory effects generated by the same Observer. A read or a write RW1 is Barrier-ordered-before a read or a write RW2 from the same Observer if and only if RW1 appears in program order before RW2 and any of the following cases apply:

• RW1 appears in program order before a DMB FULL that appears in program order before RW2.
• At least one of RW1 and RW2 is generated by an atomic instruction with both Acquire and Release semantics.
• RW1 is a write W1 generated by an instruction with Release semantics and RW2 is a read R2 generated by an instruction with Acquire semantics.
• RW₁ is a read R₁ and either:
  — R₁ appears in program order before a DMB LD that appears in program order before RW₂.
  — R₁ is generated by an instruction with Acquire or AcquirePC semantics.
• RW₂ is a write W₂ and either:
  — RW₁ is a write W₁ appearing in program order before a DMB ST that appears in program order before W₂.
  — W₂ is generated by an instruction with Release semantics.
  — RW₁ appears in program order before a write W₃ generated by an instruction with Release semantics and W₂ is Coherence-after W₃.

**Locally-ordered-before**

Dependencies, Load/Store-Exclusive, atomic and barrier instructions can be composed within an observer to create externally-visible order. A read or write (RW₁) is *Locally-ordered-before* a read or write (RW₂) from the same observer if and only if any of the following apply:

• RW₁ *Dependency-ordered-before* RW₂.
• RW₁ is *Atomic-ordered-before* RW₂.
• RW₁ is *Barrier-ordered-before* RW₂.
• RW₁ is Locally-ordered-before a read or a write that is Locally-ordered-before RW₂.

**Ordered-before**

An arbitrary pair of Memory effects is ordered if it can be linked by a chain of ordered accesses consistent with external observation. A read or a write RW₁ is *Ordered-before* a read or a write RW₂ if and only if any of the following cases apply:

• RW₁ is *Observed-by* RW₂.
• RW₁ is Locally-ordered-before RW₂.
• RW₁ is Ordered-before a read or write that is Ordered-before RW₂.
• If ARMv8.5-MemTag is implemented, RW₁ is Tag-ordered-before RW₂.

**Tag-determined-by**

If ARMv8.5-MemTag is implemented, a Checked access read or write, RW₁, is *Tag-determined-by* a Tag read R₂ if and only if all of the following applies:

• RW₁ and R₂ are generated by the same instruction.
• R₂ reads the Allocation Tag at a tag physical address and compares it with the physical address Tag passed as part of the access RW₁.

If the result of the comparison can cause a precise exception and the result if negative then RW₁ does not architecturally occur.

**Tag-ordered-before**

If ARMv8.5-MemTag is implemented, a read, R₁, is *Tag-ordered-before* a read or a write RW₂ generated by the same instruction if and only if R₁ is a Tag read and RW₂ is a Checked data access Tag-determined-by R₁.

### B2.3.3 Ordering constraints

The Armv8 memory model is described as being *Other-multi-copy atomic*. The definition of Other-multi-copy atomic is as follows:

**Other-multi-copy atomic**

In an *Other-multi-copy atomic* system, it is required that a write from an Observer, if observed by a different Observer, is then observed by all other Observers that access the Location coherently. It is, however, permitted for an Observer to observe its own writes prior to making them visible to other observers in the system.
The Other-multi-copy atomic property of the Armv8 memory model is enforced by placing constraints on the possible executions of a program. Those executions that meet the constraints given by the ordering model are said to be architecturally well-formed. An implementation that is executing a program is only permitted to exhibit behavior consistent with an architecturally well-formed execution:

**Architecturally well-formed**

An architecturally well-formed execution must satisfy both of the following requirements:

**Internal visibility requirement**

For a read or a write RW₁ that appears in program order before a read or a write RW₂ to the same Location, the internal visibility requirement requires that exactly one of the following statements is true:

- RW₂ is a write W₂ that is Coherence-after RW₁.
- RW₁ is a write W₁ and RW₂ is a read R₂ such that either:
  - R₂ Reads-from W₁.
  - R₂ Reads-from another write that is Coherence-after W₁.
- RW₁ and RW₂ are both reads R₁ and R₂ such that R₁ Reads-from a write W₃ and either:
  - R₂ Reads-from W₃.
  - R₂ Reads-from another write that is Coherence-after W₃.

--- Note ---

If a Memory effect M₁ from an Observer appears in program order before a Memory effect M₂ from the same Observer, then M₁ will be seen to occur before M₂ by that Observer.

**External visibility requirement**

For a read or a write RW₁ from an Observer that is Ordered-before a read or a write RW₂ from a different Observer, the external visibility constraint requires that RW₂ is not Observed-by RW₁. This means that an Architecturally well-formed execution must not exhibit a cycle in the Ordered-before relation.

--- Note ---

If a Memory effect M₁ from an Observer is Ordered-before another Memory effect M₂, from a different Observer, then M₁ will be seen to occur before M₂ by all Observers in the system.

### B2.3.4 Completion and endpoint ordering

Interaction between Observers in a system is not restricted to communication via shared variables in coherent memory. For example, an Observer could configure an interrupt controller to raise an interrupt on another Observer as a form of message passing. These interactions typically involve an additional agent, which defines the instruction sequence that is required to establish communication links between different Observers. When these forms of interaction are used in conjunction with shared variables, a DSB instruction can be used to enforce ordering between them.

For all memory, the completion rules are defined as:

- A read R₁ to a Location is complete for a shareability domain when all of the following are true:
  - Any write to the same Location by an Observer within the shareability domain will be Coherence-after R₁.
  - Any translation table walks associated with R₁ are complete for that shareability domain.
• A write \( W_1 \) to a Location is complete for a shareability domain when all of the following are true:
  — Any write to the same Location by an Observer within the shareability domain will be Coherence-after \( W_1 \).
  — Any read to the same Location by an Observer within the shareability domain will either Reads-from \( W_1 \) or Reads-from a write that is Coherence-after \( W_1 \).
  — Any translation table walks associated with the write are complete for that shareability domain.

• A translation table walk is complete for a shareability domain when the memory accesses, including the updates to translation table entries, associated with the translation table walk are complete for that shareability domain, and the TLB is updated.

• A cache maintenance instruction is complete for a shareability domain when the memory effects of the instruction are complete for that shareability domain, and any translation table walks that arise from the instruction are complete for that shareability domain.

• A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated are complete.

The completion of any cache or TLB maintenance instruction includes its completion on all PEs that are affected by both the instruction and the \( \text{DSB} \) operation that is required to guarantee visibility of the maintenance instruction.

Note

These completion rules mean that, for example, a cache maintenance instruction that operates by VA to the PoC completes only after memory at the PoC has been updated.

Additionally, for Device-nGnRnE memory, a read or write of a Location in a Memory-mapped peripheral that exhibits side-effects is complete only when the read or write both:

• Can begin to affect the state of the Memory-mapped peripheral.
• Can trigger all associated side-effects, whether they affect other peripheral devices, PEs, or memory.

Note

This requirement for Device-nGnRnE memory is consistent with the memory access having reached the peripheral endpoint.

Peripherals

This section defines a Memory-mapped peripheral and the total order of reads and writes to a peripheral which is defined as the Peripheral coherence order:

Memory-mapped peripheral

A Memory-mapped peripheral occupies a memory region of IMPLEMENTATION DEFINED size and can be accessed using load and store instructions. Memory effects to a Memory-mapped peripheral can have side-effects, such as causing the peripheral to perform an action. Values that are read from addresses within a Memory-mapped peripheral might not correspond to the last data value written to those addresses. As such, Memory effects to a Memory-mapped peripheral might not appear in the Reads-from or Coherence order relations.

Peripheral coherence order

The Peripheral coherence order of a Memory-mapped peripheral is a total order on all reads and writes to that peripheral.

Note

The Peripheral coherence order for a Memory-mapped peripheral signifies the order in which accesses arrive at the endpoint.
For a read or a write RW₁ and a read or a write RW₂ to the same peripheral, then RW₁ will appear in the Peripheral coherence order for the peripheral before RW₂ if either of the following cases apply:

- RW₁ and RW₂ are accesses using Non-cacheable or Device attributes and RW₁ is Ordered-before RW₂.
- RW₁ and RW₂ are accesses using Device-nGnRE or Device-nGnRnE attributes and RW₁ appears in program order before RW₂.

**Out-of-band-ordered-before**

A read or a write RW₁ is Out-of-band-ordered-before a read or a write RW₂ if and only if either of the following cases apply:

- RW₁ appears in program order before a DSB instruction that begins an IMPLEMENTATION DEFINED instruction sequence indirectly leading to the generation of RW₂.
- RW₁ is Ordered-before a read or a write RW₃ and RW₃ is Out-of-band-ordered-before RW₂.

If a Memory effect M₁ is Out-of-band-ordered-before a read or a write M₂, then M₁ is seen to occur before M₂ by all Observers.

**B2.3.5 Ordering of instruction fetches**

For two memory locations A and B, if A has been written to and been made coherent with the instruction fetches of the shareability domain, before an update to B by an observer in the same shareability domain, then the instruction stream of each observer in the shareability domain will not see the updated value of B without also seeing the updated value of A.

A write has been made coherent with an instruction fetch of a shareability domain when:

\[
\text{CTR_EL0.\{DIC, IDC\} == \{0, 0\}}
\]

The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

\[
\text{CTR_EL0.\{DIC, IDC\} == \{1, 0\}}
\]

The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain.

\[
\text{CTR_EL0.\{DIC, IDC\} == \{0, 1\}}
\]

The write is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

\[
\text{CTR_EL0.\{DIC, IDC\} == \{1, 1\}}
\]

The write is complete for the shareability domain.

--- **Note** ---

Microarchitecturally, this means that these situations cannot both be true in an implementation:

- After delays in fetching from memory, the instruction queue can have entries written into it out of order.
- For an implementation:
  - When \text{CTR_EL0.DIC == 0}, if there is an outstanding entry in the instruction queue, then later entries in the instruction queue are not impacted by the IC IVAU instructions of a different core.
  - When \text{CTR_EL0.DIC == 1}, if there is a write to the location that is held in the queue when there is an outstanding entry in the instruction queue for an older entry, then the instruction queue does not have entries invalidated from it.
B2.3.6 Restrictions on the effects of speculation

This section covers restrictions on speculation effects, including:

- Restrictions on the effects of speculation in Armv8.0.
- Speculative Store Bypass Safe (SSBS).
- Restrictions on the effects of speculation in Armv8.5 on page B2-124.

Restrictions on the effects of speculation in Armv8.0

The Armv8.0 architecture places certain restrictions on the effects of speculation. These are:

- Each load from a location using a particular VA after an exception return that is a Context synchronization event will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception exit.
- Each load from a location using a particular VA after an exception entry that is a Context synchronization event will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception entry.
- Any load from a location using a particular VA before an exception entry that is a Context synchronization event will not speculatively read data from a store to the same location using the same VA after the exception entry.
- Any load from a location using a particular VA before an exception return that is a Context synchronization event will not speculatively read data from a store to the same location using the same VA after the exception exit.
- When data is loaded under speculation with a translation fault, it cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by instructions newer than the load in the speculative sequence.
- When data is loaded under speculation from a location without a translation for the translation regime being speculated in, the data cannot be used to form an address, generate condition codes, or generate SVE predicate values to be used by instructions newer than the load in the speculative sequence.

Speculative Store Bypass Safe (SSBS)

When ARMv8.0-SSBS is implemented, PSTATE.SSBS is a control that can be set by software to indicate whether hardware is permitted to load or store speculatively in such a manner that could be exploited to produce a cache timing side channel, which uses an address derived from a register value that has been loaded from memory using a load instruction that speculatively read an entry for the location being loaded from, where the entry that is speculatively read is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

When the value of PSTATE.SSBS is 0, hardware is not permitted to load or store speculatively in this way.

When the value of PSTATE.SSBS is 1, hardware is permitted to load or store speculatively in this way.

Note

- If speculation is permitted, then cache timing side channels can lead to addresses being derived using reads of address values that have been speculatively loaded from memory to a register.
- Software written for architectures from Armv8.0 to Armv8.4 will set SPSR_ELx.SSBS to 0. This means that PSTATE.SSBS will not set, so hardware will not be permitted to use speculative loads with outstanding memory disambiguation issues for any subsequent speculative memory accesses if there is any possibility of those subsequent memory accesses creating a cache timing side channel.
Restrictions on the effects of speculation in Armv8.5

From Armv8.5 there are some further restrictions on the effects of speculation in addition to those in Armv8.0:

- Data loaded under speculation with a permission or domain fault cannot be used to form an address, to generate condition codes, or to generate SVE predicate values to be used by instructions newer than the load in the speculative sequence.

- Any System register read under speculation to a register that is not architecturally accessible from the current Exception level cannot be used to form an address, to generate condition codes, or to generate SVE predicate values to be used by instructions newer than the load in the speculative sequence.

Note

As the effects of speculation are not architecturally visible, this restriction requires that the effect of any speculation cannot give rise to side channels that will leak the values of memory locations, System registers, or Special-purpose registers to a level of privilege that would otherwise not be able to determine those values.

- For all execution prediction resources that predict address or register values, speculative execution at one hardware defined context should be separated in a hard-to-determine manner from the predictions trained in a different hardware defined context. In the case of this definition, the hardware defined context is determined by:
  - The Exception level.
  - The Security state.
  - When executing at EL1, the VMID.
  - When executing at EL0 and using the EL1&0 translation regime, the ASID and the VMID.
  - When executing at EL0 and using the EL2&0 translation regime, the ASID.
  - When in AArch64 state, the current SCXTNUM_ELx value.

Note

The definition of “hard-to-determine manner” is left open to implementations. Examples could include the complete separation of prediction resources, or the isolation of the predictions using a cryptographic or pseudo-random mechanism to separate each context.

- The architecture does not require that prediction resources that simply predict the direction of a branch are separated in this way.

B2.3.7 Memory barriers

Memory barrier is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring Load/Store instructions. The memory barriers defined by the Armv8 architecture provide a range of functionality, including:

- Ordering of Load/Store instructions.
- Completion of Load/Store instructions.
- Context synchronization.

The following subsections describe the Armv8 memory barrier instructions:

- Instruction Synchronization Barrier (ISB) on page B2-125
- Data Memory Barrier (DMB) on page B2-125.
- Data Synchronization Barrier (DSB) on page B2-128.
- Speculation Barrier (SB) on page B2-126.
- Consumption of Speculative Data Barrier (CSDB) on page B2-126.
- Speculative Store Bypass Barrier (SSBB) on page B2-126.
- Profiling Synchronization Barrier (PSB CSYNC) on page B2-127.
- Physical Speculative Store Bypass Barrier (PSSBB) on page B2-127.
- **Trace Synchronization Barrier (TSB CSYNC)** on page B2-127
- **Shareability and access limitations on the data barrier operations** on page B2-129.
- **LoadLOAcquire, StoreLORelease** on page B2-130.

--- **Note** ---

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are only available when software execution is at EL1 or higher.

DMB and DSB instructions affect reads and writes to the memory system generated by Load/Store instructions and data or unified cache maintenance instructions being executed by the PE. Instruction fetches or accesses caused by a hardware translation table access are not explicit accesses.

### Instruction Synchronization Barrier (ISB)

An ISB instruction ensures that all instructions that come after the ISB instruction in program order are fetched from the cache or memory after the ISB instruction has completed. Using an ISB ensures that the effects of context-changing operations executed before the ISB are visible to the instructions fetched after the ISB instruction. Examples of context-changing operations that require the insertion of an ISB instruction to ensure the effects of the operation are visible to instructions fetched after the ISB instruction are:

- Completed cache and TLB maintenance instructions.

Any context-changing operations appearing in program order after the ISB instruction only take effect after the ISB has been executed.

The pseudocode function for the operation of an ISB is `InstructionSynchronizationBarrier()`. See also *Memory barriers on page D4-2501.*

### Data Memory Barrier (DMB)

The DMB instruction is a memory barrier instruction that ensures the relative order of memory accesses before the barrier with memory accesses after the barrier. The DMB instruction does not ensure the completion of any of the memory accesses for which it ensures relative order.

The full definition of the DMB is covered formally in the *Definition of the Armv8 memory model* on page B2-115 and this introduction to the DMB instruction is not intended to contradict that section.

The basic principle of a DMB instruction is to introduce order between memory accesses that are specified to be affected by the DMB options supplied as arguments to the DMB instruction. The DMB instruction ensures that all affected memory accesses by the PE executing the DMB that appear in program order before the DMB and those which originate from a different PE, to the extent required by the DMB options, which have been Observed-by the PE before the DMB is executed, are Observed-by each PE, to the extent required by the DMB options, before any affected memory accesses that appear in program order after the DMB are Observed-by that PE.

The use of a DMB creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

DMB only affects memory accesses and the operation of data cache and unified cache maintenance instructions, see *A64 Cache maintenance instructions on page D4-2482.* It has no effect on the ordering of any other instructions executing on the PE. A DMB instruction intended to ensure the completion of cache maintenance instructions must have an access type of both loads and stores.

The pseudocode function for the operation of a DMB is `DataMemoryBarrier()`.
Speculation Barrier (SB)

An SB is a memory barrier that prevents speculative execution of instructions until after the barrier has completed when those instructions could be observed through side-channels.

Until the barrier completes, the speculative execution of any instruction appearing later in the program order than the barrier:

- Cannot be performed to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be performed when predicting that an instruction that could generate an exception does not generate an exception.

Speculative execution of an SB instruction:

- Cannot be as a result of control flow speculation.
- Cannot be as a result of data value speculation.
- Can be as a result of predicting that an instruction that could generate an exception does not generate an exception.

An SB instruction can complete when:

- It is known that it is not speculative.
- All the predicted data values generated by instructions appearing in program order before the SB instruction have their predicted values confirmed.

Note

The SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched, so long as the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after the SB instruction.

Consumption of Speculative Data Barrier (CSDB)

The CSDB instruction is a memory barrier instruction that controls speculative execution and data value prediction. This includes:

- Data value predictions of any instructions.
- PSTATE.{N,Z,C,V} predictions of any instructions other than conditional branch instructions appearing in program order before the CSDB that have not been architecturally resolved.
- Predictions of SVE predication state for any SVE instructions.

For purposes of the definition of CSDB, PSTATE.{N,Z,C,V} is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or PSTATE.{N,Z,C,V} predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

Speculative Store Bypass Barrier (SSBB)

The SSBB is a memory barrier that prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.
The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the SSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the SSBB.

- When a load to a location appears in program order before the SSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the SSBB.

Profiling Synchronization Barrier (PSB CSYNC)

The PSB CSYNC is a memory barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. A following DSB instruction completes when the writes to the profiling buffer have completed.

If the Statistical Profiling Extension is not implemented, this instruction executes as a NOP.

Physical Speculative Store Bypass Barrier (PSSBB)

The PSSBB is a memory barrier that prevents speculative loads from bypassing earlier stores to the same physical address under certain conditions.

The semantics of the Physical Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the PSSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the PSSBB.

- When a load to a location appears in program order before the PSSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the PSSBB.

Trace Synchronization Barrier (TSB CSYNC)

The TSB CSYNC is a memory barrier instruction that preserves the relative order of memory accesses to System registers due to trace operations and other memory accesses to the same registers.

A trace operation is an operation of the PE Trace Unit generating trace for an instruction when ARMv8.4-Trace is implemented and enabled.

A TSB CSYNC is not required to execute in program order with respect to other instructions. This includes being reordered with respect to other trace instructions. One or more context synchronization events are required to ensure that TSB CSYNC is executed in the necessary order.

If trace is generated between a context synchronization event and a TSB CSYNC operation, these trace operations may be reordered with respect to the TSB CSYNC operation, and therefore may not be synchronized.
The following situations are synchronized using a TSB CSYNC:

• A direct write B to a System register is ordered after an indirect read or indirect write of the same register by a trace operation A, if all of the following are true:
  — A is executed in program order before a context synchronization event C.
  — C is in program order before a TSB CSYNC operation T.
  — B is executed in program order after T.

• A direct read B of a System register is ordered after an indirect write to the same register by a trace operation A if all the following are true:
  — A is executed in program order before a context synchronization event C1.
  — C1 is in program order before TSB CSYNC operation T.
  — T is executed in program order before a second context synchronization event C2.
  — B is executed in program order after C2.

A TSB CSYNC operation is not needed to ensure a direct write B to a System register is ordered before an indirect read or indirect write of the same register by a trace operation A, if all the following are true:

• A is executed in program order after a context synchronization event C.
• B is executed in program order before C.

The pseudocode function for the operation of a TSB CSYNC is TraceSynchronizationBarrier().

**Data Synchronization Barrier (DSB)**

A DSB is a memory barrier that ensures that memory accesses that occur before the DSB have completed before the completion of the DSB instruction. In doing this, it acts as a stronger barrier than a DMB and all ordering that is created by a DMB with specific options is also generated by a DSB with the same options.

Execution of a DSB:

• At EL2 ensures that any memory accesses caused by Speculative translation table walks from the EL1&0 translation regime have been observed.

• At EL3 ensures that any memory accesses caused by speculative translation table walks from the EL2 or EL2&0 translation regimes.

For more information, see *Use of out-of-context translation regimes on page D5-2526.*

A DSB executed by a PE, PEe, completes when all of the following apply:

• All explicit memory accesses of the required access types appearing in program order before the DSB are complete for the set of observers in the required shareability domain.

• If the required access types of the DSB is reads and writes, then all cache maintenance instructions, all TLB maintenance instructions, and all PSB CYNC instructions issued by PEe before the DSB are complete for the required shareability domain.

In addition, no instruction that appears in program order after the DSB instruction can alter any state of the system or perform any part of its functionality until the DSB completes other than:

• Being fetched from memory and decoded.

• Reading the general-purpose, SIMD and floating-point, Special-purpose, or System registers that are directly or indirectly read without causing side-effects.

If ARMv8.5-MemTag is implemented and enabled on completion of a DSB instruction, all updates to TFSR ELx.TFx or TFSRE0_EL1.TFx due to Tag Check fails caused by accesses for which the DSB operates will be complete. For more information on ARMv8.5-MemTag see Chapter D6 Armv8.5 Memory Tagging Extension.

The pseudocode function for the operation of a DSB is DataSynchronizationBarrier().

See also *Memory barriers on page D4-2501.*
Shareability and access limitations on the data barrier operations

The DMB and DSB instructions take an argument that specifies:

- The shareability domain over which the instruction must operate. This is one of:
  - Full system.
  - Outer Shareable.
  - Inner Shareable.
  - Non-shareable.

- The accesses for which the instruction operates. This is one of:
  - Read and write accesses, both before and after the barrier instruction.
  - Write accesses only, before and after the barrier instruction.
  - Read accesses before the barrier instruction, and read and write accesses after the barrier instruction.

**Note**

This form of a DMB or DSB instruction can be described as a Load-Load/Store barrier.

For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) on page B2-125 or Data Synchronization Barrier (DSB) on page B2-128.

Table B2-1 shows how these options are encoded in the `<option>` field of the instruction:

<table>
<thead>
<tr>
<th>Accesses</th>
<th>Shareability domain</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before the barrier</td>
<td>After the barrier</td>
</tr>
<tr>
<td>Reads and writes</td>
<td>Full system</td>
</tr>
<tr>
<td>Reads and writes</td>
<td>Outer Shareable</td>
</tr>
<tr>
<td>Read</td>
<td>Inner Shareable</td>
</tr>
<tr>
<td>Read</td>
<td>Non-shareable</td>
</tr>
</tbody>
</table>

See the instruction descriptions for more information:

- DMB on page C6-888.
- DSB on page C6-891.

**Note**

ISB also supports an optional limitation argument that can only contain one value that corresponds to full system operation, see ISB on page C6-912.

Load-Acquire, Load-AcquirePC, and Store-Release

Armv8 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores. These instructions support the Release Consistency sequentially consistent (RCsc) model. In addition, ARMv8.3-RCPC provides Load-AcquirePC instructions. The combination of Load-AcquirePC and Store-Release can be used to support the weaker Release Consistency processor consistent (RCpc) model.

The full definitions of the Load-Acquire and Load-AcquirePC instructions are covered formally in the Definition of the Armv8 memory model on page B2-115. This introduction to the Load-Acquire and Load-AcquirePC instructions is not intended to contradict that section.

The basic principle of both Load-Acquire and Load-AcquirePC instructions is to introduce order between the memory access generated by the Load-Acquire or Load-AcquirePC instruction and the memory accesses appearing in program order after the Load-Acquire or Load-AcquirePC instruction, such that the memory access generated by the Load-Acquire or Load-AcquirePC instruction is Observed-by each PE, to the extent that the PE is required to
observe the access coherently, before any of the memory accesses appearing in program order after the Load-Acquire or Load-AcquirePC instruction are Observed-by that PE, to the extent that the PE is required to observe the accesses coherently.

The use of a Load-Acquire or Load-AcquirePC instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The full definition of the Store-Release instruction is covered formally in the Definition of the Armv8 memory model on page B2-115 and this introduction to the Store-Release instruction is not intended to contradict that section.

The basic principle of a Store-Release instruction is to introduce order between the memory accesses generated by the PE executing the Store-Release instruction, together with those which originate from a different PE, to the extent that the PE is required to observe them coherently, Observed-by the PE before executing the Store-release.

The use of a Store-Release instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

Where a Load-Acquire appears in program order after a Store-Release, then the memory access generated by the Store-Release instruction is Observed-by each PE, to the extent that PE is required to observe the access coherently, before the memory access generated by the Load-Acquire instruction are Observed-by that PE, to the extent that the PE is required to observe the access coherently. In addition, the use of a Load-Acquire, Load-AcquirePC or a Store-Release instruction on accesses to a Memory-mapped peripheral introduces order between the Memory effects of the instructions that access that peripheral, as described in the definition of Peripheral coherence order.

Load-Acquire, Load-AcquirePC and Store-Release, other than Load-Acquire Exclusive Pair and Store-Release-Exclusive Pair, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

Load-Acquire Exclusive Pair and Store-Release Exclusive Pair access two data elements. The address supplied to the instructions must be aligned to twice the size of the element being loaded, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction only has the release semantics if the store is successful.

—— Note ———
• Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
  — That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
  — That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.

• The Load-Acquire, Load-AcquirePC, and Store-Release instructions can remove the requirement to use the explicit DMB instruction.

LoadLOAcquire, StoreLORelease

For each PE, the Non-secure physical memory map is divided into a set of LORegions using a table that is held within the PE. Any PA in the Non-secure memory map can be a member of one LORegion. If a PA is assigned to more than one LORegion, then an implementation might treat it as if it has been assigned to fewer LORegions than that have been specified. A PA in the Secure physical memory map cannot be a member of any LORegion. For more information, see Limited ordering regions on page B2-131.

Armv8.1 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores that apply in relation to the defined LORegions. The new variants of the Load-Acquire and Store-Release instructions are LoadLOAcquire and StoreLORelease. See LoadLOAcquire/StoreLORelease on page C3-204.

For all memory types, these instructions have the following ordering requirements:

• LoadLOAcquire has the same semantics as Load-Acquire except that the memory accesses affected lie within the same LORegion as the address of the memory access generated by the LoadLOAcquire instruction. See Load-Acquire, Load-AcquirePC, and Store-Release on page B2-129.
• StoreLORelease has the same semantics as Store-Release except that the memory accesses affected lie within the same LORegion as the address of the memory access generated by the StoreLORelease instruction. See Load-Acquire, Load-AcquirePC, and Store-Release on page B2-129.

In addition, for accesses to Memory-mapped peripherals:

• LoadLOAcquire has the same semantics as Load-Acquire except that the affected Memory effects of instructions that access the peripheral lie within the same LORegion as the address of the memory access generated by the LoadLOAcquire instruction. See Load-Acquire, Load-AcquirePC, and Store-Release on page B2-129.

• StoreLORelease has the same semantics as Store-Release except that the affected Memory effects of instructions that access the peripheral lie within the same LORegion as the address of the memory access generated by the StoreLORelease instruction. See Load-Acquire, Load-AcquirePC, and Store-Release on page B2-129.

_________ Note ___________
The LoadLOAcquire/StoreLORelease instructions can remove the requirement to use the explicit DMB instruction.

B2.3.8 Limited ordering regions

Armv8.1 introduces limited ordering regions (LORegions), which allow large systems to perform special load-acquire and store-release instructions that provide order between the memory accesses to a region of the PA map as observed by a set of observers.

This feature is supported in AArch64 state only.

Specification of the LORegions

The LORegions are defined in the Non-secure physical memory map using a set of LORegion descriptors. The number of LORegion descriptors is IMPLEMENTATION DEFINED, and can be discovered by reading the LORID_EL1 register.

Each LORegion descriptor consists of:

• A tuple of the following values:
  — A Start Address.
  — An End Address.
  — An LORegion Number.
• Valid bit which indicates whether that LORegion descriptor is valid.

A memory location lies within the LORegion identified by the LORegion Number if the PA lies between the Start Address and the End Address, inclusive. The Start Address must be defined to be aligned to 64KB and the End Address must be defined as the top byte of a 64KB block of memory.

The LORegion descriptors are programmed using the LORSA_EL1, LOREA_EL1, LORN_EL1, and LORC_EL1 registers in the System register space. These registers are only supported in the Non-secure memory map.

If a LoadLOAcquire or a StoreLORelease does not match with any LORegion, then:

• The LoadLOAcquire will behave as a Load-Acquire, and will be ordered in the same way with respect to all accesses, independent of their LORegions.
• The StoreLORelease will behave as a Store-Release, and will be ordered in the same way with respect to all accesses, independent of their LORegions.

_________ Note ___________
If no LORegions are implemented, then the LoadLOAcquire and StoreLORelease will therefore behave as a Load-Acquire and Store-Release.
A new access type `AccType_LIMITEDORDERED` has been added for these limited ordering instructions to be identified.
B2.4 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. Armv8 defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- Introduction to caches.
- Memory hierarchy.
- Application level access to functionality related to caches on page B2-134
- Implication of caches for the application programmer on page B2-135.
- Preloading caches on page B2-137.

B2.4.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a tag.
- The associated data.

Caches increase the average speed of a memory access. Caching takes account of two principles of locality:

**Spatial locality**

An access to one Location is likely to be followed by accesses to adjacent Locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

**Temporal locality**

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a cache line. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access occurs to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. Armv8 permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

B2.4.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an Armv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. Figure B2-1 on page B2-134 shows an example of such a system in an Armv8-A system that supports virtual addressing.
The AArch64 Application Level Memory Model

B2.4 Caches and memory hierarchy

--- Note ---

In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the processing element, as shown in Figure B2-1.

Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches that are located at the levels closest to the main memory. Memory coherency for cache topologies can be defined using the conceptual points Point of Unification (PoU), Point of Coherency (PoC), Point of Persistence (PoP), and Point of Deep Persistence (PoDP).

For more information, including the definitions of PoU, PoC, PoP, and PoDP, see About cache maintenance in AArch64 state on page D4-2478.

If ARMv8.5-MemTag is implemented and enabled the behavior of cache maintenance instructions is modified for more information see Allocation Tags on page D6-2661.

The cacheability and shareability memory attributes

Cacheability and shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

**Cacheability**

This attribute defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer Cacheability locations.

**Shareability**

This attribute defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer Shareability domains.

For more information about Cacheability and Shareability, see Memory types and attributes on page B2-143.

B2.4.3 Application level access to functionality related to caches

As indicated in About the Application level programmers’ model on page B1-98, the application level corresponds to execution at EL0. The architecture defines a set of cache maintenance instructions that software can use to manage cache coherency. Software executing at a higher Exception level can enable use of some of this functionality from EL0, as follows:

**When the value of SCTLR_EL1.UCI is 1**

Software executing at EL0 can access:

- The data cache maintenance instructions, DC CVAU, DC CVAC, DC CVAP, DC CVADP, and DC CIVAC.

See The data cache maintenance instruction (DC) on page D4-2483.
The AArch64 Application Level Memory Model

B2.4 Caches and memory hierarchy

- The instruction cache maintenance instruction IC IVAU. See *The instruction cache maintenance instruction (IC)* on page D4-2483.

  Attempted execution of these instructions might generate a Permission fault as described in *Permission fault* on page D5-2623.

**When the value of SCTLR_EL1.UCT is 1**

  Software executing at EL0 can access the cache type register. See CTR_EL0.

**When the value of SCTLR_EL1.DZE is 1**

  Software executing at EL0 can access the data cache zero instruction DC ZVA. See *Data cache zero instruction* on page D4-2492.

  The SCTLR_EL1.{UCI, UCT, DZE} control fields are only accessible by software executing at EL1 or higher.

  When HCR_EL2.{E2H, TGE} == 1 the controls {UCI, UCT and DZE} are found in SCTLR_EL2.

  This functionality is UNDEFINED at EL0 when the value of the corresponding SCTLR_EL1 control field is 0, see:

  - *Traps to EL1 of EL0 execution of cache maintenance instructions* on page D1-2328.
  - *Traps to EL1 of EL0 accesses to the CTR_EL0* on page D1-2329.
  - *Traps to EL1 of EL0 execution of DC ZVA instructions* on page D1-2330.

B2.4.4   Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.
- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

**Data coherency issues**

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
  — Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
  — Not enabling caches in the system.

- By using cache maintenance instructions to manage the coherency issues in software. See *Application level access to functionality related to caches* on page B2-134.

- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see *Non-shareable Normal memory* on page B2-145 and *Shareable, Inner Shareable, and Outer Shareable Normal memory* on page B2-144.
Note
The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations, the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

Note
Not all these mechanisms are directly available to software operating at EL0 and might involve interaction with software operating at a higher Exception level.

Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last Context synchronization event on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being refetched from memory. In the absence of a Context synchronization event, there is no limit on the number of times such an instruction might be executed without being refetched from memory.

The Arm architecture requires the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory. A write has been made coherent with an instruction fetch of a shareability domain when:

CTR_EL0.{DIC, IDC} == {0, 0}

The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {1, 0}

The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {0, 1}

The write is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {1, 1}

The write is complete for the shareability domain.

If software requires coherency between instruction execution and memory, it must manage this coherency using Context synchronization events and cache maintenance instructions. The following code sequence can be used to allow a PE to execute code that the same PE has written.

; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Wt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Xn.
STR Wt, [Xn]
DC CVAU, Xn ; Clean data cache by VA to point of unification (PoU)
DSB ISH ; Ensure visibility of the data cleaned from cache
IC IVAU, Xn  ; Invalidate instruction cache by VA to PoU
DSB ISH ; Ensure completion of the invalidations
ISB ; Synchronize the fetched instruction stream
Note

- If this sequence is not executed between writing data to a location and executing the instruction at that location, the lack of coherency between instruction caches and memory means that the instructions that are executed might be the old instruction or the updated instruction, and which is used can arbitrarily vary during execution. It must not be assumed by software, before the synchronization sequence is executed, that when the updated instruction has been seen, the old instruction will not be seen again.

- For Non-cacheable or Write-Through accesses, the clean data cache by VA instruction is not required. However, the invalidate instruction cache instruction is required because the Armv8-A AArch64 architecture allows Non-cacheable accesses to be held in an instruction cache. See Non-cacheable accesses and instruction caches on page D4-2477.

- This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The Armv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See Concurrent modification and execution of instructions on page B2-112.

- The system software controls whether these cache maintenance instructions are available to the application level by setting SCTLR_EL1.UCI.

B2.4.5 Preloading caches

The Arm architecture provides memory system hints PRFM, LDNP, and STNP that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring the data or instruction locations into caches.

The Preload instructions are hints, and so implementations can treat them as NOPs without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous External abort, which is taken using an SError interrupt exception. For more information, see ISS encoding for an exception from a Data Abort on page D13-2943.

PrefetchHint{} defines the prefetch hint types.

The Hint_Prefetch() function signals to the memory system that memory accesses of the type hint to or from the specified address are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as preloading the specified address into one or more caches as indicated by the innermost cache level target and non-temporal hint stream.

For more information on PRFM and Load/Store instructions that provide hints to the memory system, see Prefetch memory on page C3-208 and Load/Store SIMD and Floating-point Non-temporal pair on page C3-206.
**B2.5 Alignment support**

This section describes alignment support. It contains the following subsections:

- **Instruction alignment.**
- **Alignment of data accesses.**

**B2.5.1 Instruction alignment**

A64 instructions must be word-aligned.

Attempting to fetch an instruction from a misaligned location results in a PC alignment fault. See *PC alignment checking* on page D1-2287.

**B2.5.2 Alignment of data accesses**

An unaligned access to any type of Device memory causes an Alignment fault.

**Unaligned accesses to Normal memory**

The behavior of unaligned accesses to Normal memory is dependent on all of the following:

- The instruction causing the memory access.
- The memory attributes of the accessed memory.
- The value of SCTLR_ELx[A, nAA].
- Whether or not ARMv8.4-LSE is implemented.

**Load or Store of Single or Multiple registers**

For all instructions that load or store single or multiple registers, but not Load-Exclusive, Store-Exclusive, Load-Acquire/Store-Release and Atomic instructions, if the address that is accessed is not aligned to the size of the data element being accessed, then:

- When the value of SCTLR_ELx.A applicable to the current Exception level is 1, an Alignment fault is generated.
- When the value of SCTLR_ELx.A applicable to the current Exception level is 0:
  - An unaligned access is performed.
  - If ARMv8.4-LSE is not implemented, the access is not guaranteed to be single-copy atomic except at the byte access level.
  - If ARMv8.4-LSE is implemented:
    - If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable memory, the memory access is single-copy atomic. For a Load-Pair or Store-Pair, including load non-temporal pair, instructions the entire memory access will be single-copy atomic.
    - If all the bytes of the memory accessed do not lie within a 16-byte quantity aligned to 16 bytes or the access is not to Normal Inner Write-Back, Outer Write-Back Cacheable memory the access is not guaranteed to be single-copy atomic except at the byte access level.

For these instructions, the definition of an unaligned access is based on the size of the accessed elements, not the overall size of the memory access. This affects SIMD element and structure loads and stores, and also Load/store pair instructions.

**Load-Exclusive/Store-Exclusive and Atomic instructions**

For Load-Exclusive/Store-Exclusive, and Atomic instructions including those with acquire or acquire-release semantics:

- When the value of SCTLR_ELx.A applicable to the current Exception level is 1, an Alignment fault is generated.
- When the value of SCTLR_ELx.A applicable to the current Exception level is 0:
If ARMv8.4-LSE is not implemented, these instructions generate an Alignment fault if the address being accessed is not aligned to the size of the data structure being accessed.

If ARMv8.4-LSE is implemented, then:

- If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable memory, an unaligned access is performed.

- If all the bytes of the memory access do not lie within a 16-byte quantity aligned to 16-bytes, or the memory access is not to Normal Inner Write-Back, Outer Write-Back Cacheable memory, then it is an IMPLEMENTATION DEFINED choice of either of the following:
  - An unaligned access is performed meeting all of the semantics of the instruction.
  - An Alignment fault is generated.

Where memory access is performed, then it is single-copy atomic.

For these instructions, the definition of an unaligned access is based on the overall access size.

**Non-atomic Load-Acquire/Store-Release instructions**

For Load-Acquire/Store-Release instructions which do not have exclusive or atomic behaviors:

When the value of SCTLR_ELx.A applicable to the current Exception level is 1, an Alignment fault is generated.

When the value of SCTLR_ELx.A applicable to the current Exception level is 0:

If ARMv8.4-LSE is not implemented, then these instructions generate an Alignment fault if the address being accessed is not aligned to the size of the data structure being accessed.

If ARMv8.4-LSE is implemented, then:

- If the memory access is not to Normal Inner Write-Back or Outer Write-Back Cacheable memory, then it is an IMPLEMENTATION DEFINED choice of either of the following:
  - An unaligned access is performed meeting all of the semantics of the instruction.
  - An Alignment fault is generated.

- If all of the bytes of the memory access do not lie within a 16-byte quantity aligned to 16 bytes then the following applies:
  - If SCTLR_ELx.nAA applicable to the current Exception level is 0 an Alignment fault is generated.
  - If SCTLR_ELx.nAA applicable to the current Exception level is 1 then an unaligned access is performed which is not guaranteed to be single-copy atomic except at the byte access level.

In this case, the architecture does not define the order of the different transactions of the access defined by the single instructions relative to each other.

--- **Note** ---

- Unaligned accesses typically take additional cycles to complete compared to a naturally-aligned access.

- An operation that is not single-copy atomic above the byte level can abort on any memory access that it makes and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the page boundary.
B2.6 Endian support

*General description of endianness in the Arm architecture* describes the relationship between endianness and memory addressing in the Arm architecture.

The following subsections then describe the endianness schemes supported by the architecture:

- *Instruction endianness* on page B2-141.
- *Data endianness* on page B2-141.

### B2.6.1 General description of endianness in the Arm architecture

This section only describes memory addressing and the effects of endianness for data elements up to quadwords of 128 bits. However, this description can be extended to apply to larger data elements.

For an address A, Figure B2-2 shows, for big-endian and little-endian memory systems, the relationship between:

- The quadword at address A.
- The doubleword at address A and A+8.
- The words at addresses A, A+4, A+8, and A+12.
- The halfwords at addresses A, A+2, A+4, A+6, A+8, A+10, A+12, and A+14.

The terms in Figure B2-2 have the following definitions:

- **B**<sub>A</sub> Byte at address A.
- **HW**<sub>A</sub> Halfword at address A.
- **MSByte** Most significant byte.
- **LSByte** Least significant byte.

</table>
The big-endian and little-endian mapping schemes determine the order in which the bytes of a quadword, doubleword, word, or halfword are interpreted. For example, a load of a word from address 0x1000 always results in an access to the bytes at memory locations 0x1000, 0x1001, 0x1002, and 0x1003. The endianness mapping scheme determines the significance of these 4 bytes.

B2.6.2 Instruction endianness

In Armv8-A, A64 instructions have a fixed length of 32 bits and are always little-endian.

B2.6.3 Data endianness

SCTLR_EL1.E0E, configurable at EL1 or higher, determines the data endianness for execution at EL0.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for SIMD and floating-point register and general-purpose register loads and stores.

- Is the size of the data element that is loaded or stored for SIMD element and data structure loads and stores.

For more information, see Endianness in SIMD operations.

--- Note

This means the Armv8 architecture introduces a requirement for 128-bit endian conversions.

Instructions to reverse bytes in a general-purpose register or a SIMD and floating-point register

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Table B2-2 shows the instructions that provide this functionality:

<table>
<thead>
<tr>
<th>Function</th>
<th>Instructions</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reverse bytes in 32-bit word or wordsa</td>
<td>REV32</td>
<td>For use with general-purpose registers</td>
</tr>
<tr>

</tr>
</tbody>
</table>

a. Can operate on multiple words.

Endianness in SIMD operations

SIMD element Load/Store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used to load and store data correctly in both big-endian and little-endian systems.

For example:
This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure B2-3. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

Memory system with little-endian addressing (LE)

Memory system with big-endian addressing (BE)

Figure B2-3 SIMD byte order example

The BigEndian() pseudocode function determines the current endianness of the data.

The BigEndianReverse() pseudocode function reverses the endianness of a bitstring.

The BigEndian() and BigEndianReverse() functions are defined in Chapter J1 Armv8 Pseudocode.

### B2.6.4 Endianness of memory-mapped peripherals

All memory-mapped peripherals defined in the Arm architecture must be little-endian.

Peripherals to which this requirement applies include:

- Memory-mapped register interfaces to a debugger, or to a cross-trigger interface, see Chapter H8 About the External Debug Registers.
- The memory-mapped register interface to the system level implementation of the Generic Timer, see Chapter I2 System Level Implementation of the Generic Timer.
- A memory-mapped register interface to the Performance Monitors, see Chapter I3 Recommended External Interface to the Performance Monitors.
- A memory-mapped register interface to the Activity Monitors, see Chapter I4 Recommended External Interface to the Activity Monitors.
- Memory-mapped register interfaces to an Arm Generic Interface Controller, see the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0.
- The memory-mapped register interface to an Arm trace component. See, for example, the ARM® Embedded Trace Macrocell Architecture Specification, ETMv4.
B2.7 Memory types and attributes

In Armv8 the ordering of accesses for addresses in memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- Normal memory.
- Device memory on page B2-147.
- Memory access restrictions on page B2-152.

B2.7.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform Speculative data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- A write to a memory location with the Normal attribute completes in finite time. This means that it is globally observed for the shareability domain of the memory location in finite time. For a Non-cacheable location, the location is observed by all observers in finite time.

- A completed write to a memory location with the Normal attribute is globally observed for the shareability domain of the memory location in finite time without the need for explicit cache maintenance instructions or barriers. For a Non-cacheable location, the completed write is globally observed for all observers in finite time without the need for explicit cache maintenance instructions or barriers.

- Writes to a memory location with the Normal memory attribute that are Non-cacheable must reach the endpoint for that location in the memory system in finite time.

- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.

- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See Multi-register loads and stores that access Normal memory on page B2-147.

--- Note ---

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
  - Read accesses can be repeated with no side-effects.
  - Repeated read accesses return the last value written to the resource being read.
  - Read accesses can fetch additional memory locations with no side-effects.
  - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
  - Unaligned accesses can be supported.
  - Accesses can be merged before accessing the target memory system.

- An instruction that generates a sequence of accesses as described in Atomicity in the Arm architecture on page B2-110 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore, one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

For accesses to Normal memory, a DMB instruction is required to ensure the required ordering.

The following sections describe the other attributes for Normal memory:

- Shareable Normal memory on page B2-144.
- Non-shareable Normal memory on page B2-145.
- Cacheability attributes for Normal memory on page B2-145.
See also:

- *Multi-register loads and stores that access Normal memory* on page B2-147.
- *Concurrent modification and execution of instructions* on page B2-112.

### Shareable Normal memory

A Normal memory location has a Shareability attribute that is one of:

- Inner Shareable, meaning it applies across the Inner Shareable shareability domain.
- Outer Shareable, meaning it applies across both the Inner Shareable and the Outer Shareable shareability domains.
- Non-shareable.

The shareability attributes define the data coherency requirements of the location, that hardware must enforce. They do not affect the coherency requirements of instruction fetches, see *Synchronization and coherency issues between data and instruction accesses* on page B2-136.

---

**Note**

- System designers can use the shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different processing elements.
- This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

---

### Shareable, Inner Shareable, and Outer Shareable Normal memory

The Arm architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is only a member of a single Inner Shareability domain.
- Each observer is only a member of a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

---

**Note**

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
- The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.

---

The details of the use of the shareability attributes are system-specific. Example B2-1 on page B2-145 shows how they might be used.
Example B2-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.

- However, between the two clusters, the caches:
  - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
  - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable shareability domain.

For shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

Non-shareable Normal memory

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

Cacheability attributes for Normal memory

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a Cacheability attribute that is one of:

- Write-Through Cacheable.
- Write-Back Cacheable.
- Non-cacheable.

Also, for Write-Through Cacheable and Write-Back Cacheable Normal memory regions:

- A region might be assigned cache allocation hints for read and write accesses.
- It is IMPLEMENTATION DEFINED whether the cache allocation hints can have an additional attribute of Transient or Non-transient.

For more information see Cacheability, cache allocation hints, and cache transient hints on page D4-2474.

A memory location can be marked as having different cacheability attributes, for example when using aliases in a VA to PA mapping:

- If the attributes differ only in the cache allocation hint, this does not affect the behavior of accesses to that location.
- For other cases, see Mismatched memory attributes on page B2-153.
The cacheability attributes provide a mechanism of coherency control with observers that lie outside the shareability domain of a region of memory. In some cases, the use of Write-Through Cacheable or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through Cacheable memory:

- A completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.

- A completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.

- For accesses to Normal memory that is Non-cacheable, a DMB instruction introduces a Barrier-ordered-before relation on all accesses to a single peripheral or block of memory that is of IMPLEMENTATION DEFINED size. For more information, see Ordering and observability on page B2-116.

--- Note ---
Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the Arm architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the inner and the outer cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

- Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.
- No cache that is controlled by the Inner cacheability attributes can lie outside a cache that is controlled by the Outer cacheability attributes.
- An implementation might not have any outer cache.

Example B2-2, Example B2-3 on page B2-147, and Example B2-4 on page B2-147 describe the possible ways of implementing a system with three levels of cache, level 1 (L1) to level 3 (L3).

--- Note ---
- L1 cache is the level closest to the PE, see Memory hierarchy on page B2-133.
- When managing coherency, system designs must consider both the inner and outer cacheability attributes, as well as the shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

--- Example B2-2 Implementation with two inner and one outer cache levels ---

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 and L2 cache.
- The Outer cacheability attribute applied to L3 cache.
Example B2-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer cacheability attribute.

Example B2-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:
- The Inner cacheability attribute applied to L1 cache.
- The Outer cacheability attribute applied to L2 and L3 cache.

Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more SIMD&FP registers from an Exception level, there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

B2.7.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for Armv8 Device memory are:
- **Gathering** Identified as G or nG, see Gathering on page B2-149.
- **Reordering** Identified as R or nR, see Reordering on page B2-150.
- **Early Write Acknowledgement** Identified as E or nE, see Early Write Acknowledgement on page B2-151.

The Armv8 Device memory types are:

- **Device-nGnRnE** Device non-Gathering, non-Reordering, No Early write acknowledgement. Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.
- **Device-nGnRE** Device non-Gathering, non-Reordering, Early Write Acknowledgement. Equivalent to the Device memory type in earlier versions of the architecture.
- **Device-nGRE** Device non-Gathering, Reordering, Early Write Acknowledgement. Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory.
- **Device-GRE** Device Gathering, Reordering, Early Write Acknowledgement. Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that Speculative accesses to Device-GRE memory is forbidden.
Collectively these are referred to as any Device memory type. Going down the list, the memory types are described as getting weaker; conversely the going up the list the memory types are described as getting stronger.

--- Note ---

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.

- The architecture does not require an implementation to distinguish between each of these memory types and Arm recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.
  - Strongly-ordered memory. This is the equivalent of the Device-nGnRnE memory type.
  - Device memory. This is the equivalent of the Device-nGnRE memory type.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

  The following exceptions to this apply:
  - Reads generated by the SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.
  - For Device memory with the Gathering attribute, reads generated by the LDRP instructions are permitted to access bytes that are not explicitly accessed by the instruction, provided that the bytes accessed are in a 128-byte window, aligned to 128-bytes, that contains at least one byte that is explicitly accessed by the instruction.
  - Where a load or store instruction performs a sequence of memory accesses, as opposed to one single-copy atomic access as defined in the rules for single-copy atomicity, these accesses might occur multiple times as a result of executing the load or store instruction. See Properties of single-copy atomic accesses on page B2-112.

--- Note ---

- An instruction that generates a sequence of accesses as described in Atomicity in the Arm architecture on page B2-110 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception, the instruction is restarted, and therefore, one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program only defines a single access. For this reason, Arm strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.

- Write speculation that is visible to other observers is prohibited for all memory types.

- A write to a memory location with any Device memory attribute completes in finite time. This means that it is globally observed for all observers in the system in finite time.

- If a location with any Device memory attribute changes without an explicit write by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.

- A completed write to a memory location with any Device memory attribute is globally observed for all observers in finite time without the need for explicit maintenance.

- Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.

- A memory location with any Device memory attribute cannot be allocated into a cache.

- Writes to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Typically, the endpoint is a peripheral or some physical memory.
• For accesses to any Device memory type, a DMB instruction introduces a Barrier-ordered-before relation on all accesses to a single peripheral or block of memory that is of IMPLEMENTATION DEFINED size. For more information, see Ordering and observability on page B2-116.

• All accesses to memory with any Device memory attribute must be aligned. Any unaligned access generates an Alignment fault at the first stage of translation that defined the location as being Device.

——— Note ————
In the EL1&0 translation regime in systems where HCR_EL2.TGE==1 and HCR_EL2.DC==0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes ESR_EL2.ISS[24] to be 0.

——— Note ————
Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as Execute-never for all Exception levels.

——— Note ————
This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as Execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as Execute-never for all Exception levels is a programming error.

See also Memory access restrictions on page B2-152.

The memory types for translation table walks cannot be defined as any Device memory type within the TCR_ELx. For the EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation table walk might be made to memory locations with any Device memory type. These accesses might be made speculatively. When the value of the HCR_EL2.PTW bit is 1, a stage 2 permission fault is generated if a first stage translation table walk is made to any Device memory type.

——— Note ————
In general, making a translation table walk to any Device memory type is the result of a programming error.

For instruction fetches, if branches cause the program counter to point to an area of memory with the Device attribute which is not marked as Execute-never for the current Exception level, an implementation can either:

• Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
• Take a Permission fault.

Gathering
In the Device memory attribute:

G Indicates that the location has the Gathering attribute.

nG Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

• Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
• Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

——— Note ————
This also applies to writebacks from the cache, whether caused by a Natural eviction or as a result of a cache maintenance instruction.
For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and
coherecy rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

• The number of memory accesses that are made corresponds to the number that would be generated by a
simple sequential execution of the program.

• All accesses occur at their programmed size, except that there is no requirement for the memory system
beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See
Multi-register loads and stores that access Device memory on page B2-152.

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not
permitted.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must
come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

--- Note ---

• A read from a memory location with the Gathering attribute can come from intermediate buffering of a
previous write, provided that:
  — The accesses are not separated by a DMB or DSB barrier that affects both of the accesses.
  — The accesses are not separated by other ordering constructions that require that the accesses are in
    order. Such a construction might be a combination of Load-Acquire and Store-Release.
  — The accesses are not generated by a Store-Release instruction.

• The Arm architecture only defines programmer visible behavior. Therefore, gathering can be performed if a
  programmer cannot tell whether gathering has occurred.

---

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the
requirements specified by the non-Gathering attribute.

An implementation is not permitted to perform an access with the non-Gathering attribute in a manner consistent
with the relaxations allowed by the Gathering attribute.

**Reordering**

In the Device memory attribute:

**R** Indicates that the location has the Reordering attribute. Accesses to the location can be reordered
within the same rules that apply to accesses to Normal Non-cacheable memory. All memory types
with the Reordering attribute have the same ordering rules as accesses to Normal Non-cacheable
memory, see Ordering relations on page B2-118.

**nR** Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

--- Note ---

Some interconnect fabrics, such as PCIe, perform very limited reordering, which is not important
for the software usage. It is outside the scope of the Arm architecture to prohibit the use of a
non-Reordering memory type with these interconnects.

---

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral
of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple
sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all
accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of
Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory
accesses are not to a peripheral, then this attribute imposes no restrictions.
Note

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the DMB instruction.
- The Arm architecture only defines programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.
- The non-Reordering property is only required by the architecture to apply the order of arrival of accesses to a single memory-mapped peripheral of an IMPLEMENTATION DEFINED size, and is not required to have an impact on the order of observation of memory accesses to SDRAM. For this reason, there is no effect of the non-Reordering attribute on the ordering relations described in Ordering and observability on page B2-116 as part of the formal definition of the memory model.

An implementation:

- Is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.
- Is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses to one physical address with the non-Reordering attribute and accesses to a different physical address with the Reordering attribute.
- Access to one physical address with the non-Reordering attribute and access to a different physical address to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

The non-Reordering attribute has no effect on the ordering of cache maintenance instructions, even if the memory location specified in the instruction has the non-Reordering attribute.

Early Write Acknowledgement

In the Device memory attribute:

- E Indicates that the location has the Early Write Acknowledgement attribute.
- nE Indicates that the location has the No Early Write Acknowledgement attribute.

For memory system endpoints where the system architecture in which the PE is operating requires that acknowledgement of a write comes from the endpoint, assigning the No Early Write Acknowledgement attribute to a Device memory location guarantees that:

- Only the endpoint of the write access returns a write acknowledgement of the access.
- No earlier point in the memory system returns a write acknowledgement.

This means that a DSB barrier instruction, executed by the PE that performed the write to the No Early Write Acknowledgement Location, completes only after the write has reached its endpoint in the memory system.

Peripherals are an example of system endpoints that require that the acknowledgement of a write comes from the endpoint.

Note

- The Early Write Acknowledgement attribute only affects where the endpoint acknowledgement is returned from, and does not affect the ordering of arrival at the endpoint between accesses, which is determined by either the Device Reordering attribute, or the use of barriers to create order.
- The areas of the physical memory map for which write acknowledgement from the endpoint is required is outside the scope of the Arm Architecture definition and must be defined as part of the system architecture in which the PE is operating. In particular, regions of memory handled as PCIe configuration writes are expected to support write acknowledgement from the endpoint.
Arm recognizes that not all areas of a physical memory map will be capable of supporting write acknowledgement from the endpoint. In particular, Arm expects that regions of memory handled as posted writes under PCIe will not support write acknowledgement from the endpoint.

For maximum software compatibility, Arm strongly recommends that all peripherals for which standard software drivers expect that the use of a DSB instruction will determine that a write has reached its endpoint are placed in areas of the physical memory map that support write acknowledgement from the endpoint.

Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture. This applies even to accesses to any type of Device memory.

For all instructions that load or store one or more SIMD and floating-point registers from an Exception level, there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions, even for access to any type of Device memory.

B2.7.3 Memory access restrictions

The following restrictions apply to memory accesses:

- For accesses to any two bytes, \( p \) and \( q \), that are generated by the same instruction:
  - The bytes \( p \) and \( q \) must have the same memory type and shareability attributes, otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an LD1, ST1, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.
  - Except for possible differences in the cache allocation hints, Arm deprecates having different cacheability attributes for bytes \( p \) and \( q \).

For the permitted CONSTRAINED UNPREDICTABLE behavior, see Crossing a page boundary with different memory types or Shareability attributes on page K1-7636.

- If the accesses of an instruction that causes multiple accesses to any type of Device memory cross an address boundary that corresponds to the smallest implemented translation granule, then behavior is CONSTRAINED UNPREDICTABLE, and Crossing a peripheral boundary with a Device access on page K1-7636 describes the permitted behaviors. For this reason, it is important that an access to a volatile memory device is not made using a single instruction that crosses an address boundary of the size of the smallest implemented translation granule.

---

**Note**

- The boundary referred to is between two Device memory regions that are both of the size of the smallest implemented translation granule and aligned to the size of the smallest implemented translation granule.
- This restriction means it is important that an access to a volatile memory device is not made using a single instruction that crosses an address boundary of the size of the smallest implemented translation granule.
- Arm expects this restriction to constrain the placing of volatile memory devices in the system memory map, rather than expecting a compiler to be aware of the alignment of memory accesses.
Mismatched memory attributes

Memory attributes are controlled by privileged software. For more information, see Chapter D5 *The AArch64 Virtual Memory System Architecture*.

Physical memory locations are accessed with mismatched attributes if all accesses to the location do not use a common definition of all of the following attributes of that location:

- Memory type, Device or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

--- Note ---

In this document, the terms *location* and *memory location* refer to any byte within the current coherency granule and are used interchangeably.

When a memory *location* is accessed with mismatched attributes, the only software visible effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory *location* might be lost. This means:
  - A read of the memory *location* by one agent might not return the value most recently written to that memory *location* by the same agent.
  - Multiple writes to the memory *location* by one agent with different memory attributes might not be ordered in program order.

- There might be a loss of coherency when multiple agents attempt to access a memory *location*.

- There might be a loss of properties derived from the memory type, as described in later bullets in this section.

- If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory *location* do not use consistent memory attributes, the Exclusives monitor state becomes **UNKNOWN**.

- Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of *Speculative* read accesses.
- Prohibition on Gathering.
- Prohibition on reordering.

For the following situations, when a physical memory *location* is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. If the only memory type mismatch associated with a memory *location* across all users of the memory *location* is between different types of Device memory, then all accesses might take the properties of the weakest Device memory type.

2. Any agent that reads that memory *location* using the same common definition of the Memory type, Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all the following conditions are met:
   - All writes are performed to an alias of the memory *location* that uses the same definition of the Memory type, Shareability and Cacheability attributes.
   - Either:
     - In the EL1&0 translation regime, *HCR_EL2.MIOCNCE* has a value of 0.
     - All aliases with write permission have the Inner Cacheability attribute the same as the Outer Cacheability attribute.
• Either:
  — All writes are performed to an alias of the memory Location that has Inner Cacheability and
    Outer Cacheability attributes both as Non-cacheable.
  — All aliases to a memory Location use a definition of the Shareability attributes that encompasses
    all the agents with permission to access the Location.

3. The possible software-visible effects caused by mismatched attributes for a memory Location are defined
   more precisely if all of the mismatched attributes define the memory Location as one of:
   • Any Device memory type.
   • Inner Non-cacheable, Outer Non-cacheable Normal memory.

   In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the
   following:
   • Possible loss of properties derived from the memory type when multiple agents attempt to access the
     memory Location.
   • Possible reordering of memory transactions to the same memory Location with different memory
     attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of
     coherency or uniprocessor semantics can be avoided by inserting \texttt{DMB} barrier instructions between
     accesses to the same memory Location that might use different attributes.

   Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

1. If the mismatched attributes for a memory location all assign the same shareability attribute to a Location that
   has a cacheable attribute, any loss of uniprocessor semantics, ordering, or coherency within a shareability
   domain can be avoided by use of software cache management. To do so, software must use the techniques
   that are required for the software management of the ordering or coherency of cacheable Locations between
   agents in different shareability domains. This means:
   • Before writing to a cacheable Location not using the Write-Back attribute, software must invalidate,
     or clean, a Location from the caches if any agent might have written to the Location with the
     Write-Back attribute. This avoids the possibility of overwriting the Location with stale data.
   • After writing to a cacheable Location with the Write-Back attribute, software must clean the Location
     from the caches, to make the write visible to external memory.
   • Before reading the Location with a cacheable attribute, software must invalidate, or clean and
     invalidate, the Location from the caches, to ensure that any value held in the caches reflects the last
     value made visible in external memory.
   • Executing a \texttt{DMB} barrier instruction, with scope that applies to the common shareability of the accesses,
     between any accesses to the same cacheable Location that use different attributes.

   In all cases:
   • Location refers to any byte within the current coherency granule.
   • A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate
     instruction.
   • In the sequences outlined in this section, all cache maintenance instructions and memory transactions
     must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the
     use of a common address, see Ordering and completion of data and instruction cache instructions on
     page D4-2489.

\textbf{Note}

With software management of coherency, race conditions can cause loss of data. A race condition occurs
when different agents write simultaneously to bytes that are in the same Location, and the invalidate, write,
clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also
occurs if the first operation of either sequence is a clean, rather than an invalidate.
2. If the mismatched attributes for a Location mean that multiple cacheable accesses to the Location might be made with different shareability attributes, then uniprocessor semantics, ordering, and coherency are guaranteed only if:

   - Each PE that accesses the Location with a cacheable attribute performs a clean and invalidate of the Location before and after accessing that Location.
   - A DMB barrier with scope that covers the full shareability of the accesses is placed between any accesses to the same memory Location that use different attributes.

   **Note**

   The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

   In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a Location, and the accesses from the different agents have different memory attributes associated with the Location, the Exclusives monitor state becomes UNKNOWN.

   Arm strongly recommends that software does not use mismatched attributes for aliases of the same Location. An implementation might not optimize the performance of a system that uses mismatched aliases.
B2.9 Synchronization and semaphores

Armv8 provides non-blocking synchronization of shared memory, using synchronization primitives. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal memory and to any type of Device memory.

--- Note ---
Use of the Armv8 synchronization primitives scales for multiprocessing system designs.

Table B2-3 shows the synchronization primitives and the associated CLREX instruction.

<sup>a</sup> Instruction in the A64 instruction set.
<sup>b</sup> A register instruction operates on a doubleword if accessing an X register, or on a word if accessing a W register.
A pair instruction operates on two doublewords if access X registers, or on two words if accessing W registers.

Except for the row showing the CLREX instruction, the two instructions in a single row are a Load-Exclusive/Store-Exclusive instruction pair. The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address \( x \) is:

- The Load-Exclusive instruction reads a value from memory address \( x \).
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address \( x \) only if no other observer, process, or thread has performed a more recent store to address \( x \). The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see Marking and the size of the marked memory block on page B2-162. A Store-Exclusive instruction to any address in the marked block clears the marking.

--- Note ---
In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

The following sections give more information:

- Exclusive access instructions and Non-shareable memory locations on page B2-157.
- Exclusive access instructions and Shareable memory locations on page B2-158.
- Marking and the size of the marked memory block on page B2-162.
- Context switch support on page B2-162.
• Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-163.
• Use of WFE and SEV instructions by spin-locks on page B2-166.

B2.9.1 Exclusive access instructions and Non-shareable memory locations

For memory locations for which the shareability attribute is Non-shareable, the exclusive access instructions rely on a local Exclusives monitor, or local monitor, that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:
• The executing PE marks the physical memory address for exclusive access.
• The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state
• If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
• A status value is returned to a register:
  — If the store took place, the status value is 0.
  — Otherwise, the status value is 1.
• The local monitor of the executing PE transitions to the Open Access state.

When an Exclusives monitor is in the Exclusive Access state, the monitor is set.

If the local monitor is in the Open Access state
• No store takes place.
• A status value of 1 is returned to a register.
• The local monitor remains in the Open Access state.

When an Exclusives monitor is in the Open Access state, the monitor is clear.

The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:

• If the write is to a PA that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
• If the write is to a PA that is marked as Exclusive Access by its local monitor, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked PA causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the PA to be marked.

Figure B2-4 on page B2-158 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.
For the local monitor state machine, as shown in Figure B2-4:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any PA, but instead treats any access as matching the address of the previous Load-Exclusive instruction.

- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.

- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the Store or StoreExcl is from another observer.

Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure B2-4.

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure B2-4.

- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure B2-4 must not indefinitely delay forward progress of execution.

B2.9.2 Exclusive access instructions and Shareable memory locations

In the context of this section, a shareable memory location is a memory location that has, or is treated as if it has, a Shareability attribute of Inner Shareable or Outer Shareable.
For shareable memory locations, exclusive access instructions rely on:

- A **local monitor** for each PE in the system, that marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in [Exclusive access instructions and Non-shareable memory locations on page B2-157](#), except that for shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
  - Updating memory.
  - Returning a status value of 0.

The local monitor can ignore accesses from other PEs in the system.

- A **global monitor** that marks a PA as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
  - Can hold at least one marked block.
  - Maintains a state machine for each marked block it can hold.

**Note**

For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is **UNPREDICTABLE** or **CONSTRAINED UNPREDICTABLE**, see [Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-163](#).

**Note**

The global monitor can either reside within the PE, or exist as a secondary monitor at the memory interfaces. The **IMPLEMENTATION DEFINED** aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

**Note**

If ARMv8.5-MemTag is implemented and enabled it is **IMPLEMENTATION DEFINED** whether a global monitor monitors access the Tag PA space. For more information see [Chapter D6. Armv8.5 Memory Tagging Extension](#).

**Note**

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all Arm PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport’s Bakery algorithm to achieve mutual exclusion.
Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global Exclusives monitor is implemented are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive or a Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an External abort.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Data Abort Fault status code of ESR_ELx.DFSC = 110101.

If the IMPLEMENTATION DEFINED MMU fault is generated for the EL1&0 translation regime then:
  - If the fault is generated because of the memory type defined in the first stage of translation, or if the second stage of translation is disabled, then this is a first stage fault and the exception is taken to EL1.
  - Otherwise, the fault is a second stage fault and the exception is taken to EL2.

The priority of this fault is IMPLEMENTATION DEFINED.

- The instruction is treated as a NOP.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN. In this case, if the store exclusive instruction is a store exclusive pair of 64-bit quantities, then the two quantities being stored might not be stored atomically.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by Arm PEs is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

**Operation of the global Exclusives monitor**

A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the PA of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other PA that has been marked by the requesting PE.

--- **Note**

The global monitor only supports a single outstanding exclusive access to shareable memory per PE.

---

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the PA accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  - A status value of 0 is returned to a register to acknowledge the successful store.
  - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE, then that state machine transitions to Open Access state.
• If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  — A status value of 1 is returned to a register to indicate that the store failed.
  — The global monitor is not affected and remains in Open Access state for the requesting PE.

• If a different PA is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  — If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
  — If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it. This means that it responds to:
• Accesses generated by PE(n).
• Accesses generated by the other observers in the shareability domain of the memory location. These accesses are identified as !n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

A global monitor:
• In the Exclusive Access state is set.
• In the Open Access state is clear.

**Clear global monitor event**

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see Mechanisms for entering a low-power state on page D1-2372.

Figure B2-5 shows the state machine for PE(n) in a global monitor.

![Global monitor state machine diagram for PE(n) in a multiprocessor system](image-url)

For more information about marking, see Marking and the size of the marked memory block on page B2-162.
Note

For the global monitor state machine, as shown in Figure B2-5 on page B2-161:

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure B2-5 on page B2-161 only shows how the operations by (n) cause state transitions of the state machine for PE(n).
- A Load-Exclusive instruction can only update the marked shareable memory address for the PE issuing the Load-Exclusive instruction.
- When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.
- It is IMPLEMENTATION DEFINED:
  - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

B2.9.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size $2^a$ bytes is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. The size of the marked memory block is called the Exclusives reservation granule. The Exclusives reservation granule is IMPLEMENTATION DEFINED in the range 4-512 words.

Note

This definition means that the Exclusives reservation granule is:

- 4 words in an implementation where $a$ is 4.
- 512 words in an implementation where $a$ is 11.

For example, in an implementation where $a$ is 4, a successful LDXR8 of address 0x341B4 defines a marked block using bits[47:4] of the address. This means that the four words of memory from 0x341B0 to 0x341BF are marked for exclusive access.

In some implementations the CTR identifies the Exclusives reservation granule, see CTR_EL0. Otherwise, software must assume that the maximum Exclusives reservation granule, 512 words, is implemented.

B2.9.4 Context switch support

An exception return clears the local monitor. As a result, performing a CLREX instruction as part of a context switch is not required in most situations.

Note

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.
B2.9.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a LDXP/STXP pair or a LDXR/STXR pair. To support different implementations of these functions, software must follow the notes and restrictions given here.

The following notes describe the use of a LoadExcl/StoreExcl instruction pair, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in Table B2-3 on page B2-156. In this context, a LoadExcl/StoreExcl pair comprises two instructions in the same thread of execution:

- The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the IsExclusiveLocal() function. If the target VA of a StoreExcl is different from the VA of the preceding LoadExcl instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The StoreExcl either passes or fails, the status value returned by the StoreExcl is UNKNOWN, and the states of the local and global monitors for that PE are UNKNOWN.

  Note
  This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with mismatched addresses, and fail for other instances of a LoadExcl/StoreExcl pair with mismatched addresses.

  The data at the address accessed by the LoadExcl, and at the address accessed by the StoreExcl, is UNKNOWN.

  This means software can rely on a LoadExcl/StoreExcl pair to eventually succeed only if the LoadExcl and the StoreExcl are executed with the same VA.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a StoreExcl instruction is the same as the transaction size of the preceding LoadExcl instruction executed in that thread. If the transaction size of a StoreExcl instruction is different from the preceding LoadExcl instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The StoreExcl either passes or fails, and the status value returned by the StoreExcl is UNKNOWN.

  Note
  This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with mismatched transaction sizes, and fail for other instances of a LoadExcl/StoreExcl pair with mismatched transaction sizes.

  The block of data of the size of the larger of the transaction sizes used by the LoadExcl/StoreExcl pair at the address accessed by the LoadExcl/StoreExcl pair, is UNKNOWN.

  This means software can rely on a LoadExcl/StoreExcl pair to eventually succeed only if the LoadExcl and the StoreExcl have the same transaction size.

- An implementation of the LoadExcl and StoreExcl instructions can require that, in any thread of execution, the StoreExcl instruction accesses the same number of registers as the preceding LoadExcl instruction executed in that thread. If the StoreExcl instruction accesses a different number of registers than the preceding LoadExcl instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. As a result, software can rely on an LoadExcl/StoreExcl pair to eventually succeed only if they access the same number of registers. For more information, see CONSTRAINED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers on page B2-165.

- LoadExcl/StoreExcl loops are guaranteed to make forward progress only if, for any LoadExcl/StoreExcl loop within a single thread of execution, the software meets all of the following conditions:
  - Between the Load-Exclusive and the Store-Exclusive, there are no explicit memory accesses, preloads, direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.
Between the Store-Exclusive returning a failing result and the retry of the corresponding Load-Exclusive:

- There are no stores or PRFM instructions to any address within the Exclusives reservation granule accessed by the Store-Exclusive.
- There are no loads or preload instructions to any address within the Exclusives reservation granule accessed by the Store-Exclusive that use a different VA alias to that address.
- There are no direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.
- All loads and stores are to a block of contiguous virtual memory of not more than 512 bytes in size.

The Exclusives monitor can be cleared at any time without an application-related cause, provided that such clearing is not systematically repeated so as to prevent the forward progress in finite time of at least one of the threads that is accessing the Exclusives monitor. However, it is permissible for the LoadExcl/StoreExcl loop not to make forward progress if a different thread is repeatedly doing any of the following in a tight loop:

- Performing stores to a PA covered by the Exclusives monitor.
- Prefetching with intent to write to a PA covered by the Exclusives monitor.
- Executing data cache clean, data cache invalidate, or data cache clean and invalidate instructions to a PA covered by the Exclusives monitor.
- Executing instruction cache invalidate all instructions.
- Executing instruction cache invalidate by VA instructions to a PA covered by the Exclusives monitor.

- Implementations can benefit from keeping the LoadExcl and StoreExcl operations close together in a single thread of execution. This minimizes the likelihood of the Exclusives monitor state being cleared between the LoadExcl instruction and the StoreExcl instruction. Therefore, for best performance, Arm strongly recommends a limit of 128 bytes between LoadExcl and StoreExcl instructions in a single thread of execution.

- The architecture sets an upper limit of 2048 bytes on the Exclusives reservation granule that can be marked as exclusive. For performance reasons, Arm recommends that objects that are accessed by exclusive accesses are separated by the size of the Exclusives reservation granule. This is a performance guideline rather than a functional requirement.

- After taking a Data Abort exception, the state of the Exclusives monitors is UNKNOWN.

- For the memory location accessed by a LoadExcl/StoreExcl pair, if the memory attributes for a StoreExcl instruction are different from the memory attributes for the preceding LoadExcl instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. Where this occurs because the translation of the accessed address changes between the LoadExcl instruction and the StoreExcl instruction, the CONSTRAINED UNPREDICTABLE behavior is as follows:

  - The StoreExcl either passes or fails, and the status value returned by the StoreExcl is UNKNOWN.

    **Note**

    This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with changed memory attributes, and fail for other instances of a LoadExcl/StoreExcl pair with changed memory attributes.

    **Note**

    The data at the address accessed by the StoreExcl is UNKNOWN.

Another bullet point in this list covers the case where the memory attributes of a LoadExcl/StoreExcl pair differ as a result of using different VAs with different attributes that point to the same PA.
The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE, and the instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same shareability domain as the PE executing the cache maintenance instruction, as determined by the shareability domain of the address being maintained.

--- Note ---
Arm strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

--- Note ---
If the mapping of the VA to PA is changed between the LoadExcl instruction and the STREX instruction, and the change is performed using a break-before-make sequence as described in Using break-before-make when updating translation table entries on page D5-2639, if the StoreExcl is performed after another write to the same PA as the StoreExcl, and that other write was performed after the old translation was properly invalidated and that invalidation was properly synchronized, then the StoreExcl will not pass its monitor check.

--- Note ---
— The TLB invalidation will clear either the local or global monitor.
— The PA will be checked between the LoadExcl and StoreExcl.

--- Note ---
The Exclusive Access state for an address accessed by a PE can be lost as a result of a PFRM PST* instruction to the same PA executed by another PE. This means that a very high rate of repeated PFRM PST* accesses to a memory location might impede the forward progress of another PE.

--- Note ---
If ARMv8.5-MemTag is implemented and enabled a store exclusive instruction which if Unchecked would not perform the store and return a status value of 1, it is CONSTRAINED UNPREDICTABLE whether:
— The instruction is a Checked access.
— The instruction is an Unchecked access.
For more information see Chapter D6 Armv8.5 Memory Tagging Extension.

--- Note ---
In the event of repeatedly-contending LoadExcl/StoreExcl instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

CONSTRANGED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers

As stated in this section, an implementation can require that the instructions of a Load-Exclusive/Store-Exclusive pair access the same number of registers. In such an implementation, this means behavior is CONSTRAINED UNPREDICTABLE if, in a single thread of execution, either:

• An LDXP instruction of two 32-bit quantities is followed by an STXR instruction of one 64-bit quantity at the same address.
• An LDXR instruction of one 64-bit quantity is followed by an STXP instruction of two 32-bit quantities at the same address.

In these cases, the CONSTRAINED UNPREDICTABLE behavior must be one of:

• The STXP or STXR instruction generates an external Data Abort.
• The STXP or STXR instruction generates an IMPLEMENTATION DEFINED MMU fault reported using the Data Abort Fault status code of ESR_ELx.DFSC = 0b110101.
• The STXP or STXR instruction always fails, returning a status of 1.
• The STXP or STXR instruction always passes, returning a status of 0.
This STXP or STXR instruction has the same pass or fail behavior that it would have had if the instruction had used the same size and number of registers as the preceding LDXR or LDXP instruction.

### B2.9.6 Use of WFE and SEV instructions by spin-locks

Armv8 provides Wait For Event, Send Event, and Send Event Local instructions, WFE, SEV, and SEVL, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in *Wait for Event mechanism and Send event on page D1-2372*. However, in Armv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

---

**Note**

This is equivalent to issuing an SEVL instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an SEV instruction after clearing a spinlock.
Part C

The AArch64 Instruction Set
Chapter C1
The A64 Instruction Set

This chapter describes the A64 instruction set. It contains the following sections:

- *About the A64 instruction set* on page C1-170.
- *Structure of the A64 assembler language* on page C1-171.
- *Address generation* on page C1-177.
- *Instruction aliases* on page C1-180.
C1.1 About the A64 instruction set

The A64 instruction set is the instruction set supported in the AArch64 Execution state.

All A64 instructions have a width of 32 bits. The A64 encoding structure breaks down into the following functional groups:

• A miscellaneous group of branch instructions, exception generating instructions, and System instructions.
• Data-processing instructions associated with general-purpose registers. These instructions are supported by two functional groups, depending on whether the operands:
  — Are all held in registers.
  — Include an operand with a constant immediate value.
• Load and store instructions associated with the general-purpose register file and the SIMD and floating-point register file.
• SIMD and scalar floating-point data-processing instructions that operate on the SIMD and floating-point registers.

The encoding hierarchy within a functional group breaks down as follows:

• A functional group consists of a set of related instruction classes. A64 instruction set encoding on page C4-252 provides an overview of the instruction encodings in the form of a list of instruction classes within their functional groups.
• An instruction class consists of a set of related instruction forms. Instruction forms are documented in one of two alphabetic lists:
  — The load, store, and data-processing instructions associated with the general-purpose registers, together with those in the other instruction classes. See Chapter C6 A64 Base Instruction Descriptions.
  — The load, store, and data-processing instructions associated with the SIMD and floating-point support. See Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions.
• An instruction form might support a single instruction syntax. Where an instruction supports more than one syntax, each syntax is an instruction variant. Instruction variants can occur because of differences in:
  — The size or format of the operands.
  — The register file used for the operands.
  — The addressing mode used for load/load/store memory operands.
Instruction variants might also arise as the result of other factors.
Instruction variants are described in the instruction description for the individual instructions.

A64 instructions have a regular bit encoding structure:

• 5-bit register operand fields at fixed positions within the instruction. For general-purpose register operands, the values 0-30 select one of 31 registers. The value 31 is used as a special case that can:
  — Indicate use of the current stack pointer, when identifying a load/store base register or in a limited set of data-processing instructions. See The stack pointer registers on page D1-2277.
  — Indicate the value zero when used as a source register operand.
  — Indicate discarding the result when used as a destination register operand.
For SIMD and floating-point register access, the value used selects one of 32 registers.
• Immediate bits that provide constant data-processing values or address offsets are placed in contiguous bitfields. Some computed values in instruction variants use one or more immediate bitfields together with the secondary encoding bitfields.

All encodings that are not fully defined are described as unallocated. An attempt to execute an unallocated instruction is UNDEFINED, unless the behavior is otherwise defined in this Manual.
C1.2 Structure of the A64 assembler language

The following sections describe the A64 assembler syntax:

- General requirements.
- Common syntax terms.
- Instruction Mnemonics on page C1-173.
- Condition code on page C1-173.
- Register names on page C1-174.

C1.2.1 General requirements

The letter W denotes a general-purpose register holding a 32-bit word, and X denotes a general-purpose register holding a 64-bit doubleword.

An A64 assembler recognizes both uppercase and lowercase variants of the instruction mnemonics and register names, but not mixed case variants. An A64 disassembler can output either uppercase or lowercase mnemonics and register names. Program and data labels are case-sensitive.

The A64 assembly language does not require the # character to introduce constant immediate operands, but an assembler must allow immediate values introduced with or without the # character. Arm recommends that an A64 disassembler outputs a # before an immediate operand.

In Example C1-1 on page C1-173, the sequence // is used as a comment leader and A64 assemblers are encouraged to accept this syntax.

C1.2.2 Common syntax terms

The following syntax terms are used frequently throughout the A64 instruction set description.

- **UPPER** Text in upper-case letters is fixed. Text in lower-case letters is variable. This means that register name Xn indicates that the X is required, followed by a variable register number, for example X29.
- **< >** Any text enclosed by angle braces, < >, is a value that the user supplies. Subsequent text might supply additional information.
- **{}** Any item enclosed by curly brackets, { }, is optional. A description of the item and how its presence or absence affects the instruction is normally supplied by subsequent text. In some cases curly braces are actual symbols in the syntax, for example when they surround a register list. These cases are called out in the surrounding text.
- **[]** Any items enclosed by square brackets, [ ], constitute a list of alternative characters. A single one of the characters can be used in that position and the subsequent text describes the meaning of the alternatives. In some case the square brackets are part of the syntax itself, such as addressing modes or vector elements. These cases are called out in the surrounding text.
- **a|b** Alternative words are separated by a vertical bar, |, and can be surrounded by parentheses to delimit them. For example, U(ADD|SUB)W represents UADDW or USUBW.
- **±** This indicates an optional + or - sign. If neither is used then + is assumed.
- **uimm** An n-bit unsigned, positive, immediate value.
- **simm** An n-bit two’s complement, signed immediate value, where n includes the sign bit.
- **SP** See Register names on page C1-174.
- **Wn** See Register names on page C1-174.
- **WSP** See Register names on page C1-174.
- **WZR** See Register names on page C1-174.
- **Xn** See Register names on page C1-174.
XZR  See Register names on page C1-174
C1.2.3 Instruction Mnemonics

The A64 assembly language overloads instruction mnemonics and distinguishes between the different forms of an instruction based on the operand types. For example, the following ADD instructions all have different opcodes. However, the programmer must only remember one mnemonic, as the assembler automatically chooses the correct opcode based on the operands. The disassembler follows the same procedure in reverse.

Example C1-1 ADD instructions with different opcodes

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD W0, W1, W2</td>
<td>// add 32-bit register</td>

C1.2.4 Condition code

The A64 ISA has some instructions that set Condition flags or test Condition codes or both. For information about instructions that set the Condition flags or use the condition mnemonics, see Condition flags and related instructions on page C6-751.

Table C1-1 shows the available Condition codes.

Table C1-1 Condition codes

a. Unordered means at least one NaN operand.

b. The Condition code NV exists only to provide a valid disassembly of the 0b1111 encoding, otherwise its behavior is identical to AL.
C1.2.5 Register names

This section describes the AArch64 registers. It contains the following subsections:

- General-purpose register file and zero register and stack pointer.
- SIMD and floating-point register file on page C1-175.
- SIMD and floating-point scalar register names on page C1-175.
- SIMD vector register names on page C1-175.
- SIMD vector element names on page C1-176.

General-purpose register file and zero register and stack pointer

The 31 general-purpose registers in the general-purpose register file are named R0-R30 and encoded in the instruction register fields with values 0-30. In a general-purpose register field the value 31 represents either the current stack pointer or the zero register, depending on the instruction and the operand position.

When the registers are used in a specific instruction variant, they must be qualified to indicate the operand data size, 32 bits or 64 bits, and the data size of the instruction.

When the data size is 32 bits, the lower 32 bits of the register are used and the upper 32 bits are ignored on a read and cleared to zero on a write.

Table C1-2 shows the qualified names for registers, where \( n \) is a register number 0-30.

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Encoding</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wn</td>
<td>32 bits</td>
<td>0-30</td>
<td>General-purpose register 0-30</td>
</tr>
<tr>
<td>Xn</td>
<td>64 bits</td>
<td>0-30</td>
<td>General-purpose register 0-30</td>
</tr>
<tr>
<td>WZR</td>
<td>32 bits</td>
<td>31</td>
<td>Zero register</td>
</tr>
<tr>
<td>XZR</td>
<td>64 bits</td>
<td>31</td>
<td>Zero register</td>
</tr>
<tr>
<td>WSP</td>
<td>32 bits</td>
<td>31</td>
<td>Current stack pointer</td>
</tr>
<tr>
<td>SP</td>
<td>64 bits</td>
<td>31</td>
<td>Current stack pointer</td>
</tr>
</tbody>
</table>

This list gives more information about the instruction arguments shown in Table C1-2:

- The names Xn and Wn both refer to the same general-purpose register, Rn.
- There is no register named W31 or X31.
- The name SP represents the stack pointer for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as a read or write of the current stack pointer. When instructions do not interpret this operand encoding as the stack pointer, use of the name SP is an error.
- The name WSP represents the current stack pointer in a 32-bit context.
- The name XZR represents the zero register for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as returning zero when read or discarding the result when written. When instructions do not interpret this operand encoding as the zero register, use of the name XZR is an error.
- The name WZR represents the zero register in a 32-bit context.
- The architecture does not define a specific name for general-purpose register R30 to reflect its role as the link register on procedure calls. However, an A64 assembler must always use W30 and X30 for this purpose, and additional software names might be defined as part of the Procedure Call Standard, see Procedure Call Standard for the Arm 64-bit Architecture.
SIMD and floating-point register file

The 32 registers in the SIMD and floating-point register file, V0-V31, hold floating-point operands for the scalar floating-point instructions, and both scalar and vector operands for the SIMD instructions. When they are used in a specific instruction form, the names must be further qualified to indicate the data shape, that is the data element size and the number of elements or lanes within the register. A similar requirement is placed on the general-purpose registers. See General-purpose register file and zero register and stack pointer on page C1-174.

--- Note ---

The data type is described by the instruction mnemonics that operate on the data. The data type is not described by the register name. The data type is the interpretation of bits within each register or vector element, whether these are integers, floating-point values, polynomials, or cryptographic hashes.

SIMD and floating-point scalar register names

SIMD and floating-point instructions that operate on scalar data only access the lower bits of a SIMD and floating-point register. The unused high bits are ignored on a read and cleared to 0 on a write.

Table C1-3 shows the qualified names for accessing scalar SIMD and floating-point registers. The letter \( n \) denotes a register number between 0 and 31.

<table>
<thead>
<tr>
<th>Size</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 bits</td>
<td>Bn</td>
</tr>
<tr>
<td>16 bits</td>
<td>Hn</td>
</tr>
<tr>
<td>32 bits</td>
<td>Sn</td>
</tr>
<tr>
<td>64 bits</td>
<td>Dn</td>
</tr>
<tr>
<td>128 bits</td>
<td>Qn</td>
</tr>
</tbody>
</table>

SIMD vector register names

If a register holds multiple data elements on which arithmetic is performed in a parallel, SIMD, manner, then a qualifier describes the vector shape. The vector shape is the element size and the number of elements or lanes. If the element size in bits multiplied by the number of lanes does not equal 128, then the upper 64 bits of the register are ignored on a read and cleared to zero on a write.

Table C1-4 shows the SIMD vector register names. The letter \( n \) denotes a register number between 0 and 31.

<table>
<thead>
<tr>
<th>Shape</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 bits × 8 lanes</td>
<td>Vn.8B</td>
</tr>
<tr>
<td>8 bits × 16 lanes</td>
<td>Vn.16B</td>
</tr>
<tr>
<td>16 bits × 4 lanes</td>
<td>Vn.4H</td>
</tr>
<tr>
<td>16 bits × 8 lanes</td>
<td>Vn.8H</td>
</tr>
<tr>
<td>32 bits × 2 lanes</td>
<td>Vn.25</td>
</tr>
</tbody>
</table>
SIMD vector element names

Appending a constant, zero-based element index to the register name inside square brackets indicates that a single element from a SIMD and floating-point register is used as a scalar operand. The number of lanes is not represented, as it is not encoded in the instruction and can only be inferred from the index value.

Table C1-5 shows the vector register names and the element index. The letter $i$ denotes the element index.

Table C1-5 Vector register names with element index

<table>
<thead>
<tr>
<th>Size</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 bits</td>
<td>$Vn.B[i]$</td>
</tr>
<tr>
<td>16 bits</td>
<td>$Vn.H[i]$</td>
</tr>
<tr>
<td>32 bits</td>
<td>$Vn.S[i]$</td>
</tr>
<tr>
<td>64 bits</td>
<td>$Vn.D[i]$</td>
</tr>
</tbody>
</table>

An assembler must accept a fully qualified SIMD register name if the number of lanes is greater than the index value. See SIMD vector register names on page C1-175. For example, an assembler must accept all of the following forms as the name for the 32-bit element in bits [63:32] of the SIMD and floating-point register $V9$:

- $V9.2S[1]$ //optional number of lanes
- $V9.4S[1]$ //optional number of lanes

--- Note ---

The SIMD and floating-point register element name $Vn.S[0]$ is not equivalent to the scalar SIMD and floating-point register name $Sn$. Although they represent the same bits in the register, they select different instruction encoding forms, either the vector element or the scalar form.

SIMD vector register list

Where an instruction operates on multiple SIMD and floating-point registers, for example vector Load/Store structure and table lookup operations, the registers are specified as a list enclosed by curly braces. This list consists of either a sequence of registers separated by commas, or a register range separated by a hyphen. The registers must be numbered in increasing order, modulo 32, in increments of one. The hyphenated form is preferred for disassembly if there are more than two registers in the list and the register number are increasing. The following examples are equivalent representations of a set of four registers $V4$ to $V7$, each holding four lanes of 32-bit elements:

- $\{ V4.4S - V7.4S \}$ //standard disassembly
- $\{ V4.4S, V5.4S, V6.4S, V7.4S \}$ //alternative representation

SIMD vector element list

Registers in a list can also have a vector element form. For example, the LD4 instruction can load one element into each of four registers, and in this case the index is appended to the list as follows:

- $\{ V4.5 - V7.5 \}[3]$ //standard disassembly
- $\{ V4.4S, V5.4S, V6.4S, V7.4S \}[3]$ //alternative with optional number of lanes
C1.3 Address generation

The A64 instruction set supports 64-bit virtual addresses (VAs). The valid VA range is determined by the following factors:

- The size of the implemented virtual address space.
- Memory Management Unit (MMU) configuration settings.

Limits on the VA size mean that the most significant bits of the virtual address do not hold valid address bits. These unused bits can hold:

- A tag, see Address tagging in AArch64 state on page D5-2506.
- If ARMv8.3-PAuth is implemented, a Pointer authentication code (PAC), see Pointer authentication in AArch64 state on page D5-2508.

For more information on memory management and address translation, see Chapter D5 The AArch64 Virtual Memory System Architecture.

C1.3.1 Register indexed addressing

The A64 instruction set allows a 64-bit index register to be added to the 64-bit base register, with optional scaling of the index by the access size. Additionally it allows for sign-extension or zero-extension of a 32-bit value within an index register, followed by optional scaling.

C1.3.2 PC-relative addressing

The A64 instruction set has support for position-independent code and data addressing:

- PC-relative literal loads have an offset range of ± 1MB.
- Process state flag and compare based conditional branches have a range of ± 1MB. Test bit conditional branches have a restricted range of ± 32KB.
- Unconditional branches, including branch and link, have a range of ± 128MB.

PC-relative Load/Store operations, and address generation with a range of ± 4GB can be performed using two instructions.

C1.3.3 Load/Store addressing modes

Load/Store addressing modes in the A64 instruction set require a 64-bit base address from a general-purpose register X0-X30 or the current stack pointer, SP, with an optional immediate or register offset. Table C1-6 shows the assembler syntax for the complete set of Load/Store addressing modes.

<table>
<thead>
<tr>
<th>Addressing Mode</th>
<th>Immediate</th>
<th>Offset</th>
<th>Extended Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base register only (no offset)</td>
<td>[base{, #0}]</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Base plus offset</td>
<td>[base{, #imm}]</td>
<td>[base, Xm{, LSL #imm}]</td>
<td>[base, Wm, (S</td>
</tr>
<tr>
<td>Pre-indexed</td>
<td>[base, #imm]!</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Post-indexed</td>
<td>[base], #imm</td>
<td>[base], Xm^</td>
<td>-</td>
</tr>
<tr>
<td>Literal (PC-relative)</td>
<td>label</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

Table C1-6 A64 Load/Store addressing modes
Some types of Load/Store instruction support only a subset of the Load/Store addressing modes listed in Table C1-6 on page C1-177. Details of the supported modes are as follows:

- **Base plus offset addressing** means that the address is the value in the 64-bit base register plus an offset.
- **Pre-indexed addressing** means that the address is the sum of the value in the 64-bit base register and an offset, and the address is then written back to the base register.
- **Post-indexed addressing** means that the address is the value in the 64-bit base register, and the sum of the address and the offset is then written back to the base register.
- **Literal addressing** means that the address is the value of the 64-bit program counter for this instruction plus a 19-bit signed word offset. This means that it is a 4-byte aligned address within ±1MB of the address of this instruction with no offset. Literal addressing can only be used for loads of at least 32 bits and for prefetch instructions. The PC cannot be referenced using any other addressing modes. The syntax for labels is specific to individual toolchains.
- **An immediate offset** can be unsigned or signed, and scaled or unscaled, depending on the type of Load/Store instruction. When the immediate offset is scaled it is encoded as a multiple of the transfer size, although the assembly language always uses a byte offset, and the assembler or disassembler performs the necessary conversion. The usable byte offsets therefore depend on the type of Load/Store instruction and the transfer size.

Table C1-7 shows the offset and the type of Load/Store instruction.

<table>
<thead>
<tr>
<th>Offset bits</th>
<th>Sign</th>
<th>Scaling</th>
<th>Write-Back</th>
<th>Load/Store type</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>Exclusive/acquire/release</td>
</tr>
<tr>
<td>7</td>
<td>Signed</td>
<td>Scaled</td>
<td>Optional</td>
<td>Register pair</td>
</tr>
<tr>
<td>9</td>
<td>Signed</td>
<td>Unscaled</td>
<td>Optional</td>
<td>Single register</td>
</tr>
<tr>
<td>12</td>
<td>Unsigned</td>
<td>Scaled</td>
<td>No</td>
<td>Single register</td>
</tr>
</tbody>
</table>

- A register offset means that the offset is the 64 bits from a general-purpose register, Xm, optionally scaled by the transfer size, in bytes, if LSL #imm is present and where #imm must be equal to log2(transfer_size).
- An extended register offset means that offset is the bottom 32 bits from a general-purpose register Wm, sign-extended or zero-extended to 64 bits, and then scaled by the transfer size if so indicated by #imm, where imm must be equal to log2(transfer_size). An assembler must accept Wm or Xm as an extended register offset, but Wm is preferred for disassembly.
- Generating an address lower than the value in the base register requires a negative signed immediate offset or a register offset holding a negative value.
- When stack alignment checking is enabled by system software and the base register is the SP, the current stack pointer must be initially quadword aligned, that is aligned to 16 bytes. Misalignment generates a Stack Alignment fault. The offset does not have to be a multiple of 16 bytes unless the specific Load/Store instruction requires this. SP cannot be used as a register offset.

### Address calculation

General-purpose arithmetic instructions can calculate the result of most addressing modes and write the address to a general-purpose register or, in most cases, to the current stack pointer.
Table C1-8 shows the arithmetic instructions that can compute addressing modes.

**Table C1-8 Arithmetic instructions to compute addressing modes**

<table>
<thead>
<tr>
<th>Addressing Form</th>
<th>Immediate</th>
<th>Offset</th>
<th>Extended Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base register (no offset)</td>
<td>MOV Xd</td>
<td>SP, base</td>
<td>-</td>
</tr>
<tr>
<td>Base plus offset</td>
<td>ADD Xd</td>
<td>SP, base, #imm</td>
<td>ADD &lt;Xd</td>
</tr>
<tr>
<td>Pre-indexed</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Post-indexed</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Literal (PC-relative)</td>
<td>ADR Xd, label</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

**Note**

- To calculate a base plus immediate offset the **ADD** instructions defined in *Arithmetic (immediate)* on page C3-214 accept an unsigned 12-bit immediate offset, with an optional left shift by 12. This means that a single **ADD** instruction cannot support the full range of byte offsets available to a single register Load/Store with a scaled 12-bit immediate offset. For example, a quadword **LDR** effectively has a 16-bit byte offset. To calculate an address with a byte offset that requires more than 12 bits it is necessary to use two **ADD** instructions. The following example shows this:

  ```
  ADD Xd, base, #(imm & 0xFFF)
  ADD Xd, Xd, #(imm>>12), LSL #12
  ```

- To calculate a base plus extended register offset, the **ADD** instructions defined in *Arithmetic (extended register)* on page C3-220 provide a superset of the addressing mode that also supports sign-extension or zero-extension of a byte or halfword value with any shift amount between 0 and 4, for example:

  ```
  ADD Xd, base, Wm, SXTW #3  // Xd = base + (SignExtend(Wm) LSL 3)
  ADD Xd, base, Wm, UXTH #4  // Xd = base + (ZeroExtend(Wm<15:0>) LSL 4)
  ```

- If the same extended register offset is used by more than one Load/Store instruction, then, depending on the implementation, it might be more efficient to calculate the extended and scaled intermediate result just once, and then reuse it as a simple register offset. The extend and scale calculation can be performed using the **SBFIZ** and **UBFIZ** bitfield instructions defined in *Bitfield move on page C3-216*, for example:

  ```
  SBFIZ Xd, Xm, #3, #32  // Xd = “Wm, SXTW #3”
  UBFIZ Xd, Xm, #4, #16  // Xd = “Wm, UXTH #4”
  ```
C1.4 Instruction aliases

Some instructions have an associated *architecture alias* that is used for disassembly of the encoding when the associated conditions are met. Architecture alias instructions are included in the alphabetic lists of instruction types and clearly presented as an alias form in descriptions for the individual instructions.
Chapter C2
About the A64 Instruction Descriptions

This chapter describes the instruction descriptions contained in Chapter C6 *A64 Base Instruction Descriptions* and Chapter C7 *A64 Advanced SIMD and Floating-point Instruction Descriptions*.

It contains the following sections:

- *Understanding the A64 instruction descriptions* on page C2-182.
- *General information about the A64 instruction descriptions* on page C2-185.
C2.1 Understanding the A64 instruction descriptions

Each instruction description in Chapter C6 and Chapter C7 has the following content:
1. A title.
2. An introduction to the instruction.
3. The instruction encoding or encodings.
4. Any alias conditions.
5. A list of the assembler symbols for the instruction.
6. Pseudocode describing how the instruction operates.
7. Notes, if applicable.

The following sections describe each of these.

C2.1.1 The title

The title of an instruction description includes the base mnemonic for the instruction.

If different forms of an instruction use the same base mnemonic, each form has its own description. In this case, the title is the mnemonic followed by a short description of the instruction form in parentheses. This is most often used when an operand is an immediate value in one instruction form, but is a register in another form.

For example, in Chapter C6 there are the following titles for different forms of the ADD instruction:
• ADD (extended register) on page C6-758.
• ADD (immediate) on page C6-761.
• ADD (shifted register) on page C6-763.

C2.1.2 An introduction to the instruction

This briefly describes the function of the instruction. The introduction is not a complete description of the instruction, and it is not definitive. If there is any conflict between it and the more detailed information that follows it, the more detailed information takes priority.

C2.1.3 The instruction encoding or encodings

This shows the instruction encoding diagram, or if the instruction has more than one encoding, shows all of the encoding diagrams. Each diagram has a subheading.

For example, for load and store instructions, the subheadings might be:
• Post-index.
• Pre-index.
• Unsigned offset.

Each diagram numbers the bits from 31 to 0. The diagram for an instruction at address A shows, from left to right, the bytes at addresses A+3, A+2, A+1, and A.

There might be variants of an encoding, if the assembler syntax prototype differs depending on the value in one or more of the encoding fields. In this case, each variant has a subheading that describes the variant and shows the distinguishing field value or values in parentheses. For example, in Chapter C6 there are the following subheadings for variants of the ADC instruction encoding:
• 32-bit variant (sf = 0).
• 64-bit variant (sf = 1).

The assembler syntax prototype for an encoding or variant of an encoding shows how to form a complete assembler source code instruction that assembles to the encoding. Unless otherwise stated, the prototype is also the preferred syntax for a disassembler to disassemble the encoding to. Disassemblers are permitted to omit optional symbols that represent the default value of a field or set of fields, to produce more readable disassembled code, provided that the output re-assembles to the same encoding.
Each encoding diagram, and its associated assembler syntax prototypes, is followed by encoding-specific pseudocode that translates the fields of that encoding into inputs for the encoding-independent pseudocode that describes the operation of the instruction. See Pseudocode describing how the instruction operates on page C2-184.

C2.1.4 Any alias conditions, if applicable

This is an optional part of an instruction description. If included, it describes the set of conditions for which an alternative mnemonic and its associated assembler syntax prototypes are preferred for disassembly by a disassembler. It includes a link to the alias instruction description that defines the alternative syntax. The alias syntax and the original syntax can be used interchangeably in the assembler source code.

Arm recommends that if a disassembler outputs the alias syntax, it consistently outputs the alias syntax.

C2.1.5 A list of the assembler symbols for the instruction

The Assembler symbols subsection of the instruction description contains a list of the symbols that the assembler syntax prototype or prototypes use, if any.

In assembler syntax prototypes, the following conventions are used:

- **< >** Angle brackets. Any symbol enclosed by these is a name or a value that the user supplies. For each symbol, there is a description of what the symbol represents. The description usually also specifies which encoding field or fields encodes the symbol.

- **{}** Brace brackets. Any symbols enclosed by these are optional. For each optional symbol, there is a description of what the symbol represents and how its presence or absence is encoded. In some assembler syntax prototypes, some brace brackets are mandatory, for example if they surround a register list. When the use of brace brackets is mandatory, they are separated from other syntax items by one or more spaces.

- **#** This usually precedes a numeric constant. All uses of # are optional in A64 assembler source code. Arm recommends that disassemblers output the # where the assembler syntax prototype includes it.

- **+/−** This indicates an optional + or - sign. If neither is coded, + is assumed.

Single spaces are used for clarity, to separate syntax items. Where a space is mandatory, the assembler syntax prototype shows two or more consecutive spaces.

Any characters not shown in this conventions list must be coded exactly as shown in the assembler syntax prototype. Apart from brace brackets, the characters shown are used as part of a meta-language to define the architectural assembler syntax for an instruction encoding or alias, but have no architecturally defined significance in the input to an assembler or in the output from a disassembler.

The following symbol conventions are used:

- **<Xn>** The 64-bit name of a general-purpose register (X0-X30) or the zero register (XZR).

- **<Wn>** The 32-bit name of a general-purpose register (W0-W30) or the zero register (WZR).

- **<Xn|SP>** The 64-bit name of a general-purpose register (X0-X30) or the current stack pointer (SP).

- **<Wn|WSP>** The 32-bit name of a general-purpose register (W0-W30) or the current stack pointer (WSP).

- **<Bn>, <Hn>, <Sn>, <Dn>, <Qn>** The 8, 16, 32, 64 or 128-bit name of a SIMD and floating-point register in a scalar context as described in section Register names on page C1-174.

- **<Vn>** The name of a SIMD and floating-point register name in a vector context as described in Register names on page C1-174.

If the description of a symbol specifies that the symbol is a register, the description might also specify that the range of permitted registers is extended or restricted. It also specifies any differences from the default rules for such fields.
C2.1.6 Pseudocode describing how the instruction operates

The Operation subsection of the instruction description contains this pseudocode.

It is encoding-independent pseudocode that provides a precise description of what the instruction does.

--- Note ---

For a description of Arm pseudocode, see Appendix K13 Arm Pseudocode Definition. This appendix also describes the execution model for an instruction.

C2.1.7 Notes, if applicable

If applicable, other notes about the instruction appear under additional subheadings.
C2.2 General information about the A64 instruction descriptions

This section provides general information about the A64 instruction descriptions. Some of this information also applies to System register descriptions, for example the terms defined in Fixed values in AArch64 instruction and System register descriptions apply to the AArch64 descriptions throughout this manual. The following subsections provide this information:

• Execution of instructions in debug state.
• Fixed values in AArch64 instruction and System register descriptions.
• Modified immediate constants in A64 instructions on page C2-186.

C2.2.1 Execution of instructions in debug state

In general, except for the instructions described in Debug state on page C3-192, the A64 instruction descriptions do not indicate any differences in the behavior of the instruction if it is executed in Debug state. For this information, see Executing instructions in Debug state on page H2-6715.

Note
For many instructions, execution is unchanged in Debug state. Executing instructions in Debug state on page H2-6715 identifies these instructions.

C2.2.2 Fixed values in AArch64 instruction and System register descriptions

This section summarizes the terms used to describe fixed values in AArch64 register and instruction descriptions. The Glossary gives full descriptions of these terms, and each entry in this section includes a link to the corresponding Glossary entry.

Note
In register descriptions, the meaning of some bits depends on the PE state. This affects the definitions of RES0 and RES1, as shown in the Glossary.

The following terms are used to describe bits or fields with fixed values:

RAZ Read-As-Zero. See Read-As-Zero (RAZ).
In diagrams, a RAZ bit can be shown as 0.

(0), RES0 Reserved, Should-Be-Zero (SBZ) or RES0.
In instruction encoding diagrams, and sometimes in other descriptions, (0) indicates an SBZ bit. If the bit is set to 1, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:
• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction executes as if the value of the bit was 0.
• Any destination registers of the instruction become UNKNOWN.
This notation can be expanded for fields, so a three-bit field can be shown as either (0)(0)(0) or as (000).
In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES0. See the Glossary definition of RES0 for more information.

Note
Some of the System instruction descriptions in this chapter are based on the field description of the input value for the instruction. These are register descriptions and therefore can include RES0 fields,

The (0) and RES0 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definitions cover these cases.

RAO Read-As-One. See Read-As-One (RAO).
In diagrams, a RAO bit can be shown as 1.

(1), RES1 Reserved, Should-Be-One (SBO) or RES1.
In instruction encoding diagrams, and sometimes in other descriptions, (1) indicates a SBO bit. If the bit is set to 0, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 1.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (1)(1)(1) or as (111).

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES1. See the Glossary definition of RES1 for more information.

**Note**

Some of the System instruction descriptions in this chapter are based on the field description of the input value for the instruction. These are register descriptions and therefore can include RES1 fields, The (1) and RES1 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definitions cover these cases.

### C2.2.3 Modified immediate constants in A64 instructions

It contains the following subsections:

- Modified immediate constants in A64 floating-point instructions.

#### Modified immediate constants in A64 floating-point instructions

Table C2-1 shows the immediate constants available in FMOV (scalar, immediate) and FMOV (vector, immediate) floating-point instructions.

<table>
<thead>
<tr>
<th>Data type</th>
<th>immediate</th>
<th>Constant a</th>
</tr>
</thead>
<tbody>
<tr>
<td>F16</td>
<td>abcddefgh</td>
<td>a8bcdefgh000000</td>
</tr>
<tr>
<td>F32</td>
<td>abcddefgh</td>
<td>a8bcbcdedefgh000000000000000000000000</td>
</tr>
<tr>
<td>F64</td>
<td>abcddefgh</td>
<td>a8bbbbbbbcbcdedefgh0000000000000000000000000000000000000000000000000</td>
</tr>
</tbody>
</table>

a. In this column, \( B = \text{NOT}(b) \). The bit pattern represents the floating-point number \((-1)^S \times 2^{\text{exp}} \times \text{mantissa}, \) where \( S = \text{UInt}(a), \) exp = UInt(NOT(b):c:d)-3 and mantissa = (16+UInt(e:f:g:h))/16.

The immediate value shown in the table is either:

- The value of the \text{im8} field for an FMOV (scalar, immediate) instruction, see FMOV (scalar, immediate) on page C7-1654.
- The value obtained by concatenating the a:b:c:d:e:f:g:h fields field for an FMOV (vector, immediate) instruction, see FMOV (vector, immediate) on page C7-1647.
Table C2-2 shows the floating-point constant values encoded in the b:c:d:e:f:g:h fields of the FMOV (vector, immediate) instruction.

**Operation of modified immediate constants, floating-point instructions**

For an A64 floating-point instruction that uses a modified immediate constant, the operation described by the `VFPExpandImm()` pseudocode function returns the value of the immediate constant.
About the A64 Instruction Descriptions
C2.2 General information about the A64 instruction descriptions
Chapter C3
A64 Instruction Set Overview

This chapter provides an overview of the A64 instruction set. It contains the following sections:

- Branches, Exception generating, and System instructions on page C3-190.
- Loads and stores on page C3-197.
- Data processing - immediate on page C3-214.
- Data processing - register on page C3-219.
- Data processing - SIMD and floating-point on page C3-227.

For a structured breakdown of instruction groups by encoding, see Chapter C4 A64 Instruction Set Encoding.
C3.1 Branches, Exception generating, and System instructions

This section describes the branch, exception generating, and System instructions. It contains the following subsections:

- Conditional branch.
- Unconditional branch (immediate).
- Unconditional branch (register) on page C3-191.
- Exception generation and return on page C3-191.
- System register instructions on page C3-192.
- System instructions on page C3-192.
- Hint instructions on page C3-193.
- Barriers and CLREX instructions on page C3-193.
- Pointer authentication instructions on page C3-194.

For information about the encoding structure of the instructions in this instruction group, see Branches, Exception Generating and System instructions on page C4-257.

Note

Software must:

- Use only BLR or BL to perform a nested subroutine call when that subroutine is expected to return to the immediately following instruction, that is, the instruction with the address of the BLR or BL instruction incremented by four.
- Use only RET to perform a subroutine return, when that subroutine is expected to have been entered by a BL or BLR instruction.
- Use only B, BR, or the instructions listed in Table C3-1 to perform a control transfer that is not a subroutine call or subroutine return described in this Note.

C3.1.1 Conditional branch

Conditional branches change the flow of execution depending on the current state of the Condition flags or the value in a general-purpose register. See Table C1-1 on page C1-173 for a list of the Condition codes that can be used for cond.

Table C3-1 shows the Conditional branch instructions.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>Branch offset range from the PC</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>B.cond</td>
<td>Branch conditionally</td>
<td>±1MB</td>

</tr>
<tr>
<td>TBZ</td>
<td>Test bit and branch if zero</td>
<td>±32KB</td>
<td>TBZ on page C6-1341</td>
</tr>
</tbody>
</table>

C3.1.2 Unconditional branch (immediate)

Unconditional branch (immediate) instructions change the flow of execution unconditionally by adding an immediate offset with a range of ±128MB to the value of the program counter that fetched the instruction. The BL instruction also writes the address of the sequentially following instruction to general-purpose register, X30.
Table C3-2 shows the Unconditional branch instructions with an immediate branch offset.

### Table C3-2 Unconditional branch instructions (immediate)

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>Immediate branch offset range from the PC</th>
<th>See</th>
</tr>
</thead>
<tbody>

<td>Branch unconditionally</td>
<td>±128MB</td>
<td>B on page C6-799</td>
</tr>
<tr>
<td>BL</td>
<td>Branch with link</td>
<td>±128MB</td>
<td>BL on page C6-812</td>
</tr>
</tbody>
</table>

### C3.1.3 Unconditional branch (register)

Unconditional branch (register) instructions change the flow of execution unconditionally by setting the program counter to the value in a general-purpose register. The BLR instruction also writes the address of the sequentially following instruction to general-purpose register X30. The RET instruction behaves identically to BR, but provides an additional hint to the PE that this is a return from a subroutine. Table C3-3 shows Unconditional branch instructions that jump directly to an address held in a general-purpose register.

### Table C3-3 Unconditional branch instructions (register)

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>

C3.1.9 Pointer authentication instructions

ARMv8.3-PAuth adds support for pointer authentication, see Pointer authentication in AArch64 state on page D5-2508. This functionality includes the A64 instructions described in this section. These instructions fall into two groups, see:

- Basic pointer authentication instructions.
- Combined instructions that include pointer authentication on page C3-196.

Basic pointer authentication instructions

Each of these instructions only performs an operation that supports pointer authentication.

Table C3-12 shows the instructions that add a Pointer Authentication Code (PAC) to the address in a register:

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>

## C3.2 Loads and stores

This section describes the Load/Store instructions. It contains the following subsections:

- **Load/Store register.**
- **Load/Store register (unscaled offset) on page C3-198.**
- **Load/Store Non-temporal Pair on page C3-200.**
- **Load/Store unprivileged on page C3-201.**
- **Load-Exclusive/Store-Exclusive on page C3-201.**
- **Load-Acquire/Store-Release on page C3-202.**
- **LoadLOAcquire/StoreLORelease on page C3-204.**
- **Load/Store scalar SIMD and floating-point on page C3-204.**
- **Load/Store Vector on page C3-206.**
- **Prefetch memory on page C3-208.**
- **Compare and Swap on page C3-209.**
- **Atomic memory operations on page C3-210.**
- **Swap on page C3-212.**
- **Memory Tagging instructions on page C3-213.**

The requirements for the alignment of data memory accesses are strict, for more information see Alignment of data accesses on page B2-138.

The additional control bits SCTLX EA0 and SCTLX EA1 control whether the stack pointer must be quadword aligned when used as a base register. See SP alignment checking on page D1-2287. Using a misaligned stack pointer generates an SP alignment fault exception.

For information about the encoding structure of the instructions in this instruction group, see Loads and Stores on page C4-266.

---

**Note**

In some cases, Load/Store instructions can lead to CONSTRAINED UNPREDICTABLE behavior. See AArch64 CONSTRAINED UNPREDICTABLE behaviors on page K1-7630.

### C3.2.1 Load/Store register

The Load/Store register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset, optionally scaled.
- Base plus a 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

See also Load/Store addressing modes on page C1-177.

If a Load instruction specifies writeback and the register being loaded is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs the load using the specified addressing mode and the base register becomes UNKNOWN. In addition, if an exception occurs during the execution of such an instruction, the base address might be corrupted so that the instruction cannot be repeated.
If a Store instruction performs a writeback and the register that is stored is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs the store to the designated register using the specified addressing mode, but the value stored is UNKNOWN.

Table C3-16 shows the Load/Store Register instructions.

</table>

### C3.2.2 Load/Store register (unscaled offset)

The Load/Store register instructions with an unscaled offset support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See Load/Store addressing modes on page C1-177.
The Load/Store register (unscaled offset) instructions are required to disambiguate this instruction class from the Load/Store register instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset, because that can represent some offset values in the same range.

The ambiguous immediate offsets are byte offsets that are both:
- In the range 0-255, inclusive.
- Naturally aligned to the access size.

Other byte offsets in the range -256 to 255 inclusive are unambiguous. An assembler program translating a Load/Store instruction, for example LDR, is required to encode an unambiguous offset using the unscaled 9-bit offset form, and to encode an ambiguous offset using the scaled 12-bit offset form. A programmer might force the generation of the unscaled 9-bit form by using one of the mnemonics in Table C3-17. Arm recommends that a disassembler outputs all unscaled 9-bit offset forms using one of these mnemonics, but unambiguous offsets can be output using a Load/Store single register mnemonic, for example, LDR.

Table C3-17 shows the Load/Store register instructions with an unscaled offset.

<td>STURH on page C6-1293</td>
</tr>
</tbody>
</table>

### C3.2.3 Load/Store Pair

The Load/Store Pair instructions support the following addressing modes:
- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also [Load/Store addressing modes on page C1-177](#).

If a Load Pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:
- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

If a Load Pair instruction specifies writeback and one of the registers being loaded is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:
- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
• The instruction performs all of the loads using the specified addressing mode, and the base register becomes UNKNOWN. In addition, if an exception occurs during the instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store Pair instruction performs a writeback and one of the registers being stored is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

• The instruction is treated as UNDEFINED.
• The instruction is treated as a NOP.
• The instruction performs all the stores of the registers indicated by the specified addressing mode, but the value stored for the base register is UNKNOWN.

Table C3-18 shows the Load/Store Pair instructions.

</tr>
<tr>
<td>STP</td>
<td>Store Pair</td>
<td>STP on page C6-1236</td>
</tr>
</tbody>
</table>

### C3.2.4 Load/Store Non-temporal Pair

The Load/Store Non-temporal Pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See Load/Store addressing modes on page C1-177.

The Load/Store Non-temporal Pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be preloaded and memory writes to be gathered to accelerate bulk memory transfers.

In addition, there is an exception to the usual memory ordering rules. If an address dependency exists between two memory reads, and a Load Non-temporal Pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, the memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a Load Non-Temporal Pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following must occur:

• The instruction is treated as UNDEFINED.
• The instruction is treated as a NOP.
• The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-19 shows the Load/Store Non-temporal Pair instructions.

</tr>
<tr>
<td>STNP</td>
<td>Store Non-temporal Pair</td>
<td>STNP on page C6-1234</td>
</tr>
</tbody>
</table>
C3.2.5 Load/Store unprivileged

The Load/Store unprivileged instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See Load/Store addressing modes on page C1-177.

The accesses permissions that apply to accesses made at EL0 apply to the memory accesses made by a Load/Store unprivileged instruction that is executed either:

- At EL1 when the Effective value of PSTATE.UAO is 0.
- At EL2 when both the Effective value of HCR_EL2.{E2H, TGE} is {1, 1} and the Effective value of PSTATE.UAO is 0.

Otherwise, memory accesses made by a Load/Store unprivileged instruction are subject to the access permissions that apply to the Exception level at which the instruction is executed. These are the permissions that apply to the corresponding Load/Store register instruction, see Load/Store register on page C3-197.

Note

This means that when the value of PSTATE.UAO is 1 the access permissions for a Load/Store unprivileged instruction are always the same as those for the corresponding Load/Store register instruction.

Table C3-20 shows the Load/Store unprivileged instructions.

<td>Store unprivileged halfword</td>
<td>STTRH on page C6-1276</td>
</tr>
</tbody>
</table>

C3.2.6 Load-Exclusive/Store-Exclusive

The Load-Exclusive/Store-Exclusive instructions support only one addressing mode:

- Base register with no offset.

See Load/Store addressing modes on page C1-177.

The Load-Exclusive instructions mark the physical address being accessed as an exclusive access. This exclusive access mark is checked by the Store-Exclusive instruction, permitting the construction of atomic read-modify-write operations on shared memory variables, semaphores, mutexes, and spinlocks. See Synchronization and semaphores on page B2-156.
The Load-Exclusive/Store-Exclusive instructions other than Load-Exclusive pair and Store-Exclusive pair require natural alignment, and an unaligned address generates an Alignment fault. Memory accesses generated by Load-Exclusive pair or Store-Exclusive pair instructions must be aligned to the size of the pair, otherwise the access generates an Alignment fault. When a Store-Exclusive pair succeeds, it causes a single-copy atomic update of the entire memory location.

Armv8.4 introduces changes to the alignment requirements of Load-Exclusive/Store-Exclusive instructions, see *Load-Exclusive/ Store-Exclusive and Atomic instructions* on page B2-138.

Table C3-21 shows the Load-Exclusive/Store-Exclusive instructions.

</tr>
</tbody>
</table>

### C3.2.7 Load-Acquire/Store-Release

The Load-Acquire, Load-AcquirePC, and Store-Release instructions support only one addressing mode:

- Base register with no offset.

See *Load/Store addressing modes* on page C1-177.

The Load-Acquire, Load-AcquirePC, and Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction. For more information about the ordering of Load-Acquire, Load-AcquirePC, and Store-Release, see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-129.

The Load-Acquire, Load-AcquirePC, and Store-Release instructions other than Load-Acquire pair and Store-Release pair require natural alignment, and an unaligned address generates an Alignment fault. Memory accesses generated by Load-Acquire pair or Store-Release pair instructions must be aligned to the size of the pair, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction only has the Release semantics if the store is successful.

Armv8.1 adds more instructions with load-acquire and store-release mechanisms, see *LoadLOAcquire/StoreLORelease* on page C3-204.

Armv8.4 introduces changes to the alignment requirements of Load-Acquire/Store-Release instructions, see *ARMv8.4-RCPC* on page A2-81.
Table C3-22 shows the Non-exclusive Load-Acquire/Store-Release instructions.

C3.2.8 LoadLOAcquire/StoreLORelease

The LoadLOAcquire/StoreLORelease instructions support only one addressing mode:

- Base register with no offset.

See Load/Store addressing modes on page C1-177.

The LoadLOAcquire/StoreLORelease instructions can remove the requirement to use the explicit DMB memory barrier instruction. For more information about the ordering of LoadLOAcquire/StoreLORelease, see LoadLOAcquire, StoreLORelease on page B2-130.

The LoadLOAcquire/StoreLORelease instructions require natural alignment, and an unaligned address generates an Alignment fault.

Table C3-24 shows the LoadLOAcquire/StoreLORelease instructions.

C3.2.9 Load/Store scalar SIMD and floating-point

The Load/Store scalar SIMD and floating-point instructions operate on scalar values in the SIMD and floating-point register file as described in SIMD and floating-point scalar register names on page C1-175. The memory addressing modes available, described in Load/Store addressing modes on page C1-177, are identical to the general-purpose register Load/Store instructions, and like those instructions permit arbitrary address alignment unless strict alignment checking is enabled. However, unlike the Load/Store instructions that transfer general-purpose registers, Load/Store scalar SIMD and floating-point instructions make no guarantee of atomicity, even when the address is naturally aligned to the size of the data.

### Load/Store scalar SIMD and floating-point register

The Load/Store scalar SIMD and floating-point register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus unscaled 9-bit signed immediate offset.
- Base plus 64-bit register offset, optionally scaled.
- Base plus 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
• PC-relative literal for loads of 32 bits or more.

For more information on the addressing modes, see *Load/Store addressing modes* on page C1-177.

---

**Note**

The unscaled 9-bit signed immediate offset address mode requires its own instruction form, see *Load/Store scalar SIMD and floating-point register (unscaled offset)*.

Table C3-25 shows the Load/Store instructions for a single SIMD and floating-point register.

</tr>
</tbody>
</table>

### Load/Store scalar SIMD and floating-point register (unscaled offset)

The Load/Store scalar SIMD and floating-point register instructions support only one addressing mode:

• Base plus an unscaled 9-bit signed immediate offset.

See also *Load/Store addressing modes* on page C1-177.

The Load/Store scalar SIMD and floating-point register (unscaled offset) instructions are required to disambiguate this instruction class from the Load/Store single SIMD and floating-point instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset. This is similar to the Load/Store register (unscaled offset) instructions, that disambiguate this instruction class from the Load/Store register instruction, see *Load/Store register (unscaled offset)* on page C3-198.

Table C3-26 shows the Load/Store SIMD and floating-point register instructions with an unscaled offset.

### Table C3-26 Load/Store SIMD and floating-point register instructions

</tr>
</thead>
<tbody>
<tr>
<td>LDUR</td>
<td>Load scalar SIMD&amp;FP register (unscaled offset)</td>
<td><em>LDUR (SIMD&amp;FP)</em> on page C7-1809</td>
</tr>
<tr>
<td>STUR</td>
<td>Store scalar SIMD&amp;FP register (unscaled offset)</td>
<td><em>STUR (SIMD&amp;FP)</em> on page C7-2121</td>
</tr>
</tbody>
</table>

### Load/Store SIMD and Floating-point register pair

The Load/Store SIMD and floating-point register pair instructions support the following addressing modes:

• Base plus a scaled 7-bit signed immediate offset.
• Pre-indexed by a scaled 7-bit signed immediate offset.
• Post-indexed by a scaled 7-bit signed immediate offset.

See also *Load/Store addressing modes* on page C1-177.
If a Load pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode and the register being loaded takes an UNKNOWN value.

Table C3-27 shows the Load/Store SIMD and floating-point register pair instructions.

<table>
<thead>

</tr>
<tr>
<td>STP</td>
<td>Store pair of scalar SIMD&amp;FP registers</td>
<td><em>STP (SIMD&amp;FP)</em> on page C7-2111</td>
</tr>
</tbody>
</table>

Load/Store SIMD and Floating-point Non-temporal pair

The Load/Store SIMD and Floating-point Non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See also *Load/Store addressing modes* on page C1-177.

The Load/Store Non-temporal pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be preloaded and memory writes to be gathered to accelerate bulk memory transfers.

In addition, there is an exception to the usual memory ordering rules. If an address dependency exists between two memory reads, and a Load non-temporal pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, those memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a Load Non-temporal pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-28 shows the Load/Store SIMD and floating-point Non-temporal pair instructions.

<td><em>STNP (SIMD&amp;FP)</em> on page C7-2109</td>
</tr>
</tbody>
</table>

C3.2.10 Load/Store Vector

The Vector Load/Store structure instructions support the following addressing modes:

- Base register only.
- Post-indexed by a 64-bit register.
Post-indexed by an immediate, equal to the number of bytes transferred.

Load/Store vector instructions, like other Load/Store instructions, allow any address alignment, unless strict alignment checking is enabled. If strict alignment checking is enabled, then alignment checking to the size of the element is performed. However, unlike the Load/Store instructions that transfer general-purpose registers, the Load/Store vector instructions do not guarantee atomicity, even when the address is naturally aligned to the size of the element.

**Load/Store structures**

Table C3-29 shows the Load/Store structure instructions. A post-increment immediate offset, if present, must be 8, 16, 24, 32, 48, or 64, depending on the number of elements transferred.

</tbody>
</table>

C3.2.11 Prefetch memory

The Prefetch memory instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset. This can be optionally scaled by 8-bits, for example LSL #3.
- Base plus a 32-bit extended register offset. This can be optionally scaled by 8-bits.
- PC-relative literal.

The prefetch memory instructions signal to the memory system that memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory access when they do occur, such as preloading the specified address into one or more caches. Because these signals are only hints, it is valid for the PE to treat any or all prefetch instructions as a NOP.

Because they are hints to the memory system, the operation of a PRFM instruction cannot cause a synchronous exception. However, a memory operation performed as a result of one of these memory system hints might in exceptional cases trigger an asynchronous event, and thereby influence the execution of the PE. An example of an asynchronous event that might be triggered is an SError interrupt.

A PRFM instruction can only have an effect on software visible structures, such as caches and translation lookaside buffers associated with memory locations that can be accessed by reads, writes, or execution as defined in the translation regime of the current Exception level.

A PRFM instruction is guaranteed not to access Device memory.

A PRFM instruction using a PLI hint must not result in any access that could not be performed by the PE speculatively fetching an instruction. Therefore, if all associated MMUs are disabled, a PLI hint cannot access any memory location that cannot be accessed by instruction fetches.

The PRFM instructions require an additional <prfop> operand to be specified, which must be one of the following:

- PLDL1KEEP, PLDL1STRM, PLDL2KEEP, PLDL2STRM, PLDL3KEEP, PLDL3STRM
- PSTL1KEEP, PSTL1STRM, PSTL2KEEP, PSTL2STRM, PSTL3KEEP, PSTL3STRM
- PLIL1KEEP, PLIL1STRM, PLIL2KEEP, PLIL2STRM, PLIL3KEEP, PLIL3STRM

<prfop> is defined as <type><target><policy>.

Here:

- <type> Is one of:
  - PLD  Prefetch for load.
  - PST  Prefetch for store.
  - PLI  Preload instructions.
- <target> Is one of:
  - L1  Level 1 cache.
C3.2 Loads and stores

L2  Level 2 cache.
L3  Level 3 cache.

<policy> Is one of:
KEEP Retained or temporal prefetch, allocated in the cache normally.
STRM Streaming or non-temporal prefetch, for data that is used only once.

PRFUM explicitly uses the unscaled 9-bit signed immediate offset addressing mode, as described in Load/Store register (unscaled offset) on page C3-198.

Table C3-31 shows the Prefetch memory instructions.

</tbody>
</table>

C3.2.12 Compare and Swap

The Compare and Swap instructions support only one addressing mode:
• Base register only.

See also Load/Store addressing modes on page C1-177.

For the purpose of permission checking, and for watchpoints, all of the Compare and Swap instructions are treated as performing both a load and a store.

The CAS instructions require natural alignment.

The CASP instructions require alignment to the total size of the memory being accessed.

All Compare and Swap instructions generate an Alignment fault if the address being accessed is not aligned to the size of the data structure being accessed.

The instructions are provided with ordering options, which map to the acquire and release definitions used in the Armv8-A architecture. If a compare and swap instruction does not perform a store, then the instruction does not have release semantics, regardless of the instruction ordering options.

The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity.

For the CAS and CASP instructions, the architecture permits that a data read clears any Exclusives monitors associated with that location, even if the compare subsequently fails. If these instructions generate a synchronous Data Abort, the registers which are compared and loaded are restored to the values held in the registers before the instruction was executed.

<table>

</tbody>
</table>
C3.2.13 Atomic memory operations

The atomic memory operation instructions support only one addressing mode:

- Base register only.

See also *Load/Store addressing modes* on page C1-177.

For the purpose of permission checking, and for watchpoints, all of the Compare and Swap instructions are treated as performing both a load and a store.

The LD<OP> and ST<OP> instructions require natural alignment, and an unaligned address generates an Alignment fault.

The instructions are provided with ordering options, which map to the acquire and release definitions used in the Armv8-A architecture. The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity. These operations map to the acquire and release definitions, and are counted as Load-Acquire and Store-Release operations respectively.

For the LD<OP> instructions, where the source and destination registers are the same, if the instruction generates a synchronous Data Abort, then the source register is restored to the value it held before the instruction was executed.

The ST<OP> instructions, and LD<OP> instructions where the destination register is WZR or XZR, are not regarded as doing a read for the purpose of a DMB LD barrier.

Armv8.4 introduces changes to the alignment requirements of Atomic instructions, see *Load-Exclusive/Store-Exclusive and Atomic instructions* on page B2-138.

C3.2 Loads and stores

C3.2.14 Swap

The swap instructions support only one addressing mode:
- Base register only.

See also Load/Store addressing modes on page C1-177.

For the purpose of permission checking, and for watchpoints, all of the Compare and Swap instructions are treated as performing both a load and a store.

The \texttt{SWP} instructions require natural alignment, and an unaligned address generates an Alignment fault.

The instructions are provided with ordering options, which map to the acquire and release definitions used in the Armv8-A architecture. The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity.

For the \texttt{SWP} instructions, where the source and destination registers are the same, if the instruction generates a synchronous Data Abort, then the source register is restored to the value it held before the instruction was executed.

C3.3 Data processing - immediate

This section describes the instruction groups for data processing with immediate operands. It contains the following subsections:

- Arithmetic (immediate).
- Logical (immediate).
- Move (wide immediate) on page C3-215.
- Move (immediate) on page C3-215.
- PC-relative address calculation on page C3-216.
- Bitfield move on page C3-216.
- Bitfield insert and extract on page C3-217
- Extract register on page C3-217.
- Shift (immediate) on page C3-217.
- Sign-extend and Zero-extend on page C3-218.

For information about the encoding structure of the instructions in this instruction group, see Data Processing -- Immediate on page C4-252.

C3.3.1 Arithmetic (immediate)

The Arithmetic (immediate) instructions accept a 12-bit unsigned immediate value, optionally shifted left by 12 bits. The Arithmetic (immediate) instructions that do not set Condition flags can read from and write to the current stack pointer. The flag setting instructions can read from the stack pointer, but they cannot write to it.

Table C3-40 shows the Arithmetic instructions with an immediate offset.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>

<td>Compare</td>
<td>CMP (immediate) on page C6-858</td>
</tr>
<tr>
<td>CMN</td>
<td>Compare negative</td>
<td>CMN (immediate) on page C6-852</td>
</tr>
</tbody>
</table>

C3.3.2 Logical (immediate)

The Logical (immediate) instructions accept a bitmask immediate value that is a 32-bit pattern or a 64-bit pattern viewed as a vector of identical elements of size \( e = 2, 4, 8, 16, 32 \) or, 64 bits. Each element contains the same sub-pattern, that is a single run of 1 to \( (e - 1) \) nonzero bits from bit 0 followed by zero bits, then rotated by 0 to \( (e - 1) \) bits. This mechanism can generate 5334 unique 64-bit patterns as 2667 pairs of pattern and their bitwise inverse.

Note

Values that consist of only zeros or only ones cannot be described in this way.

The Logical (immediate) instructions that do not set the Condition flags can write to the current stack pointer, for example to align the stack pointer in a function prologue.
Note
Apart from ANDS, and its TST alias, Logical (immediate) instructions do not set the Condition flags. However, the final results of a bitwise operation can be tested by a CBZ, CBNZ, TBZ, or TBNZ conditional branch.

Table C3-41 shows the Logical immediate instructions.

<table>
<thead>
<tr>

</tbody>
</table>

C3.3.3 Move (wide immediate)
The Move (wide immediate) instructions insert a 16-bit immediate, or inverted immediate, into a 16-bit aligned position in the destination register. The value of the other bits in the destination register depends on the variant used. The optional shift amount can be any multiple of 16 that is smaller than the register size.

Table C3-42 shows the Move (wide immediate) instructions.

<table>
<thead>
<tr>

</tr>
<tr>
<td>MOVK</td>
<td>Move wide with keep</td>
<td>MOVK on page C6-1098</td>
</tr>
</tbody>
</table>

C3.3.4 Move (immediate)
The Move (immediate) instructions are aliases for a single MOVZ, MOVN, or ORR (immediate with zero register), instruction to load an immediate value into the destination register. An assembler must permit a signed or unsigned immediate, as long as its binary representation can be generated using one of these instructions, and an assembler error results if the immediate cannot be generated in this way. On disassembly, it is unspecified whether the immediate is output as a signed or an unsigned value.

If there is a choice between the MOVZ, MOVN, and ORR instruction to encode the immediate, then an assembler must prefer MOVZ to MOVN, and MOVN or MOVN to ORR, to ensure reversability. A disassembler must output ORR (immediate with zero register) MOVZ, and MOVN, as a MOV mnemonic except that the underlying instruction must be used when:
- ORR has an immediate that can be generated by a MOVZ or MOVN instruction.
- A MOVN instruction has an immediate that can be encoded by MOVZ.
- MOVZ #0 or MOVN #0 have a shift amount other than LSL #0.
Table C3-43 shows the Move (immediate) instructions.

### C3.3.5 PC-relative address calculation

The `ADR` instruction adds a signed, 21-bit immediate to the value of the program counter that fetched this instruction, and then writes the result to a general-purpose register. This permits the calculation of any byte address within ±1MB of the current PC.

The `ADRP` instruction shifts a signed, 21-bit immediate left by 12 bits, adds it to the value of the program counter with the bottom 12 bits cleared to zero, and then writes the result to a general-purpose register. This permits the calculation of the address at a 4KB aligned memory region. In conjunction with an `ADD` (immediate) instruction, or a Load/Store instruction with a 12-bit immediate offset, this allows for the calculation of, or access to, any address within ±4GB of the current PC.

---

**Note**
The term *page* used in the `ADRP` description is short-hand for the 4KB memory region, and is not related to the virtual memory translation granule size.

Table C3-44 shows the instructions used for PC-relative address calculations are as follows:

<table>
<thead>
<tr>
<th>Mnemonic</th>

</tr>
</tbody>
</table>

### C3.3.6 Bitfield move

The Bitfield move instructions copy a field of constant width from bit 0 in the source register to a constant bit position in the destination register, or from a constant bit position in the source register to bit 0 in the destination register. The remaining bits in the destination register are set as follows:

- For `BFM`, the remaining bits are unchanged.
- For `UBFM`, the lower bits, if any, and upper bits, if any, are set to zero.
- For `SBFM`, the lower bits, if any, are set to zero, and the upper bits, if any, are set to a copy of the most-significant bit in the copied field.
Table C3-45 shows the Bitfield move instructions.

</tr>
</tbody>
</table>

**C3.3.8 Extract register**

Depending on the register width of the operands, the Extract register instruction copies a 32-bit or 64-bit field from a constant bit position within a double-width value formed by the concatenation of a pair of source registers to a destination register.

Table C3-47 shows the Extract (immediate) instructions.

C3.4 Data processing - register

This section describes the instruction groups for data processing with all register operands. It contains the following subsections:

- Arithmetic (shifted register).
- Arithmetic (extended register) on page C3-220.
- Arithmetic with carry on page C3-221.
- Flag manipulation instructions on page C3-221.
- Logical (shifted register) on page C3-221.
- Move (register) on page C3-222.
- Shift (register) on page C3-222.
- Multiply and divide on page C3-223.
- CRC32 on page C3-224.
- Bit operation on page C3-225.
- Conditional select on page C3-225.
- Conditional comparison on page C3-226.

For information about the encoding structure of the instructions in this instruction group, see Data Processing -- Register on page C4-299.

C3.4.1 Arithmetic (shifted register)

The Arithmetic (shifted register) instructions apply an optional shift operator to the second source register value before performing the arithmetic operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators LSL, ASR, and LSR accept an immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator implies LSL #0, which means that there is no shift. A disassembler must not output LSL #0. However, a disassembler must output all other shifts by zero.

The current stack pointer, SP or WSP, cannot be used with this class of instructions. See Arithmetic (extended register) on page C3-220 for arithmetic instructions that can operate on the current stack pointer.

Table C3-50 shows the Arithmetic (shifted register) instructions.

<td>NEGS on page C6-1116</td>
</tr>
</tbody>
</table>
### C3.4.2 Arithmetic (extended register)

The extended register instructions provide an optional sign-extension or zero-extension of a portion of the second source register value, followed by an optional left shift by a constant amount of 1-4, inclusive.

The extended shift is described by the mandatory extend operator $SXTB$, $SXTH$, $SXTW$, $UXTB$, $UXTH$, or $UXTW$. This is followed by an optional left shift amount. If the shift amount is not specified, the default shift amount is zero. A disassembler must not output a shift amount of zero.

For 64-bit instruction forms, the additional operators $UXTX$ and $SXTX$ use all 64 bits of the second source register with an optional shift. In that case, Arm recommends $UXTX$ as the operator. If and only if at least one register is SP, Arm recommends use of the LSL operator name, rather than $UXTX$, and when the shift amount is also zero then both the operator and the shift amount can be omitted. $UXTW$ and $SXTW$ both use all 32 bits of the second source register with an optional shift. In that case Arm recommends $UXTW$ as the operator. If and only if at least one register is WSP, Arm recommends use of the LSL operator name, rather than $UXTW$, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

For 32-bit instruction forms, the operators $UXTW$ and $SXTW$ both use all 32 bits of the second source register with an optional shift. In that case, Arm recommends $UXTW$ as the operator. If and only if at least one register is WSP, Arm recommends use of the LSL operator name, rather than $UXTW$, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

The non-flag setting variants of the extended register instruction permit the use of the current stack pointer as either the destination register and the first source register. The flag setting variants only permit the stack pointer to be used as the first source register.

In the 64-bit form of these instructions, the final register operand is written as $Wm$ for all except the $UXTX$/LSL and $SXTX$ extend operators. For example:

```assembly
CMP X4, W5, SXTW
ADD X1, X2, W3, UXTB #2
SUB SP, SP, X1  // SUB SP, SP, X1, UXTX #0
```

Table C3-51 shows the Arithmetic (extended register) instructions.

C3.4.3 Arithmetic with carry

The Arithmetic with carry instructions accept two source registers, with the carry flag as an additional input to the calculation. They do not support shifting of the second source register.

Table C3-52 shows the Arithmetic with carry instructions

<table>
<thead>
<tr>

<td>Negate with carry and set flags</td>
<td>NGCS on page C6-1120</td>
</tr>
</tbody>
</table>

C3.4.4 Flag manipulation instructions

The Flag manipulation instructions set the value of the NZCV condition flags directly.

The instructions SETF8 and SETF16 accept one source register and set the NZV condition flags based on the value of the input register. The instruction RMIF accepts one source register and two immediate values, rotating the first source register using the first immediate value and setting the NZCV condition flags masked by the second immediate value.

The instructions XAFLAG and AXFLAG convert PSTATE condition flags between the FCMP instruction format and an alternative format. See Table C6-1 on page C6-752 for more information.

Table C3-53 shows the Flag manipulation instructions

<table>
<thead>

</tr>
<tr>
<td>XAFLAG</td>
<td>Convert from alternative format to FCMP comparison format</td>
<td>XAFLAG on page C6-1368</td>
</tr>
</tbody>
</table>

C3.4.5 Logical (shifted register)

The Logical (shifted register) instructions apply an optional shift operator to the second source register value before performing the main operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators LSL, ASR, LSR, and ROR accept a constant immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.
Omitting the shift operator and amount implies \textit{LSL \#0}, which means that there is no shift. A disassembler must not output \textit{LSL \#0}. However, a disassembler must output all other shifts by zero.

\begin{table}
\centering
\caption{Logical (shifted register) instructions}
\begin{tabular}{ | l | l | l |}
\hline
\textbf{Mnemonic} & \textbf{Instruction} & \textbf{See} \\
\hline
\texttt{AND} & Bitwise AND & \textit{AND (shifted register)} on page C6-777 \\
\texttt{ANDS} & Bitwise AND and set flags & \textit{ANDS (shifted register)} on page C6-781 \\
\texttt{BIC} & Bitwise bit clear & \textit{BIC (shifted register)} on page C6-808 \\
\texttt{BICS} & Bitwise bit clear and set flags & \textit{BICS (shifted register)} on page C6-810 \\
\texttt{EON} & Bitwise exclusive OR NOT & \textit{EON (shifted register)} on page C6-894 \\
\texttt{EOR} & Bitwise exclusive OR & \textit{EOR (shifted register)} on page C6-898 \\
\texttt{ORR} & Bitwise inclusive OR & \textit{ORR (shifted register)} on page C6-1127 \\
\texttt{MVN} & Bitwise NOT & \textit{MVN} on page C6-1112 \\

\texttt{TST} & Test bits & \textit{TST (shifted register)} on page C6-1347 \\
\hline
\end{tabular}
\end{table}

C3.4.6 Move (register)

The Move (register) instructions are aliases for other data processing instructions. They copy a value from a general-purpose register to another general-purpose register or the current stack pointer, or from the current stack pointer to a general-purpose register.

\begin{table}
\centering
\caption{MOV register instructions}
\begin{tabular}{ | l | l | l |}
\hline
\textbf{Mnemonic} & \textbf{Instruction} & \textbf{See} \\
\hline
\texttt{MOV} & Move register & \textit{MOV (register)} on page C6-1096 \\
& Move register to SP or move SP to register & \textit{MOV (to/from SP)} on page C6-1089 \\
\hline
\end{tabular}
\end{table}

C3.4.7 Shift (register)

In the Shift (register) instructions, the shift amount is the positive value in the second source register modulo the register size. The register width of the instruction controls whether the new bits are fed into the result on a right shift or rotate at bit[63] or bit[31].
Table C3-56 shows the Shift (register) instructions.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

C3.4.8 Multiply and divide

This section describes the instructions used for integer multiplication and division. It contains the following subsections:

- *Multiply*.
- *Divide* on page C3-224.

Multiply

The Multiply instructions write to a single 32-bit or 64-bit destination register, and are built around the fundamental four operand multiply-add and multiply-subtract operation, together with 32-bit to 64-bit widening variants. A 64-bit to 128-bit widening multiple can be constructed with two instructions, using **SMULH** or **UMULH** to generate the upper 64 bits. Table C3-58 shows the Multiply instructions.

<table>
<thead>
<tr>
<th>Mnemonic</th>

<td>SMADDL on page C6-1178</td>
</tr>
<tr>
<td>SMSUBL</td>
<td>Signed multiply-subtract long</td>
<td>SMSUBL on page C6-1182</td>
</tr>
</tbody>
</table>
The Divide instructions compute the quotient of a division, rounded towards zero. The remainder can then be computed as (numerator - (quotient × denominator)), using the MSUB instruction.

If a signed integer division (\texttt{INT\_MIN} / \texttt{-1}) is performed where \texttt{INT\_MIN} is the most negative integer value representable in the selected register size, then the result overflows the signed integer range. No indication of this overflow is produced and the result that is written to the destination register is \texttt{INT\_MIN}.

A division by zero results in a zero being written to the destination register, without any indication that the division by zero occurred.

Table C3-59 shows the Divide instructions.

### C3.4.9 CRC32

The CRC32 instructions operate on the general-purpose register file to update a 32-bit CRC value from an input value comprising 1, 2, 4, or 8 bytes. There are two different classes of CRC instructions, CRC32, and CRC32C, that support two commonly used 32-bit polynomials, known as CRC-32 and CRC-32C.

To fit with common usage, the bit order of the values is reversed as part of the operation.

When bits[19:16] of \texttt{ID\_AA64ISAR0\_EL1} are set to \texttt{0b0001}, the CRC instructions are implemented.

These instructions are optional in an Armv8.0 implementation.

All implementations of Armv8.1 architecture and later are required to implement the CRC32 instructions.
Table C3-60 shows the CRC instructions.

C3.4.11 Conditional select

The Conditional select instructions select between the first or second source register, depending on the current state of the Condition flags. When the named condition is true, the first source register is selected and its value is copied without modification to the destination register. When the condition is false the second source register is selected and its value might be optionally inverted, negated, or incremented by one, before writing to the destination register.

Other useful conditional set and conditional unary operations are implemented as aliases of the four Conditional select instructions.
Table C3-62 shows the Conditional select instructions.

### Table C3-62  Conditional select instructions

C3.4.12   Conditional comparison

The Conditional comparison instructions provide a conditional select for the NZCV Condition flags, setting the flags to the result of an arithmetic comparison of its two source register values if the named input condition is true, or to an immediate value if the input condition is false. There are register and immediate forms. The immediate form compares the source register to a small 5-bit unsigned value.

Table C3-63 shows the Conditional comparison instructions.

C3.5 Data processing - SIMD and floating-point

This section describes the instruction groups for data processing with SIMD and floating-point register operands.

Common features of SIMD instructions gives general information about SIMD instructions.

The following subsections describe the scalar floating-point data processing instructions:

- Floating-point move (register) on page C3-228.
- Floating-point move (immediate) on page C3-228.
- Floating-point conversion on page C3-229.
- Floating-point round to integral value on page C3-230.
- Floating-point multiply-add on page C3-232.
- Floating-point arithmetic (one source) on page C3-232.
- Floating-point arithmetic (two sources) on page C3-232.
- Floating-point minimum and maximum on page C3-233.
- Floating-point comparison on page C3-233.
- Floating-point conditional select on page C3-234.

The following subsections describe the SIMD data processing instructions:

- SIMD move on page C3-234
- SIMD arithmetic on page C3-234.
- SIMD compare on page C3-237.
- SIMD widening and narrowing arithmetic on page C3-237.
- SIMD table lookup on page C3-246.
- SIMD by element arithmetic on page C3-240.
- SIMD permute on page C3-242.
- SIMD immediate on page C3-242.
- SIMD shift (immediate) on page C3-242.
- SIMD floating-point and integer conversion on page C3-243.
- SIMD reduce (across vector lanes) on page C3-244.
- SIMD pairwise arithmetic on page C3-245.
- SIMD dot product on page C3-246.
- SIMD table lookup on page C3-246.
- SIMD complex number arithmetic on page C3-246.
- The Cryptographic Extension on page C3-247.

For information about the encoding structure of the instructions in this instruction group, see Data Processing -- Scalar Floating-Point and Advanced SIMD on page C4-309.

For information about the floating-point exceptions, see Floating-point exceptions and exception traps on page D1-2313.

C3.5.1 Common features of SIMD instructions

A number of SIMD instructions come in three forms:

**Wide**

Indicated by the suffix \( W \). The element width of the destination register and the first source operand is double that of the second source operand.

**Long**

Indicated by the suffix \( L \). The element width of the destination register is double that of both source operands.

**Narrow**

Indicated by the suffix \( N \). The element width of the destination register is half that of both source operands.
In addition, each vector form of the instruction is part of a pair, with a second and upper half suffix of 2, to identify the variant of the instruction:

- Where a SIMD operation widens or lengthens a 64-bit vector to a 128-bit vector, the instruction provides a second part operation that can extract the source from the upper 64 bits of the source registers.
- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the instruction provides a second-part operation that can pack the result of a second operation into the upper part of the same destination register.

--- Note ---

This is referred to as a *lane set specifier*.

### C3.5.2 Floating-point move (register)

The Floating-point move (register) instructions copy a scalar floating-point value from one register to another register without performing any conversion.

Some of the Floating-point move (register) instructions overlap with the functionality provided by the Advanced SIMD instructions `DUP`, `INS`, and `UMOV`. However, Arm recommends using the `FMOV` instructions when operating on scalar floating-point data to avoid the creation of scalar floating-point code that depends on the availability of the Advanced SIMD instruction set.

Table C3-64 shows the Floating-point move (register) instructions.

#### Table C3-64 Floating-point move (register) instructions

<table>

</tr>
<tr>
<td></td>
<td>Floating-point move to or from general-purpose register without conversion</td>
<td>FMOV (general) on page C7-1651</td>
</tr>
</tbody>
</table>

### C3.5.3 Floating-point move (immediate)

The Floating-point move (immediate) instructions convert a small constant immediate floating-point value into a half-precision, single-precision, or double-precision scalar floating-point value in a SIMD and floating-point register.

The floating-point constant can be specified either in decimal notation, such as 12.0 or -1.2e1, or as a string beginning with `0x` followed by a hexadecimal representation of the IEEE 754 half-precision, single-precision, or double-precision encoding. Arm recommends that a disassembler uses the decimal notation, provided that this displays the value precisely.

--- Note ---

When ARMv8.2-FP16 is not implemented, the only half-precision instructions that are supported are floating-point conversions between half-precision, single-precision, and double-precision.

The floating-point value must be expressible as $(\pm n/16 \times 2^r)$, where $n$ is an integer in the range $16 \leq n \leq 31$ and $r$ is an integer in the range of $-3 \leq r \leq 4$, that is a normalized binary floating-point encoding with one sign bit, four bits of fraction, and a 3-bit exponent.

Table C3-65 shows the Floating-point move (immediate) instruction:

#### Table C3-65 Floating-point move (immediate) instruction

<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>FMOV</td>
<td>Floating-point move immediate</td>
<td>FMOV (scalar, immediate) on page C7-1654</td>
</tr>
</tbody>
</table>
C3.5.4 Floating-point conversion

The following subsections describe the conversion of floating-point values:

- Convert floating-point precision.
- Convert between floating-point and integer or fixed-point.

Convert floating-point precision

These instructions convert a floating-point scalar with one precision to a floating-point scalar with a different precision, using the current rounding mode as specified by FPCR.RMode.

Table C3-66 shows the Floating-point precision conversion instruction.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>FCVT</td>
<td>Floating-point convert precision (scalar)</td>
<td>FCVT on page C7-1512</td>
</tr>
</tbody>
</table>

Convert between floating-point and integer or fixed-point

These instructions convert a floating-point scalar in a SIMD and floating-point register to or from a signed or unsigned integer or fixed-point value in a general-purpose register. For a fixed-point value, a final immediate operand indicates that the general-purpose register holds a fixed-point number and fbits indicates the number of bits after the binary point. fbits is in the range 1-32 inclusive for a 32-bit general-purpose register name, and 1-64 inclusive for a 64-bit general-purpose register name.

These instructions can cause the following floating-point exceptions:

Invalid Operation

Occurs if the floating-point input is a NaN, infinity, or a numerical value that cannot be represented in the destination register. An out of range integer or fixed-point result is saturated to the size of the destination register.

Inexact

Occurs if the numeric result that differs from the input value.

Input Denormal

As Flush-to-zero on page A1-54 describes, when Flush-to-zero mode is enabled, occurs when zero replaces a double-precision or single-precision denormal input.

Note

When ARMv8.2-FP16 is implemented, a half-precision denormal input that is flushed to zero does not generate an Input Denormal exception.

Table C3-67 shows the Floating-point and fixed-point conversion instructions.

</tbody>
</table>
C3.5 Data processing - SIMD and floating-point

### C3.5.5 Floating-point round to integral value

The following subsections describe instructions which round a floating-point number to an integral valued floating-point number in the same format:

- Floating-point round to an integer of the same size as the register
- Floating-point round to 32-bit or 64-bit integer on page C3-231

#### Floating-point round to an integer of the same size as the register

The following instructions round a floating-point value to an integer floating-point value of the same size.

For these instructions:
- A zero input gives a zero result with the same sign.
- An infinite input gives an infinite result with the same sign.
- A NaN is propagated as in normal floating-point arithmetic.

</tbody>
</table>
These instructions can cause the following floating-point exceptions:

**Invalid Operation**
Occurs in response to a floating-point input of a signaling NaN.

**Inexact, FRINTX instruction only**
Occurs if the result is numeric and does not have the same numerical value as the input.

**Input Denormal**
As *Flush-to-zero on page A1-54* describes, when Flush-to-zero mode is enabled, occurs when zero replaces a double-precision or single-precision denormal input.

--- Note ---
When ARMv8.2-FP16 is implemented, a half-precision denormal input that is flushed to zero does not generate an Input Denormal exception.

</tr>
</tbody>
</table>

**Floating-point round to 32-bit or 64-bit integer**
The following instructions are present if ARMv8.5-FRINT is implemented. The instructions round to a value that fits in a 32-bit integer or a 64-bit integer size, and use either round towards zero or the ambient rounding model.

**Invalid Operation**
Forced to be the most negative integer representable in the target size, and occurs in response to a floating-point input of a signaling NaN, an infinite input, or an out of range input.

**Inexact**
Occurs if the result is numeric and does not have the same numerical value as the input.

**Input Denormal**
As *Flush-to-zero on page A1-54* describes, when Flush-to-zero mode is enabled, occurs when zero replaces a double-precision or single-precision denormal input.
Table C3-69 shows the Floating-point round to 32-bit or 64-bit integer instructions.

</tbody>
</table>
### C3.5.9 Floating-point minimum and maximum

The \( \min(x, y) \) and \( \max(x, y) \) operations return a quiet NaN when either \( x \) or \( y \) is NaN.

As described in *Flush-to-zero* on page A1-54, in flush-to-zero mode, denormal operands are flushed to zero before comparison, and if the result of the comparison is the flushed value, then a zero value is returned. Where both \( x \) and \( y \) are zero, or denormal values flushed to zero, with different signs, then +0.0 is returned by \( \max() \) and -0.0 by \( \min() \).

The \( \minNum(x, y) \) and \( \maxNum(x, y) \) operations follow the IEEE 754-2008 standard and return the numerical operand when one operand is numerical and the other a quiet NaN. Apart from this additional handling of a single quiet NaN the result is then identical to \( \min(x, y) \) and \( \max(x, y) \).

Table C3-73 shows the Floating-point instructions that can perform floating-point minimum and maximum operations.

</tr>
</tbody>
</table>

### C3.5.10 Floating-point comparison

These instructions set the NZCV Condition flags in PSTATE, based on the result of a comparison of two operands. If the floating-point comparisons are unordered, where one or both operands are a form of NaN, the C and V bits are set to 1 and the N and Z bits are cleared to 0.

**Note**

The NZCV flags in the FPSR are associated with AArch32 state. The A64 floating-point comparison instructions do not change the Condition flags in the FPSR.

For the conditional Floating-point comparison instructions, if the condition is TRUE, the flags are updated to the result of the comparison, otherwise the flags are updated to the immediate value that is defined in the instruction encoding.

The quiet compare instructions generate an Invalid Operation floating-point exception if either of the source operands is a signaling NaN. The signaling compare instructions generate an Invalid Operation floating-point exception if either of the source operands is any type of NaN.

**Note**

If ARMv8.5-CondM is implemented, instructions AXFLAG and XAFLAG convert between the PSTATE condition flag format used by the FCMP instruction and an alternative format. See \textit{ARMv8.4-CondM} on page A2-81 for more information.

C3.5.14  **SIMD compare**

The SIMD compare instructions compare vector or scalar elements according to the specified condition and set the destination vector element to all ones if the condition holds, or to zero if the condition does not hold.

**Note**

Some of the comparisons, such as LS, LE, LO, and LT, can be made by reversing the operands and using the opposite comparison, HS, GE, HI, or GT.

Table C3-78 shows that SIMD compare instructions.

</table>
The SIMD floating-point and integer conversion instructions generate the Invalid Operation floating-point exception in response to a floating-point input of NaN, infinity, or a numerical value that cannot be represented within the destination register. An out of range integer or a fixed-point result is saturated to the size of the destination register. A numeric result that differs from the input raises the Inexact floating-point exception.
Table C3-85 shows the SIMD floating-point and integer conversion instructions.

### C3.5.24 SIMD dot product

**ARMv8.2-DotProd** provides SIMD instructions that perform the dot product of the four 8-bit subelements of the 32-bit elements of one vector with the four 8-bit subelements of a second vector. It provides two forms of the instructions, each with signed and unsigned versions:

**Vector form** The dot product is calculated for each element of the first vector with the corresponding element of the second element.

**Indexed form** The dot product is calculated for each element of the first vector with the element of the second vector that is indicated by the index argument to the instruction.

**Note** That is, a single element from the second vector is used, and the dot product is calculated between each element of the first vector and this single element from the second vector.

### C3.5.26 SIMD complex number arithmetic

**ARMv8.3-CompNum** provides SIMD instructions that perform arithmetic on complex numbers held in element pairs in vector registers, where the less significant element of the pair contains the real component and the more significant element contains the imaginary component.

These instructions provide double-precision and single-precision versions. If **ARMv8.2-FP16** is implemented they also provide half-precision versions, otherwise the half-precision encodings are UNDEFINED.
Table C3-90 shows the ARMv8.3-CompNum SIMD instructions:

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>FCADD</td>
<td>Floating-point complex add</td>
<td>FCADD on page C7-1468</td>
</tr>
<tr>
<td>FCMLA</td>

</tr>
<tr>
<td>FCMLA</td>
<td>Floating-point complex multiply accumulate (indexed form)</td>
<td>FCMLA (by element) on page C7-1495</td>
</tr>
</tbody>
</table>

A pair of FCMLA instructions can be used to perform a complex number multiplication. This is demonstrated in Complex multiplication on page K10-7730.

C3.5.27 The Cryptographic Extension

The instructions provided by the optional Armv8.0 Cryptographic Extension use the SIMD and floating-point register file. For more information about the functions they provide see:

- Announcing the Advanced Encryption Standard.
- The Galois/Counter Mode of Operation.
- Announcing the Secure Hash Standard.

Table C3-91 shows the Armv8.0 Cryptographic Extension instructions.

a. The Cryptographic Extension adds the variant of the instruction that operates on two 64-bit polynomials.

See The Armv8 Cryptographic Extension on page A2-66 for information about the permitted implementation options for the Cryptographic Extension.
Armv8.2 extensions to the Cryptographic Extension

Armv8.2 provides two optional extensions to the Cryptographic Extension, see:

- **Armv8.2-SHA, SHA2-512 and SHA3**.
- **Armv8.2-SM, SM3 and SM4** on page C3-249.

**Armv8.2-SHA, SHA2-512 and SHA3**

Armv8.2-SHA provides:

- Instructions to accelerate the SHA-2 hash algorithm using a digest that is larger than 256 bits. The relevant standards are SHA-384, SHA-512, SHA-512/224 and SHA-512/256. These are all based on the SHA-512 computation, and therefore this set of instructions is described as the SHA512 instructions.

- Instructions to accelerate the SHA-3 hash algorithm. This set of instructions is described as the SHA3 instructions.

Implementation of ARMv8.2-SHA requires the implementation of the SHA1 and SHA2-256 instructions from the Armv8.0 Cryptographic Extension.

--- Note ---

Implementation of ARMv8.2-SHA does not require the implementation of the AES instructions, and the 64-bit polynomial variants of the PMULL instructions, from the Armv8.0 Cryptographic Extension.

---

When ARMv8.2-SHA is implemented:

- The value of ID_AA64ISAR0_EL1.SHA2 is 0b0010, indicating support for the SHA512 instructions.
- The value of ID_AA64ISAR0_EL1.SHA3 is 0b0001, indicating support for the SHA3 instructions.

Table C3-92 shows the ARMv8.2-SHA SHA512 instructions:

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Instruction</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHA512H</td>

</tr>
<tr>
<td>SHA512SU1</td>
<td>SHA512 Schedule Update 1</td>
<td>SHA512SU1 on page C7-1916</td>
</tr>
</tbody>
</table>

---

**Use of the SHA512 instructions** on page K10-7732 shows an example of the use of these instructions to calculate a SHA512 hash iteration. This example code is not part of the architectural definition of these instructions.

Table C3-93 on page C3-249 shows the ARMv8.2-SHA SHA3 instructions. The SHA-3 hash algorithm is based on a running digest of 1600 bytes, arranged as a five by five array of 64-bit registers. The Arm acceleration of these instructions is based on mapping the 25 64-bit values into 25 vector registers, with each 64-bit value occupying the same 64-bit element in each vector. A series of transformations is performed on these registers as part of a round of the SHA-3 hash calculation.

The SIMD nature of the vector registers means the acceleration can compute two parallel SHA3 hash calculations, where one calculation is performed using the zeroth 64-bit element of each vector, and the other calculation is performed using the first 64-bit element of each vector.

--- Note ---

This is useful because the SHA-3 family of standards is being extended to introduce a fast parallel hash algorithm that benefits from being able to calculate SHA-3 hashes in parallel.
To provide acceleration where the SIMD calculation is not required, the instructions provide variants that operate only on the zeroth 64-bit elements. These are provided as a power optimization.

<table>
<thead>
<tr>
<th>Mnemonic</th>

</tr>
</tbody>
</table>

Use of the SHA3 instructions on page K10-7733 shows an example of the use of these instructions to calculate the combined theta, phi, rho and chi operations of a SHA3 iteration. This example code is not part of the architectural definition of these instructions.

**Armv8.2-SM, SM3 and SM4**

ARMv8.2-SM provides:

- Instructions to accelerate the SM3 hash algorithm, the standard Chinese hash algorithm. These are described as the SM3 instructions.

- Instructions to accelerate the SM4 encryption algorithm, the standard Chinese encryption algorithm. This set of instructions is described as the SM4 instructions.

ARMv8.2-SM can be implemented independently of any part of the Armv8.0 Cryptographic Extension, and independently of ARMv8.2-SHA.

**Note**

This means that Armv8.2 permits an implementation of the Cryptographic Extension that provides only the ARMv8.2-SM functionality.

When ARMv8.2-SM is implemented:

- The value of ID_AA64ISAR0_EL1.SM3 is 0b0001, indicating support for the SM3 instructions.
- The value of ID_AA64ISAR0_EL1.SM4 is 0b0001, indicating support for the SM4 instructions.

Table C3-94 shows the Armv8.2-SM SM3 instructions. The SM3 algorithm computes a digest of 256 bits, that can be held in two vector registers. The SM3 instructions include instructions to accelerate the computation of the hash and the schedule update.

**Note**

The SM3 instruction names refer to intermediate variables defined as part of the SM3 Cryptographic Hash Algorithm specification.

</tr>
</tbody>
</table>
Use of the SM3 instructions on page K10-7734 shows an example of the use of these instructions to generate an SM3 hash. This example code is not part of the architectural definition of these instructions.

Table C3-95 shows the Armv8.2-SM SM4 instructions. The SM4 algorithm is 128-bit wide block cipher. The SM4E instruction accelerates a single round of encryption or decryption, and the SM4EKEY instruction accelerates a single round of key generation:

<table>

<td>SM4 Key</td>
<td>SM4EKEY on page C7-1947</td>
</tr>
</tbody>
</table>

Use of the SM4 instructions on page K10-7736 shows an example of the use of these instructions to perform SM4 encryption and decryption. This example code is not part of the architectural definition of these instructions.
Chapter C4
A64 Instruction Set Encoding

This chapter describes the encoding of the A64 instruction set. It contains the following section:

• A64 instruction set encoding on page C4-252.

In this chapter:

• In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
• In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.
C4.1 A64 instruction set encoding

The A64 instruction encoding is:

| 31 29 28 | 25 24 | 23 22 | 21 20 | 19 18 | 17 16 | 15 14 | 13 12 | 11 10 | 9  8 | 7  6 | 5  4 | 3  2 | 1  0 |
|---------|-------|-------|-------|-------|-------|-------|-------|-------|------|------|------|------|------|------|
| op0     |       |       |       |       |       |       |       |       |      |      |      |      |      |      |

C4.1.2 Data Processing -- Immediate

This section describes the encoding of the Data Processing -- Immediate group. The encodings in this section are decoded from A64 instruction set encoding.
This section describes the encoding of the PC-rel. addressing instruction class. The encodings in this section are decoded from *Data Processing -- Immediate* on page C4-252.

```
|31|30|29|28|25|23|22| | | | | | | |0|

```
Add/subtract (immediate, with tags)

This section describes the encoding of the Add/subtract (immediate, with tags) instruction class. The encodings in this section are decoded from Data Processing -- Immediate on page C4-252.

Logical (immediate)

This section describes the encoding of the Logical (immediate) instruction class. The encodings in this section are decoded from Data Processing -- Immediate on page C4-252.
Move wide (immediate)

This section describes the encoding of the Move wide (immediate) instruction class. The encodings in this section are decoded from Data Processing -- Immediate on page C4-252.

Chapter C5
The A64 System Instruction Class

This chapter describes the A64 System instruction class, and the System instruction class encoding space, that is a subset of the System registers encoding space. It contains the following sections:

- The System instruction class encoding space on page C5-362.
- Special-purpose registers on page C5-374.
- A64 System instructions for cache maintenance on page C5-459.
- A64 System instructions for address translation on page C5-520.
- A64 System instructions for TLB maintenance on page C5-543.
- A64 System instructions for prediction restriction on page C5-739.

See General information about the A64 instruction descriptions on page C2-185 for information about entries used in the instruction encoding descriptions.
The System instruction class encoding space

Part of the A64 instruction encoding space is assigned to instructions that access the System register encoding space. These instructions provide:

- Access to System registers, including the debug registers, that provide system control, and system status information.
- Access to Special-purpose registers such as SPSR_ELx, ELR_ELx, and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the CLREX instruction.
- Architectural hint instructions.

This section describes the general model for accessing this functionality.

Note

- See Fixed values in AArch64 instruction and System register descriptions on page C2-185 for information about abbreviations used in the System instruction descriptions.

In AArch32 state much of this functionality is provided through the System register interface described in The AArch32 System register interface on page G1-5567. In AArch64 state, the parameters used to characterize the System register encoding space are \{op0, op1, CRn, CRm, op2\}. These are based on the parameters that characterize the AArch32 System register encoding space, which reflect the original implementation of these registers, as described in Background to the System register interface on page G1-5568. In Armv8, there is no particular significance to the naming of these parameters, and no functional distinction between the op0 parameters and the CRx parameters.

Principles of the System instruction class encoding describes some general properties of these encodings. System instruction class encoding overview on page C5-363 then describes the top-level encoding of these instructions, and the following sections then describe the next level of the encoding hierarchy of System instructions and Special-purpose registers:

- op0==0b00, architectural hints, barriers and CLREX, and PSTATE access on page C5-364.
- op0==0b01, cache maintenance, TLB maintenance, and address translation instructions on page C5-366.
- op0==0b11, Moves to and from Special-purpose registers on page C5-372.

For the description of the next level of encoding hierarchy of System registers, see:

- op0==0b10, Moves to and from debug and trace System registers on page D12-2801.
- op0==0b11, Moves to and from non-debug System registers, Special-purpose registers on page D12-2803.
- Reserved encodings for IMPLEMENTATION DEFINED registers on page D12-2815.

Principles of the System instruction class encoding

In Armv8, an encoding in the System instruction space is identified by a set of arguments, \{op0, op1, CRn, CRm, op2\}. These form an encoding hierarchy, where:

- op0 Defines the top-level division of the encoding space, see System instruction class encoding overview on page C5-363.
- op1 Identifies the lowest Exception level at which the encoding is accessible, as follows:
  - Accessible at EL0 op1 has the value 3.
  - Accessible at EL1 op1 has the value 0, 1, or 2. The value is the same as the op1 value used to access the equivalent AArch32 register.
  - Accessible at EL2 op1 has the value 4.
  - Accessible at EL3 op1 has the value 6.
The A64 System Instruction Class

C5.1 The System instruction class encoding space

Arm strongly recommends that implementers adopt this use of op1 when using the IMPLEMENTATION DEFINED regions of the encoding space described in Reserved encodings for IMPLEMENTATION DEFINED registers on page D12-2815.

C5.1.2 System instruction class encoding overview

The encoding of the System instruction class describes each instruction as being either:

- A transfer to a System register. This is a System instruction with the semantics of a write.
- A transfer from a System register. This is a System instruction with the semantics of a read.

A System instruction that initiates an operation operates as if it was making a transfer to a register.

In the AArch64 instruction set, the decode structure for the System instruction class is:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>16</th>
<th>15</th>
<th>12</th>
<th>11</th>
<th>8</th>
<th>7</th>
<th>5</th>
<th>4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>L</td>
<td>op0</td>
<td>op1</td>
<td>CRn</td>
<td>CRm</td>
<td>op2</td>
<td>Ri</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The value of L indicates the transfer direction:

0 Transfer to System register.
1 Transfer from System register.

The op0 field is the top level encoding of the System instruction type. Its possible values are:

0b00

These encodings provide:

- Instructions with an immediate field for accessing PSTATE, the current PE state.
- The architectural hint instructions.
- Barriers and the CLREX instruction.

For more information about these encodings, see op0==0b00, architectural hints, barriers and CLREX, and PSTATE access on page C5-364.

0b01

These encodings provide the cache maintenance, TLB maintenance, and address translation instructions.

______ Note ________

These are equivalent to operations in the AArch32 (coproc==0b1111) encoding space.

______ Note ________

For more information, see op0==0b01, cache maintenance, TLB maintenance, and address translation instructions on page C5-366.

0b10

These encodings provide moves to and from:

- Legacy AArch32 System registers for execution environments, to provide access to these registers from higher Exception levels that are using AArch64.
- Debug and trace registers.

______ Note ________

These are equivalent to the registers in the AArch32 (coproc==0b1110) encoding space.

______ Note ________

For more information, see op0==0b10, Moves to and from debug and trace System registers on page D12-2801.

0b11

These encodings provide:

- Moves to and from Non-debug System registers. The accessed registers provide system control, and system status information.

______ Note ________

The accessed registers are equivalent to the registers in the AArch32 (coproc==0b1111) encoding space.

______ Note ________

- Access to Special-purpose registers.
UNDEFINED behaviors

In the System register instruction encoding space, the following principles apply:

- All unallocated encodings are treated as UNDEFINED.
- All encodings with \( L = 1 \) and \( \text{op0} = 0b0x \) are UNDEFINED, except for encodings in the area reserved for IMPLEMENTATION DEFINED use, see Reserved encodings for IMPLEMENTATION DEFINED registers on page D12-2815.

For registers and operations that are accessible from a particular Exception level, any attempt to access those registers from a lower Exception level is UNDEFINED.

If a particular Exception level:

- Defines a register to be RO, then any attempt to write to that register, at that Exception level, is UNDEFINED. This means that any access to that register with \( L = 0 \) is UNDEFINED.
- Defines a register to be WO, then any attempt to read from that register, at that Exception level, is UNDEFINED. This means that any access to that register with \( L = 1 \) is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED, but see the recommendation in Principles of the System instruction class encoding on page C5-362.

C5.1.3 \( \text{op0} = 0b00 \), architectural hints, barriers and CLREX, and PSTATE access

The different groups of System register instructions with \( \text{op0} = 0b00 \):

- Are identified by the value of CRn.
- Are always encoded with a value of 0b11111 in the Rt field.

The encoding of these instructions is:

\[
\begin{array}{ccccccccccccccccccc}
1 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & L & 0 & 0 & \text{op1} & \text{CRn} & \text{CRm} & \text{op2} & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\]

The encoding of the CRn field is as follows:
- \( \text{op0} = 0b0010 \) See Architectural hint instructions.
- \( \text{op0} = 0b0011 \) See Barriers and CLREX on page C5-365.
- \( \text{op0} = 0b0100 \) See Instructions for accessing the PSTATE fields on page C5-366.

Architectural hint instructions

Within the \( \text{op0} = 0b00 \) encodings, the architectural hint instructions are identified by CRn having the value \( 0b0010 \). The encoding of these instructions is:

\[
\begin{array}{ccccccccccccccccccc}
1 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & \text{op<6:0>} & 1 & 1 & 1 & 1 \\
\end{array}
\]

The value of \( \text{op<6:0>} \), formed by concatenating the CRn and op2 fields, determines the hint instruction as follows:
- \( \text{op0} = 0b000000 \) NOP instruction.
- \( \text{op0} = 0b000001 \) YIELD instruction.
- \( \text{op0} = 0b000010 \) WFE instruction.
- \( \text{op0} = 0b000011 \) WFI instruction.
- \( \text{op0} = 0b000100 \) SEV instruction.
- \( \text{op0} = 0b000101 \) SEVL instruction.
The A64 System Instruction Class

C5.1 The System instruction class encoding space

Unallocated values. These encodings behave as NOPs.

- **0b0001000**  ESB instruction.
- **0b0010001**  PSB CSYNC instruction.
- **0b0010010**  TSB CSYNC instruction.

These instructions are described in Chapter C6 A64 Base Instruction Descriptions.

--- Note ---

- Instruction encodings with bits[4:0] not set to \(\text{0b11111}\) are UNDEFINED.
- The operation of the A64 instructions for architectural hints are identical to the corresponding A32 and T32 instructions.

---

Barriers and CLREX

Within the op0==0b00 encodings, the barriers and CLREX instructions are identified by CRn having the value 0b0011. The encoding of these instructions is:

<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>
<th>19 18 16 15</th>
<th>12 11 8 7</th>
<th>5 4 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 0 1 0 1 0 1</td>
<td>0 0 0 0 1 0</td>
<td>0 0 1 1</td>
<td>CRn</td>
<td>op2</td>
<td>1 1 1 1</td>
</tr>
</tbody>
</table>

The value of op2 determines the instruction, as follows.

- **0b010**  CLREX instruction.
- **0b100**  DSB instruction.
- **0b101**  DMB instruction.
- **0b110**  ISB instruction.
- **0b000, 0b001, 0b011, 0b111**  UNDEFINED.

These instructions are described in Chapter C6 A64 Base Instruction Descriptions.

--- Note ---

- Instruction encodings with bits[4:0] not set to \(\text{0b11111}\) are UNDEFINED.
- The operation of the A64 instructions for barriers and CLREX are identical to the corresponding A32 and T32 instructions.

---

For more information about:

- The barrier instructions, see Memory barriers on page B2-124.
- The CLREX instruction, see Synchronization and semaphores on page B2-156.
Instructions for accessing the PSTATE fields

Within the op0==0b00 encodings, the instructions that can be used to modify PSTATE fields directly are identified by CRn having the value 0b100. The encoding of these instructions is:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>
<th>12 11  8  7  5  4  0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CRn CRm op1 Imm4 op2 1 1 1 1 1</td>
<td></td>
</tr>
</tbody>
</table>

These instructions are:

- CFINV  ; Inverts the value of PSTATE.C
- MSR DAIIFSet, #Imm4 ; Used to set any or all of DAIIF to 1
- MSR DAIIFClr, #Imm4 ; Used to clear any or all of DAIIF to 0
- MSR SPSel, #Imm4 ; Used to select the Stack Pointer, between SP_EL0 and SP_ELx
- MSR PAN, #Imm4  ; Used to set the value of PSTATE.PAN

The value of op2 selects the instruction form, which defines the constraints on the values of the op1 and Imm4 arguments, as follows:

- op2==0b000  Selects the CFINV instruction.
- op2==0b011  Selects the MSR UAO instruction.
- op2==0b100  Selects the MSR PAN instruction.
- op2==0b101  Selects the MSR SPSel instruction.
- op2==0b110  Selects the MSR DAIIFSet instruction, that sets the specified PSTATE.{D, A, I, F} bits to 1.
- op2==0b111  Selects the MSR DAIIFClr instruction, that clears the specified PSTATE.{D, A, I, F} bits to 0.

All other combinations of op1 and op2 are reserved, and the corresponding instructions are UNDEFINED.

Note
For PSTATE updates, instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.

 Writes to PSTATE. {PAN, D, A, I, F} occur in program order without the need for additional synchronization. Changing PSTATE.SPSel to use SP_EL0 synchronizes any updates to SP_EL0 that have been written by an MSR to SP_EL0, without the need for additional synchronization.

C5.1.4  op0==0b01, cache maintenance, TLB maintenance, and address translation instructions

The System instructions are encoded with op0==0b01. The different groups of System instructions are identified by the values of CRn and CRm, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15</th>
<th>12 11  8  7  5  4  0</th>
</tr>
</thead>
<tbody>
<tr>
<td>op0 CRn CRm op2 X</td>
<td>----------------------</td>
</tr>
</tbody>
</table>

The grouping of these instructions depending on the CRn and CRm fields is as follows:

- CRn==7  The instruction group is determined by the value of CRm, as follows:
  - CRm=={1, 5}  Instruction cache maintenance instructions.
    See Cache maintenance instructions, and data cache zero operation on page C5-367.
  - CRm==3  Prediction restriction instructions.
    See Prediction restriction instructions on page C5-368.
  - CRm==4  Data cache zero operation.
    See Cache maintenance instructions, and data cache zero operation on page C5-367.
The A64 System Instruction Class
C5.1 The System instruction class encoding space

CRm==\{6, 10, 11, 12, 14\}

Data cache maintenance instructions.

See Cache maintenance instructions, and data cache zero operation.

CRm==8

See Address translation instructions on page C5-368.

CRn==8

See TLB maintenance instructions on page C5-369.

CRn==\{11, 15\}

See Reserved encoding space for IMPLEMENTATION DEFINED instructions on page C5-371.

Cache maintenance instructions, and data cache zero operation

Table C5-1 lists the Cache maintenance instructions and their encodings. Instructions that take an argument include Xt in the instruction syntax. For instructions that do not take an argument, the Xt field is encoded as 0b11111. For these instructions, if the Xt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Xt field is set to 0b11111.

<tr>
<td>AT S1E3W, $X_t$</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

For more information about these instructions, see *Address translation instructions* on page D5-2561.
TLB maintenance instructions

Table C5-4 lists the TLB maintenance instructions and their encodings. Instructions that take an argument include Xt in the instruction syntax. For instructions that do not take an argument, the Xt field is encoded as 0b11111. For these instructions, if the Xt field is not set to 0b11111, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Xt field is set to 0b11111.

<td>6 1</td>
<td></td>
</tr>
<tr>
<td>TLBI RVAE3, Xt</td>
<td>5</td>
<td></td>
</tr>
<tr>
<td>TLBI ALLE3</td>
<td>7 0</td>
<td></td>
</tr>
<tr>
<td>TLBI VAE3, Xt</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>TLBI VAE3, Xt</td>
<td>5</td>
<td></td>
</tr>
</tbody>
</table>

The value of L defines the use of Rt as follows:

0  Rt is an argument supplied to the instruction.
1  Rt is a result returned by the instruction.

IMPLEMENTATION DEFINED instructions in this encoding space are accessed using the SYS and SYSL instructions, see SYS on page C6-1337 and SYSL on page C6-1339.
C5.1.5 op0==0b11, Moves to and from Special-purpose registers

The instructions that move data to and from non-debug System registers are encoded with op0==0b11, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 12 11 8 7 5 4 0 |
|-----------------------|-----------------|-----------------|
| op0                  | CRn             | CRm             |
| 1 1 0 1 0 1 0 0 L 1 1 | op1             | CRn             |
|                      | CRm             | op2             |
|                      | Rt              |                 |

Instructions for accessing Special-purpose registers

The value of CRn provides the next level of decode of these instructions. For Special-purpose registers, the value of CRn is 4.

The A64 instructions for accessing Special-purpose registers are:

- MSR <Special-purpose register>, Xt ; Write to Special-purpose register
- MRS Xt, <Special-purpose register> ; Read from Special-purpose register

For these accesses, CRn has the value 4. The encoding for Special-purpose register accesses is:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 16 15 12 11 8 7 5 4 0 |
|-----------------------|-----------------|-----------------|
| op0                  | CRn             | CRm             |
| 1 1 0 1 0 1 0 0 L 1 1 | op1             | CRn             |
|                      | CRm             | op2             |
|                      | Rt              |                 |

The full list of Special-purpose registers is in Table C5-5. The characteristic of a Special-purpose register is that all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization.

Table C5-5 lists the encodings for op1, CRn, and op2 fields for accesses to the Special-purpose registers in AArch64.

See also Reserved encodings for IMPLEMENTATION DEFINED registers on page D12-2815.
All direct and indirect reads and writes to Special-purpose registers appear to occur in program order relative to other instructions.
C5.2 Special-purpose registers

This section describes the following Special-purpose registers:

- **CurrentEL**, that holds PSTATE.EL, and that software can read to determine the current Exception level.
- **DAIF**, that holds the current PSTATE.{D, A, I, F} interrupt mask bits.
- **DIT**, that holds the PSTATE.DIT bit.
- **ELR_EL1**, that holds the address to return to for an exception return from EL1.
- **ELR_EL2**, that holds the address to return to for an exception return from EL2.
- **ELR_EL3**, that holds the address to return to for an exception return from EL3.
- **FPCR**, that provides control of floating-point operation.
- **FPSR**, that provides floating-point status information.
- **NZCV**, that holds the PSTATE.{N, Z, C, V} condition flags.
- **PAN**, that holds the PSTATE.PAN state bit.
- **SP_EL0**, that holds the stack pointer for EL0.
- **SP_EL1**, that holds the stack pointer for EL1.
- **SP_EL2**, that holds the stack pointer for EL2.
- **SP_EL3**, that holds the stack pointer for EL3.
- **SPSel**, that holds PSTATE.SP, that at EL1 or higher selects the current SP.
- **SPSR_abt**, that holds process state on taking an exception to AArch32 Abort mode.
- **SPSR_EL1**, that holds process state on taking an exception to AArch64 EL1.
- **SPSR_EL2**, that holds process state on taking an exception to AArch64 EL2.
- **SPSR_EL3**, that holds process state on taking an exception to AArch64 EL3.
- **SPSR_fiq**, that holds process state on taking an exception to AArch32 FIQ mode.
- **SPSR_irq**, that holds process state on taking an exception to AArch32 IRQ mode.
- **SPSR_und**, that holds process state on taking an exception to AArch32 Undefined mode.
- **SSBS**, that holds the PSTATE.SSBS bit.
- **TCO**, that holds the PSTATE.TCO bit.
- **UAO**, that holds the PSTATE.UAO bit.

The following registers are also Special-purpose registers:

- **DLR_EL0**, that holds the address to return to for a return from Debug state.
- **DSPSR_EL0**, that holds process state on entry to Debug state.
C5.2.1 CurrentEL, Current Exception Level

The CurrentEL characteristics are:

**Purpose**

Holds the current Exception level.

**Configurations**

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CurrentEL is a 64-bit register.

**Field descriptions**

The CurrentEL bit assignments are:

![Bit assignments diagram]

**Bits [63:4]**

Reserved, RES0.

**EL, bits [3:2]**

Current Exception level. Possible values of this field are:

- 0b00 EL0
- 0b01 EL1
- 0b10 EL2
- 0b11 EL3

When the HCR_EL2.NV bit is 1, EL1 read accesses to the CurrentEL register return the value of 0b10 in this field.

This field resets to the highest implemented Exception Level.

**Bits [1:0]**

Reserved, RES0.

**Accessing the CurrentEL**

Accesses to this register use the following encodings in the System instruction encoding space:
### MRS <Xt>, CurrentEL

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b11</td>
<td>0b00</td>
<td>0b0100</td>
<td>0b0010</td>
<td>0b01</td>
</tr>
</tbody>
</table>
C5.2.2 DAIF, Interrupt Mask Bits

The DAIF characteristics are:

**Purpose**

Allows access to the interrupt mask bits.

**Configurations**

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DAIF is a 64-bit register.

**Field descriptions**

The DAIF bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:10</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>9</td>
<td>Process state D mask.</td>
</tr>
<tr>
<td>8</td>
<td>SError interrupt mask bit.</td>
</tr>
<tr>
<td>7</td>
<td>IRQ mask bit.</td>
</tr>
<tr>
<td>6</td>
<td>FIQ mask bit.</td>
</tr>
</tbody>
</table>
```

**D, bit [9]**

Process state D mask. The possible values of this bit are:

- **0b0**: Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are not masked.
- **0b1**: Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are masked.

When the target Exception level of the debug exception is higher than the current Exception level, the exception is not masked by this bit.

This field resets to 1.

**A, bit [8]**

SError interrupt mask bit. The possible values of this bit are:

- **0b0**: Exception not masked.
- **0b1**: Exception masked.

This field resets to 1.

**I, bit [7]**

IRQ mask bit. The possible values of this bit are:

- **0b0**: Exception not masked.
- **0b1**: Exception masked.

This field resets to 1.

**F, bit [6]**

FIQ mask bit. The possible values of this bit are:

- **0b0**: Exception not masked.
- **0b1**: Exception masked.
This field resets to 1.

Bits [5:0]
Reserved, RES0.

**Accessing the DAIF**

For details on the operation of the MSR (immediate) accessor, see MSR (immediate) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:

### **MRS <Xt>, DAIF**

<table>
<thead>
<tr>

C5.2.3 DIT, Data Independent Timing

The DIT characteristics are:

**Purpose**

Allows access to the Data Independent Timing bit.

**Configurations**

This register is present only when ARMv8.4-DIT is implemented. Otherwise, direct accesses to DIT are UNDEFINED.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DIT is a 64-bit register.

**Field descriptions**

The DIT bit assignments are:

![DIT Bit Diagram]

**Bits [63:25]**

Reserved, RES0.

**DIT, bit [24]**

Data Independent Timing.

- **0b0**  The architecture makes no statement about the timing properties of any instructions.
- **0b1**  The architecture requires that:
  - The timing of every load and store instruction is insensitive to the value of the data being loaded or stored.
  - For certain data processing instructions, the instruction takes a time which is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
  - For certain data processing instructions, the response of the instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

The data processing instructions affected by this bit are:

- All cryptographic instructions. These instructions are:
  - AESD, AESE, AESIMC, AESMC, SHA1C, SHA1H, SHA1M, SHA1P, SHA1SU1, SHA256H, SHA256H2, SHA256SU0, SHA256SU1, SHA512H, SHA512H2, SHA512SU0, SHA512SU1, EOR3, RAX1, XAR, BCAX, SM3SS1, SM3TT1A, SM3TT1B, SM3TT2A, SM3TT2B, SM3PARTW1, SM3PARTW2, SM4E, and SM4EK.
The A64 System Instruction Class
C5.2 Special-purpose registers

•

A subset of those instructions which use the general-purpose register file. These instructions
are:
—

•

ADC, ADCS, ADD, ADDS, AND, ANDS, ASR, ASRV, BFC, BFI, BFM, BFXIL, BIC, BICS, CCMN, CCMP, CFINV,

UXTL2, UZP1, UZP2, XTN, XTN2, ZIP1, and ZIP2.

Note
The architecture makes no statement about the timing properties when the PSTATE.DIT bit is not
set. However, it is likely that many of these instructions have timing that is invariant of the data in
many situations.
In particular, Arm strongly recommends that the Armv8.3 pointer authentication instructions do not
have their timing dependent on the key value used in the pointer authentication in all cases,
regardless of the PSTATE.DIT bit.
This field resets to 0.
Bits [23:0]
Reserved, RES0.

C5.2.4   ELR_EL1, Exception Link Register (EL1)

The ELR_EL1 characteristics are:

**Purpose**

When taking an exception to EL1, holds the address to return to.

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

ELR_EL1 is a 64-bit register.

**Field descriptions**

The ELR_EL1 bit assignments are:

![Register Bit Assignments](image)

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Return address.</td>
</tr>
</tbody>
</table>

An exception return from EL1 using AArch64 makes ELR_EL1 become UNKNOWN.
This field resets to an architecturally UNKNOWN value.

**Accessing the ELR_EL1**

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic ELR_EL1 or ELR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

C5.2.5  ELR_EL2, Exception Link Register (EL2)

The ELR_EL2 characteristics are:

Purpose

When taking an exception to EL2, holds the address to return to.

Configurations

AArch64 System register ELR_EL2[31:0] is architecturally mapped to AArch32 System register ELR_hyp[31:0].
This register has no effect if EL2 is not enabled in the current Security state.
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ELR_EL2 is a 64-bit register.

Field descriptions

The ELR_EL2 bit assignments are:

Bits [63:0]

Return address.

An exception return from EL2 using AArch64 makes ELR_EL2 become UNKNOWN.
When EL2 is in AArch32 Execution state and an exception is taken from EL0, EL1, or EL2 to EL3 and AArch64 execution, the upper 32-bits of ELR_EL2 are either set to 0 or hold the same value that they did before AArch32 execution. Which option is adopted is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.
This field resets to an architecturally UNKNOWN value.

Accessing the ELR_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic ELR_EL2 or ELR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

C5.2.7  FPCR, Floating-point Control Register

The FPCR characteristics are:

**Purpose**
Controls floating-point behavior.

**Configurations**
The named fields in this register map to the equivalent fields in the AArch32 FPSCR.

It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
FPCR is a 64-bit register.

**Field descriptions**
The FPCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>26</td>
<td>AHP, Alternative half-precision control bit:</td>
</tr>
<tr>
<td>25</td>
<td>DN, Default NaN mode control bit:</td>
</tr>
<tr>
<td>24</td>
<td>RMode</td>
</tr>
<tr>
<td>18</td>
<td>Len</td>
</tr>
<tr>
<td>19</td>
<td>Stride</td>
</tr>
<tr>
<td>15</td>
<td>RES0</td>
</tr>
<tr>
<td>8</td>
<td>FZ</td>
</tr>
</tbody>
</table>

**Bits [63:27]**
Reserved, RES0.

**AHP, bit [26]**
Alternative half-precision control bit:
- 0: IEEE half-precision format selected.
- 1: Alternative half-precision format selected.

This bit is only used for conversions between half-precision floating-point and other floating-point formats.

The data-processing instructions added as part of the ARMv8.2-FP16 extension always use the IEEE half-precision format, and ignore the value of this bit.

This field resets to an architecturally UNKNOWN value.

**DN, bit [25]**
Default NaN mode control bit:
- 0: NaN operands propagate through to the output of a floating-point operation.
- 1: Any operation involving one or more NaNs returns the Default NaN.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.
This field resets to an architecturally UNKNOWN value.

**FZ, bit [24]**

Flush-to-zero mode control bit:

- **0b0**: Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
- **0b1**: Flush-to-zero mode enabled.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.
This bit has no effect on half-precision calculations.
This field resets to an architecturally UNKNOWN value.

**RMode, bits [23:22]**

Rounding Mode control field. The encoding of this field is:

- **0b00**: Round to Nearest (RN) mode.
- **0b01**: Round towards Plus Infinity (RP) mode.
- **0b10**: Round towards Minus Infinity (RM) mode.
- **0b11**: Round towards Zero (RZ) mode.

The specified rounding mode is used by both scalar and Advanced SIMD floating-point instructions.
This field resets to an architecturally UNKNOWN value.

**Stride, bits [21:20]**

This field has no function in AArch64 state, and non-zero values are ignored during execution in AArch64 state. It is included only for context saving and restoration of the AArch32 FPSCR.Stride field.
This field resets to an architecturally UNKNOWN value.

**FZ16, bit [19]**

*When ARMv8.2-FP16 is implemented:*

Flush-to-zero mode control bit on half-precision data-processing instructions:

- **0b0**: Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
- **0b1**: Flush-to-zero mode enabled.

The value of this bit applies to both scalar and Advanced SIMD floating-point half-precision calculations. A half-precision floating-point number that is flushed to zero as a result of the value of the FZ16 bit does not generate an Input Denormal exception.
This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**Len, bits [18:16]**

This field has no function in AArch64 state, and non-zero values are ignored during execution in AArch64 state. It is included only for context saving and restoration of the AArch32 FPSCR.Len field.
This field resets to an architecturally UNKNOWN value.

**IDE, bit [15]**

Input Denormal floating-point exception trap enable. Possible values are:

- **0b0**: Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.IDC bit is set to 1.
Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IDC bit. The trap handling software can decide whether to set the FPSR.IDC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

This field resets to an architecturally UNKNOWN value.

**Bits [14:13]**

Reserved, RES0.

**IXE, bit [12]**

Inexact floating-point exception trap enable. Possible values are:

- **0b0**: Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.IXC bit is set to 1.
- **0b1**: Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IXC bit. The trap handling software can decide whether to set the FPSR.IXC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

This field resets to an architecturally UNKNOWN value.

**UFE, bit [11]**

Underflow floating-point exception trap enable. Possible values are:

- **0b0**: Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.UFC bit is set to 1.
- **0b1**: Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.UFC bit. The trap handling software can decide whether to set the FPSR.UFC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

This field resets to an architecturally UNKNOWN value.

**OFE, bit [10]**

Overflow floating-point exception trap enable. Possible values are:

- **0b0**: Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.OFC bit is set to 1.
- **0b1**: Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.OFC bit. The trap handling software can decide whether to set the FPSR.OFC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

This field resets to an architecturally UNKNOWN value.

**DZE, bit [9]**

Divide by Zero floating-point exception trap enable. Possible values are:

- **0b0**: Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.DZC bit is set to 1.
- **0b1**: Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.DZC bit. The trap handling software can decide whether to set the FPSR.DZC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.
If the implementation does not support this exception, this bit is RAZ/WI.
This field resets to an architecturally UNKNOWN value.

**IOE, bit [8]**
Invalid Operation floating-point exception trap enable. Possible values are:

- **0b0**: Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.IOC bit is set to 1.
- **0b1**: Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IOC bit. The trap handling software can decide whether to set the FPSR.IOC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.
If the implementation does not support this exception, this bit is RAZ/WI.
This field resets to an architecturally UNKNOWN value.

**Bits [7:0]**
Reserved, RES0.

**Accessing the FPCR**
Accesses to this register use the following encodings in the System instruction encoding space:

C5.2.8 FPSR, Floating-point Status Register

The FPSR characteristics are:

**Purpose**

Provides floating-point system status information.

**Configurations**

The named fields in this register map to the equivalent fields in the AArch32 FPSCR. RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

FPSR is a 64-bit register.

**Field descriptions**

The FPSR bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>31</td>
<td>N, negative condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.N flag instead. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>30</td>
<td>Z, zero condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.Z flag instead. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>29</td>
<td>C, carry condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.C flag instead. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>28</td>
<td>V, overflow condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.V flag instead. This field resets to an architecturally UNKNOWN value.</td>
</tr>
</tbody>
</table>
```
QC, bit [27]
Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.
This field resets to an architecturally UNKNOWN value.

Bits [26:8]
Reserved, RES0.

IDC, bit [7]
Input Denormal cumulative floating-point exception bit. This bit is set to 1 to indicate that the Input Denormal floating-point exception has occurred since 0 was last written to this bit.
How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IDE bit. This bit is only set to 1 to indicate a floating-point exception if FPCR.IDE is 0, or if trapping software sets it.
This field resets to an architecturally UNKNOWN value.

Bits [6:5]
Reserved, RES0.

IXC, bit [4]
Inexact cumulative floating-point exception bit. This bit is set to 1 to indicate that the Inexact exception floating-point has occurred since 0 was last written to this bit.
How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IXE bit. This bit is only set to 1 to indicate a floating-point exception if FPCR.IXE is 0, or if trapping software sets it.
This field resets to an architecturally UNKNOWN value.

UFC, bit [3]
Underflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Underflow floating-point exception has occurred since 0 was last written to this bit.
How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.UFE bit. This bit is only set to 1 to indicate a floating-point exception if FPCR.UFE is 0, or if trapping software sets it.
This field resets to an architecturally UNKNOWN value.

OFC, bit [2]
Overflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Overflow floating-point exception has occurred since 0 was last written to this bit.
How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.OFE bit. This bit is only set to 1 to indicate a floating-point exception if FPCR.OFE is 0, or if trapping software sets it.
This field resets to an architecturally UNKNOWN value.

DZC, bit [1]
Divide by Zero cumulative floating-point exception bit. This bit is set to 1 to indicate that the Divide by Zero floating-point exception has occurred since 0 was last written to this bit.
How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.DZE bit. This bit is only set to 1 to indicate a floating-point exception if FPCR.DZE is 0, or if trapping software sets it.
This field resets to an architecturally UNKNOWN value.

IOC, bit [0]
Invalid Operation cumulative floating-point exception bit. This bit is set to 1 to indicate that the Invalid Operation floating-point exception has occurred since 0 was last written to this bit.
How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the 
FPCR.IOE bit. This bit is only set to 1 to indicate a floating-point exception if FPCR.IOE is 0, 
or if trapping software sets it.

This field resets to an architecturally UNKNOWN value.

C5.2.9 NZCV, Condition Flags

The NZCV characteristics are:

**Purpose**

Allows access to the condition flags.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

NZCV is a 64-bit register.

**Field descriptions**

The NZCV bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>31</td>
<td>N, bit [31] Negative condition flag. Set to 1 if the result of the last flag-setting instruction was negative.</td>
</tr>
<tr>
<td>30</td>
<td>Z, bit [30] Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.</td>
</tr>
<tr>
<td>29</td>
<td>C, bit [29] Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.</td>
</tr>
<tr>
<td>28</td>
<td>V, bit [28] Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.</td>
</tr>
<tr>
<td>27</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

**Accessing the NZCV**

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, NZCV

<table>

C5.2.10   PAN, Privileged Access Never

The PAN characteristics are:

**Purpose**

Allows access to the Privileged Access Never bit.

**Configurations**

This register is present only when ARMv8.1-PAN is implemented. Otherwise, direct accesses to PAN are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

PAN is a 64-bit register.

**Field descriptions**

The PAN bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[63:23]</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td></td>
<td>0b0  Privileged reads and write are not disabled by this mechanism.</td>
</tr>
<tr>
<td></td>
<td>0b1  Disables privileged read and write accesses to addresses accessible at EL0 for an enabled stage 1 translation regime that defines the EL0 permissions.</td>
</tr>
<tr>
<td>[21:0]</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

The value of this bit is usually preserved on taking an exception, except in the following situations:

- When the target of the exception is EL1, and the value of the SCTLR_EL1.SPAN bit is 0, this bit is set to 1.
- When the target of the exception is EL2, HCR_EL2.{E2H, TGE} is {1, 1}, and the value of the SCTLR_EL2.SPAN bit is 0, this bit is set to 1.

**Accessing the PAN**

For details on the operation of the MSR (immediate) accessor, see MSR (immediate) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:
**MRS <Xt>, PAN**

C5.2.11 SP_EL0, Stack Pointer (EL0)

The SP_EL0 characteristics are:

**Purpose**

Holds the stack pointer associated with EL0. At higher Exception levels, this is used as the current stack pointer when the value of SPSel.SP is 0.

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SP_EL0 is a 64-bit register.

**Field descriptions**

The SP_EL0 bit assignments are:

![Stack pointer bit assignments](image)

**Bits [63:0]**

Stack pointer.

This field resets to an architecturally UNKNOWN value.

**Accessing the SP_EL0**

When the value of PSTATE.SP is 0, this register is accessible at all Exception levels as the current stack pointer.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, SP_EL0**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>

C5.2.12 SP_EL1, Stack Pointer (EL1)

The SP_EL1 characteristics are:

**Purpose**
Holds the stack pointer associated with EL1. When executing at EL1, the value of **SPSel.SP** determines the current stack pointer:

<table>
<thead>
<tr>
<th><strong>SPSel.SP</strong></th>
<th><strong>Current stack pointer</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>SP_EL0</td>
</tr>
<tr>
<td>0b1</td>
<td>SP_EL1</td>
</tr>
</tbody>
</table>

**Configurations**
RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**
SP_EL1 is a 64-bit register.

**Field descriptions**
The SP_EL1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:0]</td>
<td>Stack pointer</td>
</tr>
<tr>
<td></td>
<td>This field resets to an architecturally <strong>UNKNOWN</strong> value.</td>
</tr>
</tbody>
</table>

**Accessing the SP_EL1**
This accessibility information only applies to accesses using the MRS or MSR instructions.

When the value of **SPSel.SP** is 1, this register is also accessible at EL1 as the current stack pointer.

--- **Note** ---
When the value of **SPSel.SP** is 0, **SP_EL0** is used as the current stack pointer at all Exception levels.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, SP_EL1**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>

        NVMem[0x240] = X[t];
    elseif EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
    endif
else if PSTATE.EL == EL2 then
    SP_EL1 = X[t];
else if PSTATE.EL == EL3 then
    SP_EL1 = X[t];
```
C5.2.13 SP_EL2, Stack Pointer (EL2)

The SP_EL2 characteristics are:

**Purpose**

Holds the stack pointer associated with EL2. When executing at EL2, the value of SPSel.SP determines the current stack pointer:

<table>
<thead>
<tr>
<th>SPSel.SP</th>
<th>Current stack pointer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>SP_EL0</td>
</tr>
<tr>
<td>0b1</td>
<td>SP_EL2</td>
</tr>
</tbody>
</table>

**Configurations**

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SP_EL2 is a 64-bit register.

**Field descriptions**

The SP_EL2 bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Stack pointer</th>
</tr>
</thead>
</table>

This field resets to an architecturally UNKNOWN value.

**Accessing the SP_EL2**

This accessibility information only applies to accesses using the MRS or MSR instructions.

When the value of SPSel.SP is 1, this register is also accessible at EL2 as the current stack pointer.

--- Note ---

When the value of SPSel.SP is 0, SP_EL0 is used as the current stack pointer at all Exception levels.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, SP_EL2**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b11</td>
<td>0b110</td>
<td>0b0100</td>

<td>0b10</td>
<td>0b0100</td>
<td>0b0001</td>
<td>0b000</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    SP_EL2 = X[t];
C5.2.14  SP_EL3, Stack Pointer (EL3)

The SP_EL3 characteristics are:

**Purpose**

Holds the stack pointer associated with EL3. When executing at EL3, the value of SPSel.SP determines the current stack pointer:

<table>
<thead>
<tr>
<th>SPSel.SP</th>
<th>Current stack pointer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0</td>
<td>SP_EL0</td>
</tr>
<tr>
<td>0b1</td>
<td>SP_EL3</td>
</tr>
</tbody>
</table>

**Configurations**

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SP_EL3 is a 64-bit register.

**Field descriptions**

The SP_EL3 bit assignments are:

![Stack pointer diagram]

**Bits [63:0]**

Stack pointer.

This field resets to an architecturally UNKNOWN value.
C5.2.15 **SPSel, Stack Pointer Select**

The SPSel characteristics are:

**Purpose**

Allows the Stack Pointer to be selected between SP_EL0 and SP_ELx.

**Configurations**

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SPSel is a 64-bit register.

**Field descriptions**

The SPSel bit assignments are:

<table>
<thead>
<tr>
<th>Bit Locations</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [63:1]</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>SP, bit [0]</td>
<td>Stack pointer to use. Possible values of this bit are:</td>
</tr>
<tr>
<td>0b0</td>
<td>Use SP_EL0 at all Exception levels.</td>
</tr>
<tr>
<td>0b1</td>
<td>Use SP_ELx for Exception level ELx.</td>
</tr>
</tbody>
</table>

This field resets to 1.

**Accessing the SPSel**

For details on the operation of the MSR (immediate) accessor, see MSR (immediate) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, SPSel**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b11</td>

</tbody>
</table>
```

- `op0` = `0b00`
- `op1` = `0b00`
- `CRn` = `0b0100`
- `op2` = `0b10`
C5.2.16 SPSR_abt, Saved Program Status Register (Abort mode)

The SPSR_abt characteristics are:

**Purpose**
Holds the saved process state when an exception is taken to Abort mode.

**Configurations**
AArch64 System register SPSR_abt[31:0] is architecturally mapped to AArch32 System register SPSR_abt[31:0].
If EL1 does not support execution in AArch32 state, this register is RES0.
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
SPSR_abt is a 64-bit register.

**Field descriptions**
The SPSR_abt bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Purpose</th>
<th>Value</th>
<th>Architectural Mapping</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved</td>
<td>RES0</td>
<td></td>
</tr>
<tr>
<td>31</td>
<td>N, bit</td>
<td></td>
<td>Negative Condition</td>
</tr>
<tr>
<td>30</td>
<td>Z, bit</td>
<td></td>
<td>Zero Condition flag.</td>
</tr>
<tr>
<td>29</td>
<td>C, bit</td>
<td></td>
<td>Carry Condition flag.</td>
</tr>
<tr>
<td>28</td>
<td>V, bit</td>
<td></td>
<td>Overflow Condition</td>
</tr>
<tr>
<td>27</td>
<td>Q, bit</td>
<td></td>
<td>Overflow or saturation</td>
</tr>
</tbody>
</table>

**Bits [63:32]**
Reserved, RES0.

**N, bit [31]**
Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Abort mode, and copied to PSTATE.N on executing an exception return operation in Abort mode.
This field resets to an architecturally UNKNOWN value.

**Z, bit [30]**
Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Abort mode, and copied to PSTATE.Z on executing an exception return operation in Abort mode.
This field resets to an architecturally UNKNOWN value.

**C, bit [29]**
Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Abort mode, and copied to PSTATE.C on executing an exception return operation in Abort mode.
This field resets to an architecturally UNKNOWN value.

**V, bit [28]**
Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Abort mode, and copied to PSTATE.V on executing an exception return operation in Abort mode.
This field resets to an architecturally UNKNOWN value.

**Q, bit [27]**
Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Abort mode, and copied to PSTATE.Q on executing an exception return operation in Abort mode.
This field resets to an architecturally UNKNOWN value.

**IT[1:0], bits [26:25]**

If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to Abort mode, and copied to PSTATE.IT[1:0] on executing an exception return operation in Abort mode.

On executing an exception return operation in Abort mode SPSR_abt.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

**J, bit [24]**

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

**SSBS, bit [23]**

*When ARMv8.0-SSBS is implemented:*

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to Abort mode, and copied to PSTATE.SSBS on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**PAN, bit [22]**

*When ARMv8.1-PAN is implemented:*

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Abort mode, and copied to PSTATE.PAN on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**DIT, bit [21]**

*When ARMv8.4-DIT is implemented:*

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Abort mode, and copied to PSTATE.DIT on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**IL, bit [20]**

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Abort mode, and copied to PSTATE.IL on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

**GE, bits [19:16]**

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Abort mode, and copied to PSTATE.GE on executing an exception return operation in Abort mode.

This field resets to an architecturally UNKNOWN value.

**IT[7:2], bits [15:10]**

If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to Abort mode, and copied to PSTATE.IT[7:2] on executing an exception return operation in Abort mode.
SPSR_abt.IT must contain a value that is valid for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

**E, bit [9]**

Endianness. Set to the value of PSTATE.E on taking an exception to Abort mode, and copied to
PSTATE.E on executing an exception return operation in Abort mode.

If the implementation does not support big-endian operation, SPSR_abt.E is RES0. If the
implementation does not support little-endian operation, SPSR_abt.E is RES1. On executing an
exception return operation in Abort mode, if the implementation does not support big-endian
operation at the Exception level being returned to, SPSR_abt.E is RES0, and if the implementation
does not support little-endian operation at the Exception level being returned to, SPSR_abt.E is
RES1.

This field resets to an architecturally UNKNOWN value.

**A, bit [8]**

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Abort mode, and
copied to PSTATE.A on executing an exception return operation in Abort mode.
This field resets to an architecturally UNKNOWN value.

**I, bit [7]**

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Abort mode, and copied
to PSTATE.I on executing an exception return operation in Abort mode.
This field resets to an architecturally UNKNOWN value.

**F, bit [6]**

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Abort mode, and copied
to PSTATE.F on executing an exception return operation in Abort mode.
This field resets to an architecturally UNKNOWN value.

**T, bit [5]**

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Abort mode, and
copied to PSTATE.T on executing an exception return operation in Abort mode.
This field resets to an architecturally UNKNOWN value.

**M[4:0], bits [4:0]**

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Abort mode, and copied to
PSTATE.M[4:0] on executing an exception return operation in Abort mode.

0b10000    User.
0b10001    FIQ.
0b10010    IRQ.
0b10011    Supervisor.
0b10111    Abort.
0b11011    Undefined.
0b11111    System.

Other values are reserved. If SPSR_abt.M[4:0] has a Reserved value, or a value for an
unimplemented Exception level, executing an exception return operation in Abort mode is an illegal
return event, as described in *Illegal return events from AArch32 state* on page G1-5524.

This field resets to an architecturally UNKNOWN value.

An exception return from EL1 using AArch64 makes SPSR_EL1 become UNKNOWN.

**Bits [63:32]**
Reserved, RES0.

**N, bit [31]**
Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL1, and copied to PSTATE.N on executing an exception return operation in EL1.
This field resets to an architecturally UNKNOWN value.

**Z, bit [30]**
Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL1, and copied to PSTATE.Z on executing an exception return operation in EL1.
This field resets to an architecturally UNKNOWN value.

**C, bit [29]**
Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL1, and copied to PSTATE.C on executing an exception return operation in EL1.
This field resets to an architecturally UNKNOWN value.

**V, bit [28]**
Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL1, and copied to PSTATE.V on executing an exception return operation in EL1.
This field resets to an architecturally UNKNOWN value.
Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to EL1, and copied to PSTATE.Q on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

IT[1:0], bits [26:25]

If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to EL1, and copied to PSTATE.IT[1:0] on executing an exception return operation in EL1.

On executing an exception return operation in EL1 SPSR_EL1.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

DIT, bit [24]

*When ARMv8.4-DIT is implemented:*

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL1, and copied to PSTATE.DIT on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

SSBS, bit [23]

*When ARMv8.0-SSBS is implemented:*

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL1, and copied to PSTATE.SSBS on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

PAN, bit [22]

*When ARMv8.1-PAN is implemented:*

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL1, and copied to PSTATE.PAN on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on taking an exception to EL1, and conditionally copied to PSTATE.SS on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL1, and copied to PSTATE.IL on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to EL1, and copied to PSTATE.GE on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.
IT[7:2], bits [15:10]

If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to EL1, and copied to PSTATE.IT[7:2] on executing an exception return operation in EL1.

SPSR_EL1.IT must contain a value that is valid for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to EL1, and copied to PSTATE.E on executing an exception return operation in EL1.

If the implementation does not support big-endian operation, SPSR_EL1.E is RES0. If the implementation does not support little-endian operation, SPSR_EL1.E is RES1. On executing an exception return operation in EL1, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_EL1.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_EL1.E is RES1.

This field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL1, and copied to PSTATE.A on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL1, and copied to PSTATE.I on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL1, and copied to PSTATE.F on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to EL1, and copied to PSTATE.T on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

M[4], bit [4]

Execution state. Set to 0b1, the value of PSTATE.nRW, on taking an exception to EL1 from AArch32 state, and copied to PSTATE.nRW on executing an exception return operation in EL1.

0b1 AArch32 execution state.

This field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch32 Mode. Set to the value of PSTATE.M[3:0] on taking an exception to EL1, and copied to PSTATE.M[3:0] on executing an exception return operation in EL1.

0b0000 User.
0b0001 FIQ.
0b0010 IRQ.
0b0011 Supervisor.
0b0111 Abort.
0b1011 Undefined.
0b1111 System.
Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL1 is an illegal return event, as described in *Illegal return events from AArch64 state* on page D1-2304.

This field resets to an architecturally UNKNOWN value.

*When exception taken from AArch64 state:*

An exception from EL1 using AArch64 makes SPSR_EL1 become UNKNOWN.

**Bits [63:32]**

Reserved, RES0.

**N, bit [31]**

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL1, and copied to PSTATE.N on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

**Z, bit [30]**

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL1, and copied to PSTATE.Z on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

**C, bit [29]**

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL1, and copied to PSTATE.C on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

**V, bit [28]**

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL1, and copied to PSTATE.V on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

**Bits [27:26]**

Reserved, RES0.

**TCO, bit [25]**

*When ARMv8.5-MemTag is implemented:*

Tag Check Override. Set to the value of PSTATE.TCO on taking an exception to EL1, and copied to PSTATE.TCO on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.
DIT, bit [24]

*When ARMv8.4-DIT is implemented:*

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL1, and copied to PSTATE.DIT on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

UAO, bit [23]

*When ARMv8.2-UAO is implemented:*

User Access Override. Set to the value of PSTATE.UAO on taking an exception to EL1, and copied to PSTATE.UAO on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

PAN, bit [22]

*When ARMv8.1-PAN is implemented:*

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL1, and copied to PSTATE.PAN on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on taking an exception to EL1, and conditionally copied to PSTATE.SS on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL1, and copied to PSTATE.IL on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

Bits [19:13]

Reserved, RES0.

SSBS, bit [12]

*When ARMv8.0-SSBS is implemented:*

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL1, and copied to PSTATE.SSBS on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

BTYPE, bits [11:10]

*When ARMv8.5-BTI is implemented:*

Branch Type Indicator. Set to the value of PSTATE.BTYPE on taking an exception to EL1, and copied to PSTATE.BTYPE on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.
Otherwise:

Reserved, RES0.

D, bit [9]

Debug exception mask. Set to the value of PSTATE.D on taking an exception to EL1, and copied to PSTATE.D on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL1, and copied to PSTATE.A on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL1, and copied to PSTATE.I on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL1, and copied to PSTATE.F on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to \(0b0\), the value of PSTATE.nRW, on taking an exception to EL1 from AArch64 state, and copied to PSTATE.nRW on executing an exception return operation in EL1.

\(0b0\) AArch64 execution state.

If AArch32 is not supported at any Exception level, this bit is RES0.

This field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.

\(0b0000\) EL0t.

\(0b0100\) EL1t.

\(0b0101\) EL1h.

Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL1 is an illegal return event, as described in *Illegal return events from AArch64 state* on page D1-2304.

The bits in this field are interpreted as follows:

- M[3:2] is set to the value of PSTATE.EL on taking an exception to EL1 and copied to PSTATE.EL on executing an exception return operation in EL1.
- M[1] is unused and is 0 for all non-reserved values.
- M[0] is set to the value of PSTATE.SP on taking an exception to EL1 and copied to PSTATE.SP on executing an exception return operation in EL1.

This field resets to an architecturally UNKNOWN value.
Accessing the SPSR_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic SPSR_EL1 or SPSR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

### MRS <Xt>, SPSR_EL1

### C5.2.18 SPSR_EL2, Saved Program Status Register (EL2)

The SPSR_EL2 characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to EL2.

**Configurations**

AArch64 System register SPSR_EL2[31:0] is architecturally mapped to AArch32 System register SPSR_hyp[31:0].

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SPSR_EL2 is a 64-bit register.

**Field descriptions**

The SPSR_EL2 bit assignments are:

*When exception taken from AArch32 state:*

<table>
<thead>
<tr>
<th>Bit</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>63:32</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>31</td>
<td>Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL2, and copied to PSTATE.N on executing an exception return operation in EL2. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>30</td>
<td>Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL2, and copied to PSTATE.Z on executing an exception return operation in EL2. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>29</td>
<td>Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL2, and copied to PSTATE.C on executing an exception return operation in EL2. This field resets to an architecturally UNKNOWN value.</td>
</tr>
<tr>
<td>28</td>
<td>Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL2, and copied to PSTATE.V on executing an exception return operation in EL2.</td>
</tr>
</tbody>
</table>

An exception return from EL2 using AArch64 makes SPSR_EL2 become UNKNOWN.

**Bits [63:32]**

Reserved, RES0.

**N, bit [31]**

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL2, and copied to PSTATE.N on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

**Z, bit [30]**

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL2, and copied to PSTATE.Z on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

**C, bit [29]**

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL2, and copied to PSTATE.C on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

**V, bit [28]**

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL2, and copied to PSTATE.V on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.

Q, bit [27]
Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to EL2, and copied to PSTATE.Q on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.

IT[1:0], bits [26:25]
If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to EL2, and copied to PSTATE.IT[1:0] on executing an exception return operation in EL2.
On executing an exception return operation in EL2 SPSR_EL2.IT must contain a value that is valid for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

DIT, bit [24]
When ARMv8.4-DIT is implemented:
Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL2, and copied to PSTATE.DIT on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

SSBS, bit [23]
When ARMv8.0-SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL2, and copied to PSTATE.SSBS on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

PAN, bit [22]
When ARMv8.1-PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL2, and copied to PSTATE.PAN on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

SS, bit [21]
Software Step. Set to the value of PSTATE.SS on taking an exception to EL2, and conditionally copied to PSTATE.SS on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.

IL, bit [20]
Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL2, and copied to PSTATE.IL on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]
Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to EL2, and copied to PSTATE.GE on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.
IT[7:2], bits [15:10]
If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to EL2, and copied to PSTATE.IT[7:2] on executing an exception return operation in EL2.
SPSR_EL2.IT must contain a value that is valid for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

E, bit [9]
Endianness. Set to the value of PSTATE.E on taking an exception to EL2, and copied to PSTATE.E on executing an exception return operation in EL2.
If the implementation does not support big-endian operation, SPSR_EL2.E is RES0. If the implementation does not support little-endian operation, SPSR_EL2.E is RES1. On executing an exception return operation in EL2, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_EL2.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_EL2.E is RES1.
This field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL2, and copied to PSTATE.A on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL2, and copied to PSTATE.I on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL2, and copied to PSTATE.F on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to EL2, and copied to PSTATE.T on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.

M[4], bit [4]
Execution state. Set to 0b1, the value of PSTATE.nRW, on taking an exception to EL2 from AArch32 state, and copied to PSTATE.nRW on executing an exception return operation in EL2.

0b1 AArch32 execution state.
This field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]
AArch32 Mode. Set to the value of PSTATE.M[3:0] on taking an exception to EL2, and copied to PSTATE.M[3:0] on executing an exception return operation in EL2.

0b0000 User.
0b0001 FIQ.
0b0010 IRQ.
0b0011 Supervisor.
0b0111 Abort.
0b1010 Hyp.
0b1011 Undefined.
Other values are reserved. If SPSR_EL2.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL2 is an illegal return event, as described in *Illegal return events from AArch64 state* on page D1-2304.

This field resets to an architecturally UNKNOWN value.

### When exception taken from AArch64 state:

![Diagram of SPSR_EL2 bits]

An exception return from EL2 using AArch64 makes SPSR_EL2 become UNKNOWN.

**Bits [63:32]**

- **Reserved, RES0.**

**N, bit [31]**

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL2, and copied to PSTATE.N on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

**Z, bit [30]**

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL2, and copied to PSTATE.Z on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

**C, bit [29]**

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL2, and copied to PSTATE.C on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

**V, bit [28]**

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL2, and copied to PSTATE.V on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

**Bits [27:26]**

- **Reserved, RES0.**

**TCO, bit [25]**

- When **ARMv8.5-MemTag is implemented:**
  - Tag Check Override. Set to the value of PSTATE.TCO on taking an exception to EL2, and copied to PSTATE.TCO on executing an exception return operation in EL2.
  
  This field resets to an architecturally UNKNOWN value.

- **Otherwise:**
  - Reserved, RES0.
DIT, bit [24]

When ARMv8.4-DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL2, and copied to PSTATE.DIT on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UAO, bit [23]

When ARMv8.2-UAO is implemented:

User Access Override. Set to the value of PSTATE.UAO on taking an exception to EL2, and copied to PSTATE.UAO on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When ARMv8.1-PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL2, and copied to PSTATE.PAN on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on taking an exception to EL2, and conditionally copied to PSTATE.SS on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL2, and copied to PSTATE.IL on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

Bits [19:13]

Reserved, RES0.

SSBS, bit [12]

When ARMv8.0-SSBS is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL2, and copied to PSTATE.SSBS on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BTYPE, bits [11:10]

When ARMv8.5-BTI is implemented:

Branch Type Indicator. Set to the value of PSTATE.BTYPE on taking an exception to EL2, and copied to PSTATE.BTYPE on executing an exception return operation in EL2.

This field resets to an architecturally UNKNOWN value.
D, bit [9]

Debug exception mask. Set to the value of PSTATE.D on taking an exception to EL2, and copied to
PSTATE.D on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL2, and copied to
PSTATE.A on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL2, and copied to
PSTATE.I on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL2, and copied to
PSTATE.F on executing an exception return operation in EL2.
This field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to 0b0, the value of PSTATE.nRW, on taking an exception to EL2 from AArch64
state, and copied to PSTATE.nRW on executing an exception return operation in EL2.
0b0 AArch64 execution state.
If AArch32 is not supported at any Exception level, this bit is RES0.
This field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.
0b0000 EL0t.
0b0100 EL1t.
0b0101 EL1h.
0b1000 EL2t.
0b1001 EL2h.

Other values are reserved. If SPSR_EL2.M[3:0] has a Reserved value, or a value for an
unimplemented Exception level, executing an exception return operation in EL2 is an illegal return
event, as described in Illegal return events from AArch64 state on page D1-2304.
The bits in this field are interpreted as follows:
• M[3:2] is set to the value of PSTATE.EL on taking an exception to EL2 and copied to
PSTATE.EL on executing an exception return operation in EL2.
• M[1] is unused and is 0 for all non-reserved values.
• M[0] is set to the value of PSTATE.SP on taking an exception to EL2 and copied to
PSTATE.SP on executing an exception return operation in EL2
This field resets to an architecturally UNKNOWN value.
Accessing the SPSR_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic SPSR_EL2 or SPSR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, SPSR_EL2**

<table>

C5.2.19 SPSR_EL3, Saved Program Status Register (EL3)

The SPSR_EL3 characteristics are:

Purpose

Holds the saved process state when an exception is taken to EL3.

Configurations

AArch64 System register SPSR_EL3[31:0] can be mapped to AArch32 System register SPSR_mon[31:0], but this is not architecturally mandated.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SPSR_EL3 is a 64-bit register.

Field descriptions

The SPSR_EL3 bit assignments are:

When exception taken from AArch32 state:

An exception return from EL3 using AArch64 makes SPSR_EL1 become UNKNOWN.

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL3, and copied to PSTATE.N on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL3, and copied to PSTATE.Z on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL3, and copied to PSTATE.C on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL3, and copied to PSTATE.V on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.
Q, bit [27]
Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to EL3, and
copied to PSTATE.Q on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

IT[1:0], bits [26:25]
If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to EL3, and copied to
PSTATE.IT[1:0] on executing an exception return operation in EL3.
On executing an exception return operation in EL3 SPSR_EL1.IT must contain a value that is valid
for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

DIT, bit [24]
When ARMv8.4-DIT is implemented:
Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL3, and
copied to PSTATE.DIT on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

SSBS, bit [23]
When ARMv8.0-SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL3, and
copied to PSTATE.SSBS on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

PAN, bit [22]
When ARMv8.1-PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL3, and
copied to PSTATE.PAN on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.
Otherwise:
Reserved, RES0.

SS, bit [21]
Software Step. Set to the value of PSTATE.SS on taking an exception to EL3, and conditionally
copied to PSTATE.SS on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

IL, bit [20]
Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL3, and copied to
PSTATE.IL on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]
Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to EL3, and
copied to PSTATE.GE on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.
IT[7:2], bits [15:10]
If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to EL3, and copied to PSTATE.IT[7:2] on executing an exception return operation in EL3.
SPSR_EL1.IT must contain a value that is valid for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

E, bit [9]
Endianness. Set to the value of PSTATE.E on taking an exception to EL3, and copied to PSTATE.E on executing an exception return operation in EL3.
If the implementation does not support big-endian operation, SPSR_EL1.E is RES0. If the implementation does not support little-endian operation, SPSR_EL1.E is RES1. On executing an exception return operation in EL3, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_EL1.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_EL1.E is RES1.
This field resets to an architecturally UNKNOWN value.

A, bit [8]
SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL3, and copied to PSTATE.A on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

I, bit [7]
IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL3, and copied to PSTATE.I on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

F, bit [6]
FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL3, and copied to PSTATE.F on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

T, bit [5]
T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to EL3, and copied to PSTATE.T on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

M[4], bit [4]
Execution state. Set to 0b1, the value of PSTATE.nRW, on taking an exception to EL3 from AArch32 state, and copied to PSTATE.nRW on executing an exception return operation in EL3.
0b1 AArch32 execution state.
This field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]
AArch32 Mode. Set to the value of PSTATE.M[3:0] on taking an exception to EL3, and copied to PSTATE.M[3:0] on executing an exception return operation in EL3.
0b0000 User.
0b0001 FIQ.
0b0010 IRQ.
0b0011 Supervisor.
0b0110 Monitor.
0b0111 Abort.
0b1010 Hyp.
The A64 System Instruction Class
C5.2 Special-purpose registers

0b1011  Undefined.
0b1111  System.

Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL3 is an illegal return event, as described in *Illegal return events from AArch64 state* on page D1-2304.

This field resets to an architecturally UNKNOWN value.

*When exception taken from AArch64 state:*

An exception return from EL3 using AArch64 makes SPSR_EL1 become UNKNOWN.

**Bits [63:32]**

Reserved, RES0.

**N, bit [31]**

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL3, and copied to PSTATE.N on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

**Z, bit [30]**

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL3, and copied to PSTATE.Z on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

**C, bit [29]**

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL3, and copied to PSTATE.C on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

**V, bit [28]**

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL3, and copied to PSTATE.V on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

**Bits [27:26]**

Reserved, RES0.

**TCO, bit [25]**

*When ARMv8.5-MemTag is implemented:*

Tag Check Override. Set to the value of PSTATE.TCO on taking an exception to EL3, and copied to PSTATE.TCO on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

---

*DISCLAIMER: This text is a direct transcription from the image provided. It is intended for educational purposes only and may not reflect the latest updates or corrections to the original source.*
DIT, bit [24]

When ARMv8.4-DIT is implemented:
Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL3, and copied to PSTATE.DIT on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

UAO, bit [23]

When ARMv8.2-UAO is implemented:
User Access Override. Set to the value of PSTATE.UAO on taking an exception to EL3, and copied to PSTATE.UAO on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

PAN, bit [22]

When ARMv8.1-PAN is implemented:
Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL3, and copied to PSTATE.PAN on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.

SS, bit [21]
Software Step. Set to the value of PSTATE.SS on taking an exception to EL3, and conditionally copied to PSTATE.SS on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

IL, bit [20]
Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL3, and copied to PSTATE.IL on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

Bits [19:13]
Reserved, RES0.

SSBS, bit [12]

When ARMv8.0-SSBS is implemented:
Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL3, and copied to PSTATE.SSBS on executing an exception return operation in EL3.
This field resets to an architecturally UNKNOWN value.

Otherwise:
Reserved, RES0.
BTYPE, bits [11:10]

When ARMv8.5-BTI is implemented:

Branch Type Indicator. Set to the value of PSTATE.BTYPE on taking an exception to EL3, and copied to PSTATE.BTYPE on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

D, bit [9]

Debug exception mask. Set to the value of PSTATE.D on taking an exception to EL3, and copied to PSTATE.D on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to EL3, and copied to PSTATE.A on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL3, and copied to PSTATE.I on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL3, and copied to PSTATE.F on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to 0b0, the value of PSTATE.nRW, on taking an exception to EL3 from AArch64 state, and copied to PSTATE.nRW on executing an exception return operation in EL3.

0b0 AArch64 execution state.

If AArch32 is not supported at any Exception level, this bit is RES0.

This field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.

0b0000 EL0t.

0b0100 EL1t.

0b0101 EL1h.

0b1000 EL2t.

0b1001 EL2h.

0b1100 EL3t.

0b1101 EL3h.

Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL3 is an illegal return event, as described in Illegal return events from AArch64 state on page D1-2304.
The bits in this field are interpreted as follows:

- M[3:2] is set to the value of PSTATE.EL on taking an exception to EL3 and copied to PSTATE.EL on executing an exception return operation in EL3.
- M[1] is unused and is 0 for all non-reserved values.
- M[0] is set to the value of PSTATE.SP on taking an exception to EL3 and copied to PSTATE.SP on executing an exception return operation in EL3.

This field resets to an architecturally UNKNOWN value.

### Accessing the SPSR_EL3

Accesses to this register use the following encodings in the System instruction encoding space:

**MRS <Xt>, SPSR_EL3**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b11</td>
<td>0b110</td>
<td>0b0100</td>
<td>0b0000</td>
<td>0b000</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then
  UNDEFINED;
elsif PSTATE.EL == EL2 then
  UNDEFINED;
elsif PSTATE.EL == EL3 then
  return SPSR_EL3;

**MSR SPSR_EL3, <Xt>**

<table>

  SPSR_EL3 = X[t];
C5.2.20 SPSR_fiq, Saved Program Status Register (FIQ mode)

The SPSR_fiq characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to FIQ mode.

**Configurations**

AArch64 System register SPSR_fiq[31:0] is architecturally mapped to AArch32 System register SPSR_fiq[31:0].

If EL1 does not support execution in AArch32 state, this register is RES0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SPSR_fiq is a 64-bit register.

**Field descriptions**

The SPSR_fiq bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>

ID070919 Non-Confidential
This field resets to an architecturally UNKNOWN value.

**IT[1:0], bits [26:25]**

If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to FIQ mode, and copied to PSTATE.IT[1:0] on executing an exception return operation in FIQ mode.

On executing an exception return operation in FIQ mode SPSR_fiq.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

**J, bit [24]**

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

**SSBS, bit [23]**

*When ARMv8.0-SSBS is implemented:*

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to FIQ mode, and copied to PSTATE.SSBS on executing an exception return operation in FIQ mode.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**PAN, bit [22]**

*When ARMv8.1-PAN is implemented:*

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to FIQ mode, and copied to PSTATE.PAN on executing an exception return operation in FIQ mode.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**DIT, bit [21]**

*When ARMv8.4-DIT is implemented:*

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to FIQ mode, and copied to PSTATE.DIT on executing an exception return operation in FIQ mode.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**IL, bit [20]**

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to FIQ mode, and copied to PSTATE.IL on executing an exception return operation in FIQ mode.

This field resets to an architecturally UNKNOWN value.

**GE, bits [19:16]**

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to FIQ mode, and copied to PSTATE.GE on executing an exception return operation in FIQ mode.

This field resets to an architecturally UNKNOWN value.

**IT[7:2], bits [15:10]**

If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to FIQ mode, and copied to PSTATE.IT[7:2] on executing an exception return operation in FIQ mode.
SPSR_fiq.IT must contain a value that is valid for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

**E, bit [9]**

Endianness. Set to the value of PSTATE.E on taking an exception to FIQ mode, and copied to PSTATE.E on executing an exception return operation in FIQ mode.
If the implementation does not support big-endian operation, SPSR_fiq.E is RES0. If the implementation does not support little-endian operation, SPSR_fiq.E is RES1. On executing an exception return operation in FIQ mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_fiq.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_fiq.E is RES1.
This field resets to an architecturally UNKNOWN value.

**A, bit [8]**

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to FIQ mode, and copied to PSTATE.A on executing an exception return operation in FIQ mode.
This field resets to an architecturally UNKNOWN value.

**I, bit [7]**

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to FIQ mode, and copied to PSTATE.I on executing an exception return operation in FIQ mode.
This field resets to an architecturally UNKNOWN value.

**F, bit [6]**

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to FIQ mode, and copied to PSTATE.F on executing an exception return operation in FIQ mode.
This field resets to an architecturally UNKNOWN value.

**T, bit [5]**

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to FIQ mode, and copied to PSTATE.T on executing an exception return operation in FIQ mode.
This field resets to an architecturally UNKNOWN value.

**M[4:0], bits [4:0]**

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to FIQ mode, and copied to PSTATE.M[4:0] on executing an exception return operation in FIQ mode.
- 0b10000  User.
- 0b10001  FIQ.
- 0b10010  IRQ.
- 0b10011  Supervisor.
- 0b10111  Abort.
- 0b11011  Undefined.
- 0b11111  System.

Other values are reserved. If SPSR_fiq.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in FIQ mode is an illegal return event, as described in *Illegal return events from AArch32 state on page G1-5524*.
This field resets to an architecturally UNKNOWN value.

**Accessing the SPSR_fiq**

Accesses to this register use the following encodings in the System instruction encoding space:
### MRS <Xt>, SPSR_fiq

If `PSTATE.EL == EL0` then
UNDEFINED;
else if `PSTATE.EL == EL1` then
    if `EL2Enabled() && HCR_EL2.NV == '1'` then
        `AArch64.SystemAccessTrap(EL2, 0x18);`
    else
        UNDEFINED;
    end if
else if `PSTATE.EL == EL2` then
    `SPSR_fiq = X[t];`
else if `PSTATE.EL == EL3` then
    `SPSR_fiq = X[t];`
end if

C5.2.21 SPSR_irq, Saved Program Status Register (IRQ mode)

The SPSR_irq characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to IRQ mode.

**Configurations**

AArch64 System register SPSR_irq[31:0] is architecturally mapped to AArch32 System register SPSR_irq[31:0].

If EL1 does not support execution in AArch32 state, this register is RES0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SPSR_irq is a 64-bit register.

**Field descriptions**

The SPSR_irq bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>

---

The A64 System Instruction Class
C5.2 Special-purpose registers
This field resets to an architecturally UNKNOWN value.

**IT[1:0], bits [26:25]**

If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to IRQ mode, and copied to PSTATE.IT[1:0] on executing an exception return operation in IRQ mode.

On executing an exception return operation in IRQ mode SPSR_irq.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

**J, bit [24]**

RES0.

In previous versions of the architecture, the \{J, T\} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

**SSBS, bit [23]**

*When ARMv8.0-SSBS is implemented:*

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to IRQ mode, and copied to PSTATE.SSBS on executing an exception return operation in IRQ mode.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**PAN, bit [22]**

*When ARMv8.1-PAN is implemented:*

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to IRQ mode, and copied to PSTATE.PAN on executing an exception return operation in IRQ mode.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**DIT, bit [21]**

*When ARMv8.4-DIT is implemented:*

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to IRQ mode, and copied to PSTATE.DIT on executing an exception return operation in IRQ mode.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**IL, bit [20]**

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to IRQ mode, and copied to PSTATE.IL on executing an exception return operation in IRQ mode.

This field resets to an architecturally UNKNOWN value.

**GE, bits [19:16]**

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to IRQ mode, and copied to PSTATE.GE on executing an exception return operation in IRQ mode.

This field resets to an architecturally UNKNOWN value.

**IT[7:2], bits [15:10]**

If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to IRQ mode, and copied to PSTATE.IT[7:2] on executing an exception return operation in IRQ mode.
SPSR_irq.IT must contain a value that is valid for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Set to the value of PSTATE.E on taking an exception to IRQ mode, and copied to
PSTATE.E on executing an exception return operation in IRQ mode.
If the implementation does not support big-endian operation, SPSR_irq.E is RES0. If the
implementation does not support little-endian operation, SPSR_irq.E is RES1. On executing an
exception return operation in IRQ mode, if the implementation does not support big-endian
operation at the Exception level being returned to, SPSR_irq.E is RES0, and if the implementation
does not support little-endian operation at the Exception level being returned to, SPSR_irq.E is
RES1.
This field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to IRQ mode, and
copied to PSTATE.A on executing an exception return operation in IRQ mode.
This field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to IRQ mode, and copied
to PSTATE.I on executing an exception return operation in IRQ mode.
This field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to IRQ mode, and copied
to PSTATE.F on executing an exception return operation in IRQ mode.
This field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to IRQ mode, and
copied to PSTATE.T on executing an exception return operation in IRQ mode.
This field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to IRQ mode, and copied to
PSTATE.M[4:0] on executing an exception return operation in IRQ mode.

0b10000 User.
0b10001 FIQ.
0b10010 IRQ.
0b10011 Supervisor.
0b10111 Abort.
0b11011 Undefined.
0b11111 System.

Other values are reserved. If SPSR_irq.M[4:0] has a Reserved value, or a value for an
unimplemented Exception level, executing an exception return operation in IRQ mode is an illegal
return event, as described in Illegal return events from AArch32 state on page G1-5524.
This field resets to an architecturally UNKNOWN value.

C5.2.22  SPSR_und, Saved Program Status Register (Undefined mode)

The SPSR_und characteristics are:

**Purpose**

Holds the saved process state when an exception is taken to Undefined mode.

**Configurations**

AArch64 System register SPSR_und[31:0] is architecturally mapped to AArch32 System register SPSR_und[31:0].

If EL1 does not support execution in AArch32 state, this register is RES0.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

SPSR_und is a 64-bit register.

**Field descriptions**

The SPSR_und bit assignments are:

```
63 32 31 30 29 28 27 26 25 24 23 22 21 20 19 16 15 10 9 8 7 6 5 4 3 2 1 0

RES0  N  Z  C  V  Q  J  IL  GE  IT[7:2]  E  A  I  F  T  M[4:0] DIT
```

- **Bits [63:32]**
  
  Reserved, RES0.

- **N, bit [31]**
  
  Negative Condition flag. Set to the value of PSTATE.N on taking an exception to Undefined mode, and copied to PSTATE.N on executing an exception return operation in Undefined mode.
  
  This field resets to an architecturally UNKNOWN value.

- **Z, bit [30]**
  
  Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to Undefined mode, and copied to PSTATE.Z on executing an exception return operation in Undefined mode.
  
  This field resets to an architecturally UNKNOWN value.

- **C, bit [29]**
  
  Carry Condition flag. Set to the value of PSTATE.C on taking an exception to Undefined mode, and copied to PSTATE.C on executing an exception return operation in Undefined mode.
  
  This field resets to an architecturally UNKNOWN value.

- **V, bit [28]**
  
  Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to Undefined mode, and copied to PSTATE.V on executing an exception return operation in Undefined mode.
  
  This field resets to an architecturally UNKNOWN value.

- **Q, bit [27]**
  
  Overflow or saturation flag. Set to the value of PSTATE.Q on taking an exception to Undefined mode, and copied to PSTATE.Q on executing an exception return operation in Undefined mode.
This field resets to an architecturally UNKNOWN value.

**IT[1:0], bits [26:25]**

If-Then. Set to the value of PSTATE.IT[1:0] on taking an exception to Undefined mode, and copied to PSTATE.IT[1:0] on executing an exception return operation in Undefined mode.

On executing an exception return operation in Undefined mode SPSR_und.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

**J, bit [24]**

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. Armv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

**SSBS, bit [23]**

*When ARMv8.0-SSBS is implemented:*

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to Undefined mode, and copied to PSTATE.SSBS on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**PAN, bit [22]**

*When ARMv8.1-PAN is implemented:*

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to Undefined mode, and copied to PSTATE.PAN on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**DIT, bit [21]**

*When ARMv8.4-DIT is implemented:*

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to Undefined mode, and copied to PSTATE.DIT on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

*Otherwise:*

Reserved, RES0.

**IL, bit [20]**

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to Undefined mode, and copied to PSTATE.IL on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

**GE, bits [19:16]**

Greater than or Equal flags. Set to the value of PSTATE.GE on taking an exception to Undefined mode, and copied to PSTATE.GE on executing an exception return operation in Undefined mode.

This field resets to an architecturally UNKNOWN value.

**IT[7:2], bits [15:10]**

If-Then. Set to the value of PSTATE.IT[7:2] on taking an exception to Undefined mode, and copied to PSTATE.IT[7:2] on executing an exception return operation in Undefined mode.
SPSR_und.IT must contain a value that is valid for the instruction being returned to.
This field resets to an architecturally UNKNOWN value.

**E, bit [9]**

Endianness. Set to the value of PSTATE.E on taking an exception to Undefined mode, and copied to PSTATE.E on executing an exception return operation in Undefined mode.

If the implementation does not support big-endian operation, SPSR_und.E is RES0. If the implementation does not support little-endian operation, SPSR_und.E is RES1. On executing an exception return operation in Undefined mode, if the implementation does not support big-endian operation at the Exception level being returned to, SPSR_und.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, SPSR_und.E is RES1.
This field resets to an architecturally UNKNOWN value.

**A, bit [8]**

SError interrupt mask. Set to the value of PSTATE.A on taking an exception to Undefined mode, and copied to PSTATE.A on executing an exception return operation in Undefined mode.
This field resets to an architecturally UNKNOWN value.

**I, bit [7]**

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to Undefined mode, and copied to PSTATE.I on executing an exception return operation in Undefined mode.
This field resets to an architecturally UNKNOWN value.

**F, bit [6]**

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to Undefined mode, and copied to PSTATE.F on executing an exception return operation in Undefined mode.
This field resets to an architecturally UNKNOWN value.

**T, bit [5]**

T32 Instruction set state. Set to the value of PSTATE.T on taking an exception to Undefined mode, and copied to PSTATE.T on executing an exception return operation in Undefined mode.
This field resets to an architecturally UNKNOWN value.

**M[4:0], bits [4:0]**

Mode. Set to the value of PSTATE.M[4:0] on taking an exception to Undefined mode, and copied to PSTATE.M[4:0] on executing an exception return operation in Undefined mode.

- 0b10000 User.
- 0b10001 FIQ.
- 0b10010 IRQ.
- 0b10011 Supervisor.
- 0b10111 Abort.
- 0b11011 Undefined.
- 0b11111 System.

Other values are reserved. If SPSR_und.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in Undefined mode is an illegal return event, as described in *Illegal return events from AArch32 state* on page G1-5524.
This field resets to an architecturally UNKNOWN value.

**Accessing the SPSR_und**

Accesses to this register use the following encodings in the System instruction encoding space:
### MRS <Xt>, SPSR_und

C5.2.23 SSBS, Speculative Store Bypass Safe

The SSBS characteristics are:

**Purpose**
Allows access to the Speculative Store Bypass Safe bit.

**Configurations**
This register is present only when ARMv8.0-SSBS is implemented. Otherwise, direct accesses to SSBS are **UNDEFINED**.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**
SSBS is a 64-bit register.

**Field descriptions**
The SSBS bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:13]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>RES0</strong></td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

**SSBS, bit [12]**
Speculative Store Bypass Safe.

Prohibits speculative loads or stores which might practically allow a cache timing side channel.

A cache timing side channel might be exploited where a load or store uses an address that is derived from a register that is being loaded from memory using a load instruction speculatively read from a memory location. If PSTATE.SSBS is enabled, the address derived from the load instruction might be from earlier in the coherence order than the latest store to that memory location with the same virtual address.

0b0 Hardware is not permitted to load or store speculatively, in a manner that could practically give rise to a cache timing side channel, using an address derived from a register value that has been loaded from memory using a load instruction (L) that speculatively reads an entry from earlier in the coherence order from that location being loaded from than the entry generated by the latest store (S) to that location using the same virtual address as L.

0b1 Hardware is permitted to load or store speculatively, in a manner that could practically give rise to a cache timing side channel, using an address derived from a register value that has been loaded from memory using a load instruction (L) that speculatively reads an entry from earlier in the coherence order from that location being loaded from than the entry generated by the latest store (S) to that location using the same virtual address as L.

The value of this bit is set to the value in the SCTLR_ELx.DSSBS field on taking an exception to ELx.

This field resets to an **IMPLEMENTATION DEFINED** value.
Bits [11:0]  
Reserved, RES0.

**Accessing the SSBS**

For details on the operation of the MSR (immediate) accessor, see MSR (immediate) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:

### *MRS <Xt>, SSBS*

C5.2.24 TCO, Tag Check Override

The TCO characteristics are:

**Purpose**

When ARMv8.5-MemTag is implemented, this register allows tag checks to be disabled globally.

**Configurations**

This register is present only when ARMv8.5-MemTag is implemented. Otherwise, direct accesses to TCO are **UNDEFINED**.

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

TCO is a 64-bit register.

**Field descriptions**

The TCO bit assignments are:

```
Bits [63:26]  
Reserved, RES0.

TCO, bit [25]  
Allows memory tag checks to be globally disabled.
0b0 Loads and Stores are not affected by this control.
0b1 Loads and Stores are unchecked.

Bits [24:0]  
Reserved, RES0.
```

**Accessing the TCO**

For details on the operation of the MSR (immediate) accessor, see **MSR (immediate)**.

Accesses to this register use the following encodings in the System instruction encoding space:

### MRS <Xt>, TCO

C5.2.25 UAO, User Access Override

The UAO characteristics are:

**Purpose**

Allows access to the User Access Override bit.

**Configurations**

This register is present only when ARMv8.2-UAO is implemented. Otherwise, direct accesses to UAO are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

UAO is a 64-bit register.

**Field descriptions**

The UAO bit assignments are:

![Bit Assignment Diagram]

**Bits [63:24]**

Reserved, RES0.

**UAO, bit [23]**

User Access Override.

0b0 The behavior of LDTR* and STTR* instructions is as defined in the base Armv8 architecture.

0b1 When executed at EL1, or at EL2 with HCR_EL2.\{E2H, TGE\} == \{1, 1\}, LDTR* and STTR* instructions behave as the equivalent LDR* and STR* instructions.

When executed at EL3, or at EL2 with HCR_EL2.E2H == 0 or HCR_EL2.TGE == 0, the LDTR* and STTR* instructions behave as the equivalent LDR* and STR* instructions, regardless of the setting of the PSTATE.UAO bit.

**Bits [22:0]**

Reserved, RES0.

**Accessing the UAO**

For details on the operation of the MSR (immediate) accessor, see MSR (immediate) in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Accesses to this register use the following encodings in the System instruction encoding space:
MRS <Xt>, UAO

if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then

C5.3  A64 System instructions for cache maintenance

This section lists the A64 System instructions for cache maintenance.
C5.3.1   DC CGDSW, Data, Allocation Tag or unified Cache line Clean of Data and Allocation Tags by Set/Way

The DC CGDSW characteristics are:

**Purpose**

Clean data and Allocation Tags in data cache by set/way.

**Configurations**

This instruction is present only when ARMv8.5-MemTag is implemented and ID_AA64PFR1_EL1.MTE != 0b0001. Otherwise, direct accesses to DC CGDSW are UNDEFINED. RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DC CGDSW is a 64-bit System instruction.

**Field descriptions**

The DC CGDSW input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>32-31</td>
<td>SetWay</td>
</tr>
<tr>
<td>4-3</td>
<td>Level</td>
</tr>
<tr>
<td>0</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

**SetWay, bits [31:4]**

Contains two fields:

- **Way**, bits[31:32-A], the number of the way to operate on.
- **Set**, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log₂(ASSOCIATIVITY), L = Log₂(LINELEN), B = (L + S), S = Log₂(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**

Reserved, RES0.

**Executing the DC CGDSW instruction**

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
The instruction performs cache maintenance on one of:
- No cache lines.
- A single arbitrary cache line.
- Multiple arbitrary cache lines.

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{DC CGDSW, } <Xt> 
\]

<table>

C5.3.2 DC CGDVAC, Data, Allocation Tag or unified Cache line Clean of Allocation Tags by VA to PoC

The DC CGDVAC characteristics are:

**Purpose**
Clean data and Allocation Tags in data cache by address to Point of Coherency.

**Configurations**
This instruction is present only when ARMv8.5-MemTag is implemented. Otherwise, direct accesses to DC CGDVAC are **UNDEFINED**.

**Attributes**
RW fields in this register reset to architecturally **UNKNOWN** values.

**Field descriptions**
The DC CGDVAC input value bit assignments are:

```
   Bits [63:0]  Virtual address to use
```

Virtual address to use. No alignment restrictions apply to this VA.

**Executing the DC CGDVAC instruction**
If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission Fault, subject to the constraints described in *Permission fault on page D5-2623*. Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see *The data cache maintenance instruction (DC) on page D4-2483*.

Accesses to this register use the following encodings in the System instruction encoding space:

C5.3.3 DC CGDVADP, Data, Allocation Tag or unified Cache line Clean of Allocation Tags by VA to PoDP

The DC CGDVADP characteristics are:

**Purpose**
Clean Allocation Tags in data cache by address to Point of Deep Persistence.
If the memory system does not identify a Point of Deep Persistence, then this instruction behaves as a DC CGVAP.

**Configurations**
This instruction is present only when ARMv8.2-DCCVADP is implemented and ARMv8.5-MemTag is implemented. Otherwise, direct accesses to DC CGDVADP are UNDEFINED. RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
DC CGDVADP is a 64-bit System instruction.

**Field descriptions**
The DC CGDVADP input value bit assignments are:

![Virtual address to use](image)

Bits [63:0]
Virtual address to use. No alignment restrictions apply to this VA.

**Executing the DC CGDVADP instruction**
If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission Fault, see Permission fault on page D5-2623.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see The data cache maintenance instruction (DC) on page D4-2483.

Accesses to this register use the following encodings in the System instruction encoding space:

C5.3.4  DC CGDVAP, Data, Allocation Tag or unified Cache line Clean of Data and Allocation Tags by VA to PoP

The DC CGDVAP characteristics are:

**Purpose**

Clean data and Allocation Tags in data cache by address to Point of Persistence.

If the memory system does not identify a Point of Persistence, then this instruction behaves as a DC CGDVAC.

**Configurations**

This instruction is present only when ARMv8.5-MemTag is implemented. Otherwise, direct accesses to DC CGDVAP are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DC CGDVAP is a 64-bit System instruction.

**Field descriptions**

The DC CGDVAP input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 0</td>
<td>Virtual address to use</td>
</tr>
</tbody>
</table>

Virtual address to use. No alignment restrictions apply to this VA.

**Executing the DC CGDVAP instruction**

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission Fault, see *Permission fault* on page D5-2623.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see *The data cache maintenance instruction (DC)* on page D4-2483.

Accesses to this register use the following encodings in the System instruction encoding space:

C5.3.5 DC CGSW, Data, Allocation Tag or unified Cache line Clean of Allocation Tags by Set/Way

The DC CGSW characteristics are:

**Purpose**
Clean Allocation Tags in data cache by set/way.

**Configurations**
This instruction is present only when ARMv8.5-MemTag is implemented and ID_AA64PPR1_EL1.MTE != 0b0001. Otherwise, direct accesses to DC CGSW are UNDEFINED. RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
DC CGSW is a 64-bit System instruction.

**Field descriptions**
The DC CGSW input value bit assignments are:

```
63  32  31  4  3  1  0
RES0  SetWay  Level  RES0

Bits [63:32]
Reserved, RES0.

SetWay, bits [31:4]
Contains two fields:
• Way, bits[31:32-A], the number of the way to operate on.
• Set, bits[B-1:L], the number of the set to operate on.
Bits[L-1:4] are RES0.
A = \log_2(\text{ASSOCIATIVITY}), L = \log_2(\text{LINELEN}), B = (L + S), S = \log_2(\text{NSETS}).
ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]
Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]
Reserved, RES0.
```

**Executing the DC CGSW instruction**
If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

• The instruction is UNDEFINED.
• The instruction performs cache maintenance on one of:
  — No cache lines.
— A single arbitrary cache line.

C5.3.9 DC CIGDSW, Data, Allocation Tag or unified Cache line Clean and Invalidate of Data and Allocation Tags by Set/Way

The DC CIGDSW characteristics are:

**Purpose**
Clean and Invalidate data and Allocation Tags in data cache by set/way.

**Configurations**
This instruction is present only when ARMv8.5-MemTag is implemented and ID_AA64PFR1_EL1.MTE ≠ 0b0001. Otherwise, direct accesses to DC CIGDSW are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
DC CIGDSW is a 64-bit System instruction.

**Field descriptions**
The DC CIGDSW input value bit assignments are:

### Bits [63:32]
Reserved, RES0.

### SetWay, bits [31:4]
Contains two fields:
- **Way**, bits[31:32-A], the number of the way to operate on.
- **Set**, bits[B-1:L], the number of the set to operate on.

Bits[4-L] are RES0.

A = \(\log_2(\text{ASSOCIATIVITY})\), L = \(\log_2(\text{LINELEN})\), B = (L + S), S = \(\log_2(\text{NSETS})\).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

### Level, bits [3:1]
Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

### Bit [0]
Reserved, RES0.

**Executing the DC CIGDSW instruction**
If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:
- The instruction is UNDEFINED.
• The instruction performs cache maintenance on one of:
  — No cache lines.
  — A single arbitrary cache line.
  — Multiple arbitrary cache lines.

Accesses to this register use the following encodings in the System instruction encoding space:

```
DC CIGDSW, <Xt>
```

<table>

C5.3.10 DC CIGDVAC, Data, Allocation Tag or unified Cache line Clean and Invalidate of Data and Allocation Tags by VA to PoC

The DC CIGDVAC characteristics are:

**Purpose**

Clean and Invalidate data and Allocation Tags in data cache by address to Point of Coherency.

**Configurations**

This instruction is present only when ARMv8.5-MemTag is implemented. Otherwise, direct accesses to DC CIGDVAC are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DC CIGDVAC is a 64-bit System instruction.

**Field descriptions**

The DC CIGDVAC input value bit assignments are:

![Virtual address to use](image)

**Bits [63:0]**

Virtual address to use. No alignment restrictions apply to this VA.

**Executing the DC CIGDVAC instruction**

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see *The data cache maintenance instruction (DC)* on page D4-2483.

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission Fault, subject to the constraints described in *Permission fault* on page D5-2623.

Accesses to this register use the following encodings in the System instruction encoding space:

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DC CSW is a 64-bit System instruction.

Field descriptions

The DC CSW input value bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>32</th>
<th>31</th>
<th>4</th>
<th>3</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SetWay</td>
<td>Level</td>
<td>RES0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

• Way, bits[31:32-A], the number of the way to operate on.

• Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log2(ASSOCIATIVITY), L = Log2(LINELEN), B = (L + S), S = Log2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing the DC CSW instruction

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

• The instruction is UNDEFINED.
The instruction performs cache maintenance on one of:

- No cache lines.
- A single arbitrary cache line.
- Multiple arbitrary cache lines.

Accesses to this register use the following encodings in the System instruction encoding space:

**DC CSW, <Xt>**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b01</td>
<td>0b000</td>
<td>0b0111</td>
<td>0b1010</td>
<td>0b010</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && !ELUsingAArch32(EL2) && HCR_EL2.TSW == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        DC_CSW(X[t]);
    endif
elsif PSTATE.EL == EL2 then
    DC_CSW(X[t]);
elsif PSTATE.EL == EL3 then
    DC_CSW(X[t]);
C5.3.16   DC CVAC, Data or unified Cache line Clean by VA to PoC

The DC CVAC characteristics are:

**Purpose**
Clean data cache by address to Point of Coherency.
When ARMv8.5-MemTag is implemented, this instruction might clean Allocation Tags from caches.

**Configurations**
AArch64 System instruction DC CVAC performs the same function as AArch32 System instruction DCCMVAC.
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
DC CVAC is a 64-bit System instruction.

**Field descriptions**
The DC CVAC input value bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Virtual address to use</td>
</tr>
</tbody>
</table>
```

Virtual address to use. No alignment restrictions apply to this VA.

**Executing the DC CVAC instruction**

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission Fault, subject to the constraints described in Permission fault on page D5-2623.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see The data cache maintenance instruction (DC) on page D4-2483.

Accesses to this register use the following encodings in the System instruction encoding space:

**DC CVAC, <Xt>**

```
<table>
<thead>
<tr>

C5.3.17  DC CVADP, Data or unified Cache line Clean by VA to PoDP

The DC CVADP characteristics are:

**Purpose**

Clean data cache by address to Point of Deep Persistence.

If the memory system does not identify a Point of Deep Persistence, then this instruction behaves as a DC CVAP.

When ARMv8.5-MemTag is implemented, this instruction might clean Allocation Tags from caches.

**Configurations**

This instruction is present only when ARMv8.2-DCCVADP is implemented. Otherwise, direct accesses to DC CVADP are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DC CVADP is a 64-bit System instruction.

**Field descriptions**

The DC CVADP input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual address to use</td>
</tr>
</tbody>
</table>

Virtual address to use. No alignment restrictions apply to this VA.

**Executing the DC CVADP instruction**

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission Fault, see *Permission fault on page D5-2623*.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see *The data cache maintenance instruction (DC) on page D4-2483*.

C5.3.20 DC GVA, Data Cache set Allocation Tag by VA

The DC GVA characteristics are:

**Purpose**

Write a value to the Allocation Tags of a naturally aligned block of N bytes, where the size of N is identified in DCZID_EL0. The Allocation Tag used is determined by the input address.

**Configurations**

This instruction is present only when ARMv8.5-MemTag is implemented. Otherwise, direct accesses to DC GVA are **UNDEFINED**.

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

DC GVA is a 64-bit System instruction.

**Field descriptions**

The DC GVA input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>63 0</td>
<td>Virtual address to use. There is no alignment restriction on the address within the block of N bytes that is used.</td>
</tr>
</tbody>
</table>

**Executing the DC GVA instruction**

When this instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory-related faults or watchpoints. If a synchronous data abort fault or a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is not set.

If the memory region being zeroed is any type of Device memory, this instruction can give an alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

This instruction behaves as a set of Stores to each byte within the block being accessed, and so it:

- Generates a Permission Fault if the translation system does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instructions.

Accesses to this register use the following encodings in the System instruction encoding space:

**DC GVA, <Xt>**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>

C5.3.21   DC GZVA, Data Cache set Allocation Tags and Zero by VA

The DC GZVA characteristics are:

**Purpose**
Zero data and write a value to the Allocation Tags of a naturally aligned block of N bytes, where the size of N is identified in DCZID_EL0. The Allocation Tag used is determined by the input address.

**Configurations**
This instruction is present only when ARMv8.5-MemTag is implemented. Otherwise, direct accesses to DC GZVA are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
DC GZVA is a 64-bit System instruction.

**Field descriptions**
The DC GZVA input value bit assignments are:

```
   63 0
   ||
   Virtual address to use
```

**Bits [63:0]**
Virtual address to use. There is no alignment restriction on the address within the block of N bytes that is used.

**Executing the DC GZVA instruction**
When this instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory-related faults or watchpoints. If a synchronous data abort fault or a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is not set.

If the memory region being zeroed is any type of Device memory, this instruction can give an alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

This instruction behaves as a set of Stores to each byte within the block being accessed, and so it:

- Generates a Permission Fault if the translation system does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instructions.

Accesses to this register use the following encodings in the System instruction encoding space:

C5.3.23 DC IGDVAC, Data, Allocation Tag or unified Cache line Invalidate of Allocation Tags by VA to PoC

The DC IGDVAC characteristics are:

**Purpose**
Invalidate data and Allocation Tags in data cache by address to Point of Coherency.

**Configurations**
This instruction is present only when ARMv8.5-MemTag is implemented and ID_AA64PFR1_EL1.MTE != 0b0001. Otherwise, direct accesses to DC IGDVAC are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**
DC IGDVAC is a 64-bit System instruction.

**Field descriptions**
The DC IGDVAC input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>0</td>
</tr>
</tbody>
</table>

Virtual address to use. No alignment restrictions apply to this VA.

**Executing the DC IGDVAC instruction**

When the instruction is executed, it can generate a watchpoint, which is prioritized in the same way as other watchpoints. If a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is set to 1.

This instruction requires write access permission to the VA, otherwise it generates a Permission Fault, subject to the constraints described in Permission fault on page D5-2623.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see The data cache maintenance instruction (DC) on page D4-2483.

Accesses to this register use the following encodings in the System instruction encoding space:

**DC IGDVAC, <Xt>**

<table>
<thead>
<tr>

C5.3.24 DC IGSW, Data, Allocation Tag or unified Cache line Invalidate of Allocation Tags by Set/Way

The DC IGSW characteristics are:

**Purpose**

Invalidate Allocation Tags in data cache by set/way.

**Configurations**

This instruction is present only when ARMv8.5-MemTag is implemented and ID_AA64FR1_EL1.MTE != 0b0001. Otherwise, direct accesses to DC IGSW are UNDEFINED. RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DC IGSW is a 64-bit System instruction.

**Field descriptions**

The DC IGSW input value bit assignments are:

![Bit assignments diagram]

**Bits [63:32]**

Reserved, RES0.

**SetWay, bits [31:4]**

Contains two fields:
- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log2(ASSOCIATIVITY), L = Log2(LINELEN), B = (L + S), S = Log2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**

Reserved, RES0.

**Executing the DC IGSW instruction**

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
— A single arbitrary cache line.
— Multiple arbitrary cache lines.

Accesses to this register use the following encodings in the System instruction encoding space:

### C5.3.27 DC IVAC, Data or unified Cache line Invalidate by VA to PoC

The DC IVAC characteristics are:

**Purpose**

Invalidate data cache by address to Point of Coherency.

When ARMv8.5-MemTag is implemented, this instruction might invalidate Allocation Tags from caches. When it invalidates Allocation Tags from caches, it also cleans them.

**Configurations**

AArch64 System instruction DC IVAC performs the same function as AArch32 System instruction DCIMVAC.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

DC IVAC is a 64-bit System instruction.

**Field descriptions**

The DC IVAC input value bit assignments are:

**Bits [63:0]**

Virtual address to use. No alignment restrictions apply to this VA.

**Executing the DC IVAC instruction**

When the instruction is executed, it can generate a watchpoint, which is prioritized in the same way as other watchpoints. If a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is set to 1.

This instruction requires write access permission to the VA, otherwise it generates a Permission Fault, subject to the constraints described in Permission fault on page D5-2623.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see The data cache maintenance instruction (DC) on page D4-2483.

Accesses to this register use the following encodings in the System instruction encoding space:

**DC IVAC, <Xt>**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>

...
DC_IVAC(X[t]);
elsif PSTATE_EL == EL3 then
  DC_IVAC(X[t]);
C5.3.28 DC ZVA, Data Cache Zero by VA

The DC ZVA characteristics are:

Purpose

Zero data cache by address. Zeroes a naturally aligned block of N bytes, where the size of N is identified in DCZID_EL0.

Configurations

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DC ZVA is a 64-bit System instruction.

Field descriptions

The DC ZVA input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:0]</th>
<th>Virtual address to use</th>
</tr>
</thead>
</table>

Virtual address to use. There is no alignment restriction on the address within the block of N bytes that is used.

Executing the DC ZVA instruction

When this instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory-related faults or watchpoints. If a synchronous data abort fault or a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is set to 0.

If the memory region being zeroed is any type of Device memory, this instruction can give an Alignment fault which is prioritized in the same way as other Alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

This instruction behaves as a set of Stores to each byte within the block being accessed, and so it:

• Generates a Permission Fault if the translation system does not permit writes to the locations.
• Requires the same considerations for ordering and the management of coherency as any other store instructions.

Accesses to this register use the following encodings in the System instruction encoding space:

**DC ZVA, <Xt>**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>

C5.3.29  IC IALLU, Instruction Cache Invalidate All to PoU

The IC IALLU characteristics are:

**Purpose**

Invalidate all instruction caches to Point of Unification.

**Configurations**

AArch64 System instruction IC IALLU performs the same function as AArch32 System instruction ICIALLU.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

IC IALLU is a 64-bit System instruction.

**Field descriptions**

IC IALLU ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the IC IALLU instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

\[

C5.3.31  IC IVAU, Instruction Cache line Invalidate by VA to PoU

The IC IVAU characteristics are:

**Purpose**

Invalidate instruction cache by address to Point of Unification.

**Configurations**

AArch64 System instruction IC IVAU performs the same function as AArch32 System instruction ICIMVAU.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

IC IVAU is a 64-bit System instruction.

**Field descriptions**

The IC IVAU input value bit assignments are:

```
+------------------+
| 63   0           |
| Virtual address  |
|   to use         |
```

**Bits [63:0]**

Virtual address to use. No alignment restrictions apply to this VA.

**Executing the IC IVAU instruction**

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see *The instruction cache maintenance instruction (IC)* on page D4-2483.

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it is IMPLEMENTATION DEFINED whether it generates a Permission Fault, see *Permission fault* on page D5-2623.

Accesses to this register use the following encodings in the System instruction encoding space:

C5.4 A64 System instructions for address translation

This section lists the A64 System instructions for address translation.
C5.4.1 AT S12E0R, Address Translate Stages 1 and 2 EL0 Read

The AT S12E0R characteristics are:

**Purpose**

Performs stage 1 and 2 address translations from EL0, with permissions as if reading from the given virtual address from EL0, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime.
- Otherwise, the EL1&0 translation regime.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

AT S12E0R is a 64-bit System instruction.

**Field descriptions**

The AT S12E0R input value bit assignments are:

<table>
<thead>

C5.4.2 AT S12E0W, Address Translate Stages 1 and 2 EL0 Write

The AT S12E0W characteristics are:

Purpose

Performs stage 1 and 2 address translations from EL0, with permissions as if writing to the given
virtual address from EL0, using the following translation regime:

- When EL2 is implemented and enabled in the Security state described by the current value
  of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the EL2&0 translation regime.
- Otherwise, the EL1&0 translation regime.

Configurations

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AT S12E0W is a 64-bit System instruction.

Field descriptions

The AT S12E0W input value bit assignments are:

<table>
<thead>

AT S1E2R is a 64-bit System instruction.

Field descriptions
The AT S1E2R input value bit assignments are:

\[
\begin{array}{cccccc}
63 & 62 & \ldots & 0 \\
\{ & \{ & \ldots & \} & \} \\
\end{array}
\]

Input address for translation

Bits [63:0]
Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S1E2R instruction
Accesses to this register use the following encodings in the System instruction encoding space:

\[ \text{AT S1E2R}, \langle Xt \rangle \]

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>

C5.4.12 AT S1E2W, Address Translate Stage 1 EL2 Write

The AT S1E2W characteristics are:

**Purpose**

Performs stage 1 address translation as defined for EL2, with permissions as if writing to the given virtual address.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

AT S1E2W is a 64-bit System instruction.

**Field descriptions**

The AT S1E2W input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>

C5.5 A64 System instructions for TLB maintenance

This section lists the A64 System instructions for TLB maintenance.

For more information about these instructions see TLB maintenance instructions on page D5-2641. In particular, for the full description of the scope of each instruction see Scope of the A64 TLB maintenance instructions on page D5-2646.
C5.5.1 TLBI ALLE1, TLB Invalidate All, EL1

The TLBI ALLE1 characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:
- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If SCR_EL3.NS is 0 and the entry would be required to translate an address using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1 and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation only applies to the PE that executes this System instruction.

**Note**

For the EL1&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

**Configurations**

There are no configuration notes.

**RW fields in this register reset to architecturally UNKNOWN values.**

**Attributes**

TLBI ALLE1 is a 64-bit System instruction.

**Field descriptions**

TLBI ALLE1 ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBI ALLE1 instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

### TLBI ALLE1(, <Xt>)

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
<th>Rt</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b01</td>
<td>0b100</td>
<td>0b1000</td>
<td>0b0111</td>
<td>0b100</td>
<td>0b1111</td>
</tr>
</tbody>
</table>

```c
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() & HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else

    elsif PSTATE.EL == EL3 then
        TLBI_ALLE1();
```
C5.5.2 TLBI ALLE1IS, TLB Invalidate All, EL1, Inner Shareable

The TLBI ALLE1IS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If SCR_EL3.NS is 0 and the entry would be required to translate an address using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1 and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Note**

For the EL1&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI ALLE1IS is a 64-bit System instruction.

**Field descriptions**

TLBI ALLE1IS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBI ALLE1IS instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{TLBI ALLE1IS}(<Xt>)
\]

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>

elsif PSTATE.EL == EL3 then
  TLBI_ALLE1IS();

C5.5.3 TLBI ALLE1OS, TLB Invalidate All, EL1, Outer Shareable

The TLBI ALLE1OS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If SCR_EL3.NS is 0 and the entry would be required to translate an address using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1 and the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

---

**Note**

For the EL1&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

---

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI ALLE1OS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI ALLE1OS is a 64-bit System instruction.

**Field descriptions**

TLBI ALLE1OS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBI ALLE1OS instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

elsif PSTATE_EL == EL3 then
  TLBI_ALLE1OS();
```

---
C5.5.4 TLBI ALLE2, TLB Invalidate All, EL2

The TLBI ALLE2 characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- If SCR_EL3.NS is 1 and the entry would be required to translate an address using the Non-secure EL2 or Non-secure EL2&0 translation regime.
- If SCR_EL3.NS is 0 and the entry would be required to translate an address using the Secure EL2 or Secure EL2&0 translation regime.

The invalidation only applies to the PE that executes this System instruction.

Configurations

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI ALLE2 is a 64-bit System instruction.

Field descriptions

TLBI ALLE2 ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBI ALLE2 instruction

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{TLBI ALLE2}_i, \ <X>_t
\]

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>

C5.5.7 TLBI ALLE3, TLB Invalidate All, EL3

The TLBI ALLE3 characteristics are:

**Purpose**

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be required to translate an address using the EL3 translation regime.

The invalidation applies to the PE that executes this System instruction.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI ALLE3 is a 64-bit System instruction.

**Field descriptions**

TLBI ALLE3 ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBI ALLE3 instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{TLBI ALLE3}_{\{<X>\}}
\]

<table>
<thead>

elsif PSTATE.EL == EL3 then
    TLBI_ALLE3IS();
C5.5.9 TLBI ALLE3OS, TLB Invalidate All, EL3, Outer Shareable

The TLBI ALLE3OS characteristics are:

**Purpose**

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be required to translate an address using the EL3 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI ALLE3OS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI ALLE3OS is a 64-bit System instruction.

**Field descriptions**

TLBI ALLE3OS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBI ALLE3OS instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

```
TLBI ALLE3OS{, <Xt>}
```

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>

elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    TLBI_ALLE3OS();
C5.5.10 TLBI ASIDE1, TLB Invalidate by ASID, EL1

The TLBI ASIDE1 characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID, and would be required to translate an address using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate an address using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate an address using the EL1&0 translation regime.

The invalidation applies to the PE that executes this System instruction.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI ASIDE1 is a 64-bit System instruction.

**Field descriptions**

The TLBI ASIDE1 input bit assignments are:

```
<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>RES0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**ASID, bits [63:48]**

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this System instruction.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

**Bits [47:0]**

Reserved, RES0.

**Executing the TLBI ASIDE1 instruction**

Accesses to this register use the following encodings in the System instruction encoding space:
TLBI ASIDE1(, <Xt>)

<table>
<thead>

C5.5.11 TLBI ASIDE1IS, TLB Invalidate by ASID, EL1, Inner Shareable

The TLBI ASIDE1IS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate an address using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate an address using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate an address using the EL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI ASIDE1IS is a 64-bit System instruction.

**Field descriptions**

The TLBI ASIDE1IS input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>ASID</td>
</tr>
<tr>
<td>48-47</td>
<td>ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this System instruction. If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.</td>
</tr>
<tr>
<td>47-0</td>
<td>Reserved, RES0</td>

C5.5.12 TLBI ASIDE1OS, TLB Invalidate by ASID, EL1, Outer Shareable

The TLBI ASIDE1OS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate an address using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate an address using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate an address using the EL1&0 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Configurations

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI ASIDE1OS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI ASIDE1OS is a 64-bit System instruction.

Field descriptions

The TLBI ASIDE1OS input value bit assignments are:

```
63  48  47  0
   |     |  |
   ASID| RES0|
       |
```

ASID, bits [63:48]

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this System instruction.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

Bits [47:0]

Reserved, RES0.

Executing the TLBI ASIDE1OS instruction

Accesses to this register use the following encodings in the System instruction encoding space:
TLBI ASIDE10S(, <Xt>)

<table>
<thead>

   TLBI_ASI[DE10S(X[t]);
C5.5.13 TLBI IPAS2E1, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1

The TLBI IPAS2E1 characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- One of the following applies:
  - SCR_EL3.NS==1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.NS==0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction see *Invalidation of TLB entries from stage 2 translations* on page D5-2650.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI IPAS2E1 is a 64-bit System instruction.

**Field descriptions**

The TLBI IPAS2E1 input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>NS (Not Secure)</td>
</tr>
<tr>
<td>62-48</td>
<td>RES0</td>
</tr>
<tr>
<td>47</td>
<td>TTL</td>
</tr>
<tr>
<td>44</td>
<td>RES0</td>
</tr>
<tr>
<td>40-36</td>
<td>IPA[47:12]</td>
</tr>
</tbody>
</table>

**NS, bit [63]**

*When ARMv8.4-SecEL2 is implemented:*

- Not Secure. Specifies the IPA space.
  - 0b0 IPA is in the Secure IPA space.
  - 0b1 IPA is in the Non-secure IPA space.

**Otherwise:**

- Reserved, RES0.

**Bits [62:48]**

- Reserved, RES0.
TTL, bits [47:44]

When ARMv8.4-TTL is implemented:

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

- **0b00xx** No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx** The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01 : Level 1.
  - 0b10 : Level 2.
  - 0b11 : Level 3.
- **0b10xx** The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01 : Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b10 : Level 2.
  - 0b11 : Level 3.
- **0b11xx** The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01 : Level 1.
  - 0b10 : Level 2.
  - 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

Bits [43:40]

Reserved, RES0.

IPA[51:48], bits [39:36]

When ARMv8.2-LPA is implemented:

Extension to IPA[47:12]. See IPA[47:12] for more details.

Otherwise:

Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match. For implementations with fewer than 48 bits, the upper bits of this field are RES0.

When ARMv8.2-LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

Executing the TLBI IPAS2E1 instruction

Accesses to this register use the following encodings in the System instruction encoding space:
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

TLBI IPAS2E1(, <X[t]>)

C5.5.14 TLBI IPAS2E1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable

The TLBI IPAS2E1IS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:
• The entry is a stage 2 only translation table entry, from any level of the translation table walk.
• One of the following applies:
  — SCR_EL3.NS==1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  — SCR_EL3.NS==0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
• The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction see Invalidation of TLB entries from stage 2 translations on page D5-2650.

Configurations

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI IPAS2E1IS is a 64-bit System instruction.

Field descriptions

The TLBI IPAS2E1IS input value bit assignments are:

```

</thead>
<tbody>
<tr>
<td>NS</td>
<td>RES0</td>
<td>TTL</td>
<td>RES0</td>
<td>IPA[47:12]</td>
<td>IPA[51:48]</td>
</tr>
</tbody>
</table>

**NS, bit [63]**

Not Secure. Specifies the IPA space.

- 0b0 IPA is in the Secure IPA space.
- 0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When ARMv8.4-SecEL2 is not implemented or is disabled in the current Security state, this field is RES0.

**Bits [62:48]**

Reserved, RES0.
TTL, bits [47:44]

When ARMv8.4-TTL is implemented:

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

- **0b00xx**: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

- **0b01xx**: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0b0xx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.

- **0b10xx**: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0b0xx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b10: Level 2.
  - 0b11: Level 3.

- **0b11xx**: The entry comes from a 64KB translation granule. The level of walk for the leaf level 0b0xx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

**Otherwise:**

Reserved, RES0.

Bits [43:40]

Reserved, RES0.

IPA[51:48], bits [39:36]

Extension to IPA[47:12]. See IPA[47:12] for more details.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match. For implementations with fewer than 48 bits, the upper bits of this field are RES0.

When ARMv8.2-LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

Executing the TLBI IPAS2E1OS instruction

C5.5.16 TLBI IPAS2LE1, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1

The TLBI IPAS2LE1 characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- One of the following applies:
  - SCR_EL3.NS==1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.NS==0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction see *Invalidation of TLB entries from stage 2 translations* on page D5-2650.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Reserved. Treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

Bits [43:40]
Reserved, RES0.

IPA[51:48], bits [39:36]

When ARMv8.2-LPA is implemented:
Extension to IPA[47:12]. See IPA[47:12] for more details.

Otherwise:
Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match. For implementations with fewer than 48 bits, the upper bits of this field are RES0.

When ARMv8.2-LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

Executing the TLBI IPAS2LE1 instruction
Accesses to this register use the following encodings in the System instruction encoding space:
if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then
  if EL2Enabled() && HCR_EL2.NV == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
  else
    UNDEFINED;
elsif PSTATE.EL == EL2 then
  TLBI_IPAS2LE1(X[t]);
elsif PSTATE.EL == EL3 then
  if !EL2Enabled() then
    //no operation
  else
    TLBI_IPAS2LE1(X[t]);

<td>0b0100</td>
<td>0b101</td>
</tr>
</tbody>
</table>

---

```
The TLBI IPAS2LE1IS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- One of the following applies:
  - SCR_EL3.NS==1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.NS==0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction see [Invalidation of TLB entries from stage 2 translations](#) on page D5-2650.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI IPAS2LE1IS is a 64-bit System instruction.

**Field descriptions**

The TLBI IPAS2LE1IS input value bit assignments are:

```
   63 62 48 47 44 43 40 39 36 35 0
NS  RES0 TTL RES0 IPA[47:12] IPA[51:48]
```

**NS, bit [63]**

*When ARMv8.4-SecEL2 is implemented:*

Not Secure. Specifies the IPA space.

- 0b0: IPA is in the Secure IPA space.
- 0b1: IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

*When ARMv8.4-SecEL2 is not implemented or is disabled in the current Security state, this field is RES0.*

**Otherwise:**

Reserved, RES0.
Bits [62:48]
Reserved, RES0.

TTL, bits [47:44]

When ARMv8.4-TTL is implemented:
Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

- 0b00xx: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- 0b01xx: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.

- 0b10xx: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b10: Level 2.
  - 0b11: Level 3.

- 0b11xx: The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

Bits [43:40]
Reserved, RES0.

IPA[51:48], bits [39:36]

C5.5.19 TLBI RIPAS2E1, TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1

The TLBI RIPAS2E1 characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- One of the following applies:
  - SCR_EL3.NS==1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.NS==0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula \[\text{BaseADDR} <= \text{VA} < \text{BaseADDR} + ((\text{NUM} +1)*2^{(5*\text{SCALE} +1)})*\text{Translation Granule Size}\].

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 000000000000.

For more information about the architectural requirements for this System instruction see *Invalidation of TLB entries from stage 2 translations* on page D5-2650.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RIPAS2E1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI RIPAS2E1 is a 64-bit System instruction.

**Field descriptions**

The TLBI RIPAS2E1 input value bit assignments are:
NS, bit [63]

*When ARMv8.4-SecEL2 is implemented:*

Not Secure. Specifies the IPA space.

- **0b0**: IPA is in the Secure IPA space.
- **0b1**: IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When ARMv8.4-SecEL2 is not implemented or is disabled in the current Security state, this field is RES0.

*Otherwise:*

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

- **0b00**: Reserved.
- **0b01**: 4K translation granule.
- **0b10**: 16K translation granule.
- **0b11**: 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- **0b00**: The entries in the range can be using any level for the translation table entries.
- **0b01**: When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved. Hardware should treat this field as **0b00**.
- **0b10**: All entries to invalidate are Level 2 translation table entries.
- **0b11**: All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

**Executing the TLBI RIPAS2E1 instruction**

Accesses to this register use the following encodings in the System instruction encoding space:
TLBI RIPAS2E1(<Xt>)

<table>

        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elsif PSTATE_EL == EL2 then
    TLBI_RIPAS2E1(X[t]);
elsif PSTATE_EL == EL3 then
    if !EL2Enabled() then
        // no operation
    else
        TLBI_RIPAS2E1(X[t]);

C5.5.20 TLBI RIPAS2E1IS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable

The TLBI RIPAS2E1IS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- One of the following applies:
  - SCR_EL3.NS==1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.NS==0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*2^(5*SCALE +1) * Translation_Granule_Size)].

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granularity:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granularity:
  - If TTL==10 and BaseADDR[24:14] is not equal to 000000000.
- For the 64K translation granularity:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 000000000000.

For more information about the architectural requirements for this System instruction see *Invalidation of TLB entries from stage 2 translations* on page D5-2650.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RIPAS2E1IS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI RIPAS2E1IS is a 64-bit System instruction.

**Field descriptions**

The TLBI RIPAS2E1IS input value bit assignments are:

```
63 62  48 47 46 45 44 43  39 38 37 36 35 34 33 32 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
NS  RES0  TG  NUM  TTL  BaseADDR
```

SCALE
NS, bit [63]

When ARMv8.4-SecEL2 is implemented:

Not Secure. Specifies the IPA space.
- `0b0`: IPA is in the Secure IPA space.
- `0b1`: IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is `RES0`, and the instruction applies only to the Non-secure IPA space.

When ARMv8.4-SecEL2 is not implemented or is disabled in the current Security state, this field is `RES0`.

Otherwise:
Reserved, `RES0`.

Bits [62:48]
Reserved, `RES0`.

TG, bits [47:46]
Translation granule size.
- `0b00`: Reserved.
- `0b01`: 4K translation granule.
- `0b10`: 16K translation granule.
- `0b11`: 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]
The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]
The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]
TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
- `0b00`: The entries in the range can be using any level for the translation table entries.
- `0b01`: When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries.
  When using a 16KB translation granule, this value is reserved. Hardware should treat this field as `0b00`.
- `0b10`: All entries to invalidate are Level 2 translation table entries.
- `0b11`: All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]
The starting address for the range of the maintenance instruction.
When using a 4KB translation granule, this field is `BaseADDR[48:12]`.
When using a 16KB translation granule, this field is `BaseADDR[50:14]`.
When using a 64KB translation granule, this field is `BaseADDR[52:16]`.

Executing the TLBI RIPAS2E1IS instruction

Accesses to this register use the following encodings in the System instruction encoding space:
TLBI RIPAS2E1IS{, <Xt>}

C5.5.21 TLBI RIPAS2E1OS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1, Outer Shareable

The TLBI RIPAS2E1OS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- One of the following applies:
  - SCR_EL3.NS==1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.NS==0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1)\times2\times(5\times\text{SCALE} +1) \times \text{Translation_Granule_Size})]$.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 0000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 000000000000.

For more information about the architectural requirements for this System instruction see [Invalidation of TLB entries from stage 2 translations](#) on page D5-2650.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RIPAS2E1OS are **UNDEFINED**.

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

TLBI RIPAS2E1OS is a 64-bit System instruction.

**Field descriptions**

The TLBI RIPAS2E1OS input value bit assignments are:

```
+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+
| 63 62 | 48 47 46 45 44 43 | 39 38 37 36 | 0 | NS | RES0 | TG | NUM | TTL | BaseADDR |
```

SCALE
NS, bit [63]
Not Secure. Specifies the IPA space.

0b0 IPA is in the Secure IPA space.
0b1 IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.
When ARMv8.4-SecEL2 is not implemented or is disabled in the current Security state, this field is RES0.

Bits [62:48]
Reserved, RES0.

TG, bits [47:46]
Translation granule size.

0b00 Reserved.
0b01 4K translation granule.
0b10 16K translation granule.
0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]
The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]
The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]
TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00 The entries in the range can be using any level for the translation table entries.
0b01 When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries.
When using a 16KB translation granule, this value is reserved. Hardware should treat this field as 0b00.
0b10 All entries to invalidate are Level 2 translation table entries.
0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]
The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing the TLBI RIPAS2E1OS instruction

Accesses to this register use the following encodings in the System instruction encoding space:
TLBI RIPAS2E1OS(, <Xt>)

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>

<td>0b1000</td>
<td>0b0100</td>
<td>0b011</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then
  if EL2Enabled() && HCR_EL2.NV == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
  else
    UNDEFINED;
elsif PSTATE.EL == EL2 then
  TLBI_RIPAS2E1OS(X[t]);
elsif PSTATE.EL == EL3 then
  if !EL2Enabled() then
    //no operation
  else
    TLBI_RIPAS2E1OS(X[t]);
C5.5.22 TLBI RIPAS2LE1, TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1

The TLBI RIPAS2LE1 characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- One of the following applies:
  - SCR_EL3.NS==1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.NS==0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1) \times 2^{5 \times \text{SCALE} +1}) \times \text{Translation Granule Size}]$.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation only applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 000000000000.

For more information about the architectural requirements for this System instruction see *Invalidation of TLB entries from stage 2 translations* on page D5-2650.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RIPAS2LE1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI RIPAS2LE1 is a 64-bit System instruction.

**Field descriptions**

        endif
    endif
endif
C5.5.23    TLBI RIPAS2LE1IS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable

The TLBI RIPAS2LE1IS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- One of the following applies:
  - SCR_EL3.NS==1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.NS==0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula \( [\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1)\times2^{(5\times\text{SCALE} +1)} \times \text{Translation_Granule\_Size})] \).

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction see *Invalidation of TLB entries from stage 2 translations* on page D5-2650.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RIPAS2LE1IS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI RIPAS2LE1IS is a 64-bit System instruction.

**Field descriptions**

The TLBI RIPAS2LE1IS input value bit assignments are:
**NS, bit [63]**

*When ARMv8.4-SecEL2 is implemented:*

Not Secure. Specifies the IPA space.

- **0b0**: IPA is in the Secure IPA space.
- **0b1**: IPA is in the Non-secure IPA space.

When the instruction is executed in Non-secure state, this field is RES0, and the instruction applies only to the Non-secure IPA space.

When ARMv8.4-SecEL2 is not implemented or is disabled in the current Security state, this field is RES0.

*Otherwise:*

Reserved, RES0.

**Bits [62:48]**

Reserved, RES0.

**TG, bits [47:46]**

C5.5.24 TLBI RIPAS2LE1OS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Outer Shareable

The TLBI RIPAS2LE1OS characteristics are:

**Purpose**

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- One of the following applies:
  - SCR_EL3.NS==1 and the entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.
  - SCR_EL3.NS==0 and the entry would be required to translate the specified IPA using the Secure EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*2^(5*SCALE +1) * Translation_Granule_Size)].

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction see *Invalidation of TLB entries from stage 2 translations* on page D5-2650.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RIPAS2LE1OS are undefined.

C5.5.25 TLBI RVAAE1, TLB Range Invalidate by VA, All ASID, EL1

The TLBI RVAAE1 characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.
- The entry is within the address range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1) \times 2^{(5 \times \text{SCALE} +1)} \times \text{Translation_Granule_Size})]\).

The invalidation applies to the PE that executes this System instruction.

**Note**

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both:
- Global entries.
- Non-global entries with any ASID.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVAAE1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI RVAAE1 is a 64-bit System instruction.

**Field descriptions**

The TLBI RVAAE1 input value bit assignments are:
Bits [63:48]

Reserved, RES0.

TG, bits [47:46]
Translation granule size.
- 0b00: Reserved.
- 0b01: 4K translation granule.
- 0b10: 16K translation granule.
- 0b11: 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]
The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]
The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]
TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
- 0b00: The entries in the range can be using any level for the translation table entries.
- 0b01: When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10: All entries to invalidate are Level 2 translation table entries.
- 0b11: All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]
The starting address for the range of the maintenance instruction.
When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

    end  
elsif PSTATE.EL == EL2 then  
    TLBI_RVAAE1(X[t]);  
elsif PSTATE.EL == EL3 then  
    TLBI_RVAAE1(X[t]);
C5.5.26 TLBI RVAAE1IS, TLB Range Invalidate by VA, All ASID, EL1, Inner Shareable

The TLBI RVAAE1IS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.
- The entry is within the address range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM}+1)*2^{5*\text{SCALE}+1})*\text{Translation_Granule_Size}]\).

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

---

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 0000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVAAE1IS are UNDEFINED.
RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI RVAAEI1S is a 64-bit System instruction.

**Field descriptions**

The TLBI RVAAEI1S input value bit assignments are:

C5.5.27 TLBI RVAAE1OS, TLB Range Invalidate by VA, All ASID, EL1, Outer Shareable

The TLBI RVAAE1OS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*2^(5*SCALE +1) * Translation_Granule_Size)].

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 0000000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 00000000000000000000000000.

Configurations

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVAAE1OS are UNDEFINED.
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI RVAAE1OS is a 64-bit System instruction.

Field descriptions

The TLBI RVAAE1OS input value bit assignments are:

RES0

Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00  Reserved.
0b01  4K translation granule.
0b10  16K translation granule.
0b11  64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

C5.5.29 TLBI RVAALE1IS, TLB Range Invalidate by VA, All ASID, Last Level, EL1, Inner Shareable

The TLBI RVAALE1IS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3 NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*2^(5*SCALE +1) * Translation_Granule_Size)].

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

Configurations

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVAALE1IS are UNDEFINED.
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI RVAALE1IS is a 64-bit System instruction.

Field descriptions

The TLBI RVAALE1IS input value bit assignments are:

Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00  Reserved.
0b01  4K translation granule.
0b10  16K translation granule.
0b11  64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

end if
C5.5.30 TLBI RVAALE1OS, TLB Range Invalidate by VA, All ASID, Last Level, EL1, Outer Shareable

The TLBI RVAALE1OS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.
- The entry is within the address range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1)*2^{(5\times\text{SCALE} +1) \times \text{Translation\_Granule\_Size}})]\).

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

---

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000000.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVAALE1OS are UNDEFINED.
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI RVAALE1OS is a 64-bit System instruction.

Field descriptions

The TLBI RVAALE1OS input value bit assignments are:

Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

- 0b00  Reserved.
- 0b01  4K translation granule.
- 0b10  16K translation granule.
- 0b11  64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

- 0b00  The entries in the range can be using any level for the translation table entries.
- 0b01  When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries.
  When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10  All entries to invalidate are Level 2 translation table entries.
- 0b11  All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

- When using a 4KB translation granule, this field is BaseADDR[48:12].
- When using a 16KB translation granule, this field is BaseADDR[50:14].
- When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.31 TLBI RVAE1, TLB Range Invalidate by VA, EL1

The TLBI RVAE1 characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.
- The entry is within the address range determined by the formula \[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1) \times 2^{(5 \times \text{SCALE} +1)} \times \text{Translation_Granule_Size})\].

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.$\text{BaseADDR}\times 2^{5\times\text{SCALE}+1}$.
  - If TTL==10 and BaseADDR[20:12] is not equal to 0000000000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.$\text{BaseADDR}\times 2^{5\times\text{SCALE}+1}$.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVAE1 are **UNDEFINED**.

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

TLBI RVAE1 is a 64-bit System instruction.

**Field descriptions**

The TLBI RVAE1 input value bit assignments are:
ASID, bits [63:48]
ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.
Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.
If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

TG, bits [47:46]
Translation granule size.
0b00  Reserved.
0b01  4K translation granule.
0b10  16K translation granule.
0b11  64K translation granule.
The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]
The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]
The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]
TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
0b00  The entries in the range can be using any level for the translation table entries.
0b01  When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries.
       When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10  All entries to invalidate are Level 2 translation table entries.
0b11  All entries to invalidate are Level 3 translation table entries.

C5.5.32 TLBI RVAE1IS, TLB Range Invalidate by VA, EL1, Inner Shareable

The TLBI RVAE1IS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.
- The entry is within the address range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) * 2^{(5 \times \text{SCALE} + 1) \times \text{Translation Granule Size}})]\).

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

--- Note ---

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 0000000000000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.
Configurations

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVAE11S are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI RVAE11S is a 64-bit System instruction.

Field descriptions

TLBI RVAE1OS, TLB Range Invalidate by VA, EL1, Outer Shareable

The TLBI RVAE1OS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.[E2H, TGE] is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.[E2H, TGE] is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.
- The entry is within the address range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1)\times2^{(5\times\text{SCALE} +1)} \times \text{Translation\_Granule\_Size})]\).

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

--- **Note** ---

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.
Conbinations

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLB RVAEI0S are UNDEFINED.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVAE2 are **UNDEFINED**.

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

TLBI RVAE2 is a 64-bit System instruction.

**Field descriptions**

The TLBI RVAE2 input value bit assignments are:
ASID, bits [63:48]

When HCR_EL2.E2H == 1:

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

Otherwise:

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00 Reserved.

0b01 4K translation granule.

0b10 16K translation granule.

0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00 The entries in the range can be using any level for the translation table entries.

0b01 When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries.

When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.

0b10 All entries to invalidate are Level 2 translation table entries.

0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing the TLBI RVAE2 instruction

C5.5.35 TLBI RVAE2IS, TLB Range Invalidate by VA, EL2, Inner Shareable

The TLBI RVAE2IS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA in the specified range determined by the formula \( \text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{(5 \times \text{SCALE} + 1)} \times \text{Translation_Granule_Size}) \), using the EL2 or EL2&0 translation regime.
- If \( \text{HCR_EL2.E2H} = 0 \), the entry is from any level of the translation table walk.
- If \( \text{HCR_EL2.E2H} = 1 \), one of the following applies:
  - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk and matches the specified ASID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If \( \text{TTL} = 01 \) and \( \text{BaseADDR}[29:12] \) is not equal to 000000000000000000.
  - If \( \text{TTL} = 10 \) and \( \text{BaseADDR}[20:12] \) is not equal to 00000000.
- For the 16K translation granule:
  - If \( \text{TTL} = 10 \) and \( \text{BaseADDR}[24:14] \) is not equal to 0000000000.
- For the 64K translation granule:
  - If \( \text{TTL} = 01 \) and \( \text{BaseADDR}[41:16] \) is not equal to 00000000000000000000000000.
  - If \( \text{TTL} = 10 \) and \( \text{BaseADDR}[28:16] \) is not equal to 00000000000.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVAE2IS are **UNDEFINED**.

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

TLBI RVAE2IS is a 64-bit System instruction.

**Field descriptions**

The TLBI RVAE2IS input value bit assignments are:
ASID, bits [63:48]

When HCR_EL2.E2H == 1:

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

Otherwise:

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00  Reserved.
0b01  4K translation granule.
0b10  16K translation granule.
0b11  64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00  The entries in the range can be using any level for the translation table entries.
0b01  When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries.
      When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10  All entries to invalidate are Level 2 translation table entries.
0b11  All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing the TLBI RVAE2IS instruction

Accesses to this register use the following encodings in the System instruction encoding space:

C5.5.36 TLBI RVAE2OS, TLB Range Invalidate by VA, EL2, Outer Shareable

The TLBI RVAE2OS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA in the specified range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{(5 \times \text{SCALE} + 1)} \times \text{Translation_Granule_Size})]\), using the EL2 or EL2&0 translation regime.
- If \(\text{HCR\_EL2\_E2H} = 0\), the entry is from any level of the translation table walk.
- If \(\text{HCR\_EL2\_E2H} = 1\), one of the following applies:
  - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk and matches the specified ASID.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If \(\text{TTL} = 01\) and BaseADDR[29:12] is not equal to 000000000000000000.
  - If \(\text{TTL} = 10\) and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granule:
  - If \(\text{TTL} = 10\) and BaseADDR[24:14] is not equal to 0000000000.
- For the 64K translation granule:
  - If \(\text{TTL} = 01\) and BaseADDR[41:16] is not equal to 000000000000000000000000.
  - If \(\text{TTL} = 10\) and BaseADDR[28:16] is not equal to 000000000000.

Configurations

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVAE2OS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI RVAE2OS is a 64-bit System instruction.

Field descriptions

The TLBI RVAE2OS input value bit assignments are:
ASID, bits [63:48]

When HCR_EL2.E2H == 1:

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

Otherwise:

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

0b00    Reserved.

0b01    4K translation granule.

0b10    16K translation granule.

0b11    64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00    The entries in the range can be using any level for the translation table entries.

0b01    When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries.

When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.

0b10    All entries to invalidate are Level 2 translation table entries.

0b11    All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.37   TLBI RVAE3, TLB Range Invalidate by VA, EL3

The TLBI RVAE3 characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.
- The entry is within the address range determined by the formula \( \text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1) \times 2^{(5 \times \text{SCALE} +1)} \times \text{Translation	extunderscore Granule	extunderscore Size}) \).

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If \( \text{TTL}==01 \) and \( \text{BaseADDR}[29:12] \) is not equal to 000000000000000000.
  - If \( \text{TTL}==10 \) and \( \text{BaseADDR}[20:12] \) is not equal to 00000000.

- For the 16K translation granule:
  - If \( \text{TTL}==10 \) and \( \text{BaseADDR}[24:14] \) is not equal to 0000000000.

- For the 64K translation granule:
  - If \( \text{TTL}==01 \) and \( \text{BaseADDR}[41:16] \) is not equal to 000000000000000000000000.
  - If \( \text{TTL}==10 \) and \( \text{BaseADDR}[28:16] \) is not equal to 000000000000.

C5.5.40 TLBI RVALE1, TLB Range Invalidate by VA, Last level, EL1

The TLBI RVALE1 characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.
- The entry is within the address range determined by the formula \([\text{BaseADDR} \leq \text{VA} \leq \text{BaseADDR} + ((\text{NUM} +1) \times 2^{(5 \times \text{SCALE} +1}) \times \text{Translation_Granule_Size})]\).

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is **UNPREDICTABLE** when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction see *Invalidation of TLB entries from stage 2 translations* on page D5-2650.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVALE1 are **UNDEFINED**.

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

TLBI RVALE1 is a 64-bit System instruction.

**Field descriptions**

The TLBI RVALE1 input value bit assignments are:
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00  The entries in the range can be using any level for the translation table entries.

0b01  When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries.

When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.

0b10  All entries to invalidate are Level 2 translation table entries.

0b11  All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing the TLBI RVALE1 instruction

Accesses to this register use the following encodings in the System instruction encoding space:

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

TG, bits [47:46]

Translation granule size.

0b00  Reserved.

0b01  4K translation granule.

0b10  16K translation granule.

0b11  64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

C5.5.41 TLBI RVALE1IS, TLB Range Invalidate by VA, Last level, EL1, Inner Shareable

The TLBI RVALE1IS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.
- The entry is within the address range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1)\times2^{(5\times\text{SCALE} +1)}\times\text{Translation_Granule_Size})]\).

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

**Configurations**

This instruction is present only when ARMv8.4-TLB is implemented. Otherwise, direct accesses to TLBI RVALE1IS are UNDEFINED.
RW fields in this register reset to architecturally UNKNOWN values.

C5.5.42   TLBI RVALE1OS, TLB Range Invalidate by VA, Last level, EL1, Outer Shareable

The TLBI RVALE1OS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.
- The entry is within the address range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1)\times2^{5\times\text{SCALE}} +1) \times \text{Translation\_Granule\_Size})\).

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000000.

Configurations

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVALE1OS are UNDEFINED.
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI RVALE1OS is a 64-bit System instruction.

Field descriptions

The TLBI RVALE1OS input value bit assignments are:

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

TG, bits [47:46]

Translation granule size.

0b00 Reserved.
0b01 4K translation granule.
0b10 16K translation granule.
0b11 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.

0b00 The entries in the range can be using any level for the translation table entries.
0b01 When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries.
  When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10 All entries to invalidate are Level 2 translation table entries.
0b11 All entries to invalidate are Level 3 translation table entries.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.
When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.43 TLBI RVALE2, TLB Range Invalidate by VA, Last level, EL2

The TLBI RVALE2 characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA in the specified range determined by the formula \([\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \times 2^{5 \times \text{SCALE} + 1} \times \text{Translation_Granule_Size})]\) using the EL2 or EL2\&0 translation regime.
- If \(\text{HCR\_EL2.E2H} = 0\), the entry is from the final level of the translation table walk.
- If \(\text{HCR\_EL2.E2H} = 1\), one of the following applies:
  - The entry is a global entry from the final level of translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk and matches the specified ASID.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 0000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVALE2 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI RVALE2 is a 64-bit System instruction.

**Field descriptions**

The TLBI RVALE2 input value bit assignments are:

```
63  48  47  46  45  44  43  39  38  37  36  0
| ASID | TG | NUM | TTL | BaseADDR |
```

**ASID, bits [63:48]**

*When HCR\_EL2.E2H == 1:*

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.
Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

**Otherwise:**

Reserved, RES0.

**TG, bits [47:46]**

Translation granule size.

- 0b00 Reserved.
- 0b01 4K translation granule.
- 0b10 16K translation granule.

C5.5.44 TLBI RVALE2IS, TLB Range Invalidate by VA, Last level, EL2, Inner Shareable

The TLBI RVALE2IS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA in the specified range determined by the formula 
  \[ \text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1)\times2^{(5\times\text{SCALE} + 1)} \times \text{Translation_Granule_Size}) \] using the EL2 or EL2&0 translation regime.
- If \( HCR\_EL2.E2H = 0 \), the entry is from the final level of the translation table walk.
- If \( HCR\_EL2.E2H = 1 \), one of the following applies:
  - The entry is a global entry from the final level of translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk and matches the specified ASID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If \( TTL=01 \) and \( \text{BaseADDR}[29:12] \) is not equal to 000000000000000000.
  - If \( TTL=10 \) and \( \text{BaseADDR}[20:12] \) is not equal to 00000000.
- For the 16K translation granule:
  - If \( TTL=10 \) and \( \text{BaseADDR}[24:14] \) is not equal to 00000000000.
- For the 64K translation granule:
  - If \( TTL=01 \) and \( \text{BaseADDR}[41:16] \) is not equal to 00000000000000000000000000.
  - If \( TTL=10 \) and \( \text{BaseADDR}[28:16] \) is not equal to 000000000000.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVALE2IS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI RVALE2IS is a 64-bit System instruction.

**Field descriptions**

The TLBI RVALE2IS input value bit assignments are:

```
   63  48  47  46  45  44  43  39  38  37  36  0
  ASID  TG  NUM  TTL  BaseADDR
   SCALE
```

**ASID, bits [63:48]**

*When \( HCR\_EL2.E2H = 1 \):*

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.
Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

**Otherwise:**

Reserved, RES0.

**TG, bits [47:46]**
Translation granule size.
- 0b00: Reserved.
- 0b01: 4K translation granule.
- 0b10: 16K translation granule.
- 0b11: 64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

**SCALE, bits [45:44]**
The exponent element of the calculation that is used to produce the upper range.

**NUM, bits [43:39]**
The base element of the calculation that is used to produce the upper range.

**TTL, bits [38:37]**
TTL Level hint. The TTL hint is only guaranteed to invalidate entries in the range that match the level described by the TTL hint.
- 0b00: The entries in the range can be using any level for the translation table entries.
- 0b01: When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
- 0b10: All entries to invalidate are Level 2 translation table entries.
- 0b11: All entries to invalidate are Level 3 translation table entries.

**BaseADDR, bits [36:0]**
The starting address for the range of the maintenance instruction.
When using a 4KB translation granule, this field is BaseADDR[48:12].
When using a 16KB translation granule, this field is BaseADDR[50:14].
When using a 64KB translation granule, this field is BaseADDR[52:16].

**Executing the TLBI RVALE2IS instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

**TLBI RVALE2IS{, <Xt>}**

<table>
<thead>

C5.5.45 TLBI RVALE2OS, TLB Range Invalidate by VA, Last level, EL2, Outer Shareable

The TLBI RVALE2OS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA in the specified range determined by the formula \[ \text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} + 1) \times (5 \times \text{SCALE} + 1) \times \text{Translation Granule Size}) \] using the EL2 or EL2&0 translation regime.
- If HCR_EL2.E2H == 0, the entry is from the final level of the translation table walk.
- If HCR_EL2.E2H == 1, one of the following applies:
  - The entry is a global entry from the final level of translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk and matches the specified ASID.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 00000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 000000000000.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RVALE2OS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI RVALE2OS is a 64-bit System instruction.

**Field descriptions**

The TLBI RVALE2OS input value bit assignments are:

```
+----------------+----------------+----------------+----------------+
| 63  48  47  46 45  44  43 39  38  37  36 0  |
| ASID  TG  NUM  TTL  BaseADDR  |
+----------------+----------------+----------------+----------------+----------------+
```

**ASID, bits [63:48]**

*When HCR_EL2.E2H == 1:*

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.
Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

Otherwise:

Reserved, RES0.

TG, bits [47:46]
Translation granule size.

0b00  Reserved.
0b01  4K translation granule.
0b10  16K translation granule.
0b11  64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]
The exponent element of the calculation that is used to produce the upper range.

end
C5.5.46 TLBI RALE3, TLB Range Invalidate by VA, Last level, EL3

The TLBI RALE3 characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.
- The entry is within the address range determined by the formula $[\text{BaseADDR} \leq \text{VA} < \text{BaseADDR} + ((\text{NUM} +1) \times 2^{(5 \times \text{SCALE} +1)} \times \text{Translation\_Granule\_Size})]$.

The invalidation applies to the PE that executes this System instruction.

The range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

Configurations

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI RALE3 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI RALE3 is a 64-bit System instruction.

Field descriptions

C5.5.49 TLBI VAAE1, TLB Invalidate by VA, All ASID, EL1

The TLBI VAAE1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to the PE that executes this System instruction.

Note

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

Configurations

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI VAAE1 is a 64-bit System instruction.

Field descriptions

The TLBI VAAE1 input value bit assignments are:

<table>
<thead>
<tr>
<th>Bits [63:48]</th>
<th>Reserved, RES0.</th>

</tbody>
</table>
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

0b11: Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level
0bxxx is encoded as:
  0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  0b01: Reserved. Treat as if TTL<3:2> is 0b00.
  0b10: Level 2.
  0b11: Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level
0bxxx is encoded as:
  0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  0b01: Level 1.
  0b10: Level 2.
  0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction,
then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be
affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and
so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:
• Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
• Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[13:12] have no effect on the operation of the
  instruction.
• Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[15:12] have no effect on the operation of the
  instruction.

Executing the TLBI VAAE1 instruction

Accesses to this register use the following encodings in the System instruction encoding space:

TLBI VAAE1(, <Xt>)

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b01</td>
<td>0b000</td>
<td>0b1000</td>
<td>0b0111</td>
<td>0b011</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then
  if EL2Enabled() && !ELUsingAArch32(EL2) && HCR_EL2.TTLB == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
  elsif EL2Enabled() && !ELUsingAArch32(EL2) && HCR_EL2.FB == '1' then
    TLBI_VAAE1IS(X[t]);
  else
    TLBI_VAAE1(X[t]);
  endif
elsif PSTATE.EL == EL2 then
  TLBI_VAAE1(X[t]);
endif
elsif PSTATE.EL == EL3 then
TLBI_VAE1(X[t]);
C5.5.50 TLBI VAAE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable

The TLBI VAAE1IS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.
- The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

--- Note ---

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAAE1IS is a 64-bit System instruction.

**Field descriptions**

The TLBI VAAE1IS input value bit assignments are:

![Bit assignments](image)

Bits [63:48] Reserved, RES0.
TTL, bits [47:44]

*When ARMv8.4-TTL is implemented:*

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

- **0b00xx**
  - No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

- **0b01xx**
  - The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
    - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
    - 0b01: Level 1.
    - 0b10: Level 2.
    - 0b11: Level 3.

- **0b10xx**
  - The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
    - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
    - 0b01: Reserved. Treat as if TTL<3:2> is 0b00.
    - 0b10: Level 2.
    - 0b11: Level 3.

- **0b11xx**
  - The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
    - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
    - 0b01: Level 1.
    - 0b10: Level 2.
    - 0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

*Otherwise:*

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

**Executing the TLBI VAAE1IS instruction**

Accesses to this register use the following encodings in the System instruction encoding space:
TLBI VAAE1IS(, <X[t]>)

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>

elsif PSTATE.EL == EL3 then
  TLBI_VAAE1IS(X[t]);
C5.5.51 TLBI VAAE1OS, TLB Invalidate by VA, All ASID, EL1, Outer Shareable

The TLBI VAAE1OS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI VAAE1OS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI VAAE1OS is a 64-bit System instruction.

**Field descriptions**

The TLBI VAAE1OS input value bit assignments are:
**Bits [63:48]**

Reserved, RES0.

**TTL, bits [47:44]**

*When ARMv8.4-TTL is implemented:*

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

- **0b00xx** No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

- **0b01xx** The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.

- **0b10xx** The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b10: Level 2.
  - 0b11: Level 3.

- **0b11xx** The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.

C5.5.52 TLBI VAAL E1, TLB Invalidate by VA, All ASID, Last level, EL1

The TLBI VAALLE1 characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of `SCR_EL3.NS`:
  - If `HCR_EL2.{E2H, TGE}` is not `{1, 1}`, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If `HCR_EL2.{E2H, TGE}` is `{1, 1}`, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to the PE that executes this System instruction.

**Note**

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI VAALLE1 is a 64-bit System instruction.

**Field descriptions**

The TLBI VAALLE1 input value bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>48-47</td>
<td>TTL</td>
</tr>
<tr>
<td>44-43</td>
<td>VA[55:12]</td>
</tr>
</tbody>
</table>

**Bits [63:48]**

Reserved, RES0.

**TTL, bits [47:44]**

*When ARMv8.4-TTL is implemented:*

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

- `0b00xx`: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- `0b01xx`: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b0: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b10: Level 2.
The entry comes from a 16KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Reserved. Treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3.

The entry comes from a 64KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction,
then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be
affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and
so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[13:12] have no effect on the operation of the
  instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[15:12] have no effect on the operation of the
  instruction.

Executing the TLBI VAALE1 instruction

Accesses to this register use the following encodings in the System instruction encoding space:

TLBI VAALE1(<XP>)

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b01</td>
<td>0b000</td>
<td>0b1000</td>
<td>0b0111</td>
<td>0b111</td>
</tr>
</tbody>
</table>

if PSTATE_EL == EL0 then
  UNDEFINED;
elsif PSTATE_EL == EL1 then
  if EL2Enabled() && !ELUsingAArch32(EL2) && HCR_EL2.TTLB == '1' then
    AArch64.SystemAccessTrap(EL2, 0x18);
  elsif EL2Enabled() && !ELUsingAArch32(EL2) && HCR_EL2.FB == '1' then
    TLBI VAALE1IS(X[t]);
  else
    TLBI VAALE1(X[t]);
  end
elsif PSTATE_EL == EL2 then
  TLBI VAALE1(X[t]);

elsif PSTATE.EL == EL3 then
    TLBI_VALEI(X[t]);
C5.5.53 TLBI VAALE1IS, TLB Invalidate by VA, All ASID, Last Level, EL1, Inner Shareable

The TLBI VAALE1IS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Note**

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VAALE1IS is a 64-bit System instruction.

**Field descriptions**

The TLBI VAALE1IS input value bit assignments are:

```
<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>44</th>
<th>43</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>TTL</td>
<td>VA[55:12]</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Bits [63:48]

Reserved, RES0.
TTL, bits [47:44]

When ARMv8.4-TTL is implemented:
Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

- 0b00xx: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

  - 0b01xx: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
- 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
- 0b01: Level 1.
- 0b10: Level 2.
- 0b11: Level 3.

  - 0b10xx: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
- 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
- 0b01: Level 1.
- 0b10: Level 2.
- 0b11: Level 3.

  - 0b11xx: The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
- 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
- 0b01: Level 1.
- 0b10: Level 2.
- 0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAALE1IS instruction

Accesses to this register use the following encodings in the System instruction encoding space:
**TLBI VAALLE1IS(</span>&lt;Xt&gt;)**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b01</td>
<td>0b000</td>
<td>0b1000</td>
<td>0b0011</td>

else
  TLBI_VAALEIIS(X[t]);
C5.5.54 TLBI VAALE1OS, TLB Invalidate by VA, All ASID, Last Level, EL1, Outer Shareable

The TLBI VAALE1OS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

--- **Note** ---

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For the EL1&0 and EL2&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

--- **Configurations** ---

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI VAALE1OS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

--- **Attributes** ---

TLBI VAALE1OS is a 64-bit System instruction.

--- **Field descriptions** ---

The TLBI VAALE1OS input value bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>48 47</th>
<th>44 43</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>TTL</td>
<td>VA[55:12]</td>
<td></td>
</tr>
</tbody>
</table>
Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When ARMv8.4-TTL is implemented:

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

- **0b00xx**: No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx**: The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.
- **0b10xx**: The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b10: Level 2.
  - 0b11: Level 3.
- **0b11xx**: The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
  - 0b01: Level 1.
  - 0b10: Level 2.
  - 0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAALE1OS instruction

Accesses to this register use the following encodings in the System instruction encoding space:

C5.5.55   TLBI VAE1, TLB Invalidate by VA, EL1

The TLBI VAE1 characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to the PE that executes this System instruction.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI VAE1 is a 64-bit System instruction.

**Field descriptions**

The TLBI VAE1 input value bit assignments are:

```
<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>44</th>
<th>43</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>TTL</td>
<td>VA[55:12]</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**ASID, bits [63:48]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.
TTL, bits [47:44]

When ARMv8.4-TTL is implemented:

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

- **0b00xx**  
  No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

- **0b01xx**  
  The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
  - **0b01**: Level 1.
  - **0b10**: Level 2.
  - **0b11**: Level 3.

- **0b10xx**  
  The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
  - **0b01**: Reserved. Treat as if TTL<3:2> is 0b00.
  - **0b10**: Level 2.
  - **0b11**: Level 3.

- **0b11xx**  
  The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  - **0b00**: Reserved. Treat as if TTL<3:2> is 0b00.
  - **0b01**: Level 1.
  - **0b10**: Level 2.
  - **0b11**: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAE1 instruction

Accesses to this register use the following encodings in the System instruction encoding space:

  TLBI_VAE1(X[t]);
C5.5.56 TLBI VAE1IS, TLB Invalidate by VA, EL1, Inner Shareable

The TLBI VAE1IS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Note**

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI VAE1IS is a 64-bit System instruction.

**Field descriptions**

The TLBI VAE1IS input value bit assignments are:
ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

TTL, bits [47:44]

When ARMv8.4-TTL is implemented:

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

C5.5.57 TLBI VAE1OS, TLB Invalidate by VA, EL1, Outer Shareable

The TLBI VAE1OS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

--- Note ---

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI VAE1OS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI VAE1OS is a 64-bit System instruction.

**Field descriptions**

The TLBI VAE1OS input value bit assignments are:
ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

TTL, bits [47:44]

When ARMv8.4-TTL is implemented:

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Reserved. Treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

• Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
• Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.

• Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

**Executing the TLBI VAE1OS instruction**

C5.5.58     TLBI VAE2, TLB Invalidate by VA, EL2

The TLBI VAE2 characteristics are:

Purpose
When EL2 is implemented and enabled in the current Security state, invalidates cached copies of
translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be required to translate the specified VA using the EL2 or the EL2&0
translation regime.
- If HCR_EL2.E2H == 0, the entry is from any level of the translation table walk.
- If HCR_EL2.E2H == 1 one of the following applies:
  — The entry is from a level of the translation table walk above the final level and matches
    the specified ASID.
  — The entry is a global entry from the final level of the translation table walk.
  — The entry is a non-global entry from the final level of the translation table walk
    and matches the specified ASID.

The invalidation applies to the PE that executes this System instruction.

Configurations
There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes
TLBI VAE2 is a 64-bit System instruction.

Field descriptions
The TLBI VAE2 input value bit assignments are:

ASID, bits [63:48]
ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by
this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless
of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being
invalidated, the upper bits are RES0.

TTL, bits [47:44]
When ARMv8.4-TTL is implemented:
Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the
address being invalidated.

- 0b00xx: No information supplied as to the translation table level. Hardware must assume that the
  entry can be from any level. In this case, TTL<1:0> is RES0.
- 0b01xx: The entry comes from a 4KB translation granule. The level of walk for the leaf level
  0bxx is encoded as:
    0b00: Reserved. Treat as if TTL<3:2> is 0b00.
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

0b01: Level 1.
0b10: Level 2.
0b11: Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
0b00: Reserved. Treat as if TTL<3:2> is 0b00.
0b01: Reserved. Treat as if TTL<3:2> is 0b00.
0b10: Level 2.
0b11: Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
0b00: Reserved. Treat as if TTL<3:2> is 0b00.
0b01: Level 1.
0b10: Level 2.
0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction,
then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value
(if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and
so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored
when the instruction is executed, because VA[13:12] have no effect on the operation of the
instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored
when the instruction is executed, because VA[15:12] have no effect on the operation of the
instruction.

Executing the TLBI VAE2 instruction

Accesses to this register use the following encodings in the System instruction encoding space:

**TLBI VAE2(, <Xt>)**

<table>
<thead>
<tr>

else
    TLBI_VAE2(X[t]);
C5.5.59 TLBI VAE2IS, TLB Invalidate by VA, EL2, Inner Shareable

The TLBI VAE2IS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be required to translate the specified VA using the EL2 or the EL2&0 translation regime.
- If HCR_EL2.E2H == 0, the entry is from any level of the translation table walk.
- If HCR_EL2.E2H == 1 one of the following applies:
  - The entry is from a level of the translation table walk above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of the translation table walk and matches the specified ASID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI VAE2IS is a 64-bit System instruction.

**Field descriptions**

The TLBI VAE2IS input value bit assignments are:

```
<table>
<thead>
<tr>
<th>63</th>
<th>48 47</th>
<th>44 43</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>TTL</td>
<td>VA[55:12]</td>
<td></td>
</tr>
</tbody>
</table>
```

**ASID, bits [63:48]**

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

**TTL, bits [47:44]**

*When ARMv8.4-TTL is implemented:*

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

- **0b00xx** No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- **0b01xx** The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Reserved. Treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction,
then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]
Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value
(if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and
so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.
The treatment of the low-order bits of this field depends on the translation granule size, as follows:
• Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
• Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[13:12] have no effect on the operation of the
  instruction.
• Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[15:12] have no effect on the operation of the
  instruction.

Executing the TLBI VAE2IS instruction

</tr>
<tr>
<td>ASID</td>
<td>TTL</td>
<td>VA[55:12]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**ASID, bits [63:48]**

*When HCR_EL2.E2H == 1:*

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

*Otherwise:*

Reserved, RES0.
TTL, bits [47:44]

When ARMv8.4-TTL is implemented:

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

- \(0b00xx\) No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
- \(0b01xx\) The entry comes from a 4KB translation granule. The level of walk for the leaf level \(0bxx\) is encoded as:
  - \(0b00\): Reserved. Treat as if TTL<3:2> is 0b00.
  - \(0b01\): Level 1.
  - \(0b10\): Level 2.
  - \(0b11\): Level 3.
- \(0b10xx\) The entry comes from a 16KB translation granule. The level of walk for the leaf level \(0bxx\) is encoded as:
  - \(0b00\): Reserved. Treat as if TTL<3:2> is 0b00.
  - \(0b01\): Reserved. Treat as if TTL<3:2> is 0b00.
  - \(0b10\): Level 2.
  - \(0b11\): Level 3.
- \(0b11xx\) The entry comes from a 64KB translation granule. The level of walk for the leaf level \(0bxx\) is encoded as:
  - \(0b00\): Reserved. Treat as if TTL<3:2> is 0b00.
  - \(0b01\): Level 1.
  - \(0b10\): Level 2.
  - \(0b11\): Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

elsif PSTATE.EL == EL3 then
    TLBI_VAE3OS(X[t]);
The TLBI VALE1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

• The entry is a stage 1 translation table entry.
• The entry would be used to translate the specified VA, and one of the following applies:
  — The entry is a global entry from the final level of lookup.
  — The entry is a non-global entry from the final level of lookup that matches the specified ASID.
• When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  — If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  — If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
• When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to the PE that executes this System instruction.

Configurations

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI VALE1 is a 64-bit System instruction.

Field descriptions

The TLBI VALE1 input value bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>44</th>
<th>43</th>
<th>...</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>TTL</td>
<td>VA[55:12]</td>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

TTL, bits [47:44]

When ARMv8.4-TTL is implemented:

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxxx is encoded as:

- 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
- 0b01: Level 1.
- 0b10: Level 2.
- 0b11: Level 3.

The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxxx is encoded as:

- 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
- 0b01: Level 1.
- 0b10: Level 2.
- 0b11: Level 3.

The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxxx is encoded as:

- 0b00: Reserved. Treat as if TTL<3:2> is 0b00.
- 0b01: Level 1.
- 0b10: Level 2.
- 0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

**Otherwise:**

Reserved, RES0.

**VA[55:12], bits [43:0]**

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

**Executing the TLBI VALE1 instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

**TLBI VALE1{, <Xt>}**

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>
<th>op2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b01</td>
<td>0b000</td>
<td>0b1000</td>
<td>0b0111</td>
<td>0b101</td>
</tr>
</tbody>
</table>

if PSTATE.EL == EL0 then
undeR|-----|-----|-----|-----|
| if EL2Enabled() & ELUsingAArch32(EL2) & HCR_EL2.TTLB == '1' then
| AArch64.SystemAccessTrap(EL2, 0x18);
| elseif EL2Enabled() & ELUsingAArch32(EL2) & HCR_EL2.FB == '1' then
TLBI_VALEIS(X[t]);

elsif PSTATE_EL == EL3 then
  TLBI_VAAE1(X[t]);
C5.5.65   TLBI VALE1IS, TLB Invalidate by VA, Last level, EL1, Inner Shareable

The TLBI VALE1IS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

**Note**

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI VALE1IS is a 64-bit System instruction.

ASID: 63:48
TTL: 47:44
VA[55:12]: 43:0
ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

TTL, bits [47:44]

When ARMv8.4-TTL is implemented:

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

<table>
<thead>
<tr>
<th>TTL&lt;3:2&gt;</th>
<th>Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Reserved. Treat as if TTL&lt;3:2&gt; is 0b00.</td>
</tr>
<tr>
<td>0b01</td>
<td>Level 1.</td>
</tr>
<tr>
<td>0b10</td>
<td>Level 2.</td>
</tr>
<tr>
<td>0b11</td>
<td>Level 3.</td>
</tr>
</tbody>
</table>

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

<table>
<thead>
<tr>
<th>TTL&lt;3:2&gt;</th>
<th>Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Reserved. Treat as if TTL&lt;3:2&gt; is 0b00.</td>
</tr>
<tr>
<td>0b01</td>
<td>Reserved. Treat as if TTL&lt;3:2&gt; is 0b00.</td>
</tr>
<tr>
<td>0b10</td>
<td>Level 2.</td>
</tr>
<tr>
<td>0b11</td>
<td>Level 3.</td>
</tr>
</tbody>
</table>

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

<table>
<thead>
<tr>
<th>TTL&lt;3:2&gt;</th>
<th>Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Reserved. Treat as if TTL&lt;3:2&gt; is 0b00.</td>
</tr>
<tr>
<td>0b01</td>
<td>Level 1.</td>
</tr>
<tr>
<td>0b10</td>
<td>Level 2.</td>
</tr>
<tr>
<td>0b11</td>
<td>Level 3.</td>
</tr>
</tbody>
</table>

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.
Executing the TLBI VALE1IS instruction

Accesses to this register use the following encodings in the System instruction encoding space:

\[
\text{TLBI VALE1IS}(\langle X[t]\rangle)
\]

<table>
<thead>
<tr>

      TLBI_VALE1IS(X[t]);
   endif
elsif PSTATE.EL == EL2 then
   TLBI_VALE1IS(X[t]);
elsif PSTATE.EL == EL3 then
   TLBI_VALE1IS(X[t]);
C5.5.66 TLBI VALE1OS, TLB Invalidate by VA, Last level, EL1, Outer Shareable

The TLBI VALE1OS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

**Note**

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI VALE1OS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI VALE1OS is a 64-bit System instruction.

**Field descriptions**

The TLBI VALE1OS input value bit assignments are:
ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

TTL, bits [47:44]

When ARMv8.4-TTL is implemented:

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Reserved. Treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as:

0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
Where a 16KB translation granule is being used, bits [1:0] of this field are \texttt{RES0} and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.

Where a 64KB translation granule is being used, bits [3:0] of this field are \texttt{RES0} and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

```
C5.5.67   TLBI VALE2, TLB Invalidate by VA, Last level, EL2

The TLBI VALE2 characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA using the EL2 or EL2&0 translation regime.
- If HCR_EL2.E2H == 0, the entry is from the final level of the translation table walk.
- If HCR_EL2.E2H == 1, one of the following applies:
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of translation table walk that matches the specified ASID.

The invalidation applies to the PE that executes this System instruction.

**Configurations**

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI VALE2 is a 64-bit System instruction.

**Field descriptions**

The TLBI VALE2 input value bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>48</th>
<th>47</th>
<th>44</th>
<th>43</th>
<th>0</th>

C5.5.68 TLBI VALE2IS, TLB Invalidate by VA, Last level, EL2, Inner Shareable

The TLBI VALE2IS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

• The entry is a stage 1 translation table entry.
• The entry would be used to translate the specified VA using the EL2 or EL2&0 translation regime.
• If HCR_EL2.E2H == 0, the entry is from the final level of the translation table walk.
• If HCR_EL2.E2H == 1, one of the following applies:
  — The entry is a global entry from the final level of the translation table walk.
  — The entry is a non-global entry from the final level of translation table walk that matches the specified ASID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Configurations

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI VALE2IS is a 64-bit System instruction.

Field descriptions

The TLBI VALE2IS input value bit assignments are:

<table>
<thead>
<tr>
<th>63</th>
<th>48 47</th>
<th>44 43</th>
<th>43 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASID</td>
<td>TTL</td>
<td>VA[55:12]</td>
<td></td>
</tr>
</tbody>
</table>

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

TTL, bits [47:44]

When ARMv8.4-TTL is implemented:

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

0b00xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

0b01xx The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as:
  0b0 : Reserved. Treat as if TTL<3:2> is 0b00.
  0b01 : Level 1.
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

0b10 : Level 2.
0b11 : Level 3.

0b10xx The entry comes from a 16KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Reserved. Treat as if TTL<3:2> is 0b00.
0b10 : Level 2.
0b11 : Level 3.

0b11xx The entry comes from a 64KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
0b00 : Reserved. Treat as if TTL<3:2> is 0b00.
0b01 : Level 1.
0b10 : Level 2.
0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction,
then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value
(if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and
so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:
• Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
• Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[13:12] have no effect on the operation of the
  instruction.
• Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[15:12] have no effect on the operation of the
  instruction.

else
    TLBI_VALE2IS(X[t]);
C5.5.69 TLBI VALE2OS, TLB Invalidate by VA, Last level, EL2, Outer Shareable

The TLBI VALE2OS characteristics are:

**Purpose**

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA using the EL2 or EL2&0 translation regime.
- If $HCR\_EL2.E2H == 0$, the entry is from the final level of the translation table walk.
- If $HCR\_EL2.E2H == 1$, one of the following applies:
  - The entry is a global entry from the final level of the translation table walk.
  - The entry is a non-global entry from the final level of translation table walk that matches the specified ASID.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI VALE2OS are **UNDEFINED**.

RW fields in this register reset to architecturally **UNKNOWN** values.

**Attributes**

TLBI VALE2OS is a 64-bit System instruction.

**Field descriptions**

The TLBI VALE2OS input value bit assignments are:

```
63  48  47  44  43    0
   |   |   |   |   |
  ASID TTL VA[55:12]
```

**ASID, bits [63:48]**

*When $HCR\_EL2.E2H == 1$:*

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are **RES0**.

*Otherwise:*

Reserved, **RES0**.

**TTL, bits [47:44]**

*When ARMv8.4-TTL is implemented:*

Translation Table Level. Indicates the level of the page table walk that holds the leaf entry for the address being invalidated.

0000xx No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is **RES0**.
The A64 System Instruction Class
C5.5 A64 System instructions for TLB maintenance

The entry comes from a 4KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
0b00: Reserved. Treat as if TTL<3:2> is 0b00.
0b01: Level 1.
0b10: Level 2.
0b11: Level 3.

The entry comes from a 16KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
0b00: Reserved. Treat as if TTL<3:2> is 0b00.
0b01: Reserved. Treat as if TTL<3:2> is 0b00.
0b10: Level 2.
0b11: Level 3.

The entry comes from a 64KB translation granule. The level of walk for the leaf level
0bxx is encoded as:
0b00: Reserved. Treat as if TTL<3:2> is 0b00.
0b01: Level 1.
0b10: Level 2.
0b11: Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction,
then no entries are required by the architecture to be invalidated from the TLB.

**Otherwise:**
Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value
(if appropriate) and VA will be affected by this System instruction.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and
so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[13:12] have no effect on the operation of the
  instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored
  when the instruction is executed, because VA[15:12] have no effect on the operation of the
  instruction.

**Executing the TLBI VALE2OS instruction**

TLBI VMALLE1, TLB Invalidate by VMID, All at stage 1, EL1

The TLBI VMALLE1 characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to the PE that executes this System instruction.

**Note**

For the EL1&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VMALLE1 is a 64-bit System instruction.

**Field descriptions**

TLBI VMALLE1 ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBI VMALLE1 instruction**

Accesses to this register use the following encodings in the System instruction encoding space:

C5.5.74 TLBI VMALLE1IS, TLB Invalidate by VMID, All at stage 1, EL1, Inner Shareable

The TLBI VMALLE1IS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

--- Note ---

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For the EL1&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

**Configurations**

There are no configuration notes.

**Attributes**

TLBI VMALLE1IS is a 64-bit System instruction.

**Field descriptions**

TLBI VMALLE1IS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBI VMALLE1IS instruction**

Accesses to this register use the following encodings in the System instruction encoding space:
TLBI VMALLE1IS(, <Xt>)

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>
<th>CRn</th>
<th>CRm</th>

elsif PSTATE.EL == EL3 then
  TLBI_VMALLE1IS();
C5.5.75 TLBI VMALLE1OS, TLB Invalidate by VMID, All at stage 1, EL1, Outer Shareable

The TLBI VMALLE1OS characteristics are:

**Purpose**

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- When EL2 is implemented and enabled in the Security state described by the current value of SCR_EL3.NS:
  - If HCR_EL2.{E2H, TGE} is not \{1, 1\}, the entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime.
  - If HCR_EL2.{E2H, TGE} is \{1, 1\}, the entry would be required to translate the specified VA using the EL2&0 translation regime.
- When EL2 is not implemented or is disabled in the current Security state, the entry would be required to translate the specified VA using the EL1&0 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

--- Note ---

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For the EL1&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

---

**Configurations**

This instruction is present only when ARMv8.4-TLBI is implemented. Otherwise, direct accesses to TLBI VMALLE1OS are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

TLBI VMALLE1OS is a 64-bit System instruction.

**Field descriptions**

TLBI VMALLE1OS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

**Executing the TLBI VMALLE1OS instruction**

Accesses to this register use the following encodings in the System instruction encoding space:
if PSTATE.EL == EL0 then
  UNDEFINED;
elsif PSTATE.EL == EL1 then
  if EL2Enabled() && !ELUsingAArch32(EL2) && HCR_EL2.TTLB == '1' then

elsif PSTATE.EL == EL3 then
  TLB_VMALLE1OS();
C5.5.76 TLBI VMALLS12E1, TLB Invalidate by VMID, All at Stage 1 and 2, EL1

The TLBI VMALLS12E1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If SCR_EL3.NS is 0, then
  - The entry would be required to translate an address using the Secure EL1&0 translation regime.
  - If ARMv8.4-SecEL2 is implemented and enabled, the entry would be used with the current VMID.
- If SCR_EL3.NS is 1, then:
  - The entry would be required to translate an address using the Non-secure EL1&0 translation regime.
  - If Non-secure EL2 is implemented, the entry would be used with the current VMID.

The invalidation applies to the PE that executes this System instruction.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

Configurations

There are no configuration notes.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TLBI VMALLS12E1 is a 64-bit System instruction.

Field descriptions

TLBI VMALLS12E1 ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBI VMALLS12E1 instruction

Accesses to this register use the following encodings in the System instruction encoding space:

TLBI VMALLS12E1{, <X>}

<table>
<thead>
<tr>
<th>op0</th>
<th>op1</th>

        TLBI_VMALLS12E1();

C5.5.77 TLBI VMALLS12E1IS, TLB Invalidate by VMID, All at Stage 1 and 2, EL1, Inner Shareable

The TLBI VMALLS12E1IS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If SCR_EL3.NS is 0, then
  - The entry would be required to translate an address using the Secure EL1&0 translation regime.
  - If ARMv8.4-SecEL2 is implemented and enabled, the entry would be used with the current VMID.
- If SCR_EL3.NS is 1, then:
  - The entry would be required to translate an address using the Non-secure EL1&0 translation regime.
  - If Non-secure EL2 is implemented, the entry would be used with the current VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, or would be defined to pass a VMID argument if SCR_EL3.EEL2==1, then:

- A PE with SCR_EL3.EEL2==1 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==0.
- A PE with SCR_EL3.EEL2==0 is not architecturally required to invalidate any entries in the Secure EL1&0 translation of a PE in the same required shareability domain with SCR_EL3.EEL2==1.
- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For the EL1&0 translation regimes, the invalidation applies to both global entries, and non-global entries with any ASID.

Configurations

There are no configuration notes.

C5.6 A64 System instructions for prediction restriction

This section lists the A64 System instructions for prediction restriction.
C5.6.1 CFP RCTX, Control Flow Prediction Restriction by Context

The CFP RCTX characteristics are:

**Purpose**

Control Flow Prediction Restriction by Context applies to all Control Flow Prediction Resources that predict execution based on information gathered within the target execution context or contexts. When this instruction is complete and synchronized, control flow prediction does not permit later speculative execution within the target execution context to be observable through side channels.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

--- Note ---

This instruction does not require the invalidation of prediction structures so long as the behavior described for completion of this instruction is met by the implementation.

On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

**Configurations**

This instruction is present only when ARMv8.0-PredInv is implemented. Otherwise, direct accesses to CFP RCTX are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CFP RCTX is a 64-bit System instruction.

**Field descriptions**

The CFP RCTX input value bit assignments are:

```
   63  49  48  47  32  31  27  26  25  24  23  17  16  15  0
       RES0  VMID  RES0  NS  EL  RES0  ASID

   GASID

   GVMID
```

**Bits [63:49]**

Reserved, RES0.

**GVMID, bit [48]**

Execution of this instruction applies to all VMIDs or a specified VMID.

- 0b0 Applies to specified VMID for an EL0 or EL1 context. For all other contexts this field is RES0.
- 0b1 Applies to all VMIDs for an EL0 or EL1 context. For all other contexts this field is RES0.

If the instruction is executed at EL0 or EL1, then this field has an Effective value of 0.

**VMID, bits [47:32]**

Only applies when bit [48] is 0 and either:
- an EL1 context.
• an EL0 context when (HCR_EL2.E2H==0 or HCR_EL2.TGE==0).

Otherwise this field is RES0.

When the instruction is executed at EL1 then this field is treated as the current VMID.

When the instruction is executed at EL0 and (HCR_EL2.E2H==0 or HCR_EL2.TGE==0) then this field is treated as the current VMID.

When the instruction is executed at EL0 and (HCR_EL2.E2H==1 and HCR_EL2.TGE==1) then this field is ignored.

Bits [31:27]

Reserved, RES0.

NS, bit [26]

Security State

0b0 Secure state

0b1 Non-secure state

If the instruction is executed in Non-secure state, this field has an Effective value of 1.

EL, bits [25:24]

Exception Level

0b00 EL0.

0b01 EL1.

0b10 EL2.

0b11 EL3.

If the instruction is executed at an exception level lower than the specified level, this instruction is treated as a NOP.

Bits [23:17]

Reserved, RES0.

GASID, bit [16]

Execution of this instruction applies to all ASIDs or a specified ASID.

0b0 Applies to specified ASID for an EL0 context. For all other contexts this field is RES0.

0b1 Applies to all ASID for an EL0 context. For all other contexts this field is RES0.

If the instruction is executed at EL0, then this field has an Effective value of 0.

ASID, bits [15:0]

Only applies for an EL0 context and when bit[16] is 0.

Otherwise this field is RES0.

When the instruction is executed at EL0 then this field is treated as the current ASID.

Executing the CFP RCTX instruction

Accesses to this register use the following encodings in the System instruction encoding space:
### CFP RCTX, <Xt>

<table>

C5.6.2 CPP RCTX, Cache Prefetch Prediction Restriction by Context

The CPP RCTX characteristics are:

**Purpose**

Cache Prefetch Prediction Restriction by Context applies to all Cache Allocation Resources that predict cache allocations based on information gathered within the target execution context or contexts.

When this instruction is complete and synchronized, cache prefetch prediction does not permit later speculative execution within the target execution context to be observable through side channels.

This instruction applies to all:

- Instruction caches.
- Data caches.
- TLB prefetching hardware used by the executing PE that applies to the supplied context or contexts.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

**Note**

This instruction does not require the invalidation of Cache Allocation Resources so long as the behavior described for completion of this instruction is met by the implementation.

On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

**Configurations**

This instruction is present only when ARMv8.0-PredInv is implemented. Otherwise, direct accesses to CPP RCTX are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

**Attributes**

CPP RCTX is a 64-bit System instruction.

0b00 EL0.
0b01 EL1.
0b10 EL2.
0b11 EL3.
If the instruction is executed at an exception level lower than the specified level, this instruction is treated as a NOP.

Bits [23:17]
Reserved, RES0.

GASID, bit [16]
Execution of this instruction applies to all ASIDs or a specified ASID.
0b0 Applies to specified ASID for an EL0 context. For all other contexts this field is RES0.
0b1 Applies to all ASID for an EL0 context. For all other contexts this field is RES0.
If the instruction is executed at EL0, then this field has an Effective value of 0.

ASID, bits [15:0]
Only applies for an EL0 context and when bit[16] is 0.
Otherwise this field is RES0.
When the instruction is executed at EL0 then this field is treated as the current ASID.

Executing the DVP RCTX instruction
Accesses to this register use the following encodings in the System instruction encoding space:
DVP RCTX, <Xt>

<table>
<thead>
<tr>
<th>op0</th>
<th>CRn</th>
<th>op1</th>
<th>op2</th>
<th>CRm</th>

        DVP_RCTX(X[t]);
      else
        if PSTATE.EL == EL3 then
          DVP_RCTX(X[t]);
Chapter C6
A64 Base Instruction Descriptions

This chapter describes the A64 base instructions.

It contains the following sections:

• About the A64 base instructions on page C6-750.
• Alphabetical list of A64 base instructions on page C6-753.
C6.1 About the A64 base instructions

Alphabetical list of A64 base instructions on page C6-753 gives full descriptions of the A64 instructions that are in the following instruction groups:

- Branch, Exception generation, and System instructions.
- Loads and stores associated with the general-purpose registers.
- Data processing (immediate).
- Data processing (register).

A64 instruction set encoding on page C4-252 provides an overview of the instruction encodings as well as of the instruction classes within their functional groups.

The rest of this section is general description of the base instructions. It contains the following subsections:

- Register size.
- Use of the PC.
- Use of the stack pointer on page C6-751.
- Condition flags and related instructions on page C6-751.

C6.1.1 Register size

Most data processing, comparison, and conversion instructions that use the general-purpose registers as the source or destination operand have two instruction variants that operate on either a 32-bit or a 64-bit value.

Where a 32-bit instruction form is selected, the following holds:

- The upper 32 bits of the source registers are ignored.
- The upper 32 bits of the destination register are set to zero.
- Right shifts and right rotates inject at bit[31], not at bit[63].
- The Condition flags, where set by the instruction, are computed from the lower 32 bits.

This distinction applies even when the results of a 32-bit instruction form are indistinguishable from the lower 32 bits computed by the equivalent 64-bit instruction form. For example, a 32-bit bitwise ORR could be performed using a 64-bit ORR and simply ignoring the top 32 bits of the result. However, the A64 instruction set includes separate 32-bit and 64-bit forms of the ORR instruction.

As well as distinct sign-extend or zero-extend instructions, the A64 instruction set also provides the ability to extend and shift the final source register of an ADD, SUB, ADDS, or SUBS instruction and the index register of a Load/Store instruction. This enables array index calculations involving a 64-bit array pointer and a 32-bit array index to be implemented efficiently.

The assembly language notation enables the distinct identification of registers holding 32-bit values and registers holding 64-bit values. See Register names on page C1-174 and Register indexed addressing on page C1-177.

C6.1.2 Use of the PC

A64 instructions have limited access to the PC. The only instructions that can read the PC are those that generate a PC relative address:

- ADR and ADRP.
- The Load register (literal) instruction class.
- Direct branches that use an immediate offset.
- The unconditional branch with link instructions, BL and BLR, that use the PC to create the return link address.

Only explicit control flow instructions can modify the PC:

- Conditional and unconditional branch and return instructions.
- Exception generation and exception return instructions.
For more details of instructions that can modify the PC, see Branches, Exception generating, and System instructions on page C3-190.

C6.1.3 Use of the stack pointer

A64 instructions can use the stack pointer only in a limited number of cases:

- Load/Store instructions use the current stack pointer as the base address:
  - When stack alignment checking is enabled by system software and the base register is SP, the current stack pointer must be initially quadword aligned. That is, it must be aligned to 16 bytes. Misalignment generates an SP alignment fault. See SP alignment checking on page D1-2287 for more information.

- Add and subtract data processing instructions in their immediate and extended register forms, use the current stack pointer as a source register or the destination register or both.

- Logical data processing instructions in their immediate form use the current stack pointer as the destination register.

C6.1.4 Condition flags and related instructions

The A64 base instructions that use the Condition flags as an input are:

- Conditional branch. The conditional branch instruction is \texttt{B.cond}.

- Add or subtract with carry. These instruction types include instructions to perform multi-precision arithmetic and calculate checksums. The add or subtract with carry instructions are \texttt{ADC}, \texttt{ADCS}, \texttt{SBC}, and \texttt{SBCS}, or an architectural alias for these instructions.

- Conditional select with increment, negate, or invert. This instruction type conditionally selects between one source register and a second, incremented, negated, inverted, or unmodified source register. The conditional select with increment, negate, or invert instructions are \texttt{CSINC}, \texttt{CSINV}, and \texttt{CSNEG}.

  These instructions also implement:
  - Conditional select or move. The Condition flags select one of two source registers as the destination register. Short conditional sequences can be replaced by unconditional instructions followed by a conditional select, \texttt{CSEL}.
  - Conditional set. Conditionally selects between 0 and 1, or 0 and -1. This can be used to convert the Condition flags to a Boolean value or mask in a general-purpose register, for example. These instructions include \texttt{CSET} and \texttt{CSETM}.

- Conditional compare. This instruction type sets the Condition flags to the result of a comparison if the original condition is true, otherwise it sets the Condition flags to an immediate value. It permits the flattening of nested conditional expressions without using conditional branches or performing Boolean arithmetic within the general-purpose registers. The conditional compare instructions are \texttt{COP} and \texttt{CON}.

The A64 base instructions that update the Condition flags as an output are:

- Flag-setting data processing instructions, such as \texttt{ADCS}, \texttt{ADDS}, \texttt{ANDS}, \texttt{BICS}, \texttt{RMIF}, \texttt{SBCS}, \texttt{SETF8}, \texttt{SETF16}, and \texttt{SUBS}, and the aliases \texttt{CMN}, \texttt{CMP}, and \texttt{TST}.

- Conditional compare instructions such as \texttt{COP}, \texttt{CON}.

- The random number generation instructions \texttt{MRS RNDR} and \texttt{MRS RNDRRS}, see Effect of random number generation instructions on Condition flags on page C6-752.

The A64 base instructions that manipulate the Condition flags are:

- The flag manipulation instruction \texttt{CFINW}, which inverts the value of the Carry flag.
• If ARMv8.5-CondM is implemented, the base instructions \texttt{AXFLAG} and \texttt{XAFLAG}. These instructions convert between the Arm floating point comparison PSTATE condition flag format and an alternative format shown in Table C6-1.

**Table C6-1 Relationship between ARM format and alternative format PSTATE condition flags**

<table>
<thead>
<tr>
<th></th>
<th>Arm format</th>
<th>Alternative format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Result</td>
<td>N Z C V</td>
<td>N Z C V</td>
</tr>
<tr>
<td>Greater than</td>
<td>0 0 1 0</td>
<td>0 0 1 0</td>
</tr>
<tr>
<td>Less than</td>
<td>1 0 0 0</td>
<td>0 0 0 0</td>
</tr>
<tr>
<td>Equal</td>
<td>0 1 1 0</td>
<td>0 1 1 0</td>
</tr>
<tr>
<td>Unordered</td>
<td>0 0 1 1</td>
<td>0 1 0 0</td>
</tr>
</tbody>
</table>

The flags can be directly accessed for a read/write using the \texttt{NZCV, Condition Flags on page C5-400}.

The A64 base instructions also include conditional branch instructions that do not use the Condition flags as an input:
• Compare and branch if a register is zero or nonzero, \texttt{CBZ} and \texttt{CBNZ}.
• Test a single bit in a register and branch if the bit is zero or nonzero, \texttt{TBZ} and \texttt{TBNZ}.

**Effect of random number generation instructions on Condition flags**

If ARMv8.5-RNG is implemented, then:
• When a valid random number is returned, the \texttt{PSTATE.NZCV} flags are set to \texttt{0b0000}.
• If the random number hardware is not capable of returning a random number in a reasonable period of time, the \texttt{PSTATE.NZCV} flags are set to \texttt{0b0100}, and the random number generation instructions return the value 0.

---

**Note**

The definition of “reasonable period of time” is IMPLEMENTATION DEFINED. The expectation is that software might use this as an opportunity to reschedule or run a different routine, perhaps after a small number of retries have failed to return a valid value.
C6.2  Alphabetical list of A64 base instructions

This section lists every instruction in the base category of the A64 instruction set. For details of the format used, see *Understanding the A64 instruction descriptions* on page C2-182.
C6.2.1 ADC

Add with Carry adds two register values and the Carry flag value, and writes the result to the destination register.

### 32-bit variant
Applies when \( sf = 0 \).

\[ \text{ADC} \ <Wd>, <Wn>, <Wm> \]

### 64-bit variant
Applies when \( sf = 1 \).

\[ \text{ADC} \ <Xd>, <Xn>, <Xm> \]

**Decode for all variants of this encoding**

\[
\begin{align*}
\text{integer } d & = \text{UInt}(Rd); \\
\text{integer } n & = \text{UInt}(Rn); \\
\text{integer } m & = \text{UInt}(Rm); \\
\text{integer } \text{datasize} & = \text{if } sf = '1' \text{ then } 64 \text{ else } 32;
\end{align*}
\]

**Assembler symbols**

- \(<Wd>\) — Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) — Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) — Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) — Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) — Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) — Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

**Operation**

\[
\begin{align*}
\text{bits(datasize)} & \text{ result}; \\
\text{bits(datasize)} & = X[n]; \\
\text{bits(datasize)} & = X[m]; \\
\text{(result, -)} & = \text{AddWithCarry} (\text{operand1}, \text{operand2}, \text{PSTATE.C}); \\
X[d] & = \text{result};
\end{align*}
\]

**Operational information**

If \( \text{PSTATE.DIT} \) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.2 ADCS

Add with Carry, setting flags, adds two register values and the Carry flag value, and writes the result to the
destination register. It updates the condition flags based on the result.

Add with Carry, setting flags, adds two register values and the Carry flag value, and writes the result to the
destination register. It updates the condition flags based on the result.

32-bit variant

Applies when sf == 0.

ADCS <Wd>, <Wn>, <Wm>

64-bit variant

Applies when sf == 1.

ADCS <Xd>, <Xn>, <Xm>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);

PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.3 ADD (extended register)

Add (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.

32-bit variant

Applies when sf == 0.

ADD <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

64-bit variant

Applies when sf == 1.

ADD <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then UNDEFINED;

Assembler symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in the "option" field. It can have the following values:

W when option = 00x
W when option = 010
X when option = x11
W when option = 10x
W when option = 110

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the
"option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- LSL|UXTW when option = 010
- UTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is
'010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the
"option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- UXTW when option = 010
- LSL|UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when
"imm3" is '000'. In all other cases <extend> is required and must be UTX when "option" is
'011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in
the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL,
and is optional when <extend> is present but not LSL.

**Operation**

\[
\begin{align*}
\text{bits(datasize)} & \text{ result; } \\
\text{bits(datasize)} & \text{ operand1 } = \text{ if } n \text{ == 31 then SP[] else X[n]; } \\
\text{bits(datasize)} & \text{ operand2 } = \text{ ExtendReg(m, extend_type, shift); } \\
\text{(result, -) } & \text{ = AddWithCarry(operand1, operand2, '0'); } \\
\text{if } d \text{ == 31 then } \\
 & \text{ SP[]} = \text{ result; } \\
\text{else } & \text{ X[d] = result; }
\end{align*}
\]

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
— The values of the NZCV flags.
ADD (immediate)

Add (immediate) adds a register value and an optionally-shifted immediate value, and writes the result to the destination register.

This instruction is used by the alias MOV (to/from SP). See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when \( sf = 0 \).

\[
\text{ADD} \ <Wd|WSP>, <Wn|WSP>, \#<imm>{, <shift>}
\]

64-bit variant
Applies when \( sf = 1 \).

\[
\text{ADD} \ <Xd|SP>, <Xn|SP>, \#<imm>{, <shift>}
\]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } \text{datasize} &= \text{if } sf = '1' \text{ then } 64 \text{ else } 32; \\
\text{bits}(\text{datasize}) \text{ imm}; \\
\text{case } \text{sh} \text{ of } \\
\text{when } '0' \text{ imm} &= \text{ZeroExtend}(\text{imm12}, \text{datasize}); \\
\text{when } '1' \text{ imm} &= \text{ZeroExtend}(\text{imm12}:\text{Zeros}(12), \text{datasize});
\end{align*}
\]

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV (to/from SP)</td>
<td>( sh = '0' &amp;&amp; imm12 = '000000000000' &amp;&amp; (Rd == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

\(<Wd|WSP>\) Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\(<Wn|WSP>\) Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

\(<Xd|SP>\) Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\(<Xn|SP>\) Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

\(<\text{imm}>\) Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

\(<\text{shift}>\) Is the optional left shift to apply to the immediate, defaulting to LSL \#0 and encoded in the "sh" field. It can have the following values:

\[
\text{LSL } \#0 \quad \text{when } \text{sh} = 0
\]
LSL #12 when sh = 1

**Operation**

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];

(result, -) = AddWithCarry(operand1, imm, '0');

if d == 31 then
  SP[] = result;
else
  X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.5   ADD (shifted register)

Add (shifted register) adds a register value and an optionally-shifted register value, and writes the result to the destination register.

32-bit variant

Applies when \( sf == 0 \).

\[
\text{ADD } <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
\]

64-bit variant

Applies when \( sf == 1 \).

\[
\text{ADD } <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
\]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d & = \text{UInt}(Rd); \\
\text{integer } n & = \text{UInt}(Rn); \\
\text{integer } m & = \text{UInt}(Rm); \\
\text{integer } \text{datasize} & = \text{if } sf == '1' \text{ then } 64 \text{ else } 32; \\
\text{if } shift == '11' & \text{ then UNDEFINED; } \\
\text{if } sf == '0' & \& \text{imm6}<5> == '1' & \text{ then UNDEFINED; } \\
\text{ShiftType } shift\_type & = \text{DecodeShift}(shift); \\
\text{integer } shift\_amount & = \text{UInt}(\text{imm6});
\end{align*}
\]

Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<shift>\) Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( shift = 00 \)
  - LSR when \( shift = 01 \)
  - ASR when \( shift = 10 \)
  
  The encoding \( shift = 11 \) is reserved.
- \(<amount>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

(result, -) = AddWithCarry(operand1, operand2, '0');
X[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.6 ADDG

Add with Tag adds an immediate value scaled by the Tag granule to the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

ARMv8.5

```
| 31 30 29 28|27 26 25 24|23 22 21 | 16|15 14 13 | 10 9 | 5 4 | 0 |
| 1 0 0 1 0 0 1 1 0 | uimm6 | [0]|0| uimm4 | Xn | Xd |

Integer variant
ADDG <Xd|SP>, <Xn|SP>, #<uimm6>, #<uimm4>
```

**Decode for this encoding**

```c
integer d = UInt(Xd);
n = UInt(Xn);
offset = LSL(ZeroExtend(uimm6, 64), LOG2_TAG_GRANULE);
```

**Assembler symbols**

- `<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Xd" field.
- `<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Xn" field.
- `<uimm6>` Is an unsigned immediate, a multiple of 16 in the range 0 to 1008, encoded in the "uimm6" field.
- `<uimm4>` Is an unsigned immediate, in the range 0 to 15, encoded in the "uimm4" field.

**Operation**

```c
operand1 = if n == 31 then SP[] else X[n];
start_tag = AArch64.AllocationTagFromAddress(operand1);
exclude = GCR_EL1.Exclude;
result;
rtag;
if AArch64.AllocationTagAccessIsEnabled() then
    rtag = AArch64.ChooseNonExcludedTag(start_tag, uimm4, exclude);
else
    rtag = '0000';
(result, -) = AddWithCarry(operand1, offset, '0');
result = AArch64.AddressWithAllocationTag(result, rtag);
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```
### ADDS (extended register)

Add (extended register), setting flags, adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMN (extended register). See Alias conditions for details of when each alias is preferred.

#### 32-bit variant

Applies when sf == 0.

\[
\text{ADDS \:<Wd>, \:<Wn|WSP>, \:<Wm>{, \:<extend> \:{#<amount>}}} \]

#### 64-bit variant

Applies when sf == 1.

\[
\text{ADDS \:<Xd>, \:<Xn|SP>, \:<R><m>{, \:<extend> \:{#<amount>}}} \]

#### Decode for all variants of this encoding

Integer \( d = \text{UInt}(Rd); \)
Integer \( n = \text{UInt}(Rn); \)
Integer \( m = \text{UInt}(Rm); \)
Integer \( \text{datasize} = \) if \( sf == '1' \) then 64 else 32;
ExtendType \( \text{extend\_type} = \text{DecodeRegExtend}(option); \)
Integer \( \text{shift} = \text{UInt}(\text{imm3}); \)
if \( \text{shift} > 4 \) then UNDEFINED;

#### Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMN (extended register)</td>
<td>Rd == '11111'</td>
</tr>
</tbody>
</table>

#### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn|WSP>\) Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn|SP>\) Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- \(<R>\) Is a width specifier, encoded in the "option" field. It can have the following values:
  - \( \text{W} \) when \( \text{option} = 00x \)
W  when option = 010
X  when option = x11
W  when option = 10x
W  when option = 110

<extend> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB  when option = 000
UXTH  when option = 001
LSL|UXTW  when option = 010
UXTX  when option = 011
SXTB  when option = 100
SXTH  when option = 101
SXTW  when option = 110
SXTX  when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB  when option = 000
UXTH  when option = 001
UXTW  when option = 010
LSL|UXTX  when option = 011
SXTB  when option = 100
SXTH  when option = 101
SXTW  when option = 110
SXTX  when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '0');</result>
PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.8    ADDS (immediate)

Add (immediate), setting flags, adds a register value and an optionally-shifted immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMN (immediate). See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when \( sf == 0 \).

\[
\text{ADDS} \ <Wd>, <Wn|WSP>, #<imm>{, <shift>}
\]

64-bit variant
Applies when \( sf == 1 \).

\[
\text{ADDS} \ <Xd>, <Xn|SP>, #<imm>{, <shift>}
\]

Decode for all variants of this encoding

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;

case sh of
  when '0' imm = ZeroExtend(imm12, datasize);
  when '1' imm = ZeroExtend(imm12:Zeros(12), datasize);
```

Alias conditions

<table>

</table>

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- LSL when shift = 00
- LSR when shift = 01
- ASR when shift = 10

The encoding shift = 11 is reserved.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

```
builtins(datasize) result;
builtins(datasize) operand1 = X[n];
builtins(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
builtins(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '0');

PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.10 ADR

Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

```
<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>

- \(<Xd|SP>\) is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- \(<Xn>\) is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<imm>\) For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".
  
  For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

**Operation**

```plaintext
bits(datasize) result;
bite(datasize) operand1 = X[n];
result = operand1 AND imm;
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.13 AND (shifted register)

Bitwise AND (shifted register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

### 32-bit variant

Applies when `sf == 0`.

```cpp
AND <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

### 64-bit variant

Applies when `sf == 1`.

```cpp
AND <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

#### Decode for all variants of this encoding

```cpp
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

#### Assembler symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when `shift = 00`
  - LSR when `shift = 01`
  - ASR when `shift = 10`
  - ROR when `shift = 11`
- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
**Operation**

\[
\begin{align*}
\text{bits(datasize) operand1} &= X[n]; \\
\text{bits(datasize) operand2} &= \text{ShiftReg}(m, \text{shift\_type}, \text{shift\_amount}); \\
\text{result} &= \text{operand1 AND operand2}; \\
X[d] &= \text{result};
\end{align*}
\]

**Operational information**

If `PSTATE.DIT` is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.14   **ANDS (immediate)**

Bitwise AND (immediate), setting flags, performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias TST (immediate). See **Alias conditions** for details of when each alias is preferred.

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift>  Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
- LSL when shift = 00
- LSR when shift = 01
- ASR when shift = 10
- ROR when shift = 11

<amount>  For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
result = operand1 AND operand2;
PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.16  ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the ASRV instruction. This means that:

- The encodings in this description are named to match the encodings of ASRV.
- The description of ASRV gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf == 0 \).

\[
\text{ASR} \ <Wd>, \ <Wn>, \ <Wm> \\
\text{is equivalent to} \\
\text{ASRV} \ <Wd>, \ <Wn>, \ <Wm>
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf == 1 \).

\[
\text{ASR} \ <Xd>, \ <Xn>, \ <Xm> \\
\text{is equivalent to} \\
\text{ASRV} \ <Xd>, \ <Xn>, \ <Xm>
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

### Operation

The description of ASRV gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### C6.2.17 ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of the sign bit in the upper bits and zeros in the lower bits, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

#### 32-bit variant

Applies when $sf == 0 && N == 0 && imms == 011111$.

$$\text{ASR } <Wd>, <Wn>, #<shift>$$

is equivalent to

$$\text{SBFM } <Wd>, <Wn>, #<shift>, #31$$

and is always the preferred disassembly.

#### 64-bit variant

Applies when $sf == 1 && N == 1 && imms == 111111$.

$$\text{ASR } <Xd>, <Xn>, #<shift>$$

is equivalent to

$$\text{SBFM } <Xd>, <Xn>, #<shift>, #63$$

and is always the preferred disassembly.

#### Assembler symbols

- $<Wd>$: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Wn>$: Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- $<Xd>$: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<Xn>$: Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- $<shift>$: For the 32-bit variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field. For the 64-bit variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.

#### Operation

The description of SBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### C6.2.18 ASRV

Arithmetic Shift Right Variable shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias `ASR (register)`. The alias is always the preferred disassembly.

#### 32-bit variant
Applies when $sf == 0$.

`ASRV <Wd>, <Wn>, <Wm>`

#### 64-bit variant
Applies when $sf == 1$.

`ASRV <Xd>, <Xn>, <Xm>`

**Decode for all variants of this encoding**

- integer $d = \text{UInt}(Rd)$;
- integer $n = \text{UInt}(Rn)$;
- integer $m = \text{UInt}(Rm)$;
- integer $datasize = \text{if } sf == '1' \text{ then } 64 \text{ else } 32$;
- `ShiftType shift_type = DecodeShift(op2)`;

**Assembler symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand2 = X[m];
result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.19 AT

Address Translate. For more information, see \( op0==0b01 \), cache maintenance, TLB maintenance, and address translation instructions on page C5-366.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 16|15 12|11 8 |7 5 4 | 0 |
|---|---|---|---|---|---|---|---|---|
| 1 1 0 1 0 1 0 0 | 0 0 1 | op1 | 0 1 1 | 1 1 0 0 | x | op2 | Rt |
```

**System variant**

AT \(<\text{at\_op}>\), \(<\text{Xt}>\)

is equivalent to

SYS \(#\text{op1}>\), \(C7\), \(<\text{Cm}>\), \(#\text{op2}>\), \(<\text{Xt}>\)

and is the preferred disassembly when \(\text{SysOp(op1,'0111',CRm,op2)} == \text{Sys\_AT}\).

**Assembler symbols**

\(<\text{at\_op}>\)

Is an AT instruction name, as listed for the AT system instruction group, encoded in the "\(\text{op1}:\text{CRm}<0>:\text{op2}\)" field. It can have the following values:

- \(\text{S1E1R}\) when \(\text{op1} = 000\), \(\text{CRm}<0> = 0\), \(\text{op2} = 000\)
- \(\text{S1E1W}\) when \(\text{op1} = 000\), \(\text{CRm}<0> = 0\), \(\text{op2} = 001\)
- \(\text{S1E0R}\) when \(\text{op1} = 000\), \(\text{CRm}<0> = 0\), \(\text{op2} = 010\)
- \(\text{S1E0W}\) when \(\text{op1} = 000\), \(\text{CRm}<0> = 0\), \(\text{op2} = 011\)
- \(\text{S1E2R}\) when \(\text{op1} = 100\), \(\text{CRm}<0> = 0\), \(\text{op2} = 000\)
- \(\text{S1E2W}\) when \(\text{op1} = 100\), \(\text{CRm}<0> = 0\), \(\text{op2} = 001\)
- \(\text{S12E1R}\) when \(\text{op1} = 100\), \(\text{CRm}<0> = 0\), \(\text{op2} = 100\)
- \(\text{S12E1W}\) when \(\text{op1} = 100\), \(\text{CRm}<0> = 0\), \(\text{op2} = 101\)
- \(\text{S12E0R}\) when \(\text{op1} = 100\), \(\text{CRm}<0> = 0\), \(\text{op2} = 110\)
- \(\text{S12E0W}\) when \(\text{op1} = 100\), \(\text{CRm}<0> = 0\), \(\text{op2} = 111\)
- \(\text{S1E3R}\) when \(\text{op1} = 110\), \(\text{CRm}<0> = 0\), \(\text{op2} = 000\)
- \(\text{S1E3W}\) when \(\text{op1} = 110\), \(\text{CRm}<0> = 0\), \(\text{op2} = 001\)

When ARMv8.2-ATS1E1 is implemented, the following values are also valid:

- \(\text{S1E1RP}\) when \(\text{op1} = 000\), \(\text{CRm}<0> = 1\), \(\text{op2} = 000\)
- \(\text{S1E1WP}\) when \(\text{op1} = 000\), \(\text{CRm}<0> = 1\), \(\text{op2} = 001\)

\(<\text{op1}>\)

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "\(\text{op1}\)" field.

\(<\text{Cm}>\)

Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

\(<\text{op2}>\)

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "\(\text{op2}\)" field.

\(<\text{Xt}>\)

Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.
Operation

The description of SYS gives the operational pseudocode for this instruction.
C6.2.20 AUTDA, AUTDZA

Authenticate Data address, using key A. This instruction authenticates a data address, using a modifier and key A. The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDA.
- The value zero, for AUTDZA.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

ARMv8.3

<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>
<th>19 18 17 16</th>
<th>15 14 13 12</th>
<th>11 10 9</th>

<td>Rn</td>
<td>Rd</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**AUTDA variant**

Applies when Z == 0.

AUTDA <Xd>, <Xn|SP>

**AUTDZA variant**

Applies when Z == 1 && Rn == 11111.

AUTDZA <Xd>

**Decode for all variants of this encoding**

```java
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HavePACExt() then
  UNDEFINED;
if Z == '0' then // AUTDA
  if n == 31 then source_is_sp = TRUE;
else // AUTDZA
  if n != 31 then UNDEFINED;
```

**Assembler symbols**

- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

**Operation**

```java
if source_is_sp then
  X[d] = AuthDA(X[d], SP[]);
else
  X[d] = AuthDA(X[d], X[n]);
```
C6.2.21 AUTDB, AUTDZB

Authenticate Data address, using key B. This instruction authenticates a data address, using a modifier and key B. The address is in the general-purpose register that is specified by <Xd>.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDB.
- The value zero, for AUTDZB.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

ARMv8.3

```
|31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 |  5  4 |   0 |
| 1 1 0 1 1 0 1 1 0 0 0 0 0 1 0 0 | Z 1 1 1 Rn Rd |
```

**AUTDB variant**

Applies when $Z = 0$.

AUTDB <Xd>, <Xn|SP>

**AUTDZB variant**

Applies when $Z = 1 && Rn == 11111$.

AUTDZB <Xd>

**Decode for all variants of this encoding**

```java
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HavePACExt() then UNDEFINED;
if Z == '0' then // AUTDB
  if n == 31 then source_is_sp = TRUE;
else // AUTDZB
  if n != 31 then UNDEFINED;
```

**Assembler symbols**

- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn|SP>` is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

**Operation**

```java
if source_is_sp then
  X[d] = AuthDB(X[d], SP[]);
else
  X[d] = AuthDB(X[d], X[n]);
```
C6.2.22  AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA

Authenticate Instruction address, using key A. This instruction authenticates an instruction address, using a modifier and key A.

The address is:
- In the general-purpose register that is specified by <Xd> for AUTIA and AUTIZA.
- In X17, for AUTIA1716.
- In X30, for AUTIASP and AUTIAZ.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTIA.
- The value zero, for AUTIZA and AUTIAZ.
- In X16, for AUTIA1716.
- In SP, for AUTIASP.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

**Integer**

ARMv8.3

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 | 5 4 | 0 ]
[ 1 1 0 1 0 1 1 0 | 0 0 0 0 1 | 0 0 | Z | 1 0 ] Rd
```

**AUTIA variant**

Applies when \( Z == 0 \).

AUTIA <Xd>, <Xn|SP>

**AUTIZA variant**

Applies when \( Z == 1 \) \&\& \( Rn == 11111 \).

AUTIZA <Xd>

**Decode for all variants of this encoding**

boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
UNDEFINED;

if Z == '0' then // AUTIA
    if n == 31 then source_is_sp = TRUE;
else // AUTIZA
    if n != 31 then UNDEFINED;

**System**

ARMv8.3
AUTIA1716 variant
Applies when CRm == 0001 && op2 == 100.

AUTIA1716

AUTIASP variant
Applies when CRm == 0011 && op2 == 101.

AUTIASP

AUTIAZ variant
Applies when CRm == 0011 && op2 == 100.

AUTIAZ

Decode for all variants of this encoding

integer d;
integer n;
boolean source_is_sp = FALSE;
case CRm:op2 of
    when '0011 100'    // AUTIAZ
d = 30;

Assembler symbols
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation for all encodings
if HavePACExt() then
    if source_is_sp then
        X[d] = AuthIA(X[d], SP[]);
    else
        X[d] = AuthIA(X[d], X[n]);
C6.2.23 AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB

Authenticate Instruction address, using key B. This instruction authenticates an instruction address, using a modifier and key B.

The address is:
- In the general-purpose register that is specified by <Xd> for AUTIB and AUTIZB.
- In X17, for AUTIB1716.
- In X30, for AUTIBSP and AUTIBZ.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTIB.
- The value zero, for AUTIZB and AUTIBZ.
- In X16, for AUTIB1716.
- In SP, for AUTIBSP.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

**Integer**

*ARMv8.3*

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 | 5 4 | 0 |
| 1 1 0 | 1 1 0 1 0 1 0 0 0 0 1 0 0 1 | 1 0 1 | Rn | Rd |
```

**AUTIB variant**

Applies when \( Z = 0 \).

**AUTIB <Xd>, <Xn|SP>**

**AUTIZB variant**

Applies when \( Z = 1 \) && \( Rn = \text{11111} \).

**AUTIZB <Xd>**

**Decode for all variants of this encoding**

```java
    boolean source_is_sp = FALSE;
    integer d = UInt(Rd);
    integer n = UInt(Rn);
    if !HavePACExt() then
        UNDEFINED;
    if Z == '0' then // AUTIB
        if n == 31 then source_is_sp = TRUE;
        else // AUTIZB
            if n != 31 then UNDEFINED;
```

**System**

*ARMv8.3*
AUTIB1716 variant

Applies when CRm == 0001 && op2 == 110.

AUTIB1716

AUTIBSP variant

Applies when CRm == 0011 && op2 == 111.

AUTIBSP

AUTIBZ variant

Applies when CRm == 0011 && op2 == 110.

AUTIBZ

Decode for all variants of this encoding

```c
integer d;
integer n;
boolean source_is_sp = FALSE;
case CRm:op2 of
    when '0011 110'    // AUTIBZ
d = 30;
n = 31;
    when '0011 111'    // AUTIBSP
d = 30;
        source_is_sp = TRUE;
    when '0001 110'    // AUTIB1716
d = 17;
n = 16;

C6.2.24 AXFLAG

Convert floating-point condition flags from Arm to external format. This instruction converts the state of the PSTATE.{N,Z,C,V} flags from a form representing the result of an Arm floating-point scalar compare instruction to an alternative representation required by some software.

ARMv8.5

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 8 7 6 5 4 3 2 1 0 |
| 1 1 0 1 0 1 0 1 0 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

CRm
```

**System variant**

AXFLAG

**Decode for this encoding**

if !HaveFlagFormatExt() then UNDEFINED;

**Operation**

bit Z = PSTATE.Z OR PSTATE.V;
bit C = PSTATE.C AND NOT(PSTATE.V);

PSTATE.N = '0';
PSTATE.Z = Z;
PSTATE.C = C;
PSTATE.V = '0';
C6.2.25   B.cond

Branch conditionally to a label at a PC-relative offset, with a hint that this is not a subroutine call or return.

```
| 31 30 29 28|27 26 25 24|23 |   |   | 5 4 3 0 |
0 1 0 1 0 1 0 0 imm19 0 cond
```

19-bit signed PC-relative branch offset variant

`B.<cond> <label>`

**Decode for this encoding**

`bits(64) offset = SignExtend(imm19:'00', 64);`

**Assembler symbols**

- `<cond>` Is one of the standard conditions, encoded in the "cond" field in the standard way.
- `<label>` Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

**Operation**

```latex
if ConditionHolds(cond) then
  BranchTo(PC[] + offset, BranchType_DIR);
```
C6.2.26  B

Branch causes an unconditional branch to a label at a PC-relative offset, with a hint that this is not a subroutine call or return.

```
[31 30 29 28][27 26 25] | | | | | 0 |
0 0 0 1 0 1 | imm26
op
```

26-bit signed PC-relative branch offset variant

B <label>

**Decode for this encoding**

bits(64) offset = SignExtend(imm26:'00', 64);

**Assembler symbols**

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

**Operation**

BranchTo(PC[] + offset, BranchType_DIR);
C6.2.27   BFC

Bitfield Clear sets a bitfield of <width> bits at bit position <lsb> of the destination register to zero, leaving the other destination bits unchanged.

This instruction is an alias of the BFM instruction. This means that:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.

**32-bit variant**

Applies when sf == 0 && N == 0.

BFC <Wd>, #<lsb>, #<width>

is equivalent to

BFM <Wd>, WZR, #(-<lsb> MOD 32), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

**64-bit variant**

Applies when sf == 1 && N == 1.

BFC <Xd>, #<lsb>, #<width>

is equivalent to

BFM <Xd>, XZR, #(-<lsb> MOD 64), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

**Assembler symbols**

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <lsb> For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- <width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

**Operation**

The description of BFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.28  BFI

Bitfield Insert copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, leaving the other destination bits unchanged.

This instruction is an alias of the BFM instruction. This means that:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.

32-bit variant
Applies when sf == 0 && N == 0.
BFI <Wd>, <Wn>, #<lsb>, #<width>
is equivalent to
BFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
and is the preferred disassembly when UInt(imms) < UInt(immr).

64-bit variant
Applies when sf == 1 && N == 1.
BFI <Xd>, <Xn>, #<lsb>, #<width>
is equivalent to
BFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
and is the preferred disassembly when UInt(imms) < UInt(immr).

Assembler symbols

- <Wd>  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn>  Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd>  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn>  Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <lsb>  For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
              For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- <width>  For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
              For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation
The description of BFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.29   BFM

Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly.

If $<\text{imms}>$ is greater than or equal to $<\text{immr}>$, this copies a bitfield of ($<\text{imms}>-<\text{immr}>+1$) bits starting from bit position $<\text{immr}>$ in the source register to the least significant bits of the destination register.

If $<\text{imms}>$ is less than $<\text{immr}>$, this copies a bitfield of ($<\text{imms}>+1$) bits from the least significant bits of the source register to bit position (regsize-$<\text{immr}>$) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases the other bits of the destination register remain unchanged.

This instruction is used by the aliases BFC, BFI, and BFXIL. See Alias conditions on page C6-805 for details of when each alias is preferred.

32-bit variant
Applies when $sf == 0 \land N == 0$.

$BFM \ <Wd>, <Wn>, \ #<\text{immr}>, \ #<\text{imms}>$

64-bit variant
Applies when $sf == 1 \land N == 1$.

$BFM \ <Xd>, <Xn>, \ #<\text{immr}>, \ #<\text{imms}>$

Decode for all variants of this encoding

```plaintext
define integer d = UInt(Rd);
define integer n = UInt(Rn);
define integer datasize = if sf == '1' then 64 else 32;
define integer R;
define bits(datasize) wmask;
define bits(datasize) tmask;
if sf == '1' \land N != '1' then UNDEFINED;
if sf == '0' \land (N != '0' \lor imms<5> != '0' \lor immr<5> != '0') then UNDEFINED;
R = UInt(immr);
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE);
```

  - The values of the NZCV flags.
C6.2.30   BFXIL

Bitfield Extract and Insert Low copies a bitfield of \(<\text{width}\>\) bits starting from bit position \(<\text{lsb}\>\) in the source register to the least significant bits of the destination register, leaving the other destination bits unchanged.

This instruction is an alias of the BFM instruction. This means that:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \(sf == 0 \&\& N == 0\).

BFXIL \(<Wd>, <Wn>, #<lsb>, #<width>\)

is equivalent to

BFM \(<Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)\)

and is the preferred disassembly when \(\text{UInt}(\text{imms}) >= \text{UInt}(\text{immr})\).

### 64-bit variant

Applies when \(sf == 1 \&\& N == 1\).

BFXIL \(<Xd>, <Xn>, #<lsb>, #<width>\)

is equivalent to

BFM \(<Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)\)

and is the preferred disassembly when \(\text{UInt}(\text{imms}) >= \text{UInt}(\text{immr})\).

### Assembler symbols

- \(<Wd>\): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\): Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\): Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{lsb}\>\): For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
- \(<\text{width}\>\): For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-\(<\text{lsb}\>\).
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-\(<\text{lsb}\>\).

### Operation

The description of BFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
BIC (shifted register)

Bitwise Bit Clear (shifted register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

32-bit variant

Applies when sf == 0.

BIC <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit variant

Applies when sf == 1.

BIC <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
LSL when shift = 00
LSR when shift = 01
ASR when shift = 10
ROR when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
Operation

\[
\text{bits(datasize) operand1 } = X[n]; \\
\text{bits(datasize) operand2 } = \text{ShiftReg}(m, \text{shift\_type}, \text{shift\_amount}); \\
\text{operand2 } = \text{NOT}(\text{operand2}); \\
\text{result } = \text{operand1 AND operand2}; \\
X[d] = \text{result};
\]

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.32   BICS (shifted register)

Bitwise Bit Clear (shifted register), setting flags, performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

32-bit variant

Applies when \( sf == 0 \).

BICS \(<Wd>, <Wm>, {<shift> #<amount>}\)

64-bit variant

Applies when \( sf == 1 \).

BICS \(<Xd>, <Xm>, {<shift> #<amount>}\)

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } m &= \text{UInt}(Rm); \\
\text{integer } \text{datasize} &= \text{if } sf == '1' \text{ then } 64 \text{ else } 32; \\
\text{if } sf == '0' \&\& \text{imm6<5>} == '1' \text{ then UNDEFINED;}
\end{align*}
\]

\[
\begin{align*}
\text{ShiftType } shift\_type &= \text{DecodeShift}(\text{shift}); \\
\text{integer } shift\_amount &= \text{UInt}(\text{imm6});
\end{align*}
\]

Assembler symbols

\(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Wm>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

\(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

\(<\text{shift}>\) Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- LSL when \( \text{shift} = 00 \)
- LSR when \( \text{shift} = 01 \)
- ASR when \( \text{shift} = 10 \)
- ROR when \( \text{shift} = 11 \)

\(<\text{amount}>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
operand2 = NOT(operand2);
result = operand1 AND operand2;
PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';
X[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.33   BL

Branch with Link branches to a PC-relative offset, setting the register X30 to PC+4. It provides a hint that this is a subroutine call.

![Instruction Format]

26-bit signed PC-relative branch offset variant
BL <label>

**Decode for this encoding**

bits(64) offset = SignExtend(imm26:'00', 64);

**Assembler symbols**

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

**Operation**

X[30] = PC[] + 4;

BranchTo(PC[] + offset, BranchType_DIRCALL);
C6.2.34   BLR

Branch with Link to Register calls a subroutine at an address in a register, setting register X30 to PC+4.

```
<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 26 25 24</th>
<th>23 22 21 20</th>
<th>19 18 17 16</th>
<th>15 14 13 12</th>
<th>11 10 9</th>
<th>5 4</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 0 1 0 1 1 0 0 1 1 1 1 1 0 0 0 0</td>
<td>0 0</td>
<td>Rn</td>
<td>0 0 0 0 0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Integer variant**

BLR <Xn>

**Decode for this encoding**

`integer n = UInt(Rn);`

**Assembler symbols**

<Xn>    Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

**Operation**

`bits(64) target = X[n];`

`X[30] = PC[] + 4;`

`BranchTo(target, BranchType_INDCALL);`
C6.2.35  BLRAA, BLRAAZ, BLRAB, BLRABZ

Branch with Link to Register, with pointer authentication. This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and calls a subroutine at the authenticated address, setting register X30 to PC+4.

The modifier is:

• In the general-purpose register or stack pointer that is specified by <Xm|SP> for BLRAA and BLRAB.
• The value zero, for BLRAAZ and BLRABZ.

Key A is used for BLRAA and BLRAAZ, and key B is used for BLRAB and BLRABZ.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

ARMv8.3

```
|31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 | 5 4 | 0 |
|1 1 0 1 0 1 1 |1 1 1 1 1 0 0 0 |1 M Rn Rm |
```

**Key A, zero modifier variant**

Applies when Z == 0 && M == 0 && Rm == 11111.

BLRAAZ <Xn>

**Key A, register modifier variant**

Applies when Z == 1 && M == 0.

BLRAA <Xn>, <Xm|SP>

**Key B, zero modifier variant**

Applies when Z == 0 && M == 1 && Rm == 11111.

BLRABZ <Xn>

**Key B, register modifier variant**

Applies when Z == 1 && M == 1.

BLRAB <Xn>, <Xm|SP>

**Decode for all variants of this encoding**

```java
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean use_key_a = (M == '0');
boolean source菽sp = ((Z == '1') && (m == 31));

if !HavePACExt() then
    UNDEFINED;
if Z == '0' && m != 31 then
    UNDEFINED;
```
Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

<Xm|SP> Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.

Operation

bits(64) target = X[n];
bits(64) modifier = if source_is_sp then SP[] else X[m];

if use_key_a then
  target = AuthIA(target, modifier);
else
  target = AuthIB(target, modifier);

X[30] = PC[] + 4;

BranchTo(target, BranchType_INDCALL);
C6.2.36   BR

Branch to Register branches unconditionally to an address in a register, with a hint that this is not a subroutine return.

```
| 31 30 29 28| 27 26 25 24| 23 22 21 20| 19 18 17 16| 15 14 13 12| 11 10  9 |  5  4 |  0 |
|1 1 0 1 0 1 1 0|0 0 0 1 1 1 0 0|0 0 0 0 0 0|0 0 0 0 0 0|
```

**Integer variant**

BR <Xn>

**Decode for this encoding**

integer n = UInt(Rn);

**Assembler symbols**

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

**Operation**

bits(64) target = X[n];

BranchTo(target, BranchType_INDIR);
C6.2.37 **BRAA, BRAAZ, BRAB, BRABZ**

Branch to Register, with pointer authentication. This instruction authenticates the address in the general-purpose register that is specified by \(<Xn>\), using a modifier and the specified key, and branches to the authenticated address.

The modifier is:

- In the general-purpose register or stack pointer that is specified by \(<Xm>|SP>\) for BRAA and BRAB.
- The value zero, for BRAAZ and BRABZ.

Key A is used for BRAA and BRAAZ, and key B is used for BRAB and BRABZ.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

**ARMv8.3**

```
<table>
<thead>
<tr>

```

**Key A, zero modifier variant**

Applies when \(Z == 0 \&\& M == 0 \&\& Rm == 11111\).

BRAAZ \(<Xn>\)

**Key A, register modifier variant**

Applies when \(Z == 1 \&\& M == 0\).

BRAA \(<Xn>\), \(<Xm>|SP>\)

**Key B, zero modifier variant**

Applies when \(Z == 0 \&\& M == 1 \&\& Rm == 11111\).

BRABZ \(<Xn>\)

**Key B, register modifier variant**

Applies when \(Z == 1 \&\& M == 1\).

BRAB \(<Xn>\), \(<Xm>|SP>\)

**Decode for all variants of this encoding**

```java
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean use_key_a = (M == '0');
boolean source_is_sp = ((Z == '1') \&\& (m == 31));

if !HavePACExt() then
  UNDEFINED;

if Z == '0' \&\& m != 31 then
  UNDEFINED;
```
Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

<Xm|SP> Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.

Operation

bits(64) target = X[n];
bits(64) modifier = if source_is_sp then SP[] else X[m];

if use_key_a then
    target = AuthIA(target, modifier);
else
    target = AuthIB(target, modifier);

BranchTo(target, BranchType_INDIR);
C6.2.38 BRK

Breakpoint instruction. A BRK instruction generates a Breakpoint Instruction exception. The PE records the exception in ESR_ELx, using the EC value 0x3c, and captures the value of the immediate argument in ESR_ELx.ISS.

<table>
<thead>
<tr>
<th>31 30 29 28</th>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**System variant**

BRK #<imm>

**Decode for this encoding**

- = HaveBTIExt();

**Assembler symbols**

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

**Operation**

AArch64.SoftwareBreakpoint(imm16);
C6.2.39   BTI

Branch Target Identification. A BTI instruction is used to guard against the execution of instructions which are not the intended target of a branch.

Outside of a guarded memory region, a BTI instruction executes as a NOP. Within a guarded memory region while PSTATE.BTYPE != 0b00, a BTI instruction compatible with the current value of PSTATE.BTYPE will not generate a Branch Target Exception and will allow execution of subsequent instructions within the memory region.

The operand <targets> passed to a BTI instruction determines the values of PSTATE.BTYPE which the BTI instruction is compatible with.

--- Note ---

Within a guarded memory region, while PSTATE.BTYPE != 0b00, all instructions will generate a Branch Target Exception, other than BRK, BTI, HLT, PACIASP, and PACIBSP, which may not. See the individual instructions for details.

ARMv8.5

**C6.2.40 CASB, CASAB, CASALB, CASLB**

Compare and Swap byte in memory reads an 8-bit byte from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- CASAB and CASALB load from memory with acquire semantics.
- CASLB and CASALB store to memory with release semantics.
- CASB has no memory ordering requirements.

For more information about memory ordering semantics see Load-Acquire, Load-AcquirePC, and Store-Release on page B2-129.

For information about memory accesses see Load/Store addressing modes on page C1-177.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is restored to the values held in the register before the instruction was executed.

- \(<imm>\) is a five bit unsigned (positive) immediate encoded in the "imm5" field.
- \(<nzcv>\) is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.
- \(<cond>\) is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
bv(datasize) operand1 = X[n];
if ConditionHolds(cond) then
    (-, flags) = AddWithCarry(operand1, imm, '0');
PSTATE.<N,Z,C,V> = flags;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
The values of the NZCV flags.
C6.2.47  CCMN (register)

Conditional Compare Negative (register) sets the value of the condition flags to the result of the comparison of a
register value and the inverse of another register value if the condition is TRUE, and an immediate value otherwise.

|31 30 29 28|27 26 25 24|23 22 21 20|16|15|12|11|10|9| 5 |4 |3 |0 |
|sf| 0 |1 |1 |1 |0 |0 |1 |0 |0 |0 |0 |0 |0 |0 |0 |0 |0 |0 |0 |0 |0 |0 |0 |0 |0 |

32-bit variant

Applies when sf == 0.

CCMN <Wn>, <Wm>, #<nzcv>, <cond>

64-bit variant

Applies when sf == 1.

CCMN <Xn>, <Xm>, #<nzcv>, <cond>

Decode for all variants of this encoding

```plaintext
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
bits(4) flags = nzcv;
```

Assembler symbols

- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<nzcv>` Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit
NZCV condition flags, encoded in the "nzcv" field.
- `<cond>` Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```plaintext
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

if ConditionHolds(cond) then
    (-, flags) = AddWithCarry(operand1, operand2, '0');
PSTATE.<N,Z,C,V> = flags;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.48 CCMP (immediate)

Conditional Compare (immediate) sets the value of the condition flags to the result of the comparison of a register value and an immediate value if the condition is TRUE, and an immediate value otherwise.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{COMP } <Wn>, \#<imm>, \#<nzcv>, <\text{cond}>
\]

64-bit variant

Applies when \( sf = 1 \).

\[
\text{COMP } <Xn>, \#<imm>, \#<nzcv>, <\text{cond}>
\]

Decode for all variants of this encoding

\[
\begin{array}{cccccccccccccccc}
\text{op} & \text{sf} & \text{imm5} & \text{cond} & \text{Rn} & \text{nzcv} \\
0 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 0 \\
\end{array}
\]

Assembler symbols

\(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(<\text{imm}>\) Is a five bit unsigned (positive) immediate encoded in the "imm5" field.

\(<\text{nzcv}>\) Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

\(<\text{cond}>\) Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

\[
\begin{align*}
\text{integer } n &= \text{UInt(Rn)}; \\
\text{integer } \text{datasize} &= \text{if sf == '1' then 64 else 32}; \\
\text{bits(4) flags} &= \text{nzcv}; \\

CRm

System variant

CFINV

Decode for this encoding

if !HaveFlagManipulateExt() then UNDEFINED;

Operation

PSTATE.C = NOT(PSTATE.C);

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.51   CFP

Control Flow Prediction Restriction by Context prevents control flow predictions that predict execution addresses, based on information gathered from earlier execution within a particular execution context, from allowing later speculative execution within that context to be observable through side-channels.

For more information, see CFP RCTX.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

ARMv8.5

**System variant**

CFP RCTX, <Xt>

is equivalent to

SYS #3, C8, C3, #4, <Xt>

and is always the preferred disassembly.

**Assembler symbols**

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
C6.2.52  CINC

Conditional Increment returns, in the destination register, the value of the source register incremented by 1 if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the CSINC instruction. This means that:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode for this instruction.

32-bit variant

Applies when sf == 0.

CINC <Wd>, <Wn>, <cond>

is equivalent to

CSINC <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

64-bit variant

Applies when sf == 1.

CINC <Xd>, <Xn>, <cond>

is equivalent to

CSINC <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINC gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.53 CINV

Conditional Invert returns, in the destination register, the bitwise inversion of the value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the CSINV instruction. This means that:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf = 0$.

CINV <Wd>, <Wn>, <cond>
is equivalent to

CSINV <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when $Rn == Rm$.

64-bit variant

Applies when $sf = 1$.

CINV <Xd>, <Xn>, <cond>
is equivalent to

CSINV <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when $Rn == Rm$.

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINV gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.54  CLREX

Clear Exclusive clears the local monitor of the executing PE.

```
[31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 8 7 6 5 4 3 2 1 0]
1 1 0 1 0 1 0 0 0 0 0 1 1 0 0 1 1 1
```

**System variant**

CLREX {<imm>}

**Decode for this encoding**

// CRm field is ignored

**Assembler symbols**

<imm> Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

**Operation**

ClearExclusiveLocal(ProcessorID());
C6.2.55 CLS

Count Leading Sign bits counts the number of leading bits of the source register that have the same value as the most significant bit of the register, and writes the result to the destination register. This count does not include the most significant bit of the source register.

32-bit variant
Applies when $sf == 0$.

CLS \(<Wd>, <Wn>\)

64-bit variant
Applies when $sf == 1$.

CLS \(<Xd>, <Xn>\)

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

Assembler symbols

\(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
\(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
\(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
\(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

integer result;
bits(datasize) operand1 = X[n];
result = CountLeadingSignBits(operand1);
X[d] = result<datasize-1:0>;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.56  CLZ

Count Leading Zeros counts the number of binary zero bits before the first binary one bit in the value of the source register, and writes the result to the destination register.

**32-bit variant**

Applies when $sf == 0$.

CLZ <Wd>, <Wn>

**64-bit variant**

Applies when $sf == 1$.

CLZ <Xd>, <Xn>

**Decode for all variants of this encoding**

```plaintext
to
to
integer d = UInt(Rd);
ingeger n = UInt(Rn);
teger datasize = if sf == '1' then 64 else 32;
```

**Assembler symbols**

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

**Operation**

```plaintext
integer result;
bias(datasize) operand1 = X[n];
result = CountLeadingZeroBits(operand1);
X[d] = result<datasize-1:0>;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.57  CMN (extended register)

Compare Negative (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ADDS (extended register) instruction. This means that:

- The encodings in this description are named to match the encodings of ADDS (extended register).
- The description of ADDS (extended register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when sf == 0.

\[
\text{CMN} \quad \text{<Wn|WSP>, <Wm>{, <extend> {#<amount>}}}
\]

is equivalent to

\[
\text{ADDS} \quad \text{WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}}
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when sf == 1.

\[
\text{CMN} \quad \text{<Xn|SP>, <R><m>{, <extend> {#<amount>}}}
\]

is equivalent to

\[
\text{ADDS} \quad \text{XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}}
\]

and is always the preferred disassembly.

### Assembler symbols

- `<Wn|WSP>` is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>` is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xn|SP>` is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>` is a width specifier, encoded in the "option" field. It can have the following values:
  - `W` when `option = 00x`
  - `W` when `option = 010`
  - `X` when `option = x11`
  - `W` when `option = 10x`
  - `W` when `option = 110`
- `<m>` is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- LSL|UXTW when option = 010
- UTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- UXTW when option = 010
- LSL|UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

The description of ADDS (extended register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.58   CMN (immediate)

Compare Negative (immediate) adds a register value and an optionally-shifted immediate value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ADDS (immediate) instruction. This means that:

• The encodings in this description are named to match the encodings of ADDS (immediate).
• The description of ADDS (immediate) gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( \text{sf} = 0 \).

\[
\text{CMN} <Wn|WSP>, \#<imm>{, <shift>}
\]

is equivalent to

\[
\text{ADDS} WZR, <Wn|WSP>, \#<imm> {, <shift>}
\]

and is always the preferred disassembly.

64-bit variant

Applies when \( \text{sf} = 1 \).

\[
\text{CMN} <Xn|SP>, \#<imm>{, <shift>}
\]

is equivalent to

\[
\text{ADDS} XZR, <Xn|SP>, \#<imm> {, <shift>}
\]

and is always the preferred disassembly.

Assembler symbols

\(<Wn|WSP>\)  Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

\(<Xn|SP>\)  Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

\(<imm>\)  Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

\(<shift>\)  Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:

<table>
<thead>
<tr>
<th>( \text{LSL} )</th>
<th>when ( \text{sh} = 0 )</th>
<th>( \text{LSL} )</th>
<th>when ( \text{sh} = 1 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>#0</td>
<td></td>
<td>#12</td>
<td></td>
</tr>
</tbody>
</table>

Operation

The description of ADDS (immediate) gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.59 CMN (shifted register)

Compare Negative (shifted register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ADDS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ADDS (shifted register).
- The description of ADDS (shifted register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when `sf == 0`.

\[
\text{CMN } <Wn>, <Wm>\{, <shift> #<amount>\}
\]

is equivalent to

\[
\text{ADDS } \text{WZR}, <Wn>, <Wm> \{, <shift> #<amount>\}
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when `sf == 1`.

\[
\text{CMN } <Xn>, <Xm>\{, <shift> #<amount>\}
\]

is equivalent to

\[
\text{ADDS } \text{XZR}, <Xn>, <Xm> \{, <shift> #<amount>\}
\]

and is always the preferred disassembly.

### Assembler symbols

- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when `shift = 00`
  - LSR when `shift = 01`
  - ASR when `shift = 10`
  - The encoding `shift = 11` is reserved.
- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
**Operation**

The description of ADDS (shifted register) gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.60   CMP (extended register)

Compare (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the SUBS (extended register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUBS (extended register).
- The description of SUBS (extended register) gives the operational pseudocode for this instruction.

32-bit variant

Applies when sf == 0.

CMP <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

is equivalent to

SUBS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

and is always the preferred disassembly.

64-bit variant

Applies when sf == 1.

CMP <Xn|SP>, <R><m>{, <extend> {#<amount>}}

is equivalent to

SUBS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

and is always the preferred disassembly.

Assembler symbols

- <Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- <R> Is a width specifier, encoded in the "option" field. It can have the following values:
  - W when option = 00x
  - W when option = 010
  - X when option = x11
  - W when option = 10x
  - W when option = 110
- <m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
<extend>
For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- LSL|UXTW when option = 010
- UTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

- UXTB when option = 000
- UXTH when option = 001
- UXTW when option = 010
- LSL|UXTX when option = 011
- SXTB when option = 100
- SXTH when option = 101
- SXTW when option = 110
- SXTX when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount>
Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation
The description of SUBS (extended register) gives the operational pseudocode for this instruction.

Operational information
If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
### C6.2.61 CMP (immediate)

Compare (immediate) subtracts an optionally-shifted immediate value from a register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the SUBS (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of SUBS (immediate).
- The description of SUBS (immediate) gives the operational pseudocode for this instruction.

#### 32-bit variant

Applies when $sf = 0$.

CMP <Wn|WSP>, #<imm>{, <shift>}

is equivalent to

SUBS WZR, <Wn|WSP>, #<imm> {, <shift>}

and is always the preferred disassembly.

#### 64-bit variant

Applies when $sf = 1$.

CMP <Xn|SP>, #<imm>{, <shift>}

is equivalent to

SUBS XZR, <Xn|SP>, #<imm> {, <shift>}

and is always the preferred disassembly.

#### Assembler symbols

- `<Wn|WSP>` is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Xn|SP>` is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<imm>` is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
- `<shift>` is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "sh" field. It can have the following values:
  - LSL #0 when $sh = 0$
  - LSL #12 when $sh = 1$

#### Operation

The description of SUBS (immediate) gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.62  CMP (shifted register)

Compare (shifted register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the SUBS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{CMP } \langle Wn \rangle, \langle Wm \rangle\{, \langle \text{shift} \rangle \#\langle \text{amount} \rangle \}
\]

is equivalent to

\[
\text{SUBS WZR, } \langle Wn \rangle, \langle Wm \rangle\{, \langle \text{shift} \rangle \#\langle \text{amount} \rangle \}
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{CMP } \langle Xn \rangle, \langle Xm \rangle\{, \langle \text{shift} \rangle \#\langle \text{amount} \rangle \}
\]

is equivalent to

\[
\text{SUBS XZR, } \langle Xn \rangle, \langle Xm \rangle\{, \langle \text{shift} \rangle \#\langle \text{amount} \rangle \}
\]

and is always the preferred disassembly.

### Assembler symbols

- \( \langle Wm \rangle \) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \( \langle Xm \rangle \) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \( \langle Xn \rangle \) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \( \langle Xm \rangle \) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \( \langle \text{shift} \rangle \) Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( \text{shift} = 00 \)
  - LSR when \( \text{shift} = 01 \)
  - ASR when \( \text{shift} = 10 \)
  - The encoding \( \text{shift} = 11 \) is reserved.
- \( \langle \text{amount} \rangle \) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.63   CMPP

Compare with Tag subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, updates the condition flags based on the result of the subtraction, and discards the result.

This instruction is an alias of the SUBPS instruction. This means that:

• The encodings in this description are named to match the encodings of SUBPS.

• The description of SUBPS gives the operational pseudocode for this instruction.

ARMv8.5

<table>
<thead>

</tbody>
</table>

**Integer variant**

CMPP <Xn|SP>, <Xm|SP>

is equivalent to

SUBPS XZR, <Xn|SP>, <Xm|SP>

and is always the preferred disassembly.

**Assembler symbols**

<Xn|SP>  Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Xn" field.

<Xm|SP>  Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Xm" field.

**Operation**

The description of SUBPS gives the operational pseudocode for this instruction.
C6.2.64  CNEG

Conditional Negate returns, in the destination register, the negated value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the CSNEG instruction. This means that:

- The encodings in this description are named to match the encodings of CSNEG.
- The description of CSNEG gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{CNEG} \ <Wd>, \ <Wn>, \ <\text{cond}>
\]

is equivalent to

\[
\text{CSNEG} \ <Wd>, \ <Wn>, \ <Wn>, \ \text{invert}(<\text{cond}>)
\]

and is the preferred disassembly when \( Rn = Rm \).

64-bit variant

Applies when \( sf = 1 \).

\[
\text{CNEG} \ <Xd>, \ <Xn>, \ <\text{cond}>
\]

is equivalent to

\[
\text{CSNEG} \ <Xd>, \ <Xn>, \ <Xn>, \ \text{invert}(<\text{cond}>)
\]

and is the preferred disassembly when \( Rn = Rm \).

Assembler symbols

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- \(<\text{cond}>\) is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSNEG gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.65  CPP

Cache Prefetch Prediction Restriction by Context prevents cache allocation predictions, based on information gathered from earlier execution within a particular execution context, from allowing later speculative execution within that context to be observable through side-channels.

For more information, see CPP RCTX.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

ARMv8.5

```
|31 30 29 28|27 26 25 24|23 22 21 20|19 18 16|15 12|11 8 7 5 4 | 0 |
|1 1 0 1 0 1 0 0|0 0 1 0 1 1 1 0 1 1 1 1 0 0 1 1 1 1 1 1|Rt |
```

**System variant**

CPP RCTX, <Xt>

is equivalent to

SYS #3, C8, C3, #7, <Xt>

and is always the preferred disassembly.

**Assembler symbols**

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
C6.2.66   CRC32B, CRC32H, CRC32W, CRC32X

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial \(0x04C11DB7\) is used for the CRC calculation.

In Armv8-A, this is an OPTIONAL instruction, and in Armv8.1 it is mandatory for all implementations to implement it.

--- Note ---
ID_AA64ISAR0_EL1.CRC32 indicates whether this instruction is supported.

---

CRC32B variant
Applies when \(sf == 0 \&\& sz == 00\).
CRC32B \(<Wd>, <Wn>, <Wm>\)

CRC32H variant
Applies when \(sf == 0 \&\& sz == 01\).
CRC32H \(<Wd>, <Wn>, <Wm>\)

CRC32W variant
Applies when \(sf == 0 \&\& sz == 10\).
CRC32W \(<Wd>, <Wn>, <Wm>\)

CRC32X variant
Applies when \(sf == 1 \&\& sz == 11\).
CRC32X \(<Wd>, <Wn>, <Xm>\)

Decode for all variants of this encoding

```
if !HaveCRCExt() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sf == '1' \&\& sz == '11' then UNDEFINED;
if sf == '0' \&\& sz == '11' then UNDEFINED;
integer size = 8 << UInt(sz);
```

Assembler symbols

- \(<Wd>\): Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.
- \(<Wn>\): Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.
- \(<Xm>\): Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.
<hm> Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.

**Operation**

```plaintext
bits(32) acc = X[n];  // accumulator
bits(size) val = X[m];  // input value
bits(32) poly = 0x04C11DB7<31:0>;

bits(32+size) tempacc = BitReverse(acc):Zeros(size);
bits(size+32) tempval = BitReverse(val):Zeros(32);

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.67 CRC32CB, CRC32CH, CRC32CW, CRC32CX

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x1EDC6F41 is used for the CRC calculation.

In Armv8-A, this is an OPTIONAL instruction, and in Armv8.1 it is mandatory for all implementations to implement it.

Note
ID_AA64ISAR0_EL1.CRC32 indicates whether this instruction is supported.

// Poly32Mod2 on a bitstring does a polynomial Modulus over \{0,1\} operation
\[
X[d] = \text{BitReverse}(\text{Poly32Mod2}(\text{tempacc} \text{ EOR tempval}, poly));
\]

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.68  CSDB

Consumption of Speculative Data Barrier is a memory barrier that controls speculative execution and data value prediction.

No instruction other than branch instructions appearing in program order after the CSDB can be speculatively executed using the results of any:

- Data value predictions of any instructions.
- PSTATE.\{N,Z,C,V\} predictions of any instructions other than conditional branch instructions appearing in program order before the CSDB that have not been architecturally resolved.
- Predictions of SVE predication state for any SVE instructions.

--- Note ---

For purposes of the definition of CSDB, PSTATE.\{N,Z,C,V\} is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or PSTATE.\{N,Z,C,V\} predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

System variant

CSDB

Decode for this encoding

// Empty.

Operation

ConsumptionOfSpeculativeDataBarrier();
C6.2.69  CSEL

Conditional Select returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register.

Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

if ConditionHolds(cond) then
    result = operand1;
else
    result = operand2;

X[d] = result;
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.70   CSET

Conditional Set sets the destination register to 1 if the condition is TRUE, and otherwise sets it to 0.

This instruction is an alias of the CSINC instruction. This means that:

• The encodings in this description are named to match the encodings of CSINC.
• The description of CSINC gives the operational pseudocode for this instruction.

32-bit variant
Applies when \(sf == 0\).

\[
CSET <Wd>, <\text{cond}>
\]

is equivalent to

\[
\text{CSINC} <Wd>, WZR, WZR, \text{invert(<\text{cond})}
\]

and is always the preferred disassembly.

64-bit variant
Applies when \(sf == 1\).

\[
CSET <Xd>, <\text{cond}>
\]

is equivalent to

\[
\text{CSINC} <Xd>, XZR, XZR, \text{invert(<\text{cond})}
\]

and is always the preferred disassembly.

Assembler symbols

\(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<\text{cond}>\) Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINC gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.71 CSETM

Conditional Set Mask sets all bits of the destination register to 1 if the condition is TRUE, and otherwise sets all bits to 0.

This instruction is an alias of the CSINV instruction. This means that:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

CSETM <Wd>, <cond>

is equivalent to

CSINV <Wd>, WZR, WZR, invert(<cond>)

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

CSETM <Xd>, <cond>

is equivalent to

CSINV <Xd>, XZR, XZR, invert(<cond>)

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<\text{cond}>\) is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

### Operation

The description of CSINV gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.72  CSINC

Conditional Select Increment returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register incremented by 1.

This instruction is used by the aliases CINC and CSET. See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when $sf == 0$.

\[
\text{CSINC} <Wd>, <Wn>, <Wm>, <\text{cond}>
\]

64-bit variant
Applies when $sf == 1$.

\[
\text{CSINC} <Xd>, <Xn>, <Xm>, <\text{cond}>
\]

Decode for all variants of this encoding

\[
\text{integer } d = \text{UInt}(\text{Rd}); \\
\text{integer } n = \text{UInt}(\text{Rn}); \\
\text{integer } m = \text{UInt}(\text{Rm}); \\
\text{integer } \text{datasize} = \text{if } sf == '1' \text{ then 64 else 32};
\]

Assembler symbols

- $<\text{Wd}>$ is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<\text{Wn}>$ is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<\text{Wm}>$ is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- $<\text{Xd}>$ is the 64-bit name of the general-purpose destination register, encoded in the "Rm" field.
- $<\text{Xn}>$ is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- $<\text{ Xm}>$ is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- $<\text{cond}>$ is one of the standard conditions, encoded in the "cond" field in the standard way.
Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

if ConditionHolds(cond) then
    result = operand1;
else
    result = operand2 + 1;

X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.73 CSINV

Conditional Select Invert returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the bitwise inversion value of the second source register.

This instruction is used by the aliases CINV and CSETM. See Alias conditions for details of when each alias is preferred.

**32-bit variant**

Applies when \( sf = 0 \).

CSINV <Wd>, <Wn>, <Wm>, <cond>

**64-bit variant**

Applies when \( sf = 1 \).

CSINV <Xd>, <Xn>, <Xm>, <cond>

**Decode for all variants of this encoding**

C6.2.75 DC

Data Cache operation. For more information, see $op0==0b01$, cache maintenance, TLB maintenance, and address translation instructions on page C5-366.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

### System variant

DC $<dc\_op>$, $<Xt>$

is equivalent to

SYS $#<op1>$, C7, $<Cm>$, $#<op2>$, $<Xt>$

and is the preferred disassembly when $SysOp(op1,'0111',CRm,op2) == Sys\_DC$.

### Assembler symbols

$<dc\_op>$

Is a DC instruction name, as listed for the DC system instruction group, encoded in the "$op1:CRm:op2" field. It can have the following values:

- IVAC: when $op1 = 000$, $CRm = 0110$, $op2 = 001$
- ISW: when $op1 = 000$, $CRm = 0110$, $op2 = 010$
- CSW: when $op1 = 000$, $CRm = 1010$, $op2 = 010$
- CISW: when $op1 = 000$, $CRm = 1110$, $op2 = 010$
- ZVA: when $op1 = 011$, $CRm = 0100$, $op2 = 001$
- CVAC: when $op1 = 011$, $CRm = 0100$, $op2 = 001$
- CVAU: when $op1 = 011$, $CRm = 1011$, $op2 = 001$
- CIVAC: when $op1 = 011$, $CRm = 1110$, $op2 = 001$

When ARMv8.5-MemTag is implemented, the following values are also valid:

- IGVAC: when $op1 = 000$, $CRm = 0110$, $op2 = 011$
- IGSW: when $op1 = 000$, $CRm = 0110$, $op2 = 100$
- IGDVAC: when $op1 = 000$, $CRm = 0110$, $op2 = 101$
- IGDSW: when $op1 = 000$, $CRm = 0110$, $op2 = 110$
- CGSW: when $op1 = 000$, $CRm = 1010$, $op2 = 100$
- CGDSW: when $op1 = 000$, $CRm = 1010$, $op2 = 110$
- CIGSW: when $op1 = 000$, $CRm = 1110$, $op2 = 100$
- CIGDSW: when $op1 = 000$, $CRm = 1110$, $op2 = 110$
- GVA: when $op1 = 011$, $CRm = 0100$, $op2 = 011$
- GZVA: when $op1 = 011$, $CRm = 0100$, $op2 = 100$
- CGVAC: when $op1 = 011$, $CRm = 1010$, $op2 = 011$
- CGDVAC: when $op1 = 011$, $CRm = 1010$, $op2 = 101$
CGVAP  when op1 = 011, CRm = 1100, op2 = 011
CGDVAP  when op1 = 011, CRm = 1100, op2 = 101
CGVADP  when op1 = 011, CRm = 1101, op2 = 011
CGDVADP when op1 = 011, CRm = 1101, op2 = 101
CIGVAC  when op1 = 011, CRm = 1110, op2 = 011
CIGDVAC when op1 = 011, CRm = 1110, op2 = 101

When ARMv8.2-DCPoP is implemented, the following value is also valid:

CVAP  when op1 = 011, CRm = 1100, op2 = 001

When ARMv8.2-DCCVADP is implemented, the following value is also valid:

CVADP  when op1 = 011, CRm = 1101, op2 = 001

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.
C6.2.76  DCPS1

Debug Change PE State to EL1, when executed in Debug state:

- If executed at EL0 changes the current Exception level and SP to EL1 using SP_EL1.
- Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS1 instruction is:

- EL1 if the instruction is executed at EL0.
- Otherwise, the Exception level at which the instruction is executed.

When the target Exception level of a DCPS1 instruction is ELx, on executing this instruction:

- ELR_ELx becomes UNKNOWN.
- SPSR_ELx becomes UNKNOWN.
- ESR_ELx becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_ELx.EE.

This instruction is UNDEFINED at EL0 in Non-secure state if EL2 is implemented and HCR_EL2.TGE == 1.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see DCPS<n> on page H2-6731.

```
|31 30 29 28|27 26 25 24|23 22 21 20| 1 0 1 0 0 0 1 1| imm16 | 5 4 3 2 1 0 |

1 1 0 1 0 0 0 1
```

**System variant**

DCPS1 {#<imm>}

**Decode for this encoding**

if !Halted() then AArch64.UndefindFault();

**Assemble symbols**

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

**Operation**

DCPSInstruction(LL);
C6.2.77 DCPS2

Debug Change PE State to EL2, when executed in Debug state:

- If executed at EL0 or EL1 changes the current Exception level and SP to EL2 using SP_EL2.
- Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS2 instruction is:

- EL2 if the instruction is executed at an exception level that is not EL3.
- EL3 if the instruction is executed at EL3.

When the target Exception level of a DCPS2 instruction is ELx, on executing this instruction:

- ELR_ELx becomes UNKNOWN.
- SPSR_ELx becomes UNKNOWN.
- ESR_ELx becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_ELx.EE.

This instruction is UNDEFINED at the following exception levels:

- All exception levels if EL2 is not implemented.
- At EL0 and EL1 if EL2 is disabled in the current Security state.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see DCPS<n> on page H2-6731.

System variant

DCPS2 {#<imm>}

Decode for this encoding

if !Halted() then AArch64.UndefinedFault();

Assembler symbols

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

DCPSInstruction(LL);
C6.2.78   DCPS3

Debug Change PE State to EL3, when executed in Debug state:

• If executed at EL3 selects SP_EL3.
• Otherwise, changes the current Exception level and SP to EL3 using SP_EL3.

The target exception level of a DCPS3 instruction is EL3.

On executing a DCPS3 instruction:

• ELR_EL3 becomes UNKNOWN.
• SPSR_EL3 becomes UNKNOWN.
• ESR_EL3 becomes UNKNOWN.
• DLR_EL0 and DSPSR_EL0 become UNKNOWN.
• The endianness is set according to SCTLR_EL3.EE.

This instruction is UNDEFINED at all exception levels if either:

• EDSR_SDD == 1.
• EL3 is not implemented.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see DCPS<n> on page H2-6731.

|31 30 29 28|27 26 25 24|23 22 21 20|  5 4 3 2 1 0 |
|1 1 0 1 0 1 0 0|1 0 1| imm16 | 0 0 0 1 1 |

System variant
DCPS3 {#imm}

Decode for this encoding
if !Halted() then AArch64.UndefineFault();

Assembler symbols
<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation
DCPSInstruction(LL);
C6.2.79  DMB

Data Memory Barrier is a memory barrier that ensures the ordering of observations of memory accesses, see Data Memory Barrier (DMB) on page B2-125.

L op1 CRn CRm op2
```

**System variant**

DVP RCTX, <Xt>

is equivalent to

SYS #3, C8, C3, #5, <Xt>

and is always the preferred disassembly.

**Assembler symbols**

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
C6.2.83 EON (shifted register)

Bitwise Exclusive OR NOT (shifted register) performs a bitwise Exclusive OR NOT of a register value and an optionally-shifted register value, and writes the result to the destination register.

32-bit variant

Applies when \( sf == 0 \).

\[
\text{EON} \ <Wd>, \ <Wn>, \ <Wm> \{, \ <\text{shift}> \ #<\text{amount}>\}
\]

64-bit variant

Applies when \( sf == 1 \).

\[
\text{EON} \ <Xd>, \ <Xn>, \ <Xm> \{, \ <\text{shift}> \ #<\text{amount}>\}
\]

Decode for all variants of this encoding

Integer \( d = \operatorname{UInt}(Rd) \);

Integer \( n = \operatorname{UInt}(Rn) \);

Integer \( m = \operatorname{UInt}(Rm) \);

Integer \( \text{datasize} = \text{if} \ sf == '1' \ \text{then} \ 64 \ \text{else} \ 32; \)

\[
\text{if} \ sf == '0' \ \&\& \ \operatorname{imm6}<5> == '1' \ \text{then} \ \text{UNDEFINED};
\]

\[
\text{ShiftType} \ shift\_type = \operatorname{DecodShift}(\text{shift});
\]

Integer \( \text{shift\_amount} = \operatorname{UInt}(\text{imm6});\)

Assembler symbols

\(<\text{Wd}>\)  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<\text{Wn}>\)  Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(<\text{Wm}>\)  Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

\(<\text{Xd}>\)  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<\text{Xn}>\)  Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

\(<\text{Xm}>\)  Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

\(<\text{shift}>\)  Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- \( \text{LSL} \) when \( \text{shift} = 00 \)
- \( \text{LSR} \) when \( \text{shift} = 01 \)
- \( \text{ASR} \) when \( \text{shift} = 10 \)
- \( \text{ROR} \) when \( \text{shift} = 11 \)

\(<\text{amount}>\)  For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
operand2 = NOT(operand2);
result = operand1 EOR operand2;
X[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.84  EOR (immediate)

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register.

32-bit variant

Applies when \( sf = 0 \) \&\& \( N = 0 \).

\[
\text{EOR}<Wd|WSP>, <Wn>, #<imm>
\]

64-bit variant

Applies when \( sf = 1 \).

\[
\text{EOR}<Xd|SP>, <Xn>, #<imm>
\]

Decode for all variants of this encoding

\[
\text{integer } d = \text{ UInt}(Rd); \\
\text{integer } n = \text{ UInt}(Rn); \\
\text{integer } \text{datasize} = \text{ if } sf = '1' \text{ then } 64 \text{ else } 32; \\
\text{bits} (\text{datasize}) \text{ imm}; \\
\text{if } sf = '0' \text{ \&\& } N \neq '0' \text{ then UNDEFINED; } \\
(imm, -) = \text{ DecodeBitMasks}(N, \text{ imms}, \text{ immr}, \text{ TRUE});
\]

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.86 ERET

Exception Return using the ELR and SPSR for the current Exception level. When executed, the PE restores PSTATE from the SPSR, and branches to the address held in the ELR.

The PE checks the SPSR for the current Exception level for an illegal return event. See Illegal return events from AArch64 state on page D1-2304.

ERET is UNDEFINED at EL0.

```
|31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 | 5 4 | 0 |
-----|-----|-----|-----|-----|-----|-----|-----|-----|
    1 1 0 1 0 1 1 | 0 1 0 0 | 1 1 1 1 | 0 0 0 0 | 0 0 1 1 1 1 | 0 0 0 0 0 0 |
```

System variant

ERET

Decode for this encoding

if PSTATE.EL == EL0 then UNDEFINED;

Operation

```
AArch64.CheckForERetTrap(FALSE, TRUE);
bits(64) target = ELR[];
AArch64.ExceptionReturn(target, SPSR[]);
```
C6.2.87 ERETAA, ERETAB

Exception Return, with pointer authentication. This instruction authenticates the address in ELR, using SP as the modifier and the specified key, the PE restores PSTATE from the SPSR for the current Exception level, and branches to the authenticated address.

Key A is used for ERETAA, and key B is used for ERETAB.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to ELR.

The PE checks the SPSR for the current Exception level for an illegal return event. See Illegal return events from AArch64 state on page D1-2304.

ERETAA and ERETAB are UNDEFINED at EL0.

ARMv8.3

| 31 30 29 28 | 27 26 25 24 | 23 22 21 20 | 19 18 17 16 | 15 14 13 12 | 11 10 9 8 7 6 5 4 | 0 1 |

integer m = UInt(Xm);
```

**Assembler symbols**

- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Xd" field.
- `<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Xn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Xm" field.

**Operation**

```
bits(64) address = if n == 31 then SP[] else X[n];
bits(64) mask = X[m];
bits(4) tag = AArch64.AllocationTagFromAddress(address);

mask<UInt(tag)> = '1';
X[d] = mask;
```
C6.2.91  HINT

Hint instruction is for the instruction set space that is reserved for architectural hint instructions.

Some encodings described here are not allocated in this revision of the architecture, and behave as NOPs. These encodings might be allocated to other hint functionality in future revisions of the architecture and therefore must not be used by software.

HINT #<imm>

System variant

Decode for this encoding

SystemHintOp op;

case CRm:op2 of
    when '0000 000' op = SystemHintOp_NOP;
    when '0000 001' op = SystemHintOp_YIELD;
    when '0000 010' op = SystemHintOp_WFE;
    when '0000 011' op = SystemHintOp_WFI;
    when '0000 100' op = SystemHintOp_SEV;
    when '0000 101' op = SystemHintOp_SEVL;
    when '0000 111' SEE "XPACLRI";
    when '0001 xxx' SEE "PACIA1716, PACIB1716, AUTIA1716, AUTIB1716";
    when '0010 000'
        if !HaveRASExt() then EndOfInstruction();    // Instruction executes as NOP
        op = SystemHintOp_ESB;
    when '0010 001'
        if !HaveStatisticalProfiling() then EndOfInstruction();    // Instruction executes as NOP
        op = SystemHintOp_PSB;
    when '0010 010'
        if !HaveSelfHostedTrace() then EndOfInstruction();    // Instruction executes as NOP
        op = SystemHintOp_TSB;
    when '0010 100'
        op = SystemHintOp_CSDB;
    when '0011 xxx'
        SEE "PACIAZ, PACIASP, PACIBZ, PACIBSP, AUTIAZ, AUTIASP, AUTIBZ, AUTIBSP";
    when '0100 xx0'
        op = SystemHintOp_BTI;
        // Check branch target compatibility between BTI instruction and PSTATE.BTYPE
        - = BTypeCompatible_BTI(op2<2:1>);
    otherwise EndOfInstruction();

Assembler symbols

<imm>  Is a 7-bit unsigned immediate, in the range 0 to 127 encoded in the "CRm:op2" field.

The encodings that are allocated to architectural hint functionality are described in the "Hints" table in the "Index by Encoding".

——— Note ————

For allocated encodings of "CRm:op2":

- A disassembler will disassemble the allocated instruction, rather than the HINT instruction.
An assembler may support assembly of allocated encodings using HINT with the corresponding <imm> value, but it is not required to do so.

### Operation

```c
case op of
  when SystemHintOp_YIELD
      Hint_Yield();
  when SystemHintOp_WFE
      if IsEventRegisterSet() then
          ClearEventRegister();
      else
          if PSTATE.EL == EL0 then
              // Check for traps described by the OS which may be EL1 or EL2.

```
C6.2.92   HLT

Halt instruction. A HLT instruction can generate a Halt Instruction debug event, which causes entry into Debug state.

| [31 30 29 28|27 26 25 24|23 22 21 20] |   |   |  5 4 3 2 1 0     |
| 1 1 0 1 0 1 0 0 0 1 0              imm16 0 0 0 0 |

System variant

HLT #<imm>

Decode for this encoding

if ESCR.HDE == '0' || !HaltingAllowed() then UndefinedFault();
-  = HaveBTIExt();

Assembler symbols

<imm>    is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

Halt(DebugHalt_HaltInstruction);
C6.2.93   HVC

Hypervisor Call causes an exception to EL2. Non-secure software executing at EL1 can use this instruction to call
the hypervisor to request a service.

The 
HVC
instruction is UNDEFINED:

• At EL0.
• At EL1 if EL2 is not enabled in the current Security state.
• When SCR_EL3.HCE is set to 0.

On executing an 
HVC
instruction, the PE records the exception as a Hypervisor Call exception in ESR_ELx, using
the EC value 0x16, and the value of the immediate argument.

| 31 30 29 28|27 26 25 24|23 22 21 20| 5 4 3 2 1 0 |

**Assembler symbols**

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

**Operation**

if !HaveEL(EL2) || PSTATE.EL == EL0 || (PSTATE.EL == EL1 && (!IsSecureEL2Enabled() && IsSecure())) then
UNDEFINED;

hvc_enable = if HaveEL(EL3) then SCR_EL3.HCE else NOT(HCR_EL2.HCD);
if hvc_enable == '0' then
AArch64.UndefinedFault();
else
AArch64.CallHypervisor(imm16);
C6.2.94   IC

Instruction Cache operation. For more information, see \textit{op0==0b01, cache maintenance, TLB maintenance, and address translation instructions on page C5-366}.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

System variant

\texttt{IC <ic\_op>{, <Xt>}}

is equivalent to

\texttt{SYS \#<op1>, C7, \#<Cm>, \#<op2>{, <Xt>}}

and is the preferred disassembly when \texttt{SysOp(op1,'011',CRm,op2) == Sys\_IC}.

Assembler symbols

\texttt{<ic\_op>} Is an IC instruction name, as listed for the IC system instruction pages, encoded in the "op1:CRm:op2" field. It can have the following values:

- \texttt{IALLUIS} when \texttt{op1 = 000, CRm = 0001, op2 = 000}
- \texttt{IALLU} when \texttt{op1 = 000, CRm = 0101, op2 = 000}
- \texttt{IVAU} when \texttt{op1 = 011, CRm = 0101, op2 = 001}

\texttt{<op1>} Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

\texttt{<Cm>} Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

\texttt{<op2>} Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

\texttt{<Xt>} Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.
C6.2.95   IRG

Insert Random Tag inserts a random Logical Address Tag into the address in the first source register, and writes the result to the destination register. Any tags specified in the optional second source register or in GCR_EL1.Exclude are excluded from the selection of the random Logical Address Tag.

ARMv8.5

| 31 30 29 28|27 26 25 24|23 22 21 20|  16|15 14 13 12|11 10 9 |  5 4 |  0 |
|---|---|---|---|---|---|---|---|---|
| 1 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 0 |

Integer variant

IRG <Xd|SP>, <Xn|SP>{, <Xm>}

Decode for this encoding

d = Uint(Xd);
n = Uint(Xn);
m = Uint(Xm);

Assembler symbols

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Xd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Xn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Xm" field. Defaults to XZR if absent.

Operation

bits(64) operand = if n == 31 then SP[] else X[n];
bits(64) exclude_reg = X[m];
bits(16) excludes = exclude_reg<15:0> OR GCR_EL1.Exclude;

</table>
```

**System variant**

ISB {<option> |<imm>}

**Decode for this encoding**

// No additional decoding required

**Assembler symbols**

- **<option>** Specifies an optional limitation on the barrier operation. Values are:
  - SY: Full system barrier operation, encoded as CRm = 0b1111. Can be omitted.
    - All other encodings of CRm are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.
- **<imm>** Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

**Operation**

```
InstructionSynchronizationBarrier();
```
C6.2.97 LDADDB, LDADDAB, LDADDLB, LDADDLB

Atomic add on byte in memory atomically loads an 8-bit byte from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not \texttt{WZR}, \texttt{LDADDB} and \texttt{LDADDALB} load from memory with acquire semantics.
- \texttt{LDADDLB} and \texttt{LDADDLB} store to memory with release semantics.
- \texttt{LDADDB} has no memory ordering requirements.

For more information about memory ordering semantics see \textit{Load-Acquire, Load-AcquirePC, and Store-Release} on page B2-129.

For information about memory accesses see \textit{Load/Store addressing modes} on page C1-177.

This instruction is used by the alias \texttt{STADDB}, \texttt{STADDLB}. See \textit{Alias conditions} on page C6-914 for details of when each alias is preferred.

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.100  LDAPR

Load-Acquire RCpc Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from the derived address in memory, and writes it to a register.

The instruction has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-129, except that:

• There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.

• The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see Load/Store addressing modes on page C1-177.

ARMv8.3

Unscaled offset variant

LDAPURH <Wt>, [<Xn|SP>{, #<simm>]}]

Decode for this encoding

bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

<Wt>   Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

    integer n = UInt(Rn);
    integer t = UInt(Rt);
    boolean tag_checked = n != 31;

Operation

if HaveMTEExt() then
    SetNotTagCheckedInstruction(!tag_checked);

    bits(64) address;
    bits(16) data;

    if n == 31 then
        CheckSPAlignment();
        address = SP[ ];
    else
address = X[n];
address = address + offset;
data = Mem[address, 2, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.106  LDAPURSB

Load-Acquire RCpc Register Signed Byte (unscaled) calculates an address from a base register and an immediate offset, loads a signed byte from memory, sign-extends it, and writes it to a register.

The instruction has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-129, except that:

• There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.

• The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see Load/Store addressing modes on page C1-177.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.112    LDAXP

Load-Acquire Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and is single-copy atomic for each doubleword at doubleword granularity. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores on page B2-156. The instruction also has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release on page B2-129. For information about memory accesses see Load/Store addressing modes on page C1-177.

32-bit variant

Applies when \( sz == 0 \).

LDAXP \(<Wt1>, <Wt2>, [<Xn|SP>\{,#0}\] \)

64-bit variant

Applies when \( sz == 1 \).

LDAXP \(<Xt1>, <Xt2>, [<Xn|SP>\{,#0}\] \)

Decode for all variants of this encoding

integer \( n = \text{UInt}(Rn) \);
integer \( t = \text{UInt}(Rt) \);
integer \( t2 = \text{UInt}(Rt2) \);

integer \( elsize = 32 \ll \text{UInt}(sz) \);
integer \( datasize = elsize \times 2 \);
boolean \( \text{tag\_checked} = n != 31 \);

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDAXP on page K1-7637.

Assembler symbols

\(<Wt1>\)    Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
\(<Wt2>\)    Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.116   **LDCLRAB, LDCLRAB, LDCLRALB, LDCLRLB**

Atomic bit clear on byte in memory atomically loads an 8-bit byte from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not $\text{WZR}$, **LDCLRAB** and **LDCLRALB** load from memory with acquire semantics.
- **LDCLRAB** and **LDCLRALB** store to memory with release semantics.
- **LDCLRB** has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-129.

For information about memory accesses see *Load/Store addressing modes* on page C1-177.

This instruction is used by the alias **STCLRB**, **STCLRLB**. See *Alias conditions* on page C6-949 for details of when each alias is preferred.

**No offset variant**

LDLARB <Wt>, [<Xn|SP>{,#0}]

**Decode for this encoding**

integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;

**Assembler symbols**

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Operation**

bits(64) address;
bits(8) data;

if HaveMTEExt() then
  SetNotTagCheckedInstruction(!tag_checked);

if n == 31 then
  CheckSPAAlignment();
  address = SP[];
else
  address = X[n];

data = Mem[address, 1, AccType_LIMITEDORDERED];
X[t] = ZeroExtend(data, 32);

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.125 LDLARH

Load LOAcquire Register Halfword loads a halfword from memory, zero-extends it, and writes it to a register. The
instruction also has memory ordering semantics as described in LoadLOAcquire, StoreLORelease on page B2-130.
For information about memory accesses, see Load/Store addressing modes on page C1-177.

Note

For this instruction, if the destination is WZR/ZXR, it is impossible for software to observe the presence of the
acquire semantic other than its effect on the arrival at endpoints.

ARMv8.1

No offset variant

LDLARH <Wt>, [<Xn|SP>{,#0}]

Decode for this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

bits(64) address;
bits(16) data;

if HaveMTEExt() then
    SetNotTagCheckedInstruction(!tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 2, AccType_LIMITEDORDERED];
X[t] = ZeroExtend(data, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.126   LDLAR

Load LOAcquire Register loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The instruction also has memory ordering semantics as described in LoadLOAcquire, StoreLORelease on page B2-130. For information about memory accesses, see Load/Store addressing modes on page C1-177.

Note

For this instruction, if the destination is WZR/ZXR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

ARMv8.1

32-bit variant

Applies when size == 10.

LDLAR <Wt>, [<Xn|SP>{{,#0}}]

64-bit variant

Applies when size == 11.

LDLAR <Xt>, [<Xn|SP>{{,#0}}]

Decode for all variants of this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
boolean tag_checked = n != 31;

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;
if HaveMTEExt() then
    SetNotTagCheckedInstruction(!tag_checked);
if n == 31 then
    CheckSPAAlignment();
    address = SP[];
else
    address = X[n];
data = Mem[address, dbytes, AccType_LIMITEDORDERED];
X[t] = ZeroExtend(data, regsize);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.127   LDNP

Load Pair of Registers, with non-temporal hint, calculates an address from a base register value and an immediate offset, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers.

For information about memory accesses, see Load/Store addressing modes on page C1-177. For information about Non-temporal pair instructions, see Load/Store Non-temporal Pair on page C3-200.

### 32-bit variant

Applies when $\text{opc} == 00$.

LDNP $\langle\text{Wt1}\rangle$, $\langle\text{Wt2}\rangle$, $\{\langle\text{Xn}||\text{SP}\rangle\{, \#\langle\text{imm}\rangle\} \}$

### 64-bit variant

Applies when $\text{opc} == 10$.

LDNP $\langle\text{Xt1}\rangle$, $\langle\text{Xt2}\rangle$, $\{\langle\text{Xn}||\text{SP}\rangle\{, \#\langle\text{imm}\rangle\} \}$

**Decode for all variants of this encoding**

// Empty.

**Notes for all encodings**

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDNP on page K1-7637.

**Assembler symbols**

- $\langle\text{Wt1}\rangle$: Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
- $\langle\text{Wt2}\rangle$: Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
- $\langle\text{Xt1}\rangle$: Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
- $\langle\text{Xt2}\rangle$: Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
- $\langle\text{Xn}||\text{SP}\rangle$: Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- $\langle\text{imm}\rangle$: For the 32-bit variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as $\langle\text{imm}\rangle/4$.
  For the 64-bit variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as $\langle\text{imm}\rangle/8$.

**Shared decode for all encodings**

            X[n] = address;

    Operational information

    If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.131   LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-177.

|31 30 29 28|27 26 25 24|23 | | | | 5 4 | 0 |
|-------------|-------------|---|---|---|---|---|---|---|---|---|
| 0 1 1 0 0 0 | | | imm19 | | | | | | Rt |

**32-bit variant**

Applies when opc == 00.

LDR <Wt>, <label>

**64-bit variant**

Applies when opc == 01.

LDR <Xt>, <label>

**Decode for all variants of this encoding**

integer t = UInt(Rt);
MemOp memop = MemOp_LOAD;
boolean signed = FALSE;
integer size;
bits(64) offset;
case opc of
  when '00'
    size = 4;
  when '01'
    size = 8;
  when '10'
    size = 4;
    signed = TRUE;
  when '11'
    memop = MemOp_PREFETCH;

offset = SignExtend(imm19:'00', 64);

**Assembler symbols**

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<label> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

**Operation**

bits(64) address = PC[] + offset;
bits(size*8) data;

if HaveMTEExt() then
  SetNotTagCheckedInstruction(TRUE);

case memop of
when MemOp_LOAD
  data = Mem[address, size, AccType_NORMAL];
  if signed then
    X[t] = SignExtend(data, 64);
  else
    X[t] = data;

when MemOp_PREFETCH
  Prefetch(address, t<4:0>);

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.132 LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted and extended. For information about memory accesses, see Load/Store addressing modes on page C1-177.

| 31 30 29 28| 27 26 25 24| 23 22 21 20| 16|15| 13| 12|11|10| 9| 5| 4| 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1| x| 1| 1| 1| 0| 0| 0| 1| 1| Rn| option| S| 1| 0| Rn| Rt |

**64-bit variant**

Applies when size == 11.

LDR <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]

**Decode for all variants of this encoding**

integer scale = UInt(size);
if option<1> == '0' then UNDEFINED; // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;

**Assembler symbols**

- <Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- <Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- <extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in the "option" field. It can have the following values:
  - UXTW when option = 010
  - LSL when option = 011
  - SXTW when option = 110
  - SXTX when option = 111
- <amount> For the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:
  - #0 when S = 0
  - #2 when S = 1
For the 64-bit variant: is the index shift amount, optional only when \(<\text{extend}>\) is not LSL. Where it is permitted to be optional, it defaults to \#0. It is encoded in the "S" field. It can have the following values:

\[
\begin{array}{ll}
\text{#0} & \text{when } S = 0 \\
\text{#3} & \text{when } S = 1 \\
\end{array}
\]

**Shared decode for all encodings**

\[
\begin{align*}
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } t &= \text{UInt}(Rt); \\
\text{integer } m &= \text{UInt}(Rm); \\

\text{regsize} &= \text{if } \text{size} == '11' \text{ then } 64 \text{ else } 32; \\
\text{integer } \text{datasize} &= 8 << \text{scale}; \\
\end{align*}
\]

**Operation**

\[
\begin{align*}
\text{bits(64) } \text{offset} &= \text{ExtendReg}(m, \text{extend_type}, \text{shift}); \\
\text{if } \text{HaveMTEExt()} \text{ then} &
\quad \text{SetNotTagCheckedInstruction}(\text{FALSE}); \\
\text{bits(64) } \text{address} &; \\
\text{bits(datasize) } \text{data} &; \\
\text{if } n == 31 \text{ then} &
\quad \text{CheckSPLignment}(); \\
\quad \text{address} &= \text{SP}(); \\
\text{else} &
\quad \text{address} &= X[n]; \\
\text{address} &= \text{address} + \text{offset}; \\
\text{data} &= \text{Mem}[\text{address}, \text{datasize DIV } 8, \text{AccType_NORMAL}]; \\
X[t] &= \text{ZeroExtend}(\text{data}, \text{regsize}); \\
\end{align*}
\]

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.133   LDRAA, LDRAB

Load Register, with pointer authentication. This instruction authenticates an address from a base register using a
modifier of zero and the specified key, adds an immediate offset to the authenticated address, and loads a 64-bit
doubleword from memory at this resulting address into a register.

Key A is used for LDRAA, and key B is used for LDRAB.

If the authentication passes, the PE behaves the same as for an LDR instruction. If the authentication fails, a
Translation fault is generated.

The authenticated address is not written back to the base register, unless the pre-indexed variant of the instruction
is used. In this case, the address that is written back to the base register does not include the pointer authentication
code.

For information about memory accesses, see Load/Store addressing modes on page C1-177.

    if n == 31 then
        SP[] = address;
    else
        X[n] = address;
```
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.135  LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it, and writes it to a register. For information about memory accesses, see Load/Store addressing modes on page C1-177.

Extended register variant

Applies when option != 011.

LDRB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]  

Shifted register variant

Applies when option == 011.

LDRB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]  

Decode for all variants of this encoding

if option<3> == '0' then UNDEFINED; \ sub-word index
ExtendType extend_type = DecodeRegExtend(option);

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
<extend> Is the index extend specifier, encoded in the "option" field. It can have the following values:
UXTW when option = 010
SXTW when option = 110
SXTX when option = 111

<amount> Is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);

Operation

bits(64) offset = ExtendReg(m, extend_type, 0);
if HaveMTEExt() then
  SetNotTagCheckedInstruction(FALSE);
bits(64) address;
b bits(8) data;

if n == 31 then

X[t] = ZeroExtend(data, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.138   LDRSB (immediate)

Load Register Signed Byte (immediate) loads a byte from memory, sign-extends it to either 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see Load/Store addressing modes on page C1-177.

bits(64) offset = LSL(ZeroExtend(imm12, 64), 2);
Notes for all encodings

For information about the CONstrained UNPREDICTable behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTable behaviors, and particularly LDRSW (immediate) on page K1-7640.

Assembler symbols

- `<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<simm>` Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
- `<pimm>` Is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4.

Shared decode for all encodings

```plaintext
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = wback || n != 31;
```

Operation for all encodings

```plaintext
if HaveMTEExt() then
    SetNotTagCheckedInstruction(!tag_checked);

bits(64) address;
bits(32) data;

boolean wb_unknown = FALSE;

if wback && n == t && n != 31 then
    c = ConstrainUnpredictable();
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
      when Constraint_WBSUPPRESS wback = FALSE;  // writeback is suppressed
      when Constraint_UNKNOWN    wb_unknown = TRUE;    // writeback is UNKNOWN
      when Constraint_UNDEF      UNDEFINED;
      when Constraint_NOP        EndOfInstruction();

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

if !postindex then
    address = address + offset;

data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);
if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    elsif postindex then
        address = address + offset;
    if n == 31 then
        SP[] = address;
    else
        X[n] = address;
```

```
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.143 LDRSW (literal)

Load Register Signed Word (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-177.

```
[31 30 29 28][27 26 25 24][23] | | | | 5 4 0 |
    1 0 0 1 1 0 0 | imm19 |   Rt
opc
```

*Literal variant*

LDRSW <Xt>, <label>

*Decode for this encoding*

integer t = UInt(Rt);
bits(64) offset;
offset = SignExtend(imm19:'00', 64);

*Assembler symbols*

<Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<label> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

*Operation*

bits(64) address = PC[] + offset;
bits(32) data;
if HaveMTEExt() then
SetNotTagCheckedInstruction(TRUE);

data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);

*Operational information*

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.144 LDRSW (register)

Load Register Signed Word (register) calculates an address from a base register value and an offset register value, loads a word from memory, sign-extends it to form a 64-bit value, and writes it to a register. The offset register value can be shifted left by 0 or 2 bits. For information about memory accesses, see Load/Store addressing modes on page C1-177.

64-bit variant

LDRSW <Xt>, [<Xn|SP>, (<Wm>|<Xm>{, <extend> {<amount>}}]

Decode for this encoding

if option<3> == '0' then UNDEFINED;  // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then 2 else 0;

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>UXTW</td>
<td>010</td>
</tr>
<tr>
<td>LSL</td>
<td>011</td>
</tr>
<tr>
<td>SXTW</td>
<td>110</td>
</tr>
<tr>
<td>SXTX</td>
<td>111</td>
</tr>
</tbody>
</table>

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>#0</td>
<td>0</td>
</tr>
<tr>
<td>#2</td>
<td>1</td>
</tr>
</tbody>
</table>

Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);

Operation

bits(64) offset = ExtendReg(m, extend_type, shift);
if HaveMTEExt() then
    SetNotTagCheckedInstruction(FALSE);
bits(64) address;
bits(32) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 4, AccType.NORMAL];
X[t] = SignExtend(data, 64);

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.145    LDSETB, LDSETAB, LDSETALB, LDSETLB

Atomic bit set on byte in memory atomically loads an 8-bit byte from memory, performs a bitwise OR with the value
held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in
the destination register.

- If the destination register is not \texttt{WZR}, LDSETAB and LDSETALB load from memory with acquire semantics.
- LDSETLB and LDSETALB store to memory with release semantics.
- LDSETB has no memory ordering requirements.

For more information about memory ordering semantics see 	extit{Load-Acquire, Load-AcquirePC, and Store-Release} on
page B2-129.

For information about memory accesses see 	extit{Load/Store addressing modes} on page C1-177.

This instruction is used by the alias STSETB, STSETLB. See 	extit{Alias conditions} on page C6-1012 for details of when
each alias is preferred.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.158 LDTRSH

Load Register Signed Halfword (unprivileged) loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value on page Glossary-7886 of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value on page Glossary-786 of HCR_EL2.<E2H, TGE> is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes on page C1-177.

32-bit variant

Applies when opc == 11.

LDTRSH <Wt>, [<Xn|SP>{, #<simm>}]

64-bit variant

Applies when opc == 10.

LDTRSH <Xt>, [<Xn|SP>{, #<simm>}]

Decode for all variants of this encoding

bits(64) offset = SignExtend(imm9, 64);

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !(EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11');

\textbf{Operational information}

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.160  LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB

Atomic unsigned maximum on byte in memory atomically loads an 8-bit byte from memory, compares it against
the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.
The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, LDUMAXAB and LDUMAXALB load from memory with acquire semantics.
- LDUMAXLB and LDUMAXALB store to memory with release semantics.
- LDUMAXB has no memory ordering requirements.

For more information about memory ordering semantics see Load-Acquire, Load-AcquirePC, and Store-Release on
page B2-129.

For information about memory accesses see Load/Store addressing modes on page C1-177.

This instruction is used by the alias STUMAXB, STUMAXLB. See Alias conditions on page C6-1045 for details
of when each alias is preferred.

ARMv8.1

LDUMAXB variant
Applies when $A == 1 \&\& R == 0$.
LDUMAXB $<\text{ds}>, <\text{dt}>, [<Xn|SP>]$

LDUMAXALB variant
Applies when $A == 1 \&\& R == 1$.
LDUMAXALB $<\text{ds}>, <\text{dt}>, [<Xn|SP>]$

LDUMAXB variant
Applies when $A == 0 \&\& R == 0$.
LDUMAXB $<\text{ds}>, <\text{dt}>, [<Xn|SP>]$

LDUMAXLB variant
Applies when $A == 0 \&\& R == 1$.
LDUMAXLB $<\text{ds}>, <\text{dt}>, [<Xn|SP>]$

Decode for all variants of this encoding

if !HaveAtomicExt() then UNDEFINED;

integer $t = \text{UInt}(Rt)$;
integer $n = \text{UInt}(Rn)$;
integer $s = \text{UInt}(Rs)$;

AccType ldactctype = if $A == '1' \&\& Rt != '11111'$ then AccType.ORDEREDATOMICRW else AccType_ATOMICRW;

**Assembler symbols**

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Operation**

```plaintext
bits(64) address;
bits(16) value;
bits(16) data;

if HaveMTEExt() then
    SetNotTagCheckedInstruction(!tag_checked);

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = MemAtomic(address, MemAtomicOp_UMIN, value, ldacctype, stacctype);

if t != 31 then
    X[t] = ZeroExtend(data, 32);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.165   LDUMIN, LDUMINA, LDUMINAL, LDUMINL

Atomic unsigned minimum on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDUMINA and LDUMINAL load from memory with acquire semantics.
- LDUMINL and LDUMINAL store to memory with release semantics.
- LDUMIN has no memory ordering requirements.

For more information about memory ordering semantics see Load-Acquire, Load-AcquirePC, and Store-Release on page B2-129.

For information about memory accesses see Load/Store addressing modes on page C1-177.

This instruction is used by the alias STUMIN, STUMINL. See Alias conditions on page C6-1056 for details of when each alias is preferred.

bits(64) address;
bits(32) data;

if n == 31 then
    CheckSPAAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);
```

### Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.172 LDXP

Load Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and is single-copy atomic for each doubleword at doubleword granularity. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores on page B2-156. For information about memory accesses see Load/Store addressing modes on page C1-177.

32-bit variant

Applies when \( sz = 0 \).

LDXP \(<Wt1>, <Wt2>, [<Xn|SP>{,#0}]\)

64-bit variant

Applies when \( sz = 1 \).

LDXP \(<Xt1>, <Xt2>, [<Xn|SP>{,#0}]\)

Decode for all variants of this encoding

integer \( n = \) UInt(Rn);
integer \( t = \) UInt(Rt);
integer \( t2 = \) UInt(Rt2);

integer \( elsize = 32 << \) UInt(sz);
integer \( datasize = elsize \cdot 2; \)
boolean \( tag\_checked = n != 31; \)

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDXP on page K1-7640.

Assembler symbols

\(<Wt1>\) Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

\(<Wt2>\) Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

\(<Xt1>\) Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

\(<Xt2>\) Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

\(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.175  LDXRH

Load Exclusive Register Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores on page B2-156. For information about memory accesses see Load/Store addressing modes on page C1-177.

No offset variant

LDXRH <Wt>, [<Xn|SP>{,#0}]

Decode for this encoding

integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = n != 31;

Assembler symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

bits(64) address;
bits(16) data;

if HaveMTEExt() then
    SetNotTagCheckedInstruction(!tag_checked);

if n == 31 then
    CheckSPAignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, 2);

data = Mem[address, 2, AccType_ATOMIC];
X[t] = ZeroExtend(data, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
C6.2.176  LSL (register)

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This instruction is an alias of the LSLV instruction. This means that:

- The encodings in this description are named to match the encodings of LSLV.
- The description of LSLV gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf \) = 0.

\[
\text{LSL} \ <Wd>, <Wn>, <Wm> \equiv \text{LSLV} \ <Wd>, <Wn>, <Wm>
\]

and is always the preferred disassembly.

64-bit variant

Applies when \( sf \) = 1.

\[
\text{LSL} \ <Xd>, <Xn>, <Xm> \equiv \text{LSLV} \ <Xd>, <Xn>, <Xm>
\]

and is always the preferred disassembly.

Assembler symbols

- \( <Wd> \) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( <Wn> \) is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \( <Wm> \) is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- \( <Xd> \) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( <Xn> \) is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \( <Xm> \) is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of LSLV gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.177  LSL (immediate)

Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

32-bit variant

 Applies when \( sf = 0 \land N = 0 \land imms \neq 011111 \).

\[
\text{LSL} \ <Wd>, \ <Wn>, \ #<shift>
\]

 is equivalent to

\[
\text{UBFM} \ <Wd>, \ <Wn>, \ #(-<shift> \mod 32), \ #(31-<shift>)
\]

and is the preferred disassembly when \( imms + 1 = \text{immr} \).

64-bit variant

 Applies when \( sf = 1 \land N = 1 \land imms \neq 111111 \).

\[
\text{LSL} \ <Xd>, \ <Xn>, \ #<shift>
\]

 is equivalent to

\[
\text{UBFM} \ <Xd>, \ <Xn>, \ #(-<shift> \mod 64), \ #(63-<shift>)
\]

and is the preferred disassembly when \( imms + 1 = \text{immr} \).

Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<\text{shift}>\) For the 32-bit variant: is the shift amount, in the range 0 to 31.
  For the 64-bit variant: is the shift amount, in the range 0 to 63.

Operation

The description of UBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.178   LSLV

Logical Shift Left Variable shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This instruction is used by the alias LSL (register). The alias is always the preferred disassembly.

32-bit variant
Applies when sf == 0.

LSLV <Wd>, <Wn>, <Wm>

64-bit variant
Applies when sf == 1.

LSLV <Xd>, <Xn>, <Xm>

Decode for all variants of this encoding

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xm> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

bits(datasize) result;
bits(datasize) operand2 = X[m];
result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.179   LSR (register)

Logical Shift Right (register) shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the LSRV instruction. This means that:

- The encodings in this description are named to match the encodings of LSRV.
- The description of LSRV gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf == 0$.

LSR $<Wd>$, $<Wn>$, $<Wm>$

is equivalent to

LSRV $<Wd>$, $<Wn>$, $<Wm>$

and is always the preferred disassembly.

64-bit variant

Applies when $sf == 1$.

LSR $<Xd>$, $<Xn>$, $<Xm>$

is equivalent to

LSRV $<Xd>$, $<Xn>$, $<Xm>$

and is always the preferred disassembly.

Assembler symbols

$<Wd>$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Wn>$ Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

$<Wm>$ Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.

$<Xd>$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Xn>$ Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

$<Xm>$ Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of LSRV gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.180   LSR (immediate)

Logical Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and
writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

32-bit variant

Applies when sf == 0 && N == 0 && imms == 011111.

LSR <Wd>, <Wn>, #<shift>

is equivalent to

UBFM <Wd>, <Wn>, #<shift>, #31

and is always the preferred disassembly.

64-bit variant

Applies when sf == 1 && N == 1 && imms == 111111.

LSR <Xd>, <Xn>, #<shift>

is equivalent to

UBFM <Xd>, <Xn>, #<shift>, #63

and is always the preferred disassembly.

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <shift> For the 32-bit variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.181 LSRV

Logical Shift Right Variable shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias LSR (register). The alias is always the preferred disassembly.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{LSRV} <\text{Wd}>, <\text{Wn}>, <\text{Wm}>
\]

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{LSRV} <\text{Xd}>, <\text{Xn}>, <\text{Xm}>
\]

#### Decode for all variants of this encoding

- \( d = \text{UInt}(\text{Rd}) \)
- \( n = \text{UInt}(\text{Rn}) \)
- \( m = \text{UInt}(\text{Rm}) \)
- \( \text{datasize} = \text{if } sf = '1' \text{ then } 64 \text{ else } 32; \)
- \( \text{ShiftType shift_type = DecodeShift(op2);} \)

#### Assembler symbols

- \( <\text{Wd}> \) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( <\text{Wn}> \) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \( <\text{Wm}> \) Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- \( <\text{Xd}> \) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \( <\text{Xn}> \) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \( <\text{Xm}> \) Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

#### Operation

\[
\begin{align*}
\text{bits(datasize) result;} \\
\text{bits(datasize) operand2 = X[m];} \\
\text{result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);} \\
\text{X[d] = result;}
\end{align*}
\]
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.182   MADD

Multiply-Add multiplies two register values, adds a third register value, and writes the result to the destination register.

This instruction is used by the alias MUL. See Alias conditions for details of when each alias is preferred.

<table>
<thead>
<tr>
<th>32-bit variant</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies when $s_f = 0$.</td>

**Decode for all variants of this encoding**

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = if $s_f = '1'$ then 64 else 32;
```

**Alias conditions**

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MUL</td>
<td>$Ra = '111111'$</td>
</tr>
</tbody>
</table>

**Assembler symbols**

- `<Wd>`  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>`  Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- `<Wm>`  Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- `<Wa>`  Is the 32-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.
- `<Xd>`  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>`  Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- `<Xm>`  Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa> Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

**Operation**

bits(destsize) operand1 = X[n];
bits(destsize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;

result = UInt(operand3) + (UInt(operand1) * UInt(operand2));

X[d] = result<destsize-1:0>;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.183   MNEG

Multiply-Negate multiplies two register values, negates the product, and writes the result to the destination register.

This instruction is an alias of the MSUB instruction. This means that:

• The encodings in this description are named to match the encodings of MSUB.
• The description of MSUB gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

\[
\text{MNEG } \langle Wd \rangle, \langle Wn \rangle, \langle Wm \rangle
\]

is equivalent to

\[
\text{MSUB } \langle Wd \rangle, \langle Wn \rangle, \langle Wm \rangle, \text{WZR}
\]

and is always the preferred disassembly.

64-bit variant

Applies when \( sf = 1 \).

\[
\text{MNEG } \langle Xd \rangle, \langle Xn \rangle, \langle Xm \rangle
\]

is equivalent to

\[
\text{MSUB } \langle Xd \rangle, \langle Xn \rangle, \langle Xm \rangle, \text{XZR}
\]

and is always the preferred disassembly.

Assembler symbols

\[
\begin{align*}
&\langle Wd \rangle & \text{Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.} \\
&\langle Wn \rangle & \text{Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.} \\
&\langle Wm \rangle & \text{Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.} \\
&\langle Xd \rangle & \text{Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.} \\
&\langle Xn \rangle & \text{Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.} \\
&\langle Xm \rangle & \text{Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.}
\end{align*}
\]

Operation

The description of MSUB gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.184 MOV (to/from SP)

Move between register and stack pointer: \( Rd = Rn \)

This instruction is an alias of the ADD (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ADD (immediate).
- The description of ADD (immediate) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{MOV } <Wd|WSP>, <Wn|WSP> \\
\text{is equivalent to} \\
\text{ADD } <Wd|WSP>, <Wn|WSP>, #0 \\
\text{and is the preferred disassembly when } (Rd == '11111' || Rn == '11111').
\]

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{MOV } <Xd|SP>, <Xn|SP> \\
\text{is equivalent to} \\
\text{ADD } <Xd|SP>, <Xn|SP>, #0 \\
\text{and is the preferred disassembly when } (Rd == '11111' || Rn == '11111').
\]

### Assembler symbols

- `<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

### Operation

The description of ADD (immediate) gives the operational pseudocode for this instruction.
C6.2.185 MOV (inverted wide immediate)

Move (inverted wide immediate) moves an inverted 16-bit immediate value to a register.

This instruction is an alias of the MOVN instruction. This means that:

- The encodings in this description are named to match the encodings of MOVN.
- The description of MOVN gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf == 0$.

MOV <Wd>, #<imm>

is equivalent to

MOVN <Wd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when $!(IsZero(imm16) && hw != '00') && !IsOnes(imm16)$.

64-bit variant

Applies when $sf == 1$.

MOV <Xd>, #<imm>

is equivalent to

MOVN <Xd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when $!(IsZero(imm16) && hw != '00')$.

Assembler symbols

- <Wd>: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xd>: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <imm>: For the 32-bit variant: is a 32-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw", but excluding 0xffff0000 and 0x0000ffff.
  - For the 64-bit variant: is a 64-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw".
- <shift>: For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.
  - For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

The description of MOVN gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.186 MOV (wide immediate)

Move (wide immediate) moves a 16-bit immediate value to a register.

This instruction is an alias of the MOVZ instruction. This means that:

- The encodings in this description are named to match the encodings of MOVZ.
- The description of MOVZ gives the operational pseudocode for this instruction.

<table>
<thead>
<tr>
<th>sf</th>
<th>1 0 1 0 0 1 0 1</th>
<th>hw</th>
<th>imm16</th>
<th>Rd</th>
</tr>
</thead>
</table>

**32-bit variant**

Applies when \( sf = 0 \).

MOV <Wd>, #<imm>

is equivalent to

MOVZ <Wd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when \( \neg (\text{IsZero(imm16)} \land \text{hw} \neq '00') \).

**64-bit variant**

Applies when \( sf = 1 \).

MOV <Xd>, #<imm>

is equivalent to

MOVZ <Xd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when \( \neg (\text{IsZero(imm16)} \land \text{hw} \neq '00') \).

**Assembler symbols**

- \(<Wd>\): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xd>\): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<imm>\): For the 32-bit variant: is a 32-bit immediate which can be encoded in "imm16:hw".
  
  For the 64-bit variant: is a 64-bit immediate which can be encoded in "imm16:hw".
- \(<shift>\): For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as \(<shift>/16\).
  
  For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as \(<shift>/16\).

**Operation**

The description of MOVZ gives the operational pseudocode for this instruction.
**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.187   MOV (bitmask immediate)

Move (bitmask immediate) writes a bitmask immediate value to a register.

This instruction is an alias of the ORR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (immediate).
- The description of ORR (immediate) gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf == 0$ && $N == 0$.

$$\text{MOV } <Wd|WSP>, \#<imm>$$

is equivalent to

$$\text{ORR } <Wd|WSP>, \text{WZR}, \#<imm>$$

and is the preferred disassembly when $! \text{MoveWidePreferred}(sf, N, \text{imms}, \text{immr})$.

64-bit variant

Applies when $sf == 1$.

$$\text{MOV } <Xd|SP>, \#<imm>$$

is equivalent to

$$\text{ORR } <Xd|SP>, \text{XZR}, \#<imm>$$

and is the preferred disassembly when $! \text{MoveWidePreferred}(sf, N, \text{imms}, \text{immr})$.

Assembler symbols

- $<Wd|WSP>$ is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- $<Xd|SP>$ is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- $<\text{imm}>$ is the 32-bit variant: is the bitmask immediate, encoded in "imms:immr", but excluding values which could be encoded by MOVZ or MOVN.
- For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

Operation

The description of ORR (immediate) gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.188  MOV (register)

Move (register) copies the value in a source register to the destination register.

This instruction is an alias of the ORR (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (shifted register).
- The description of ORR (shifted register) gives the operational pseudocode for this instruction.

32-bit variant

Applies when $sf == 0$.

MOV $<Wd>$, $<Wm>$
is equivalent to

ORR $<Wd>$, WZR, $<Wm>$

and is always the preferred disassembly.

64-bit variant

Applies when $sf == 1$.

MOV $<Xd>$, $<Xm>$
is equivalent to

ORR $<Xd>$, XZR, $<Xm>$

and is always the preferred disassembly.

Assembler symbols

$<Wd>$  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Wm>$  Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.

$<Xd>$  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Xm>$  Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of ORR (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.189   MOVK

Move wide with keep moves an optionally-shifted 16-bit immediate value into a register, keeping other bits unchanged.

32-bit variant

Applies when $sf = 0$.

MOVK <Wd>, #<imm>{, LSL #<shift>}

64-bit variant

Applies when $sf = 1$.

MOVK <Xd>, #<imm>{, LSL #<shift>}

Decode for all variants of this encoding

```c
integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
integer pos;
if sf == '0' && hw<1> == '1' then UNDEFINED;
pos = UInt(hw:'0000');
```

Assembler symbols

- **<Wd>** Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Xd>** Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<imm>** Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
- **<shift>** For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.
  - For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

```c
bits(datasize) result;
result = X[d];
result<pos+15:pos> = imm16;
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.190  MOVN

Move wide with NOT moves the inverse of an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (inverted wide immediate). See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when \( sf = 0 \).

\[
\text{MOVN} <Wd>, #<imm>{, LSL #<shift>}
\]

64-bit variant
Applies when \( sf = 1 \).

\[
\text{MOVN} <Xd>, #<imm>{, LSL #<shift>}
\]

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } datasize &= \text{if } sf = '1' \text{ then } 64 \text{ else } 32; \\
\text{integer } pos &= 0; \\
\text{if } sf = '0' \&\& hw<1> = '1' \text{ then UNDEFINED; } \\
\text{pos} &= \text{UInt(hw:}'0000'');
\end{align*}
\]

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>of variant</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV (inverted wide immediate)</td>
<td>64-bit</td>
<td>(! (\text{IsZero}(imm16) &amp;&amp; hw != '00'))</td>
</tr>
<tr>
<td>MOV (inverted wide immediate)</td>
<td>32-bit</td>
<td>(! (\text{IsZero}(imm16) &amp;&amp; hw != '00') &amp;&amp; ! \text{IsOnes}(imm16))</td>
</tr>
</tbody>
</table>

Assembler symbols

\(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<imm>\) Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

\(<\text{shift}>\) For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as \(<\text{shift}>/16\).

For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as \(<\text{shift}>/16\).

Operation

\[
\text{bits(datasize)} \text{ result;}
\]

\[
\text{result} = \text{Zeros();}
\]
result<pos+15:pos> = imm16;
result = NOT(result);
X[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.191   MOVZ

Move wide with zero moves an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (wide immediate). See Alias conditions for details of when each alias is preferred.

32-bit variant
Applies when $\text{sf} = 0$.

$\text{MOVZ <Wd>, } \#\text{<imm>}\{, \text{LSL } \#\text{<shift>}\}$

64-bit variant
Applies when $\text{sf} = 1$.

$\text{MOVZ <Xd>, } \#\text{<imm>}\{, \text{LSL } \#\text{<shift>}\}$

Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d &= \text{UInt}(\text{Rd}); \\
\text{integer } \text{datasize} &= \text{if } \text{sf} == '1' \text{ then 64 else 32;} \\
\text{integer } \text{pos} &= \text{if } \text{sf} == '0' && \text{hw}<1> == '1' \text{ then UNDEFINED} \\
&\quad \text{pos} = \text{UInt}(\text{hw}:0000'); \\
\end{align*}
\]

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>

Assembler symbols

- $<\text{Wd}>$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<\text{Xd}>$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<\text{imm}>$ Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
- $<\text{shift}>$ For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as $<\text{shift}>/16$.
  For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as $<\text{shift}>/16$.

Operation

\[
\begin{align*}
\text{bits(\text{datasize}) result;} \\
\text{result} &= \text{Zeros}(); \\
\end{align*}
\]
result<pos+15:pos> = imm16;
X[d] = result;

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.192 MRS

Move System Register allows the PE to read an AArch64 System register into a general-purpose register.

System variant
MRS <Xt>, (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>)

Decode for this encoding
AArch64.CheckSystemAccess('1':o0, op1, CRn, CRm, op2, Rt, L);
integer t = UInt(Rt);
integer sys_op0 = 2 + UInt(o0);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);

Assembler symbols
<Xt> Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
<systemreg> Is a System register name, encoded in the "o0:op1:CRn:CRm:op2".
The System register names are defined in Chapter D13 AArch64 System Register Descriptions.
<op0> Is an unsigned immediate, encoded in the "o0" field. It can have the following values:
2 when o0 = 0
3 when o0 = 1
<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

Operation
X[t] = AArch64.SysRegRead(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2);
C6.2.193 MSR (immediate)

Move immediate value to Special Register moves an immediate value to selected bits of the PSTATE. For more information, see PSTATE.

The bits that can be written by this instruction are:

- PSTATE.D, PSTATE.A, PSTATE.I, PSTATE.F, and PSTATE.SP.
- If ARMv8.0-SSBS is implemented, PSTATE.SSBS.
- If ARMv8.1-PAN is implemented, PSTATE.PAN.
- If ARMv8.2-UAO is implemented, PSTATE.UAO.
- If ARMv8.4-DIT is implemented, PSTATE.DIT.
- If ARMv8.5-MemTag is implemented, PSTATE.TCO.

```
| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 |16|15 14 13 12|11| 8 | 7 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------|----------|----------|------|---|----------|---|----|---|---|---|---|---|---|---|---|
| 1 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | op1 | 0 | 1 | 0 | 0 | CRm | op2 | 1 | 1 | 1 | 1 | 1 |
```

System variant

MSR <pstatefield>, #<imm>

Decode for this encoding

if op1 == '000' && op2 == '000' then SEE "CFINV";
if op1 == '000' && op2 == '001' then SEE "XAFLAG";
if op1 == '000' && op2 == '010' then SEE "AXFLAG";

AArch64.CheckSystemAccess('00', op1, '0100', CRm, op2, '11111', '0');

    AArch64.SystemAccessTrap(EL1, 0x18); // Exception_SystemRegisterTrap

Assembler symbols

<statefield> Is a PSTATE field name, encoded in the "op1:op2" field. It can have the following values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPSel</td>
<td>op1 = 000, op2 = 101</td>
</tr>
<tr>
<td>DAIFSet</td>
<td>op1 = 011, op2 = 110</td>
</tr>
<tr>
<td>DAIFClr</td>
<td>op1 = 011, op2 = 111</td>
</tr>
</tbody>
</table>

When ARMv8.2-UAO is implemented, the following value is also valid:
UAO         when op1 = 000, op2 = 011

When ARMv8.1-PAN is implemented, the following value is also valid:
PAN         when op1 = 000, op2 = 100

When ARMv8.0-SSBS is implemented, the following value is also valid:
SSBS        when op1 = 011, op2 = 001

When ARMv8.4-DIT is implemented, the following value is also valid:
DIT         when op1 = 011, op2 = 010

When ARMv8.5-MemTag is implemented, the following value is also valid:
TCO         when op1 = 011, op2 = 100

See PSTATE on page C4-260 when op1 = 000, op2 = 00x.

See PSTATE on page C4-260 when op1 = 000, op2 = 010.

The following encodings are reserved:

- op1 = 000, op2 = 11x.
- op1 = 001, op2 = xxx.
- op1 = 010, op2 = xxx.
- op1 = 011, op2 = 000.
- op1 = 011, op2 = 011.
- op1 = 011, op2 = 101.
- op1 = 1xx, op2 = xxx.

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

Operation

C6.2.194 MSR (register)

Move general-purpose register to System Register allows the PE to write an AArch64 System register from a general-purpose register.

System variant

MSR (<systemreg>|<op0>_<op1>_,<Cn>_<Cm>_<op2>), <Xt>

Decode for this encoding

\[
\text{AArch64.CheckSystemAccess('1':o0, op1, CRn, CRm, op2, Rt, L);} \\
\text{integer t = UInt(Rt);} \\
\text{integer sys_op0 = 2 + UInt(o0);} \\
\text{integer sys_op1 = UInt(op1);} \\
\text{integer sys_op2 = UInt(op2);} \\
\text{integer sys_crn = UInt(CRn);} \\
\text{integer syscrm = UInt(CRm);} \\
\]

Assembler symbols

<systemreg> Is a System register name, encoded in the "o0:op1:CRn:CRm:op2".
   The System register names are defined in Chapter D13 AArch64 System Register Descriptions.
<op0> Is an unsigned immediate, encoded in the "o0" field. It can have the following values:
   2 when o0 = 0
   3 when o0 = 1
<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

\[
\text{AArch64.SysRegWrite(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, X[t]);}
\]
C6.2.195  MSUB

Multiply-Subtract multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register.

This instruction is used by the alias MNEG. See Alias conditions for details of when each alias is preferred.

32-bit variant

Applies when $sf == 0$.

MSUB $<Wd>$, $<Wn>$, $<Wm>$, $<Wa>$

64-bit variant

Applies when $sf == 1$.

MSUB $<Xd>$, $<Xn>$, $< Xm>$, $<Xa>$

Decode for all variants of this encoding

integer $d = $UInt(Rd);
integer $n = $UInt(Rn);
integer $m = $UInt(Rm);
integer $a = $UInt(Ra);
integer destsize = if $sf == '1'$ then 64 else 32;

Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MNEG</td>
<td>Ra == '11111'</td>
</tr>
</tbody>
</table>

Assembler symbols

$<Wd>$ Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Wn>$ Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

$<Wm>$ Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

$<Wa>$ Is the 32-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

$<Xd>$ Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

$<Xn>$ Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

$<Xm>$ Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

**Operation**

\[
\begin{align*}
\text{bits}(\text{destsize}) \text{ operand1} &= X[n]; \\
\text{bits}(\text{destsize}) \text{ operand2} &= X[m]; \\
\text{bits}(\text{destsize}) \text{ operand3} &= X[a]; \\
\text{integer result}; \\
\text{result} &= \text{UInt(operand3)} - (\text{UInt(operand1)} \times \text{UInt(operand2)}); \\
X[d] &= \text{result}_{\text{destsize}-1:0};
\end{align*}
\]

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Multiply: \( Rd = Rn \times Rm \)

This instruction is an alias of the MADD instruction. This means that:

- The encodings in this description are named to match the encodings of MADD.
- The description of MADD gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[ \text{MUL} <Wd>, <Wn>, <Wm> \]

is equivalent to

\[ \text{MADD} <Wd>, <Wn>, <Wm>, WZR \]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[ \text{MUL} <Xd>, <Xn>, <Xm> \]

is equivalent to

\[ \text{MADD} <Xd>, <Xn>, <Xm>, XZR \]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \(<Wm>\) is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- \(<Xd>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \(<Xm>\) is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

### Operation

The description of MADD gives the operational pseudocode for this instruction.
C6.2.197 MVN

Bitwise NOT writes the bitwise inverse of a register value to the destination register.

This instruction is an alias of the ORN (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ORN (shifted register).
- The description of ORN (shifted register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{MVN} \, <Wd>, \, <Wm>\{, \, <\text{shift}> \, \#<\text{amount}>\}
\]

is equivalent to

\[
\text{ORN} \, <Wd>, \, WZR, \, <Wm>\{, \, <\text{shift}> \, \#<\text{amount}>\}
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{MVN} \, <Xd>, \, <Xm>\{, \, <\text{shift}> \, \#<\text{amount}>\}
\]

is equivalent to

\[
\text{ORN} \, <Xd>, \, XZR, \, <Xm>\{, \, <\text{shift}> \, \#<\text{amount}>\}
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wm>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xm>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<\text{shift}>\) Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL   when \( \text{shift} = 00 \)
  - LSR   when \( \text{shift} = 01 \)
  - ASR   when \( \text{shift} = 10 \)
  - ROR   when \( \text{shift} = 11 \)
- \(<\text{amount}>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

The description of ORN (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.198   NEG (shifted register)

Negate (shifted register) negates an optionally-shifted register value, and writes the result to the destination register.

This instruction is an alias of the SUB (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUB (shifted register).
- The description of SUB (shifted register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{NEG } <Wd>, <Wm>{, <shift> #<amount>} \\
\]

is equivalent to

\[
\text{SUB } <Wd>, WZR, <Wm> {, <shift> #<amount>} \\
\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{NEG } <Xd>, <Xm>{, <shift> #<amount>} \\
\]

is equivalent to

\[
\text{SUB } <Xd>, XZR, <Xm> {, <shift> #<amount>} \\
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wm>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xm>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<\text{shift}>\) Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( \text{shift} = 00 \)
  - LSR when \( \text{shift} = 01 \)
  - ASR when \( \text{shift} = 10 \)
  - The encoding \( \text{shift} = 11 \) is reserved.
- \(<\text{amount}>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

The description of SUB (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.199 NEGS

Negate, setting flags, negates an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is an alias of the SUBS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when \( sf = 0 \).

\[
\text{NEGS} \ <Wd>, \ <Wm>{, \ <shift> \ #<amount>}\]

is equivalent to

\[
\text{SUBS} \ <Wd>, \ WZR, \ <Wm> {, \ <shift> \ #<amount>}\]

and is always the preferred disassembly.

### 64-bit variant

Applies when \( sf = 1 \).

\[
\text{NEGS} \ <Xd>, \ <Xm>{, \ <shift> \ #<amount>}\]

is equivalent to

\[
\text{SUBS} \ <Xd>, \ XZR, \ <Xm> {, \ <shift> \ #<amount>}\]

and is always the preferred disassembly.

### Assembler symbols

- \(<Wd>\): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wm>\): Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xm>\): Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<shift>\): Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

  - \(\text{LSL}\): when \( shift = 00 \)
  - \(\text{LSR}\): when \( shift = 01 \)
  - \(\text{ASR}\): when \( shift = 10 \)

  The encoding \( shift = 11 \) is reserved.

- \(<amount>\): For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
Operation

The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.200 NGC

Negate with Carry negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register.

This instruction is an alias of the SBC instruction. This means that:

- The encodings in this description are named to match the encodings of SBC.
- The description of SBC gives the operational pseudocode for this instruction.

### 32-bit variant

Applies when $sf = 0$.

$\text{NGC } <\text{Wd}>, <\text{Wm}>$

is equivalent to

$\text{SBC } <\text{Wd}>, \text{WZR}, <\text{Wm}>$

and is always the preferred disassembly.

### 64-bit variant

Applies when $sf = 1$.

$\text{NGC } <\text{Xd}>, <\text{Xm}>$

is equivalent to

$\text{SBC } <\text{Xd}>, \text{XZR}, <\text{Xm}>$

and is always the preferred disassembly.

### Assembler symbols

- $<\text{Wd}>$ is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<\text{Wm}>$ is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- $<\text{Xd}>$ is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- $<\text{Xm}>$ is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

### Operation

The description of SBC gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.201 NGCS

Negate with Carry, setting flags, negates the sum of a register value and the value of NOT (Carry flag), and writes
the result to the destination register. It updates the condition flags based on the result.

This instruction is an alias of the SBCS instruction. This means that:

- The encodings in this description are named to match the encodings of SBCS.
- The description of SBCS gives the operational pseudocode for this instruction.

32-bit variant

Applies when \( sf = 0 \).

NGCS <Wd>, <Wm>
is equivalent to
SBCS <Wd>, WZR, <Wm>
and is always the preferred disassembly.

64-bit variant

Applies when \( sf = 1 \).

NGCS <Xd>, <Xm>
is equivalent to
SBCS <Xd>, XZR, <Xm>
and is always the preferred disassembly.

Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wm>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xm>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SBCS gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.202  NOP

No Operation does nothing, other than advance the value of the program counter by 4. This instruction can be used for instruction alignment purposes.

———  Note  ————

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

System variant

NOP

Decode for this encoding

// Empty.

Operation

// do nothing

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.203 ORN (shifted register)

Bitwise OR NOT (shifted register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MVN. See *Alias conditions* for details of when each alias is preferred.

### 32-bit variant

Applies when \( sf == 0 \).

\[
\text{ORN } <Wd>, <Wn>, <Wm>\{, <shift> \#<amount>\}
\]

### 64-bit variant

Applies when \( sf == 1 \).

\[
\text{ORN } <Xd>, <Xn>, <Xm>\{, <shift> \#<amount>\}
\]

#### Decode for all variants of this encoding

\[
\begin{align*}
\text{integer } d & = \text{UInt}(Rd); \\
\text{integer } n & = \text{UInt}(Rn); \\
\text{integer } m & = \text{UInt}(Rm); \\
\text{integer } \text{datasize} & = \text{if } sf == '1' \text{ then } 64 \text{ else } 32; \\
\text{if } sf == '0' \&\& \text{imm6}<5> & == '1' \text{ then UNDEFINED}; \\
\text{ShiftType } \text{shift_type} & = \text{DecodeShift} (\text{shift}); \\
\text{integer } \text{shift_amount} & = \text{UInt} (\text{imm6}); \\
\end{align*}
\]

#### Alias conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>is preferred when</th>

</table>

#### Assembler symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<\text{shift}>\) Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:
  - LSL when \( \text{shift} = \text{00} \)
  - LSR when \( \text{shift} = \text{01} \)
ASR     when shift = 10
ROR     when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
          For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
operand2 = NOT(operand2);
result = operand1 OR operand2;
X[d] = result;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  — The values of the data supplied in any of its registers.
  — The values of the NZCV flags.
C6.2.204 ORR (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate register value, and writes the result to the destination register.

This instruction is used by the alias MOV (bitmask immediate). See Alias conditions for details of when each alias is preferred.

### 32-bit variant
Applies when \( sf == 0 \land N == 0 \).

**ORR \(<Wd|WSP>, <Wn>, #<imm>\)**

### 64-bit variant
Applies when \( sf == 1 \).

**ORR \(<Xd|SP>, <Xn>, #<imm>\)**

**Decode for all variants of this encoding**

\[
\begin{align*}
\text{integer } d &= \text{UInt}(Rd); \\
\text{integer } n &= \text{UInt}(Rn); \\
\text{integer } \text{datasize} &= \text{if } sf == '1' \text{ then } 64 \text{ else } 32; \\
\text{bits}(\text{datasize}) \text{ imm}; \\
\text{if } sf == '0' \land N != '0' \text{ then UNDEFINED}; \\
(\text{imm}, -) &= \text{DecodeBitMasks}(N, \text{imms}, \text{immr}, \text{TRUE});
\end{align*}
\]

**Alias conditions**

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
C6.2.206 PACDA, PACDZA

Pointer Authentication Code for Data address, using key A. This instruction computes and inserts a pointer authentication code for a data address, using a modifier and key A.

The address is in the general-purpose register that is specified by \(<xd>\).

The modifier is:

- In the general-purpose register or stack pointer that is specified by \(<xn|sp>\) for PACDA.
- The value zero, for PACDZA.

ARMv8.3

| 31 30 29 28|27 26 25 24|23 22 21 20|19 18 17 16|15 14 13 12|11 10 9 | 5 4 | 0 |
| 1 1 1 0 1 0 1 1 0 0 0 0 0 1 0 0 | Z 0 1 0 |

**PACDA variant**

Applies when \(Z == 0\).

PACDA \(<xd>, <xn|sp>\)

**PACDZA variant**

Applies when \(Z == 1 \&\& Rn == 11111\).

PACDZA \(<xd>\)

*Decode for all variants of this encoding*

```c
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HavePACExt() then
    UNDEFINED;
if Z == '0' then // PACDA
    if n == 31 then source_is_sp = TRUE;
else // PACDZA
    if n != 31 then UNDEFINED;
```

**Assembler symbols**

- \(<xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<xn|sp>\) Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

**Operation**

```c
if source_is_sp then
    X[d] = AddPACDA(X[d], SP[]);
else
    X[d] = AddPACDA(X[d], X[n]);
```
C6.2.207  PACDB, PACDZB

Pointer Authentication Code for Data address, using key B. This instruction computes and inserts a pointer authentication code for a data address, using a modifier and key B.

The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDB.
- The value zero, for PACDZB.

ARMv8.3

PACDB variant

Applies when Z == 0.

PACDB <Xd>, <Xn|SP>

PACDZB variant

Applies when Z == 1 && Rn == 11111.

PACDZB <Xd>

Decode for all variants of this encoding

```java
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HavePACExt() then
    UNDEFINED;
if Z == '0' then // PACDB
    if n == 31 then source_is_sp = TRUE;
else // PACDZB
    if n != 31 then UNDEFINED;
```

Assembler symbols

- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```java
if source_is_sp then
    X[d] = AddPACDB(X[d], SP[]);
else
    X[d] = AddPACDB(X[d], X[n]);
```
C6.2.208 PACGA

Pointer Authentication Code, using Generic key. This instruction computes the pointer authentication code for an address in the first source register, using a modifier in the second source register, and the Generic key. The computed pointer authentication code is returned in the upper 32 bits of the destination register.

ARMv8.3

    X[d] = AddPACGA(X[n], SP[]);
else
    X[d] = AddPACGA(X[n], X[m]);
```
C6.2.209   PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA

Pointer Authentication Code for Instruction address, using key A. This instruction computes and inserts a pointer authentication code for an instruction address, using a modifier and key A.

The address is:

- In the general-purpose register that is specified by \(<Xd>\) for PACIA and PACIZA.
- In X17, for PACIA1716.
- In X30, for PACIASP and PACIAZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by \(<Xn|SP>\) for PACIA.
- The value zero, for PACIZA and PACIAZ.
- In X16, for PACIA1716.
- In SP, for PACIASP.

PACIASP

PACIAZ variant
Applies when CRm == 0011 && op2 == 000.

PACIAZ

Decode for all variants of this encoding
integer d;
integer n;
boolean source_is_sp = FALSE;
case CRm:op2 of
  when '0011 000'    // PACIAZ
    d = 30;
    n = 31;
  when '0011 001'    // PACIASP
    d = 30;
    source_is_sp = TRUE;
    if HaveBTIExt() then
      // Check for branch target compatibility between PSTATE.BTYPE
      // and implicit branch target of PACIASP instruction.
      - = BTypeCompatible_PACIXSP();
  when '0001 000'    // PACIA1716
    d = 17;
    n = 16;
  when '0001 010' SEE "PACIB";
  when '0001 100' SEE "AUTIA";
  when '0001 110' SEE "AUTIB";
  when '0011 01x' SEE "PACIB";
  when '0011 10x' SEE "AUTIA";
  when '0011 11x' SEE "AUTIB";
  when '0000 111' SEE "XPACLRI";

Assembler symbols
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation for all encodings
if HavePACEx() then
  if source_is_sp then
    X[d] = AddPACIA(X[d], SP[0]);
  else
    X[d] = AddPACIA(X[d], X[n]);

C6.2.210 PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB

Pointer Authentication Code for Instruction address, using key B. This instruction computes and inserts a pointer authentication code for an instruction address, using a modifier and key B.

The address is:

- In the general-purpose register that is specified by <Xd> for PACIB and PACIZB.
- In X17, for PACIB1716.
- In X30, for PACIBSP and PACIBZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACIB.
- The value zero, for PACIZB and PACIBZ.
- In X16, for PACIB1716.
- In SP, for PACIBSP.

Integer

**PACIB** variant

Applies when Z == 0.

PACIB <Xd>, <Xn|SP>

**PACIZB** variant

Applies when Z == 1 && Rn == 11111.

PACIZB <Xd>

**Decode for all variants of this encoding**

boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UNDEFINED;

if Z == '0' then // PACIB
    if n == 31 then source_is_sp = TRUE;
else // PACIZB
    if n != 31 then UNDEFINED;

**System**

ARMv8.3
PACIB1716 variant

Applies when CRm == 0001 && op2 == 010.

PACIB1716

PACIBSP variant

Applies when CRm == 0011 && op2 == 011.

PACIBSP

PACIBZ variant

Applies when CRm == 0011 && op2 == 010.

PACIBZ

Decode for all variants of this encoding

```plaintext
integer d;
integer n;
boolean source_is_sp = FALSE;

case CRm:op2 of
  when '0011 010'    // PACIBZ
    d = 30;
    n = 31;
  when '0011 011'    // PACIBSP
    d = 30;
    source_is_sp = TRUE;
    if HaveBTIExt() then
      // Check for branch target compatibility between PSTATE.BTYPE
      // and implicit branch target of PACIBSP instruction.
      _ = BTypeCompatible_PACIBSP();
    when '0001 010'    // PACIB1716
    d = 17;
    n = 16;
    when '0001 000' SEE "PACIA";
    when '0001 100' SEE "AUTIA";
    when '0001 110' SEE "AUTIB";
    when '0011 00x' SEE "PACIA";
    when '0011 10x' SEE "AUTIA";
    when '0011 11x' SEE "AUTIB";
    when '0000 111' SEE "XPACLRI";
```

Assembler symbols

- `<Xd>`  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn|SP>`  Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation for all encodings

```plaintext
if HavePACExt() then
  if source_is_sp then
    X[d] = AddPACIB(X[d], SP[]);
  else
    X[d] = AddPACIB(X[d], X[n]);
```
C6.2.211 PRFM (Immediate)

Prefetch Memory (immediate) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory on page C3-208.

For information about memory accesses, see Load/Store addressing modes on page C1-177.

Unsigned offset variant

PRFM (<prfop>|#<imm5>, [<Xn|SP>{, #<pimm>}]

Decode for this encoding

bits(64) offset = LSL(ZeroExtend(imm12, 64), 3);

Assembler symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.
  <type> is one of:
  PLD Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
  PLI Preload instructions, encoded in the "Rt<4:3>" field as 0b01.
  PST Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.
  <target> is one of:
  L1 Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
  L2 Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
  L3 Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.
  <policy> is one of:
  KEEP Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
  STRM Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory on page C3-208.

For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<pimm> Is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.
Shared decode for all encodings

integer n = UInt(Rn);
integer t = UInt(Rt);

Operation

if HaveMTEExt() then
    SetNotTagCheckedInstruction(TRUE);

bits(64) address;
if n == 31 then
    address = SP[];
else
    address = X[n];

address = address + offset;
Prefetch(address, t<4:0>);
C6.2.212 PRFM (literal)

Prefetch Memory (literal) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory on page C3-208.

For information about memory accesses, see Load/Store addressing modes on page C1-177.

Literal variant

PRFM (<prfop>|#<imm5>), <label>

Decode for this encoding

integer t = UInt(Rt);
bits(64) offset;
offset = SignExtend(imm19:'00', 64);

Assembler symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.

<type> is one of:
- PLD Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
- PLI Preload instructions, encoded in the "Rt<4:3>" field as 0b01.
- PST Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.

<target> is one of:
- L1 Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
- L2 Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
- L3 Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

<policy> is one of:
- KEEP Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
- STRM Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory on page C3-208.

For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<label> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.
Operation

bits(64) address = PC[] + offset;

if HaveMTEExt() then
    SetNotTagCheckedInstruction(TRUE);

Prefetch(address, t<4:0>);
C6.2.213 PRFM (register)

Prefetch Memory (register) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory on page C3-208.

For information about memory accesses, see Load/Store addressing modes on page C1-177.

Interner variant

PRFM (<prfop>|#<imm5>), [<Xn|SP>, (<Wm>|<Xm>{{, <extend> {<amount>}}}}

Decode for this encoding

if option<1> == '0' then UNDEFINED; // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
inther shift = if S == '1' then 3 else 0;

Assembler symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.

<type> is one of:
PLD Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
PLI Preload instructions, encoded in the "Rt<4:3>" field as 0b01.
PST Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.

<target> is one of:
L1 Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
L2 Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
L3 Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

<policy> is one of:
KEEP Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
STRM Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory on page C3-208.

For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
When option<@> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in the "option" field. It can have the following values:

- UXTW when option = 010
- LSL when option = 011
- SXTW when option = 110
- SXTX when option = 111

Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #3 when S = 1

Shared decode for all encodings

```c
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```

Operation

```c
bits(64) offset = ExtendReg(m, extend_type, shift);
if HaveMTEExt() then
    SetNotTagCheckedInstruction(TRUE);

bits(64) address;
if n == 31 then
    address = SP[];
else
    address = X[n];

address = address + offset;
Prefetch(address, t<4:0>);
```
C6.2.214   PRFUM

Prefetch Memory (unscaled offset) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFUM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory on page C3-208.

For information about memory accesses, see Load/Store addressing modes on page C1-177.

Unscaled offset variant

PRFUM (<prfop>|#<imm5>), [<Xn|SP>{, #<simm>}]

Decode for this encoding

\[
\text{bits}(64) \text{ offset} = \text{SignExtend}(\text{imm9}, 64);
\]

Assembler symbols

- **<prfop>** Is the prefetch operation, defined as <type><target><policy>.
  - **<type>** is one of:
    - PLD  Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
    - PLI  Preload instructions, encoded in the "Rt<4:3>" field as 0b01.
    - PST  Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.
  - **<target>** is one of:
    - L1  Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
    - L2  Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
    - L3  Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.
  - **<policy>** is one of:
    - KEEP  Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
