Glossary
Preface

This preface introduces the *ARMv8-M Architecture Reference Manual*. It contains the following sections:

- *About this book* on page xii.
- *Using this book* on page xiii.
- *Conventions* on page xv.
- *Additional reading* on page xvii.
- *Feedback* on page xviii.
About this book

This manual documents the microcontroller profile of version 8 of the ARM® Architecture, the ARMv8-M architecture profile. For short definitions of all the ARMv8 profiles see About the ARMv8 architecture, and architecture profiles on page A1-24.

This manual has the following parts:

**Part A**  Provides an introduction to the ARMv8-M architecture.

**Part B**  Describes the architectural rules.

**Part C**  Describes the T32 instruction set.

**Part D**  Describes the registers.

**Part E**  Describes the ARMv8-M pseudocode.

**Part F**  Describes the packet protocols.

**Part G, Appendix**  Provides additional architectural information.
Using this book

The information in this manual is organized into parts, as described in this section.

Part A, ARMv8-M Architecture Introduction and Overview

Part A gives an overview of the ARMv8-M architecture profile, including its relationship to the other ARM PE architectures. It introduces the terminology used to describe the architecture, and gives an overview of the optional architectural extensions. It contains the following chapter:

Chapter A1 Introduction

Read this for an introduction to the ARMv8-M architecture.

Part B, ARMv8-M Architecture Rules

Part B describes the architecture rules. It contains the following chapters:

Chapter B1 Resets

Read this for a description of the reset rules.

Chapter B2 Power Management

Read this for a description of the power management rules.

Chapter B3 Programmers’ Model

Read this for a description of the programmers model rules.

Chapter B4 Floating-point Support

Read this for a description of the floating-point support rules.

Chapter B5 Memory Model

Read this for a description of the memory model rules.

Chapter B6 Synchronization and Semaphores

Read this for a description of the rules on non-blocking synchronization of shared memory.

Chapter B7 The System Address Map

Read this for a description of the system address map rules.

Chapter B8 The ARMv8-M Protected Memory System Architecture

Read this for a description of the protected memory system architecture rules.

Chapter B9 The System Timer, SysTick

Read this for a description of the system timer rules.

Chapter B10 Nested Vectored Interrupt Controller

Read this for a description of the Nested Vectored Interrupt Controller (NVIC) rules.

Chapter B11 Debug

Read this for a description of the debug rules.

Chapter B12 Debug and Trace Components

Read this for a description of the debug and trace component rules.
Part C, ARMv8-M Instructions

Part C describes the instructions. It contains the following chapters:

**Chapter C1 Instruction Set Overview**
Read this for an overview of the instruction set and the instruction set encoding.

**Chapter C2 Instruction Specification**
Read this for a description of each instruction, arranged by instruction mnemonic.

Part D, ARMv8-M Registers

Part D describes the registers. It contains the following chapter:

**Chapter D1 Register Specification**
Read this for a description of the registers.

Part E, ARMv8-M Pseudocode

Part E describes the pseudocode. It contains the following chapters:

**Chapter E1 ARM Pseudocode Definition**
Read this for a definition of the pseudocode that ARM documentation uses.

**Chapter E2 Pseudocode Specification**
Read this for a description of the pseudocode.

Part F, Packet Protocols

Part F describes the packet protocols. It contains the following chapter:

**Chapter F1 ITM and DWT Packet Protocol Specification**
Read this for a description of the protocol for packets that are used to send the data generated by the ITM and DWT to an external debugger.

Part G, Appendix

This manual contains the following appendix:

**Appendix G1 Architectural Constraints on UNPREDICTABLE behaviors**
Read this for a description of the architecturally-required constraints on UNPREDICTABLE behaviors in the ARMv8 architecture.
Conventions

The following sections describe conventions that this book can use:

- **Typographic conventions.**
- **Signals.**
- **Numbers.**
- **Pseudocode descriptions.**
- **Assembler syntax descriptions on page xvi.**

**Typographic conventions**

The typographical conventions are:

- **italic** Introduces special terminology, and denotes citations.
- **bold** Denotes signal names, and is used for terms in descriptive lists, where appropriate.
- **monospace** Used for assembler syntax descriptions, pseudocode, and source code examples.
  Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.

**SMALL CAPITALS**

Used for a few terms that have specific technical meanings, and are included in the Glossary.

**Colored text** Indicates a link. This can be:
- A URL, for example `http://infocenter.arm.com`.
- A cross-reference, that includes the page number of the referenced information if it is not on the current page, for example, `Standard assembler syntax fields on page C1-252`.
- A link, to a chapter or appendix, or to a glossary entry, or to the section of the document that defines the colored term, for example `ADC (immediate)`.

**Signals**

In general this specification does not define processor signals, but it does include some signal examples and recommendations.

The signal conventions are:

- **Signal level** The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:
  - HIGH for active-HIGH signals.
  - LOW for active-LOW signals.
- **Lowercase n** At the start or end of a signal name denotes an active-LOW signal.

**Numbers**

Numbers are normally written in decimal. Binary numbers are preceded by `0b`, and hexadecimal numbers by `0x`. In both cases, the prefix and the associated value are written in a monospace font, for example `0xFFFF0000`. To improve readability, long numbers can be written with an underscore separator between every four characters, for example `0xFFFF_0000_0000_0000`. Ignore any underscores when interpreting the value of a number.

**Pseudocode descriptions**

This book uses a form of pseudocode to provide precise descriptions of the specified functionality. This pseudocode is written in a monospace font, and is described in Part E ARMv8-M Pseudocode.
Assembler syntax descriptions

This book contains numerous syntax descriptions for assembler instructions and for components of assembler instructions. These are shown in a monospace font, and use the conventions described in *A list of the assembler symbols for the instruction* on page C1-246.
Additional reading

This section lists relevant publications from ARM and third parties.

See the Infocenter http://infocenter.arm.com, for access to ARM documentation.

ARM publications

• Procedure Call Standard for the ARM Architecture (ARM GENC 003534).
• Run-time ABI for the ARM Architecture (ARM IHI 0043).

• TrustZone® technology for ARMv8-M Architecture Version 1.0 (ARM 100690_0100_00_en).

For information about the ARMv6-M architecture profile, see the ARMv6-M Architecture Reference Manual (ARM DDI 0419).

For information about the ARMv7-M architecture profile, see the ARMv7-M Architecture Reference Manual (ARM DDI 0403).

For information about the ARMv8-A architecture profile, see the ARM® Architecture Reference Manual, ARMv8, for ARMv8-A architecture profile (ARM DDI 0487).

Other publications

The following publications are referred to in this manual, or provide more information:

   ——— Note ————
   This document does not adopt the terminology defined in the 2008 issue of the standard.

   ————

Feedback

ARM welcomes feedback on its documentation.

Feedback on this book

If you have comments on the content of this book, send an e-mail to errata@arm.com. Give:

• The title.
• The number, ARM DDI 0553A.c.
• The page numbers to which your comments apply.
• The rule identifiers to which your comments apply, if applicable.
• A concise explanation of your comments.

ARM also welcomes general suggestions for additions and improvements.

Note

ARM tests PDFs only in Adobe Acrobat and Acrobat Reader, and cannot guarantee the appearance or behavior of any document when viewed with any other PDF reader.
Part A

ARMv8-M Architecture Introduction and Overview
Chapter A1
Introduction

This chapter introduces the ARMv8 architecture, the architecture profiles it defines, and the ARMv8-M architecture profile defined by this manual. It contains the following sections:

- About the ARMv8 architecture, and architecture profiles on page A1-24.
- The ARMv8-M architecture profile on page A1-25.
A1.1 Document layout and terminology

This section describes the structure and scope of, and the terminology that is used in, this manual. It does not constitute part of the manual, and must not be interpreted as implementation guidance.

A1.1.1 Structure of the document

This architecture manual describes the behavior of the processing element as a set of individual rules.

Each rule is clearly identified by the letter R, followed by a random group of subscript letters that do not reflect any intended order or priority, for example R_{BCVF}. In the following example, R_{BCVF} is simply a random rule identifier that has no significance apart from uniquely identifying a rule in this manual.

Rules must not be read in isolation, and where more than one rule relating to a particular feature exists, individual rules are grouped into sections and subsections to provide the proper context. Where appropriate, these sections contain a short introduction to aid the reader.

An implementation that conforms to all the rules described in this specification constitutes an ARMv8-M compliant implementation. An implementation whose behavior deviates from these rules is not compliant with the ARMv8-M architecture.

Some sections contain additional information and guidance that do not constitute rules. This information and guidance is provided purely as an aid to understanding the architecture. Information statements are clearly identified by the letter I, followed by a random group of subscript letters, for example I_{PRTD}.

Note

ARM strongly recommends that implementers read all chapters and sections of this document to ensure that an implementation is compliant.

An implementation that conforms to all the rules described in this specification but chooses to ignore any additional information and guidance is compliant with the ARMv8-M architecture.

In the following parts of this manual, architectural rules are not identified by a specific prefix and a random group of subscript numbers:

- Part C ARMv8-M Instruction Set.
- Part D ARMv8-M Registers.
- Part E ARMv8-M Pseudocode.
- Part F Debug Packet Protocols.
- Appendix G1 Architectural Constraints on UNPREDICTABLE behaviors.

A1.1.2 Scope of the document

This manual contains only rules and information that relate specifically to the ARMv8-M architecture. It does not include any information about other ARM architectures, nor does it describe similarities between ARMv8-M and other architectures.
Readers must not assume that the rules provided in this specification are applicable to an ARMv7-M or ARMv6-M implementation, nor must they assume that the rules that are applicable to an ARMv7-M or ARMv6-M implementation are equally applicable to an ARMv8-M implementation.

### A1.3 Intended audience

This manual is written for users who want to design, implement, or program an ARMv8-M PE in a range of ARM-compliant implementations from simple uniprocessor implementations to complex multiprocessor systems. It does not assume familiarity with previous versions of the M-profile architecture.

The manual provides a precise, accurate, and correct set of rules that must be followed in order for an ARMv8-M implementation to be architecturally compliant. It is an explicit reference manual, and not a general introduction to, or user guide for, the ARMv8-M architecture.

The following quick-reference guides might be of interest to software engineers:

- *Introduction to the ARMv8-M Architecture Version 1.0.*
- *Memory Protection Unit (MPU) Version 1.0.*
- *Real-time Operating System Design Considerations Version 1.0.*
- *TrustZone® technology for ARMv8®-M Architecture Version 1.0.*

### A1.4 Terminology, phrases

This subsection identifies some standard words and phrases that are used in the ARM architecture documentation. These words and phrases have an ARM-specific definition, which is described in this section.

**Architecturally visible**

Something that is visible to the controlling agent. The controlling agent might be software.

**ARM recommends**

A particular usage that ensures consistency and usability. Following all the rules listed in this manual leads to a predictable outcome that is compliant with the architecture, but might produce an unexpected output. Adhering to a recommendation ensures that the output is as expected.

**ARM strongly recommends**

Something that is essentially mandatory, but that it is outside the scope of the architecture described in this manual. Failing to adhere to a strong recommendation can break the system, although the PE itself remains compliant with the architecture that is described in this manual.

**Finite time**

An action will occur at some point in the future. Finite time does not make any statement about the time involved. However, delaying an action longer than is absolutely necessary might have an adverse impact on performance.

**Permitted**

Allowed behavior.

**Required**

Mandatory behavior.

**Support**

The implementation has implemented a particular feature.

### A1.5 Terminology, ARMv8-M specific terms

For definitions of ARMv8-M specific terms, see the *Glossary.*
A1.2 About the ARMv8 architecture, and architecture profiles

ARMv8-M is documented as one of a set of architecture profiles. These profiles are defined as follows:

ARM defines three architecture profiles:

A Application profile:
  - Supports a Virtual Memory System Architecture (VMSA) based on a Memory Management Unit (MMU).
  - Supports the A64, A32, and T32 instruction sets.

R Real-time profile:
  - Supports a Protected Memory System Architecture (PMSA) based on a Memory Protection Unit (MPU).
  - Supports the A32 and T32 instruction sets.

M Microcontroller profile, described in this manual:
  - Implements a programmers' model designed for low-latency interrupt processing, with hardware stacking of registers and support for writing interrupt handlers in high-level languages.
  - Optionally implements a variant of the R-profile PMSA.
  - Supports a variant of the T32 instruction set.

This Architecture Reference Manual describes only the ARMv8-M profile.
A1.3 The ARMv8-M architecture profile

The M-profile architecture has historically included:

- The opportunity to include simple pipeline designs offering leading edge system performance levels in a broad range of markets and applications.
- Highly deterministic operation:
  - Single or low cycle count execution.
  - Minimal interrupt latency, with short pipelines.
  - Capable of cacheless operation.
- Excellent targeting of C/C++ code. This aligns with the ARM programming standards in this area:
  - Exception handlers are standard C/C++ functions, entered using standard calling conventions.
- Design support for deeply embedded systems:
  - Low pincount devices.
- Support for debug and software profiling for event-driven systems.

The simplest ARMv8-M implementation, without any of the optional extensions, is a Baseline implementation, see ARMv8-M variants on page A1-27. The ARMv8-M Baseline offers improvements over previous M-profile architectures in the following areas:

- The optional Security Extension.
- An improved, optional, Memory Protection Unit (MPU) model.
- Alignment with ARMv8-A and ARMv8-R memory types.
- Stack pointer limit checking.
- Improved support for multi-processing.
- Better alignment with C11 and C11++ standards.
- Enhanced debug capabilities.

A1.3.1 Security Extension

The ARMv8-M architecture introduces a number of new instructions to the M-profile architecture to support asset protection. These instructions are only available to implementations that support the Security Extension, see ARMv8-M variants on page A1-27.

A1.3.2 MPU model

The ARMv8-M architecture provides a default memory map and permits implementations to include an optional MPU. The optional MPU uses the Protected Memory System Architecture (PMSA\textsuperscript{8}v8) and contains improved flexibility in the MPU region definition, see Chapter B8 The ARMv8-M Protected Memory System Architecture.

A1.3.3 Nested Vector Interrupt Controller

The Nested Vector Interrupt Controller (NVIC) is used for integrated interrupt and exception handling and prioritization. ARMv8-M increases the number of interrupts that can potentially be supported by the NVIC to 480 for external sources, and includes automatic vectoring and priority management, and automatic state preservation. see Chapter B10 Nested Vectored Interrupt Controller.

A1.3.4 Stack pointers

The ARMv8-M architecture introduces stack limit registers that trigger an exception on a stack overflow. The number of stack limit registers available to an implementation is determined by the ARMv8-M variant that is implemented, see Stack pointer on page B3-46.
A1.3.5 The ARMv8-M instruction set

ARMv8-M only supports execution of T32 instructions. The ARMv8-M architecture adds instructions to support:

- Improved facilitation of execute-only code generation.
- Improved code optimization.
- Exclusive memory access instructions to enhance support for multiprocessor systems.
- Semaphores and atomics (Load-Acquire/Store-Release instructions).

The Floating-point (FP) Extension adds floating-point instructions to the T32 instruction set, see Chapter B4 Floating-point Support.

For more information about the instructions, see Chapter C1 Instruction Set Overview and Chapter C2 Instruction Specification.

A1.3.6 Debug

The ARMv8-M architecture introduces:

- Enhanced breakpoint and watchpoint functionality.
- Improvements to the Instrumentation Trace Macrocell (ITM).
- Comprehensive trace and self-hosted debug extensions to make embedded software easier to debug and trace.

For more information about debug, see Chapter B11 Debug and Chapter B12 Debug and Trace Components.
A1.4 ARMv8-M variants

The ARMv8-M architecture has the following optional extensions:

• The Main Extension.
• The Security Extension.

—— Note ————

The ARMv8-M Security Extension can also be referred to as ARM® TrustZone® for ARMv8-M.

—— Note ————

• The Floating-point Extension.
• The Digital Signal Processing (DSP) Extension.
• The Debug Extension.
• The MPU Extension.

Only a PE that implements the Main Extension can implement the Floating-point Extension or the DSP Extension.

—— Note ————

• A PE with the Main Extension is also referred to as a Mainline implementation.
• A PE without the Main Extension is also referred to as a Baseline implementation. A Baseline implementation has a subset of the instructions, registers, and features, of a Mainline implementation.
• ARMv7-M compatibility requires the Main Extension.
• ARMv6-M compatibility is provided by all ARMv8-M implementations.
A1 Introduction
A1.4 ARMv8-M variants
Part B

ARMv8-M Architecture Rules
Chapter B1
Resets

This chapter specifies the ARMv8-M reset rules. It contains the following section:
• *Resets, Cold reset and Warm reset* on page B1-32.
B1.1 Resets, Cold reset and Warm reset

There are two resets:

- Cold reset.
- Warm reset.

On a Cold reset, registers that have a defined reset value contain that value.

On a Warm reset, some debug register control fields that have a defined reset value remain unchanged, but otherwise all registers that have a defined reset value contain that value.

On a Warm reset, the PE performs the actions described by the `TakeReset()` pseudocode.

`AIRCR.SYSRESETREQ` is required to cause a Warm reset.

For `AIRCR.SYSRESETREQ`, the architecture does not guarantee that the reset takes place immediately.

A Warm reset takes the PE out of Debug state.

See also:

- Chapter B11 Debug
Chapter B2
Power Management

This chapter specifies the ARMv8-M power management rules. It contains the following section:

• *Power management on page B2-34.*
B2.1 Power management

The following instructions hint to the PE hardware that it can suspend execution and enter a low-power state:

- Wait for Event (WFE).
- Wait For Interrupt (WFI).
- Sleep on exit (SleepOnExit).

B2.1.1 The Wait for Event (WFE) instruction

When a WFE instruction is executed, then if the state of the Event register is clear, the PE can suspend execution and enter a low-power state.

When a WFE instruction is executed, then if the state of the Event register is set, the instruction clears the register and completes immediately.

If the PE enters a low-power state on a WFE instruction, it remains in that low-power state until it receives a WFE wakeup event. When the PE recognizes a WFE wakeup event, the WFE instruction completes. The following are WFE wakeup events:

- The execution of a SEV instruction by any PE.
- When SCR.SEVONPEND is 1, any exception entering the pending state.
- Any exception at a priority that would preempt the current execution priority, taking into account any active exceptions and including the effects of any software-controlled priority booting by AIRCR.PRIS == 1 and PRIMASK, FAULTMASK, or BASEPRI.
- If debug is enabled, a debug event.

The ARMv8-M architecture does not define the exact nature of the low-power state entered on a WFE instruction, except that it must not cause a loss of memory coherency.

ARM recommends that software always uses the WFE instruction in a loop.

See also:

- WaitForEvent on page E2-1294.
- SendEvent on page E2-1272.

B2.1.2 The Event register

The Event register is a single-bit register for each PE in the system.

The Event register for a PE is set by any of the following:

- Any WFE wakeup event.
- Exception entry.
- Exception return.

When the Event register is set, it is an indication that an event has occurred since the register was last cleared, and that the event might require some action by the PE.

A reset clears the Event register.

Software cannot read, and cannot write to, the Event register directly.

See also:

- SetEventRegister on page E2-1273.
- ClearEventRegister on page E2-1165.
- EventRegistered on page E2-1184.
### B2.1.3 The Wait for Interrupt (WFI) instruction

When a WFI instruction is executed, the PE can suspend execution and enter a low-power state. If it does, it remains in that state until it receives a WFI wakeup event. When the PE recognizes a WFI wakeup event, the WFI instruction completes. The following are WFI wakeup events:

- A reset.
- Any asynchronous exception at a priority that, ignoring the effect of PRIMASK (so that behavior is as if PRIMASK is 0), would preempt any currently active exceptions.
- An IMPLEMENTATION DEFINED WFI wakeup event.
- If debug is enabled, a debug event.

ARM recommends that software always uses the WFI instruction in a loop.

See also:

- WaitForInterrupt on page E2-1294.

### B2.1.4 Sleep on exit

It is IMPLEMENTATION DEFINED whether the SleepOnExit() function causes the PE to enter a low-power state during the return from the only active exception and the PE returns to thread mode.

The PE enters a low-power state on return from an exception if all of the following are true:

- EXC_RETURN.Mode == 1.
- SCR.SLEEPONEXIT == 1.

If the sleep-on-exit function is enabled, it is IMPLEMENTATION DEFINED at which point in the exception return process the PE enters a low-power state.

The wakeup events for the sleep-on-exit function are identical to the WFI instruction wakeup events.

See also:

- SleepOnExit on page E2-1277.
- Exception return on page B3-75.
Chapter B3
Programmers’ Model

This chapter specifies the ARMv8-M programmers’ model architecture rules. It contains the following sections:

- PE modes, Thread mode and Handler mode on page B3-39.
- Privileged and unprivileged execution on page B3-40.
- Registers on page B3-41.
- XPSR, APSR, IPSR, and EPSR on page B3-42.
- Security states, Secure state, and Non-secure state on page B3-44.
- Security states, register banking between them on page B3-45.
- Stack pointer on page B3-46.
- Exception numbers and exception priority numbers on page B3-47.
- Exception enable, pending, and active bits on page B3-50.
- Security states, exception banking on page B3-51.
- Faults on page B3-53.
- Exception states on page B3-56.
- Priority model on page B3-57.
- Secure address protection on page B3-60.
- Security state transitions on page B3-61.
- Function calls from Secure state to Non-secure state on page B3-62.
- Function returns from Non-secure state on page B3-63.
- Exception handling on page B3-64.
- Exception entry, context stacking on page B3-66.
- Exception entry, register clearing after context stacking on page B3-71.
- Stack limit checks on page B3-72.
- Exception return on page B3-75.
- Integrity signature on page B3-78.
- Exceptions during exception entry on page B3-79.
• Exceptions during exception return on page B3-80.
• Tail-chaining on page B3-81.
• Exceptions, instruction resume, or instruction restart on page B3-83.
• Vector tables on page B3-85.
• Hardware-controlled priority escalation to HardFault on page B3-87.
• Special-purpose mask registers, PRIMASK, BASEPRI, FAULTMASK, for software-controlled priority boosting on page B3-88.
• Lockup on page B3-90.
• Exception during a singleword load operation on page B3-95.
• Special-purpose CONTROL register on page B3-96.
• Saving context on process switch on page B3-97.
• Context Synchronization Event on page B3-98.
• Coprocessor support on page B3-99.
B3.1 PE modes, Thread mode and Handler mode

There are two PE modes:
• Thread mode.
• Handler mode.

A common usage model for the PE modes is:

**Thread mode**

Applications

**Handler mode**

OS kernel and associated functions. Software that manages system resources.

The PE handles all exceptions in Handler mode.

Thread mode is selected on reset. The IPSR is set to zero on reset.

See also:
• *Privileged and unprivileged execution* on page B3-40.
• *Interrupt Program Status Register (IPSR)* on page B3-42.
• *Security states, Secure state, and Non-secure state* on page B3-44.
B3.2 Privileged and unprivileged execution

**Thread mode**
Execution can be privileged or unprivileged.

**Handler mode**
Execution is always privileged.

**CONTROL.nPRIV** determines whether execution in Thread mode is unprivileged.

In a PE without the Main Extension, it is IMPLEMENTATION DEFINED whether CONTROL.nPRIV can be set to 1.

Privileged execution has access to all resources.

See also:
- PE modes, Thread mode and Handler mode on page B3-39.
B3.3 Registers

There are the following types of registers:

**General-purpose registers, all 32-bit:**
- R0-R12 (R<n>).
- R13. This is the Stack Pointer (SP).
- R14. This is the Link Register (LR).

**Program Counter, 32-bit:**
- R15 is the Program Counter (PC).

**Special-purpose registers**
- Mask Registers:
  - 1-bit exception mask register, PRIMASK.
  - 8-bit base priority mask register, BASEPRI.
  - 1-bit fault mask register, FAULTMASK.
- A 2-bit, 3-bit, or 4-bit CONTROL register.
- Two 32-bit Stack Pointer Limit registers, MSPLIM and PSPLIM, if the Main Extension is not implemented the Non-secure versions of these registers are RAZ/WI.
- A combined 32-bit Program Status Register (XPSR), comprising:
  - Application Program Status Register (APSR).
  - Interrupt Program Status Register (IPSR).
  - Execution Program Status Register (EPSR).
- A 32-bit Combined Exception Return Program Status Register, RETPSR.

**Memory-mapped registers**
- All other registers.

Extensions might add more registers to the base register set.

In a PE with the Main Extension, the LR is set to 0xFFFFFFFF on Warm reset. Otherwise, it becomes UNKNOWN on Cold or Warm resets.

The PC is loaded with the reset handler start address on Cold reset and Warm reset.

Except for writes to the CONTROL register, any change to a special-purpose register by a CPS or MSR instruction is guaranteed:
- Not to affect that CPS or MSR instruction, or any instruction preceding it in program order.
- To be visible to all instructions that appear in program order after the CPS or MSR.

See also:
- Chapter B7 The System Address Map.
- Special-purpose mask registers, PRIMASK, BASEPRI, FAULTMASK, for software-controlled priority boosting on page B3-88.
- Special-purpose CONTROL register on page B3-96.
- Stack limit checks on page B3-72.
- XPSR, APSR, IPSR, and EPSR on page B3-42.
- Resets, Cold reset and Warm reset on page B1-32.
- Chapter D1 Register Specification.
B3.4 XPSR, APSR, IPSR, and EPSR

The APSR, IPSR, and EPSR combine to form one register, the XPSR:

<table>
<thead>
<tr>
<th>APSR</th>
<th>IPSR</th>
<th>EPSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>C</td>
<td>ICI/ IT††</td>
</tr>
<tr>
<td>Z</td>
<td>V</td>
<td>T</td>
</tr>
<tr>
<td>Q</td>
<td></td>
<td>ICI/ IT††</td>
</tr>
<tr>
<td>GE[3:0]†</td>
<td>0 or Exception Number</td>
<td></td>
</tr>
</tbody>
</table>

All unused bits in any of the APSR, IPSR, or EPSR, or any unused bits in the combined XPSR, are reserved.

The `MRS` and `MSR` instructions recognize the following mnemonics for accessing the APSR, IPSR, or EPSR, or a combination of them:

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Registers accessed</th>
</tr>
</thead>
<tbody>
<tr>
<td>APSR</td>
<td>APSR</td>
</tr>
<tr>
<td>IPSR</td>
<td>IPSR</td>
</tr>
<tr>
<td>EPSR</td>
<td>EPSR</td>
</tr>
<tr>
<td>IAPSR</td>
<td>IPSR and APSR</td>
</tr>
<tr>
<td>EAPSR</td>
<td>EPSR and APSR</td>
</tr>
<tr>
<td>IEPSR</td>
<td>IPSR and EPSR</td>
</tr>
<tr>
<td>XPSR</td>
<td>APSR, IPSR, and EPSR</td>
</tr>
</tbody>
</table>

See also:
- *Registers on page B3-41.*
- *Application Program Status Register (APSR).*
- *Interrupt Program Status Register (IPSR).*
- *Execution Program Status Register (EPSR) on page B3-43.*

B3.4.1 Application Program Status Register (APSR)

Software can use `MRS` and `MSR` instructions to access the APSR.

Application-level software can access the APSR, regardless of whether the application-level software is privileged or unprivileged.

See also:
- *XPSR, APSR, IPSR, and EPSR.*
- *APSR, Application Program Status Register on page D1-822.*

B3.4.2 Interrupt Program Status Register (IPSR)

When the PE is in Thread mode, the IPSR value is zero.
When the PE is in Handler mode:

- In the case of a taken exception, the IPSR holds the exception number of the exception being handled.
- When there has been a function call from Secure state to Non-secure state, the IPSR has the value of 1.

The PE updates the IPSR on exception entry and return.

Software can use \texttt{MRS} instructions to read the IPSR. The PE ignores writes to the IPSR by \texttt{MSR} instructions.

See also:

- \textit{XPSR, APSR, IPSR, and EPSR} on page B3-42.
- \textit{Function calls from Secure state to Non-secure state} on page B3-62.
- \textit{IPSR, Interrupt Program Status Register} on page D1-998.
- \textit{BLX, BLXNS} on page C2-351.

### B3.4.3 Execution Program Status Register (EPSR)

A reset sets \texttt{EPSR.T} to the value of bit[0] of the reset vector.

Bit[0] of the reset vector must be 1 if the PE is to execute the code indicated by the reset vector.

When \texttt{EPSR.T} is:

- 0 Any attempt to execute any instruction generates:
  - An INVSTATE UsageFault, in a PE with the Main Extension.
  - A HardFault, in a PE without the Main Extension.
- 1 The Instruction set state is T32 state and all instructions are decoded as T32 instructions.

The intent is that the Instruction set state is always T32 state.

All EPSR fields read as zero using an \texttt{MRS} instruction. The PE ignores writes to the EPSR by an \texttt{MSR} instruction.

See also:

- \textit{XPSR, APSR, IPSR, and EPSR} on page B3-42.
- \textit{EPSR, Execution Program Status Register} on page D1-929.
B3.5 Security states, Secure state, and Non-secure state

A PE with the Security Extension has two Security states:

- Secure state.
  - Secure Thread mode.
  - Secure Handler mode.
- Non-secure state.
  - Non-secure Thread mode.
  - Non-secure Handler mode.

If the Security Extension is implemented, memory areas and other critical resources that are marked as secure can only be accessed when the PE is executing in Secure state,

A PE with the Security Extension resets into Secure state on both of the ARMv8-M resets, Cold reset and Warm reset.

A PE without the Security Extension behaves as though reset into Non-secure state.

See also:
- *PE modes, Thread mode and Handler mode* on page B3-39.
- *Privileged and unprivileged execution* on page B3-40.
- *Security states, register banking between them* on page B3-45.
- *Security states, exception banking* on page B3-51.
- *Security state transitions* on page B3-61.
- *Resets, Cold reset and Warm reset* on page B1-32.
B3.6 Security states, register banking between them

In a PE with the Security Extension, some registers are banked between the Security states. When a register is banked in this way, there is a distinct instance of the register in Secure state and another distinct instance of the register in Non-secure state.

In a PE with the Security Extension:

- The general-purpose registers that are banked are:
  - R13. This is the Stack Pointer (SP).
- The special-purpose registers that are banked are:
  - The Mask registers, PRIMASK, BASEPRI, andFAULTMASK.
  - The CONTROL register.
  - The main and process Stack Pointer Limit registers, MSPLIM and PSPLIM.
- The System Control Space (SCS) is banked.

For MRS and MSR instructions, SYSm[7] in the instruction encoding specifies whether the Secure or the Non-secure instance of a banked register is accessed:

<table>
<thead>
<tr>
<th>Accesses from</th>
<th>SYSm[7]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure state</td>
<td>Secure instance</td>
</tr>
<tr>
<td>Non-secure state</td>
<td>Non-secure instance</td>
</tr>
</tbody>
</table>

This specification uses the following naming convention to identify banked registers:

<register name>_S

The Secure instance of the register.

<register name>_NS

The Non-secure instance of the register.

<register name>

The instance that is associated with the current Security state.

See also:

- Registers on page B3-41.
- Security states, Secure state, and Non-secure state on page B3-44.
- Stack pointer on page B3-46.
- The System Control Space (SCS) on page B7-172.
B3.7 Stack pointer

In a PE with the Security Extension, four stacks and four stack pointer registers are implemented:

<table>
<thead>
<tr>
<th>Stack</th>
<th>Stack pointer register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure Main</td>
<td>MSP_S</td>
</tr>
<tr>
<td>Process</td>
<td>PSP_S</td>
</tr>
<tr>
<td>Non-secure Main</td>
<td>MSP_NS</td>
</tr>
<tr>
<td>Process</td>
<td>PSP_NS</td>
</tr>
</tbody>
</table>

Otherwise, two stacks and two stack pointer registers are implemented:

<table>
<thead>
<tr>
<th>Stack</th>
<th>Stack pointer register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main</td>
<td>MSP</td>
</tr>
<tr>
<td>Process</td>
<td>PSP</td>
</tr>
</tbody>
</table>

In Handler mode, the PE uses the main stack.

In Thread mode, CONTROL.SPSEL determines whether the PE uses the main or process stack.

In a PE with the Security Extension, the Secure main stack, MSP_S, is selected and initialized on reset. Otherwise, MSP is selected and initialized on reset.

<stack_pointer_register_name>[1:0] is always treated as RES0, so that all stack pointers are always guaranteed to be word-aligned.

After the exception entry stacking operation, the stack pointer is doubleword-aligned.

ARM recommends that the Secure stacks be located in Secure memory.

See also:
- Security states, Secure state, and Non-secure state on page B3-44.
- PE modes, Thread mode and Handler mode on page B3-39.
- Exception entry, context stacking on page B3-66.
- Vector tables on page B3-85.
- Registers on page B3-41.
- Stack limit checks on page B3-72.
### B3.8 Exception numbers and exception priority numbers

Each exception has an associated *exception number* and an associated *priority number*.

In a PE with the Main Extension, the exceptions, their associated numbers, and their associated priority numbers are as follows:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Exception number</th>
<th>Priority number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reset</td>
<td>1</td>
<td>-4&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
<tr>
<td>Secure HardFault when AIRCR.BFHFNMINS is 1&lt;sup&gt;b&lt;/sup&gt;</td>
<td>3</td>
<td>-3</td>
</tr>
<tr>
<td>NMI</td>
<td>2</td>
<td>-2</td>
</tr>
<tr>
<td>Secure HardFault when AIRCR.BFHFNMINS is 0</td>
<td>3</td>
<td>-1</td>
</tr>
<tr>
<td>Non-secure HardFault</td>
<td>3</td>
<td>-1</td>
</tr>
<tr>
<td>MemManage fault</td>
<td>4</td>
<td>Software configurable</td>
</tr>
<tr>
<td>BusFault</td>
<td>5</td>
<td>Software configurable</td>
</tr>
<tr>
<td>UsageFault</td>
<td>6</td>
<td>Software configurable</td>
</tr>
<tr>
<td>SecureFault</td>
<td>7&lt;sup&gt;c&lt;/sup&gt;</td>
<td>Software configurable</td>
</tr>
<tr>
<td>Reserved</td>
<td>8-10</td>
<td>-</td>
</tr>
<tr>
<td>SVCAll</td>
<td>11</td>
<td>Software configurable</td>
</tr>
<tr>
<td>DebugMonitor</td>
<td>12</td>
<td>Software configurable</td>
</tr>
<tr>
<td>Reserved</td>
<td>13</td>
<td>-</td>
</tr>
<tr>
<td>PendSV</td>
<td>14</td>
<td>Software configurable</td>
</tr>
<tr>
<td>SysTick</td>
<td>15</td>
<td>Software configurable</td>
</tr>
<tr>
<td>External interrupt 0</td>
<td>16</td>
<td>Software configurable</td>
</tr>
<tr>
<td>External interrupt N</td>
<td>16+N</td>
<td>Software configurable</td>
</tr>
</tbody>
</table>

- **a.** Highest priority.
- **b.** When AIRCR.BFHFNMINS is 1, faults that target Secure state that are escalated to HardFault are still Secure HardFaults. That is, the value of AIRCR.BFHFNMINS does not affect faults that target Secure state that are escalated to HardFaults. This table row applies to such faults.
- **c.** In a PE without the Security Extension, exception number 7 is reserved.
In a PE without the Main Extension, the exceptions, their associated numbers, and their associated priority numbers are as follows:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Exception number</th>
<th>Priority number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reset</td>
<td>1</td>
<td>-4\textsuperscript{a}</td>
</tr>
<tr>
<td>Secure HardFault when AIRCR.BFHFNMINS is 1\textsuperscript{b}</td>
<td>3</td>
<td>-3</td>
</tr>
<tr>
<td>NMI</td>
<td>2</td>
<td>-2</td>
</tr>
<tr>
<td>Secure HardFault when AIRCR.BFHFNMINS is 0</td>
<td>3</td>
<td>-1</td>
</tr>
<tr>
<td>Non-secure HardFault</td>
<td>3</td>
<td>-1</td>
</tr>
<tr>
<td>Reserved</td>
<td>4-10</td>
<td>-</td>
</tr>
<tr>
<td>SVCAll</td>
<td>11</td>
<td>Software configurable</td>
</tr>
<tr>
<td>Reserved</td>
<td>12-13</td>
<td>-</td>
</tr>
<tr>
<td>PendSV</td>
<td>14</td>
<td>Software configurable</td>
</tr>
<tr>
<td>SysTick</td>
<td>15</td>
<td>Software configurable</td>
</tr>
<tr>
<td>External interrupt 0</td>
<td>16</td>
<td>Software configurable</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>External interrupt N</td>
<td>16+N</td>
<td>Software configurable</td>
</tr>
</tbody>
</table>

\textsuperscript{a} Highest priority.

\textsuperscript{b} When AIRCR.BFHFNMINS is 1, faults that target Secure state that are escalated to HardFault are still Secure HardFaults. That is, the value of AIRCR.BFHFNMINS does not affect faults that target Secure state that are escalated to HardFaults. This table row applies to such faults.

The maximum supported number of external interrupts is 496, regardless of whether the Main Extension is implemented.

The architecture permits an implementation to omit external configurable interrupts where no external device is connected to the corresponding interrupt pin. Where an implementation omits such an interrupt, the corresponding pending, active, enable, and priority registers are RES0.

For exceptions with software configurable priority numbers, software configures the priority numbers by using registers SHPR1 - SHPR3 in the System Control Block (SCB).

Software configurable priority numbers start at 0, the highest software configurable exception priority number.
In a PE with the Main Extension, the number of software configurable priority numbers is an IMPLEMENTATION DEFINED power of two in the range 8-256:

<table>
<thead>
<tr>
<th>Number of priority bits of SHPRn.PRI_n implemented(^a)</th>
<th>Number of software configurable priority numbers</th>
<th>Minimum priority number (highest priority)</th>
<th>Maximum priority number (lowest priority)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>8</td>
<td>0</td>
<td>0b11100000 = 224</td>
</tr>
<tr>
<td>4</td>
<td>16</td>
<td>0</td>
<td>0b11110000 = 240</td>
</tr>
<tr>
<td>5</td>
<td>32</td>
<td>0</td>
<td>0b11111000 = 248</td>
</tr>
<tr>
<td>6</td>
<td>64</td>
<td>0</td>
<td>0b11111100 = 252</td>
</tr>
<tr>
<td>7</td>
<td>128</td>
<td>0</td>
<td>0b11111110 = 254</td>
</tr>
<tr>
<td>8</td>
<td>256</td>
<td>0</td>
<td>0b11111111 = 255</td>
</tr>
</tbody>
</table>

\(^a\) All low-order bits of these fields that are not implemented as priority bits are RES0, as shown in the maximum priority number column.

In a PE without the Main Extension, the number of software configurable priority numbers is 4:

<table>
<thead>
<tr>
<th>Number of priority bits of SHPRn.PRI_n implemented(^a)</th>
<th>Number of software configurable priority numbers</th>
<th>Minimum priority number (highest priority)</th>
<th>Maximum priority number (lowest priority)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>4</td>
<td>0</td>
<td>0b11000000 = 192</td>
</tr>
</tbody>
</table>

\(^a\) SHPRn.PRI_n[5:0] are RES0, as shown in the maximum priority number column.

See also:
- Security states, exception banking on page B3-51.
- Faults on page B3-53.
- Priority model on page B3-57.
### B3.9 Exception enable, pending, and active bits

The SHCSR, ICSR, DEMCR, NVIC_IABR<\textless n\textgreater>, NVIC_ISPR<\textless n\textgreater>, NVIC_ISER<\textless n\textgreater>, and STIR contain exception enable, pending, and active fields.

The following exceptions are always enabled and therefore do not have an exception enable bit:
- HardFault.
- NMI.
- SVCall.
- PendSV.

In a PE without the Security Extension:
- Privileged execution can pend interrupts by writing to the NVIC_ISPR<\textless n\textgreater>.
- When CCR.USERSETMPEND is 1, unprivileged execution can pend interrupts by writing to the STIR.

In a PE with the Security Extension:
- Software can use the STIR to pend any Secure or Non-secure interrupt, as follows:

<table>
<thead>
<tr>
<th>Secure state</th>
<th>Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Privileged execution</td>
<td>Can use STIR to pend any Secure or Non-secure interrupt.</td>
</tr>
<tr>
<td>Unprivileged execution</td>
<td>When CCR.USERSETMPEND_S is 1, can use STIR to pend any Secure or Non-secure interrupt, otherwise a BusFault is generated.</td>
</tr>
</tbody>
</table>

- Software can use STIR_NS to pend a Non-secure interrupt, as follows:

<table>
<thead>
<tr>
<th>Secure state</th>
<th>Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Privileged execution</td>
<td>Can use STIR_NS to pend a Non-secure interrupt.</td>
</tr>
<tr>
<td>Unprivileged execution</td>
<td>When CCR.USERSETMPEND_NS is 1, can use STIR_NS to pend a Non-secure interrupt, otherwise a BusFault is generated.</td>
</tr>
</tbody>
</table>

- Software can use NVIC_ISPR<\textless n\textgreater> to pend any Secure or Non-secure interrupt, as follows:

<table>
<thead>
<tr>
<th>Secure state</th>
<th>Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Privileged execution</td>
<td>Can use NVIC_ISPR&lt;\textless n\textgreater&gt; to pend any Secure or Non-secure interrupt.</td>
</tr>
<tr>
<td>Unprivileged execution</td>
<td>Fault</td>
</tr>
</tbody>
</table>

- Software can use NVIC_ISPR<\textless n\textgreater>_NS to pend a Non-secure interrupt, as follows:

<table>
<thead>
<tr>
<th>Secure state</th>
<th>Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Privileged execution</td>
<td>Can use NVIC_ISPRN_NS to pend a Non-secure interrupt.</td>
</tr>
<tr>
<td>Unprivileged execution</td>
<td>Fault</td>
</tr>
</tbody>
</table>
B3.10 Security states, exception banking

RPJHV In a PE with the Security Extension, some exceptions are banked. A banked exception has all of the following:

- Banked enabled, pending, and active bits.
- A banked SHPRn.PRI field.
- A banked exception vector.
- A state relevant handler.

A banked exception targets the Security state that it is taken from.

RNBMV Reset always targets Secure state.

IDDKC NMI can be configured to target either Security state, by using AIRCR.BFHFNMINS.

IHGFM BusFault can be configured to target either Security state, by using AIRCR.BFHFNMINS.

RMQWN SecureFault always targets Secure state.

IWSSL DebugMonitor targets Secure state if the status bit DEMCR.SDME is 1. Otherwise, it targets Non-secure state.

IDQLX Each external interrupt, 0-N, targets the Security state that its NVIC_ITNS<n>.<bit number> dictates.

### Exception Banked

<table>
<thead>
<tr>
<th>Exception</th>
<th>Banked</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reset</td>
<td>No</td>
</tr>
<tr>
<td>HardFault</td>
<td>Yes</td>
</tr>
<tr>
<td>NMI</td>
<td>No</td>
</tr>
<tr>
<td>MemManage fault</td>
<td>Yes</td>
</tr>
<tr>
<td>BusFault</td>
<td>No</td>
</tr>
<tr>
<td>UsageFault</td>
<td>Yes</td>
</tr>
<tr>
<td>SecureFault</td>
<td>No</td>
</tr>
<tr>
<td>SVC</td>
<td>Yes</td>
</tr>
<tr>
<td>DebugMonitor</td>
<td>No</td>
</tr>
<tr>
<td>PendSV</td>
<td>Yes</td>
</tr>
<tr>
<td>SysTick</td>
<td>Yes</td>
</tr>
<tr>
<td>External interrupt 0</td>
<td>No</td>
</tr>
<tr>
<td>..</td>
<td>..</td>
</tr>
<tr>
<td>..</td>
<td>..</td>
</tr>
<tr>
<td>..</td>
<td>..</td>
</tr>
<tr>
<td>External interrupt N</td>
<td>No</td>
</tr>
</tbody>
</table>

a. HardFault only behaves as a banked exception if AIRCR.BFHFNMINS is 1, otherwise it behaves as an unbanked exception targeting Secure state.
b. Exception type is present only if the Main Extension is implemented.
In this rule, `<exception>` is one of:
- NMI.
- BusFault.
- DebugMonitor.
- External interrupt N.

When `<exception>` targets Secure state, the Non-secure view of its SHPRn.PRI field, and enabled, pending, and active bits, are RAZ/WI.

Secure software must ensure that when changing the target Security state of an exception, the exception is not pending or active.

See also:
- *Exception numbers and exception priority numbers* on page B3-47.
- *Vector tables* on page B3-85.
### B3.11 Faults

There are the following Fault Status Registers:

- HardFault Status Register (HFSR). Present only if the Main Extension is implemented.
- MemManage Fault Status Register (MMFSR). Present only if the Main Extension is implemented.
- BusFault Status Register (BFSR). Present only if the Main Extension is implemented.
- UsageFault Status Register (UFSR). Present only if the Main Extension is implemented.
- SecureFault Status Register (SFSR). Present only if the Main Extension and Security Extension are implemented.
- Debug Fault Status Register (DFSR). Present only if Halting debug or the Main Extension is implemented.
- Auxiliary Fault Status Register (AFSR). The contents of this register are IMPLEMENTATION DEFINED.

In a PE with the Main Extension, the MMFSR, BFSR, and UFSR combine to form one register, called the Configurable Fault Status Register (CFSR).

There are the following Fault Address Registers:

- MemManage Fault Address Register (MMFAR). Present only if the Main Extension is implemented.
- BusFault Address Register (BFAR). Present only if the Main Extension is implemented.
- SecureFault Address Register (SFAR). Present only if the Main Extension is implemented.

**MMFAR** is updated only for a MemManage fault on a direct data access.

**BFAR** is updated only for a BusFault on a data access, a precise fault.

ARM strongly recommends that software clears the BFAR, or shared fault address register, when changing AIRCR.BFHIFNMINS so as not to expose the last accessed address to the other Security state.

Each fault address register has an associated valid bit. When the PE updates the fault address register, the PE sets the valid bit to one.

<table>
<thead>
<tr>
<th>Fault address register</th>
<th>Valid bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>MMFAR</td>
<td>MMFSR.MMARVALID</td>
</tr>
<tr>
<td>BFAR</td>
<td>BFSR.BFARVALID</td>
</tr>
<tr>
<td>SFAR</td>
<td>SFSR.SFARVALID</td>
</tr>
</tbody>
</table>

If the Security Extension is not implemented, it is IMPLEMENTATION DEFINED whether separate BFAR and MMFAR are implemented. If one shared fault address register is implemented, then on a fault that would otherwise update the shared fault address register, if one of the other valid bits is set to one it is IMPLEMENTATION DEFINED whether:

- The shared fault address register is updated, the valid bit for the fault is set, and the other valid bit is cleared.
- The shared fault address register is not updated, and the valid bits are not changed.

If the Security Extension is implemented, it is IMPLEMENTATION DEFINED whether separate BFAR and MMFAR_NS are implemented. If one shared fault address register is implemented, then on a fault that would otherwise update the shared fault address register, if one of the other valid bits is set to one, it is IMPLEMENTATION DEFINED whether:

- The shared fault address register is updated, the valid bit for the fault is set, and the other valid bit is cleared.
- The shared fault address register is not updated, and the valid bits are not changed.

If the Security Extension is implemented, it is IMPLEMENTATION DEFINED whether a separate SFAR and MMFAR_S are implemented. If one secure shared fault address register is implemented, then on a fault that would otherwise update the secure shared fault address register, if the other valid bit for the secure shared fault address register is set to one it is IMPLEMENTATION DEFINED whether:

- The shared secure fault address register is updated, the valid bit for the fault is set, and the other valid bit for the secure shared fault address register is cleared.
- The secure shared fault address register is not updated, and the valid bits for the secure shared fault address register is not changed.
In a PE with the Main Extension, the faults are:

<table>
<thead>
<tr>
<th>Exception number</th>
<th>Exception</th>
<th>Fault</th>
<th>Fault status bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>HardFault</td>
<td>HardFault on a vector table entry read error</td>

<td>BFSR.IMPRECISERR</td>
</tr>
<tr>
<td></td>
<td></td>
<td>BusFault on context unstacking by hardware</td>
<td>BFSR.UNSTKERR</td>
</tr>
<tr>
<td></td>
<td></td>
<td>BusFault on context stacking by hardware</td>
<td>BFSR.STKERR</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When lazy FP context preservation is active, a BusFault on saving FP context to the stack</td>
<td>SFSR.LSPERR</td>
</tr>
<tr>
<td>6</td>
<td>UsageFault</td>
<td>UsageFault, undefined instruction</td>
<td>UFSR.UNDEFINSTR</td>
</tr>
<tr>
<td></td>
<td></td>
<td>UsageFault, invalid Instruction set state because EPSR.T is 0</td>
<td>UFSR.INVSTATE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>UsageFault, failed integrity check on exception return</td>
<td>UFSR.INVPC</td>
</tr>
<tr>
<td></td>
<td></td>
<td>UsageFault, no coprocessor</td>
<td>UFSR.NOCP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>UsageFault, stack overflow</td>
<td>UFSR.STKOF</td>
</tr>
<tr>
<td></td>
<td></td>
<td>UsageFault, unaligned access when CCR.UNALIGN_TRP is 1</td>
<td>UFSR.UNALIGNED</td>
</tr>
<tr>
<td></td>
<td></td>
<td>UsageFault, divide by zero when CCR.DIV_0_TRP is 1</td>
<td>UFSR.DIVBYZERO</td>
</tr>
</tbody>
</table>
In a PE without the Main Extension, the faults remain the same as for a PE with the Main Extension, but the enable, pending, and active bits for the following faults are RAZ/WI in the SHCSR:

- MemManage fault.
- BusFault.
- UsageFault.
- SecureFault.

In a PE without the Main Extension, the faults are:

<table>
<thead>
<tr>
<th>Exception number</th>
<th>Exception</th>
<th>Fault</th>
<th>Fault status bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>SecureFault</td>
<td>SecureFault, invalid Secure state entry point</td>
<td>SFSR.INVEP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SecureFault, invalid integrity signature when unstacking</td>
<td>SFSR.INVIS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SecureFault, invalid exception return</td>
<td>SFSR.INVER</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SecureFault, attribution unit violation</td>
<td>SFSR.AUVIOL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SecureFault, invalid transition from Secure state</td>
<td>SFSR.INVTRAN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SecureFault, lazy FP context preservation error</td>
<td>SFSR.LSPERR</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SecureFault, lazy FP context error</td>
<td>SFSR.LSER</td>
</tr>
</tbody>
</table>

Fault conditions that would generate a SecureFault in a PE with the Main Extension instead generate a Secure HardFault in a PE without the Main Extension.

For the exact circumstances under which each of the ARM v8-M faults is generated, see the appropriate Fault Status Register description.

- *Hardware-controlled priority escalation to HardFault* on page B3-87.
- Chapter B11 Debug.
B3.12 Exception states

ICTFJ An exception, other than reset, has the following possible states:

Active
An exception that either:
• Is being handled.
• Was being handled. The handler was preempted by a handler for a higher priority exception.

Pending
An exception that has been generated, but that is not active.

Inactive
The exception has not been generated.

Active and pending
One instance of the exception is active, and a second instance of the exception is pending.
Only asynchronous exceptions can be active and pending. Synchronous exceptions are either inactive, pending, or active.
B3.13 Priority model

Lower priority numbers take precedence.

The current execution priority is:

1. If any exceptions are active, the current execution priority is the priority number of the active exception with the lowest SHPRn.PRI group priority field value.
2. The current execution priority then includes any effects of any software-controlled priority boosting by AIRCR.PRIS==1 and PRIMASK, FAULTMASK, and BASEPRI.

When no exception is active and no priority boosting is active, the instruction stream that is executing has a priority number of (maximum supported priority number+1).

Execution at a particular priority can only be preempted by an exception with a lower group priority field value.

In a PE with the Main Extension, BASEPRI and each SHPRn.PRI_n and NVICn.PRI_Nn are 8-bit fields that AIRCR.PRIGROUP splits into two fields, a group priority field and a subpriority field:

<table>
<thead>
<tr>
<th>AIRCR.PRIGROUP value</th>
<th>Group priority field</th>
<th>Subpriority field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>[7:1]</td>
<td>[0]</td>
</tr>
<tr>
<td>1</td>
<td>[7:2]</td>
<td>[1:0]</td>
</tr>
<tr>
<td>2</td>
<td>[7:3]</td>
<td>[2:0]</td>
</tr>
<tr>
<td>3</td>
<td>[7:4]</td>
<td>[3:0]</td>
</tr>
<tr>
<td>4</td>
<td>[7:5]</td>
<td>[4:0]</td>
</tr>
<tr>
<td>5</td>
<td>[7:6]</td>
<td>[5:0]</td>
</tr>
<tr>
<td>6</td>
<td>[7]</td>
<td>[6:0]</td>
</tr>
<tr>
<td>7</td>
<td>-</td>
<td>[7:0]</td>
</tr>
</tbody>
</table>

a. All low-order bits of these fields that are not implemented as priority bits are RES0.

In a PE without the Main Extension, AIRCR.PRIGROUP is RES0, therefore each SHPRn.PRI_n and NVICn.PRI_Nn is split into two as follows:

<table>
<thead>
<tr>
<th>AIRCR.PRIGROUP value</th>
<th>Group priority field</th>
<th>Subpriority field</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>[7:1]</td>
<td>[0]</td>
</tr>
</tbody>
</table>

a. SHPRn.PRI_n[5:0] are RES0.

If there are multiple pending exceptions, the pending exception with the lowest group priority field value takes precedence.

If multiple pending exceptions have the same group priority field value, the pending exception with the lowest subpriority field value takes precedence.

If multiple pending exceptions have the same group priority field value and the same subpriority field value, the pending exception with the lowest exception number takes precedence.

If a pending Secure exception and a pending Non-secure exception both have the same group priority field value, the same subpriority field value, and the same exception number, the Secure exception takes precedence.
The following is an example of exceptions with different priorities:

**Example B3-1**

This example considers the following exceptions, that all have software configurable priority numbers:

- A has the highest priority.
- B has medium priority.
- C has lowest priority.

Example sequence of events:

1. No exception is active and no priority boosting is active.
2. B is generated. The PE takes exception B and starts executing the handler for it. Exception B is now active and the current execution priority is that of B.
3. A is generated. A is higher priority, therefore A preempts B, and the PE starts executing the handler for A. Exception A is now active and the current execution priority is that of A. Exception B remains active.
4. C is generated. C has the lowest priority, therefore it is pending.
5. The PE reduces the priority of A to a priority that is lower than C. B is now the highest priority active exception, therefore the execution priority moves to that of B. The PE continues executing the handler for A at the priority of B. After completing A, the PE restarts the handler for B. After completing B, the PE takes exception C and starts executing the handler for it. C is now active and the current execution priority is that of C.

In a PE with the Security Extension, when AIRCR.PRIS is 1, each Non-secure SHPRn_NS.PRI_n priority field value [7:0] has the following sequence applied to it:

1. Is divided by two.
2. The constant 0x80 is then added to it.

This maps the Non-secure SHPRn_NS.PRI_n group priority field values to the bottom half of the priority range. When this sequence is applied, any effects of AIRCR.PRIGROUP have already been taken into account, so the subpriority field is dropped and the sequence is only applied to the group priority field.

The following diagram shows an example. In this example, all 8 bits of SHPRn_NS.PRI_n are implemented as priority bits and AIRCR.PRIGROUP_NS is set to 0.
In this example, the mapping is:

<table>
<thead>
<tr>
<th>Non-secure group priority field value</th>
<th>Mapped to</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>0x80</td>
</tr>
<tr>
<td>0x02</td>
<td>0x81</td>
</tr>
<tr>
<td>0x04</td>
<td>0x82</td>
</tr>
<tr>
<td>0x06</td>
<td>0x83</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>0xFE</td>
<td>0xFE</td>
</tr>
</tbody>
</table>

In this example, Secure exceptions in the range 0x00 - 0x7E have priority over all Non-secure exceptions.

In a PE without the Main Extension but with the Security Extension when AIRCR.PRIS is set to 1 the Non-secure exception is mapped to the lower half of the priority range, as shown in the table:

<table>
<thead>
<tr>
<th>Non-secure group priority field value</th>
<th>Mapped to</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>0x80</td>
</tr>
<tr>
<td>0x40</td>
<td>0xA0</td>
</tr>
<tr>
<td>0x80</td>
<td>0xC0</td>
</tr>
<tr>
<td>0xC0</td>
<td>0xE0</td>
</tr>
</tbody>
</table>

See also:

- *Exception numbers and exception priority numbers* on page B3-47.
- *Exception states* on page B3-56.
- *Special-purpose mask registers, PRIMASK, BASEPRI, FAULTMASK, for software-controlled priority boosting* on page B3-88.
Secure address protection

**NS-Req** defines the Security state that the PE requests that a memory access be performed in.

**NS-Attr** marks a memory access as Secure or Non-secure.

For data accesses, NS-Req is equal to the current Security state.

For data accesses, NS-Attr is determined as follows:

<table>
<thead>
<tr>
<th>NS-Req</th>
<th>Security attribute of the location being accessed</th>
<th>NS-Attr</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure</td>
<td>X</td>
<td>Non-secure</td>
</tr>
<tr>
<td>Secure</td>
<td>Non-secure</td>
<td>Non-secure</td>
</tr>
<tr>
<td>Secure</td>
<td>Secure</td>
<td>Secure</td>
</tr>
</tbody>
</table>

For instruction fetches, NS-Req and NS-Attr are equal to the Security attribute of the location being accessed. NS-Attr also determines the Security state of the PE.

It is not possible to execute Secure code in Non-secure state, or Non-secure code in Secure state.

See also:

- Security state transitions on page B3-61.
B3.15  Security state transitions

For a branch to an address in the other Security state, the following table shows when the PE changes Security state:

<table>
<thead>
<tr>
<th>Current Security state</th>
<th>Security attribute of the branch target address</th>
<th>Security state change</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure</td>
<td>Non-secure</td>
<td>Change to Non-secure state if the branch was an interstating branch instruction, B00S or BL0S, with the least significant bit of its target address set to 0. Otherwise:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• In a PE with the Main Extension, an INVTRAN SecureFault is generated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• In a PE without the Main Extension, a Secure HardFault is generated.</td>
</tr>
<tr>
<td>Non-secure</td>
<td>Secure and Non-secure callable</td>
<td>Change to Secure state if both:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The branch target address contains an SG instruction.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The whole of the instruction at the branch target address is flagged as Secure and Non-secure callable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Otherwise:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• In a PE with the Main Extension, an INVEP SecureFault is generated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• In a PE without the Main Extension, a Secure HardFault is generated.</td>
</tr>
<tr>
<td>Non-secure</td>
<td>Secure and not Non-secure callable</td>
<td>In a PE with the Main Extension, an INVEP SecureFault is generated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In a PE without the Main Extension, a Secure HardFault is generated.</td>
</tr>
</tbody>
</table>

IKWMP

SG instructions in Secure memory are valid entry points to Secure code. They prevent Non-secure code from being able to jump to arbitrary addresses in Secure code.

IWJRL

When an interstating branch is executed in Secure state, the least significant bit of the target address indicates the target Security state:

1  The target Security state is Secure.
0  The target Security state is Non-secure.

Interstating branches are UNDEFINED in Non-secure state.

RXNVW

If sequential instruction execution crosses from Non-secure memory to Secure memory, then if the Secure memory entry point contains an SG instruction and the whole of the instruction at the Secure memory entry point is flagged as Secure and Non-secure callable, it is CONSTRAINED UNPREDICTABLE whether:

• The PE changes to Secure state.
• A fault is generated:
  — An INVEP SecureFault in a PE with the Main Extension.
  — A Secure HardFault in a PE without the Main Extension.

RDWXH

When an exception is taken to the other Security state, the PE automatically transitions to that other Security state.

See also:

• Instruction set, interstating support on page C1-262.
**B3.16 Function calls from Secure state to Non-secure state**

If a BLXNS interstating branch generates a change from Secure state to Non-secure state, then before the Security state change:

- The return address, which is the address of the instruction after the instruction that caused the function call, the IPSR value and CONTROL.SFPA are stored onto the current stack, as shown in the following figure. ReturnAddress[0] is set to 1 to indicate a return to the T32 instruction set state. The IPSR is stacked in the partial RETPSR, and CONTROL.SFPA is stacked in bit [20] of the partial RETPSR.

<table>
<thead>
<tr>
<th>SP offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x08</td>
</tr>
<tr>
<td>0x04</td>
</tr>
<tr>
<td>0x00</td>
</tr>
<tr>
<td>ReturnAddress</td>
</tr>
</tbody>
</table>

  Original SP

- If the PE is in Handler mode, IPSR has the value of 1.
- The FNC_RETURN value is saved in the LR.

Behavior is UNPREDICTABLE when a function call stack frame is not doubleword-aligned.

The PE hardware does not ensure doubleword-alignment of function call stack frames.

ARM recommends that when Secure code calls a Non-secure function, any registers not being used to pass function arguments are set to zero.

See also:
- *Instruction set, interstating support on page C1-262.*
B3.17 Function returns from Non-secure state

An interstating function return begins with one of the following instructions loads a FNC_RETURN value into the PC:

- A `POP` or `LDM` that includes loading the PC.
- An `LDR` with the PC as a destination.
- A `BX` with any register.
- A `BXNS` with any register.

On detecting a FNC_RETURN value in the PC:

- The FNC_RETURN stack frame is unstacked.
- EPSR_IT is set to 0b00.
- The following integrity checks on function return are performed:
  - A check that IPSR is zero or 1 before the value of it is restored.
  - A check that if the return is to Thread mode, the stacked IPSR value is zero.
  - A check that if the return is to Handler mode, the stacked IPSR value is nonzero.
- The following UNPREDICTABLE behavior checks are performed:
  - Doubleword alignment check.
  - A check that the IPSR value is a valid exception number.

The FNC_RETURN value is:

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
</table>
| 1 1 1 1 1 1 1 0 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 | S

Bits[31:1] This is what identifies the value as a FNC_RETURN value.

Bit[0], S The function return was from:

- 0 Secure state.
- 1 Non-secure state.

Any failed integrity check on function return generates:

**In a PE with the Main Extension:**

A Secure INVPC UsageFault that is synchronous to the instruction that loaded the FNC_RETURN value into the PC.

**Otherwise:**

A Secure HardFault that is synchronous to the instruction that loaded the FNC_RETURN value into the PC.

When the FNC_RETURN stack frame is unstacked on detecting an FNC_RETURN value being loaded into the PC, if ReturnAddress[0] is 0, the PE generates an INVSTATE UsageFault.
B3.18 Exception handling

RYFHR An exception that does not cause lockup sets both:
• The pending bit of its handler, or the pending bit of the HardFault handler, to 1.
• The associated fault status information.

RULDB When a pending exception has a lower group priority field value than current execution, including accounting for any priority adjustment by AIRCR.PRIS, the pending exception preempts current execution.

RWBND Preemption of current execution causes the following basic sequence:
1. R0-R3, R12, R14, RETPSR, and CONTROL.SFPA are stacked.
2. The return address is determined and stacked.
3. Optional stacking of FP context, which might be any one of the following:
   • No stacking or preservation of the FP context.
   • Stacking the basic FP context.
   • Stacking the basic FP context and the additional FP context.
   • Lazy FP state preservation.
4. LR is set to EXC_RETURN.
5. Optional clearing of registers, depending on the Security state transition.
6. The following flags are also cleared:
   • IT State is cleared, if the Main Extension is implemented.
   • CONTROL.FPCA is cleared, if the Floating point Extension is implemented.
   • CONTROL.SFPA is cleared, if the Floating point Extension and the Security Extension are implemented.
7. A transition to the Security state of the exception being activated.
8. The exception to be taken is chosen, and IPSR.Exception is set accordingly. The setting of IPSR.Exception to a nonzero value causes the PE to change to Handler mode.
9. CONTROL.SPSL is set to 0, to select the main stack, dependent on the Security state being targeted.
10. The pending bit of the exception to be taken is set to 0. The active bit of the exception to be taken is set to 1.
11. The Security state is changed to the Security state of the exception that is being activated.
12. The registers are cleared, depending on the transition of the Security state. The registers are divided between the caller and callee registers. If the Security state transition is from Secure to Non-secure state all the registers are cleared to 0. In all other cases, the caller registers are set to an UNKNOWN value and the callee registers remain unchanged and are not stacked.
13. EPSR.T is set to bit[0] of the exception vector for the exception to be taken.
14. The PC is set to the exception vector for the exception to be taken.

IPSGQ The HandleException, ExceptionEntry, PushStack, ExceptionTaken, and ActivateException pseudocode describes the full exception handling sequence.

RNJVF During exception entry, if it is found that the exception and the exception vector are associated with different Security states an INVEP or INVTRAN SecureFault is generated, unless the exception is associated with Non-secure state and is targeting an SG instruction that is located in memory that is Secure and Non-secure callable.

RQLHB The return address is one of:
• On return from a synchronous exception, other than an SVCall exception, the address of the instruction that caused the exception.
• On return from an asynchronous exception, the address of the next instruction in the program order.
• On return from an SVCall exception, the address of the next instruction in the program order.

RXKDD The least significant bit of the return address from an exception (ReturnAddress[0]) is RES0.

B3.19 Exception entry, context stacking

RPWWG

In a PE without the Security Extension and without the Floating-point Extension (regardless of whether the Main Extension is implemented), on taking an exception, the PE hardware saves state context onto the stack that the SP register points to. The state context that is saved is eight 32-bit words:
- RETPSR.
- ReturnAddress.
- R14. This is the Link Register (LR).
- R12.
- R3-R0.

RPTRL

In a PE without the Security Extension but with the Floating-point and Main Extensions, on taking an exception, the PE hardware saves state context onto the stack that the SP register points to. If CONTROL.FPCA is 1 when the exception is taken, then in addition to the state context being saved, there are the following possible modes for the FP context:
- Stack the FP context.
- Reserve space on the stack for the FP context. This is called lazy FP context preservation.

RPLHM

In a PE with the Security Extension but without the Floating-point Extension (regardless of whether the Main Extension is implemented), on taking an exception, the PE hardware:

1. Saves state context onto the stack that the SP register points to.
2. If exception entry is to Non-secure state, regardless of whether a higher priority derived or late-arriving exception targeting Secure state occurs, the PE hardware extends the stack frame, and also saves additional state context, as shown below:

In a PE with the Security Extension, Floating-point Extension, and Main Extension, on taking an exception from:

**Non-secure state**

Behavior is the same as a PE without the Security Extension but with the Floating-point Extension.

**Secure state when CONTROL.FPCA is 0**

Behavior is the same as for a PE with the Security Extension but without the Floating-point Extension.

**Secure state when CONTROL.FPCA is 1**

The PE hardware:

1. Saves state context onto the stack that the SP register points to.

2. If FPCCR_S.TS is 0 when the exception is taken, the PE hardware either stacks the FP context or reserves space on the stack for the FP context.
   - If FPCCR_S.TS is 1 when the exception is taken, the PE hardware either stacks both the FP context and additional FP context, or reserves space on the stack for both the FP context and additional FP context.

3. If exception entry is to Non-secure state, including when a higher priority derived or late-arriving exception targeting Secure state occurs, the PE hardware extends the stack frame, and also saves the additional state context.
The following figure shows PE stacking behavior when CONTROL.FPCA is 1, FPPCR_S.TS is 1 (and both the FP context and additional FP context is stacked), and exception entry is to Non-secure state:

### RBKVD

On an exception, the RETPSR value that is stacked is all of the following:

- The APSR, IPSR, and EPSR.
- CONTROL.SPFA, in RETPSR[20].

In addition, on an exception, the PE uses RETPSR.SPREALIGN to indicate whether the PE realigned the stack to make it doubleword-aligned:

- 1: The PE realigned the stack.
- 0: The PE did not realign the stack.

### RQDKQ

Full descending stacks are used.

### RPWBW

In a PE with the Floating-point Extension:

- Because setting FPCCR.ASPEN to one causes the PE to automatically set CONTROL.FPCA to 1 on the execution of a floating-point instruction, setting FPCCR.ASPEN to one means that the PE hardware automatically either:
  - Stacks FP context on taking an exception.
  - Uses lazy FP context preservation on taking an exception.

If CONTROL.FPCA is 1, it is FPCCR.LSPEN that determines which of the above the PE hardware performs:

- 0: The PE hardware automatically stacks FP context on taking an exception. In a PE that also includes the Security Extension, if FPCCR_S.TS is 1, the hardware stacks the additional FP context and the FP context.
- 1: The PE hardware uses lazy FP context preservation on taking an exception, and sets all of:
  - The FPCAR, to point to the reserved S0 stack address.
  - FPCCR.LSPACT to 1.
  - FPCCR.{USER, THREAD, HFREADY, MMRDY, BFRDY, SFRDY, MONRDY, UFRDY}, to record the permissions and fault possibilities to be applied to any subsequent FP context save.

In a PE that also includes the Security Extension, if FPCCR_S.TS is 1, the hardware reserves space on the stack for both the FP context and the additional FP context. Otherwise, the hardware only reserves space on the stack for the FP context.

### RGHDJ

Execution of a floating-point instruction while FPCCR.LSPACT == 1 indicates that lazy FP context preservation is active.

### RMBXL

If software attempts to execute a floating-point instruction while lazy FP context preservation is active, the access permissions that CPACR and NSACR define are checked against the context that activated lazy FP context preservation, as stored in the FPCCR.

- If no permission violation is detected, the PE:
  1. Saves FP context to the reserved area on the stack, as identified by the FPCAR.
  2. Sets FPCCR.LSPACT to 0 to indicate that lazy FP context preservation is no longer active.
  3. Processes the floating-point instruction.
- If a permission violation is detected, the PE generates a NOCP UsageFault and does not save FP context to the reserved area on the stack.

This check is performed regardless of whether the Security Extension is implemented.

### RLGNS

In a PE with the Floating-point Extension, when the following conditions are met on exception entry, the PE generates a Secure NOCP UsageFault and does not allocate space on the stack for FP context:

- CONTROL.FPCA is 1.
- NSACR.CP10 is 0.
- The Background state is Non-secure state.

### RKMBN

In a PE with the Security Extension and Floating-point Extension, if lazy FP context preservation is activated when FPCCR.LSPACT is already set to 1, the PE generates an LSERR SecureFault.
In a PE with the Security Extension and the Floating-point Extension CONTROL.SFPA is set automatically by hardware on any of the following events:

- An SG instruction fetched from secure memory and executed in Non-secure state clears CONTROL.SFPA to zero.
- A BXNS instruction that causes a transition from Secure state to Non-secure state clears CONTROL.SFPA to zero.
- A BLXNS instruction that causes a transition from Secure state to Non-secure state preserves the value in CONTROL.SFPA in the FNC_RETURN stack frame and then clears CONTROL.SFPA to zero.
- A valid instruction that loads FNC_RETURN into the PC sets CONTROL.SFPA to the value retrieved from the FNC_RETURN payload.
- CONTROL.SFPA is saved and restored on exception entry or return in the RETPSR value in the stack frame.
- Exception entry, including tail chaining, clears CONTROL.SFPA to zero.
- If the value of FPCCR.ASPEN is one, then any floating-point instruction (excluding VLLDM and VLSTM) executed in Secure state sets the value of CONTROL.SFPA to one. If the value of FPCCR.ASPEN is one and the value of CONTROL.SFPA is zero when a floating-point instruction is executed in the Secure state, the FPSCR value is taken from the values set in FPDSCR.

- Integrity signature on page B3-78.
- PushStack on page E2-1259.
### B3.20 Exception entry, register clearing after context stacking

**RDRRB**

In a PE without the Security Extension and without the Floating-point Extension, the PE hardware sets R0-R3, R12, APSR, and EPSR to an UNKNOWN value after it has pushed *state context* to the stack.

**RDJRX**

In a PE without the Security Extension but with the Floating-point Extension:

- The PE hardware sets R0-R3, R12, APSR, and EPSR to an UNKNOWN value after it has pushed state context to the stack.
- The PE hardware sets S0-S15 and the FPSCR to an UNKNOWN value after it has pushed *FP context* to the stack.

**RSNDB**

In a PE with the Security Extension but without the Floating-point Extension, after the PE hardware has pushed state context to the stack, it sets R0-R3, R12, APSR, and EPSR to:

- An UNKNOWN value if the exception is taken to Secure state.
- Zero if the exception is taken to Non-secure state.

If the PE did not also push *additional state context* to the stack, as indicated by EXC_RETURN.DCRS, the values of R4-R11 remain unchanged.

If the PE also pushed additional state context to the stack, as indicated by EXC_RETURN.DCRS, then afterwards:

- If the Background state is Non-secure, R4-R11 remain unchanged.
- If the Background state is Secure, the PE sets R4-R11 to:
  - An UNKNOWN value if the exception is taken to Secure state.
  - Zero if the exception is taken to Non-secure state.

**RJWBK**

In a PE with the Security Extension and Floating-point Extension, register clearing behavior after context stacking is as follows:

#### State context and additional state context

Register clearing behavior is the same as for a PE with the Security Extension but without the Floating-point Extension.

#### FP context and additional FP context

- If FPCCR_S.TS is 0 when the FP context is pushed to the stack, S0-S15 and the FPSCR are set to an UNKNOWN value after stacking.
- If FPCCR_S.TS is 1 when the FP context and additional FP context are both pushed to the stack, S0-S31 and the FPSCR are set to zero after stacking.

In both cases, CONTROL.FPCA is set to 0 to indicate that the Floating-point Extension is not active.

See also:

- *Exception entry, context stacking* on page B3-66.
- *Tail-chaining* on page B3-81.
B3.21 Stack limit checks

In a PE with the Main and Security Extensions, there are four stack limit registers:

<table>
<thead>
<tr>
<th>Security state</th>
<th>Stack</th>
<th>Stack limit register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure</td>
<td>Main</td>
<td>MSPLIM_S</td>
</tr>
<tr>
<td></td>
<td>Process</td>
<td>PSPLIM_S</td>
</tr>
<tr>
<td>Non-secure</td>
<td>Main</td>
<td>MSPLIM_NS</td>
</tr>
<tr>
<td></td>
<td>Process</td>
<td>PSPLIM_NS</td>
</tr>
</tbody>
</table>

In a PE with the Main Extension but without the Security Extension, there are two stack limit registers:

<table>
<thead>
<tr>
<th>Stack</th>
<th>Stack limit register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main</td>
<td>MSPLIM</td>
</tr>
<tr>
<td>Process</td>
<td>PSPLIM</td>
</tr>
</tbody>
</table>

In a PE without the Main Extension but with the Security Extension, there are:

- No stack limit registers in Non-secure state.
- Two stack limit registers in Secure state.

<table>
<thead>
<tr>
<th>Security state</th>
<th>Stack</th>
<th>Stack limit register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure</td>
<td>Main</td>
<td>MSPLIM_S</td>
</tr>
<tr>
<td></td>
<td>Process</td>
<td>PSPLIM_S</td>
</tr>
</tbody>
</table>

In a PE without the Main Extension and without the Security Extension, MSPLIM_S and PSPLIM_S are invisible. These registers hold stack limit values.

A stack can descend to its stack limit value. Any attempt to descend the stack further than its stack limit value is a violation of the stack limit.

xSPLIM_x[2:0] are treated as RES0, so that all stack pointer limits are always guaranteed to be doubleword-aligned. Bits [31:3] of the xSPLIM_x registers are writeable.

Stack limit checks are performed during the creation of a stack frame for all of the following:

- Exception entry.
- Tail-chaining from a Secure to a Non-secure exception.
- A function call from Secure code to Non-secure code.

On a violation of a stack limit during either exception entry or tail-chaining:

- In a PE with the Main Extension, a synchronous STKOF UsageFault is generated. Otherwise, a HardFault is generated.
- The stack pointer is set to the stack limit value.
- Push operations to addresses below the stack limit value are not performed.
- It is IMPLEMENTATION DEFINED whether push operations to addresses equal to or above the stack limit value are performed.

On a violation of a Secure stack limit during a function call:

- In a PE with the Main Extension, a synchronous STKOF UsageFault is generated. Otherwise, a Secure HardFault is generated.
• Push operations to addresses below the stack limit value are not performed.
• It is IMPLEMENTATION DEFINED whether push operations to addresses equal to or above the stack limit value are performed.

Unstacking operations are not subject to stack limit checking.

Updates to the stack pointer by the following instructions are subjected to stack limit checking:

• ADD (SP plus immediate).
• ADD (SP plus register).
• SUB (SP minus immediate).
• SUB (SP minus register).
• BLX, BLXNS.
• LDC, LDC2 (immediate).
• LDMDB, LDMEA.
• LDR (immediate).
• LDR (literal).
• LDR (register).
• LDRB (immediate).
• LDRD (immediate).
• LDRH (immediate).
• LDRSB (immediate).
• LDRSH (immediate).
• MOV (register).
• POP.
• PUSH.
• VPUSH.
• STC, STC2.
• STM, STMEA, STMEA.
• STR (immediate).
• STRB (immediate).
• STRD (immediate).
• STRH (immediate).
• VLDM.
• VSTM.

Updates to the stack pointer by the MSR instruction targeting SP_NS are subject to stack limit checking. Updates to the stack pointer and stack pointer limit by any other MSR instruction are not subject to stack limit checking.

LDR instructions write to two registers, the address register and the destination register. The stack limit check only carried out against the address register. Updates to the stack pointer by the LDR instructions are only subject to stack limit checking if the stack pointer is the address register.

For all other instructions that can update the stack pointer and stack pointer limit, it is IMPLEMENTATION DEFINED whether stack limit checking is performed.

When an instruction updates the stack pointer, if it results in a violation of the stack limit, it is the modification of the stack pointer that generates the exception, rather than an access that uses the out-of-range stack pointer.

On a violation of a stack limit when an instruction updates the stack pointer:

• It is IMPLEMENTATION DEFINED whether accesses to addresses equal to or above the stack limit value are performed.
• It is IMPLEMENTATION DEFINED whether the destination register or registers of load instructions are updated as long as the base register, stack pointer, and PC are not modified.
• Accesses below the stack limit are not performed.
CCR.STKOFHFNMIGN controls whether stack limit violations are IGNORED while executing at a requested execution priority that is negative.

It is UNKNOWN whether a stack limit check is performed on any use of the SP marked as UNPREDICTABLE.

Store operations using the SP as a base register do not perform any stores below the associated stack limit address.

It is UNKNOWN whether Load/Store instructions that specify the SP as a base register and attempt a read or write below the associated stack limit but write back a value greater than the stack limit address generate a STKOF UsageFault.

See also:
- Stack pointer on page B3-46.
- Tail-chaining on page B3-81.
- Appendix G1 Architectural Constraints on UNPREDICTABLE behaviors.
B3.22 Exception return

RKPSS

The PE begins an exception return when both of the following are true:

• The PE is in Handler mode.
• One of the following instructions loads an EXC_RETURN value, 0xFF000000, into the PC:
  — A POP or LDM that includes loading the PC.
  — An LDR with the PC as a destination.
  — A BX with any register.
  — A BXNS with any register.

When both of these are true, then on detecting an EXC_RETURN value in the PC, the PE unstacks the exception stack frame and resumes execution of the unstacked context.

If an EXC_RETURN value is loaded into the PC by an instruction other than those listed, or from the vector table, the value is treated as an address.

If an EXC_RETURN value is loaded into the PC when the PE is in Thread mode, the value is treated as an address.

RBLMQ

In an EXC_RETURN value:

Bits[31:24] These are 0xFF. This is what identifies the value as an EXC_RETURN value.

Bit [6], S In a PE with the Security Extension, the exception was taken from:
  0 Non-secure state. Restore registers from the Non-secure stack.
  1 Secure state. Restore registers from the Secure stack.

In a PE without the Security Extension, RES0.

Bit [5], DCRS

In a PE with the Security Extension:
  0 Stacking of the additional state context can be skipped.
  1 Do not skip any stacking.

In a PE without the Security Extension, RES1.

Bit[4], FType

In a PE with the Main and Floating-point Extensions:
  0 The PE allocated space on the stack for FP context.
  1 The PE did not allocate space on the stack for FP context.

In a PE without the Main Extension, or with the Main Extension but without the Floating-point Extension, RES1.

Bit[3], Mode

Return to:
  0 Handler mode.
  1 Thread mode.

Bit[2], SPSEL

Restore registers from the:
  0 Main stack.
  1 Process stack.

Bit[1] RES0.

Bit[0], ES

In a PE with the Security Extension, the exception was taken to:
  0 Non-secure state.
  1 Secure state.

In a PE without the Security Extension, RES0.

RTXDW

Behavior is UNPREDICTABLE if EXC_RETURN.FType is 0 and the Floating-point Extension is not implemented.
Behavior is UNPREDICTABLE if EXC\_RETURN[23:7] are not all 1.

Behavior is UNPREDICTABLE if any of the following are true and the Security Extension is not implemented:

- EXC\_RETURN.S is 1.
- EXC\_RETURN.DCRS is 0.
- EXC\_RETURN.ES is 1.

In a PE without the Main Extension, behavior is UNPREDICTABLE if EXC\_RETURN[1] is 1.

The following integrity checks on exception return are performed on every exception return:

1. In a PE with the Security Extension, the integrity check that is called the EXC\_RETURN.ES validation check, as follows:
   - If the PE was in Non-secure state when EXC\_RETURN was loaded into the PC and either
     EXC\_RETURN.DCRS is 0 or EXC\_RETURN.ES is 1, an INVER SecureFault is generated and the
     PE sets EXC\_RETURN.ES to 0.

2. A check that the exception number being returned from, as held in the IPSR, is shown as active in the SHCSR
   or NVIC\_IABR<n>. If this check fails:
   - In a PE with the Main Extension, an INVPC UsageFault is generated. If the PE includes the Security
     Extension, the INVPC UsageFault targets the Security state that the exception return instruction was
     executed in.
   - In a PE without the Main Extension, a HardFault is generated. If the PE includes the Security
     Extension, the HardFault targets the Security state that EXC\_RETURN.S specifies.

3. In a PE with the Main Extension, an INVPC UsageFault is generated if EXC\_RETURN[1] is 1. If the PE
   includes the Security Extension, the INVPC UsageFault targets the Security state that the exception return
   instruction was executed in.

4. A check that if the return is to Thread mode, the value that is restored to the IPSR from the RETPSR is zero,
   or that if the return is to Handler mode, the value that is restored to the IPSR from the RETPSR is non-zero.
   If this check fails:
   - In a PE with the Main Extension, an INVPC UsageFault is generated. If the PE includes the Security
     Extension, the INVPC UsageFault targets the Background state.
   - In a PE without the Main Extension, a HardFault is generated. If the PE includes the Security
     Extension, the HardFault targets the Security state that EXC\_RETURN.S specifies.

When returning from Non-secure state, EXC\_RETURN.ES is treated as zero for all purposes other than raising the
INVER integrity check.

On returning from Non-secure state, if EXC\_RETURN.ES causes an INVER integrity check failure, the subsequent
EXC\_RETURN.DCRS bit that is presented in the LR on entry to the next exception is permitted to be UNKNOWN.

ARM recommends that the subsequent EXC\_RETURN.DCRS bit that is presented in the LR on entry to the next
exception is not UNKNOWN.

In a PE with the Security Extension, after the EXC\_RETURN.ES validation check has been performed on an
exception return:
- If EXC\_RETURN.ES is 1, EXC\_RETURN.SPSEL is written to CONTROL\_S.SPSEL.
- If EXC\_RETURN.ES is 0, EXC\_RETURN.SPSEL is written to CONTROL\_NS.SPSEL.

In a PE with the Security Extension, on an exception return that successfully returns to the Background state, with
no tail-chaining or failed integrity checks, the Security state is set to EXC\_RETURN.S.

In a PE with the Security Extension, after a successful exception return to the Background state, the PE is in the
correct Security state before the next instruction from the background code is executed. This means that in the case
where the Background state is Secure state, there is no need for an SG instruction at the exception return address.

In a PE with the Floating-point Extension, on exception entry:
1. EXC\_RETURN.FType is saved as the inverse of CONTROL.FPCA.
2. CONTROL.FPCA is then cleared to 0 if it was 1, or remains unchanged if it was 0.
On exception return, the inverse of EXC_RETURN[4] is written to CONTROL.FPCA.

In a PE with the Floating-point Extension, when the following conditions are met on exception return, the PE hardware sets S0-S15 and the FPSCR to zero:
- CONTROL.FPCA is 1.
- FPCCR.CLRONRET is 1.
- If the PE implements the Security Extension FPCCR_S.LSPACT is 0.

If the PE implements the Security Extension and all these fields are 1 on exception return, the PE generates an LSERR SecureFault instead.

In a PE with the Security Extension and the Floating-point Extension, when the following conditions are met on exception return, the PE generates an LSERR SecureFault:
- EXC_RETURN[4] is 0.
- The stack contains Secure FP context, that would be unstacked on the return. That is, FPCCR_S.LSPACT is 1.
- The return is to Non-secure state.

In a PE with the Floating-point Extension, if the PE abandons unstacking of the floating-point registers to tail-chain into another exception:
- If the Security Extension is implemented, the PE must clear to zero any floating-point registers that would have been unstacked.
- If the Security Extension is not implemented, the floating-point registers that would have been unstacked become UNKNOWN.

See also:
- Exception handling on page B3-64.
B3.23 Integrity signature

**RPHBP**

In a PE with the Floating-point Extension, the integrity signature value is:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
| 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 | 1 | 1 | 0 | 1 | 1 | 0 | 1 | 1 | 0 | 1 | SFTC |

In a PE with the Floating-point Extension, when returning from a Non-secure exception to Secure state, if the unstacked integrity signature does not match this value, including if SFTC does not match EXC_RETURN[4], a SecureFault is generated.

**RRJSP**

In a PE without the Floating-point Extension, the integrity signature value is:

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
| 1 | 1 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 |

In a PE without the Floating-point Extension, when returning from a Non-secure exception to Secure state, if the unstacked integrity signature does not match this value, a Secure HardFault is generated.

**IFFTS**

The integrity signature is an XN address. When performing a function return from Non-secure code, if the integrity signature value is restored to the PC as the function return address, a MemManage fault is generated when the PE attempts execution.

See also:
- *Exception entry, context stacking on page B3-66.*
- *Exception return on page B3-75.*
B3.24 Exceptions during exception entry

During exception entry exceptions can occur, for example asynchronous exceptions, or the exception entry sequence itself might cause an exception, for example a MemManage fault on the push to the stack.

Any exception that occurs during exception entry is a late-arriving exception, and:

- The exception that caused the original entry sequence is the original exception.
- The priority of the code stream running at the time of the original exception is the preempted priority.

When the exception entry sequence itself causes an exception, the latter exception is a derived exception.

The following mechanism is called late-arrival preemption:

- The PE takes a late-arriving exception during an exception entry if the late-arriving exception is higher priority, including accounting for any priority adjustment by AIRCR.PRIS. In this case:
  - The late-arriving exception uses the exception entry sequence started by the original exception. The original exception remains pending.
  - The PE takes the original exception after returning from the late-arriving exception.

For:

- Derived exceptions, late-arrival preemption is mandatory.
- Late-arriving asynchronous exceptions, it is IMPLEMENTATION DEFINED whether late-arrival preemption is used. If the PE does not implement late-arrival preemption for late-arriving asynchronous exceptions, late-arriving asynchronous exceptions become pending.

If the group priority field value of a derived exception is higher than or equal to the preempted priority:

- If the derived exception is a DebugMonitor exception, it is IGNORED.
- Otherwise, the PE escalates the derived exception to HardFault.

If a higher priority late-arriving Secure exception occurs during entry to a Non-secure exception when the Background state is Secure, it is IMPLEMENTATION DEFINED whether:

- The stacking of the additional state context is rolled back.
- The stacking of the additional state context is completed and EXC_RETURN.DCRS is set to 0.

The architecture does not specify the point during exception entry at which the PE recognizes the arrival of an asynchronous exception.

See also:

- Exception numbers and exception priority numbers on page B3-47.
- Priority model on page B3-57.
- Exception states on page B3-56.
- Exception handling on page B3-64.
- Tail-chaining on page B3-81.
B3.25 Exceptions during exception return

IKXPV During exception return exceptions can occur, for example asynchronous exceptions, or the exception return might itself cause an exception.

Any exception that occurs during exception return is a late-arriving exception.

When the exception return sequence itself causes an exception, the latter exception is a derived exception.

RTRFM When a late-arriving exception during exception return is higher priority than the priority being returned to, the PE takes the late-arriving exception by using tail-chaining.

IMBNG The architecture does not specify the point during exception return at which the PE recognizes the arrival of an asynchronous exception. If a PE recognizes an asynchronous exception after an exception return has completed, there is no opportunity to tail-chain the asynchronous exception.

RMJDN If the priority of a derived exception during exception return is equal to or lower than the priority being returned to:
• If the derived exception is a DebugMonitor exception, the PE ignores the derived exception.
• Otherwise, the PE escalates the derived exception to HardFault and the escalated exception is tail-chained.

RDHK If the priority of a derived exception during exception return, after priority escalation if appropriate, is higher priority than the priority being returned to, the PE uses tail-chaining to take the derived exception.

See also:
• Exception numbers and exception priority numbers on page B3-47.
• Priority model on page B3-57.
• Exception return on page B3-75.
• Tail-chaining on page B3-81.
B3.26 Tail-chaining

Tail-chaining behavior is as follows:

- On detecting an `EXC_RETURN` value in the PC, if there is a pending exception that is higher priority than the priority being returned to, the PE hardware:
  1. Does not unstack the stack.
  2. Takes the pending exception.

Tail-chaining is an optimization. It removes unstacking and stacking operations. In the following example the second exception is a `tail-chained exception`:

All in Non-secure state:

![Diagram showing tail-chaining](image)

If tail-chaining prevents a derived exception on exception return, the derived exception might instead be generated on the return from the last tail-chained exception.

When the Background state is Secure state, if tail-chaining causes a change of Security state from Secure to Non-secure, additional context is saved on taking the Non-secure exception:

In a PE without the FP Extension:
When multiple exceptions are tail-chained, EXC_RETURN.DCRS is used to keep track of whether the additional context is stacked. The following figure is an example:

<table>
<thead>
<tr>
<th>Secure state</th>
<th>Non-secure state</th>
<th>Secure state</th>
<th>Non-secure state</th>
<th>Secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td>State context and additional state context pushed to stack(^a).</td>
<td></td>
<td></td>
<td>Unstacking all additional context is skipped.</td>
<td>PE sets EXC_RETURN.DCRS to 0.</td>
</tr>
</tbody>
</table>

\(^a\) In a PE with the FP Extension, FP context and additional FP context is also stacked if CONTROL.FPCA is 1.

When multiple exceptions are tail-chained, a Secure tail-chained exception after a Non-secure exception cannot rely on any registers containing the values they had when no exception was active.

ARM recommends that Secure exception handlers clear the FP context registers to zero before they return.

If software has set FPCCR.CLRONRET to 1, hardware automatically clears the FP context registers to zero on exception return.

If the PE recognizes a new asynchronous exception while it is tail-chaining, and the new asynchronous exception has a higher priority than the next tailed-chained exception, the PE can, instead, take the new asynchronous exception, using late-arrival preemption.

This rule is true even if the next tail-chained exception is a derived exception on exception return. The PE can, instead, take the new asynchronous exception. If it does, the derived exception becomes pending.

See also:

* Exception entry, context stacking on page B3-66.
* Exceptions during exception return on page B3-80.
The PE can take an exception during execution of a Load Multiple or Store Multiple instruction, effectively halting the instruction, and resume execution of the instruction after returning from the exception. This is called **instruction resume**. Instruction resume is supported only when the Main Extension is implemented.

The PE can abandon execution of a Load Multiple or Store Multiple instruction to take an exception, and after returning from the exception, restart the Load Multiple or Store Multiple instruction again from the start of the instruction. This is called **instruction restart**. Instruction restart is supported regardless of whether the Main Extension is implemented.

Instructions that the PE can halt to use instruction resume are called **exception-continuable instructions**.

The exception-continuable instructions are **LDM**, **LDMDB**, **STM**, **STMDB**, **POP**, and **PUSH**. In a PE with the Floating-point Extension, the floating-point exception-continuable instructions are **VLDM**, **VLLDM**, **VLSTM**, **VSTM**, **VPOP**, and **VPUSH**.

Where a fault is taken during the execution of a **VLLDM** instruction the PE must abandon the stacking of the Secure floating-point register contents and save the state so that on return from the fault the instruction can be restarted.

It is IMPLEMENTATION DEFINED whether a **VLLDM** or **VLSTM** instruction aborts or completes when an interrupt occurs.

When the PE is using instruction resume, EPSR.ICI is set to a non-zero value that is the continuation state of the exception-continuable instruction:

- For **LDM**, **LDMDB**, **STM**, **STMDB**, **POP**, and **PUSH** instructions, ICI contains the number of the first register in the register list that must be loaded or stored after instruction resume.
- For the floating-point instructions **VLDM**, **VSTM**, **VPOP**, and **VPUSH**, ICI contains the number of the lowest numbered doubleword Floating-point Extension register that was not loaded or stored before the PE took the exception.

The ICI values shown in the following table are **valid EPSR.ICI values**:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>ICI[7:6] = 0b00</td>
<td>ICI[5:2] = reg_num</td>
<td>ICI[1:0] = 0b00</td>
</tr>
<tr>
<td>ICI[7:6] = 0b00</td>
<td>ICI[5:2] = 0b0000</td>
<td>ICI[1:0] = 0b00</td>
</tr>
</tbody>
</table>

Behavior is UNPREDICTABLE if EPSR.ICI contains a valid EPSR.ICI non-zero value and the register number that it contains is either:

- Not in the register list of the exception-continuable Load Multiple or Store Multiple instruction.
- The first register in the register list of the exception-continuable Load Multiple or Store Multiple instruction.

The PE generates an INVSTATE UsageFault if EPSR.ICI contains a valid EPSR.ICI non-zero value and the instruction being executed is not a Load Multiple or Store Multiple instruction.

If the PE uses instruction resume during a Load Multiple instruction, then after the exception return, the values of all registers in the register list are UNKNOWN, except for the following:

- Registers that are marked by EPSR.ICI as already loaded.
- The base register.
- The PC.

If the PE is using instruction restart, ARM recommends that software does not use Load Multiple or Store Multiple instructions with data in volatile memory.

When a Load Multiple instruction has the PC in its register list, if the PE uses instruction resume or instruction restart during the instruction:

- If the PC is loaded before generation of the exception, the PE must restore the PC before taking the exception, so that after the exception the PE returns to either:
  - Continue execution of the Load Multiple instruction, if the PE used instruction resume.
  - Restart the Load Multiple instruction, if the PE used instruction restart.
In a PE without the Main Extension, if the PE takes any exception during any Load Multiple or Store Multiple instruction, including **PUSH** and **POP**, the PE uses instruction restart and the base register is restored to the original value.

In a PE with the Main Extension, if the PE takes an exception during any Load Multiple or Store Multiple instruction, including **PUSH** and **POP**:

- If the instruction is not in an IT block and the exception is an asynchronous exception, the PE uses instruction resume and EPSR.ICI holds the continuation state. The base register is restored to the original value except in the following cases:

  **Interrupt of an instruction that is using SP as the base register**
  
  The SP that is presented to the exception entry sequence is lower than any element pushed by an STM, or not yet popped by an LDM.
  
  For Decrement Before (DB) variants of the instruction, the SP is set to the final value. This is the lowest value in the list.
  
  For Increment After (IA) variants of the instruction, the SP is restored to the initial value. This is the lowest value in the list.

  **Interrupt of an instruction that is not using SP as the base register**
  
  The base register is set to the final value, whether the instruction is a Decrement Before (DB) variant or an Increment After (IA) variant.

  - For all other cases:
    - The PE uses instruction restart and the base register is restored to the original value. If the instruction is not in an IT block, EPSR.ICI is cleared to zero.

When a Load Multiple instruction includes its base register in its register list, if the PE takes an exception during the instruction:

- The base register is restored to the original value, and:
  - If the instruction is in an IT block, the PE uses instruction restart.
  - If the instruction is not in an IT block, and the PE takes the exception after it loads the base register, EPSR.ICI can be set to an **IMPLEMENTATION DEFINED** value that will load at least the base register and subsequent locations again after returning from the interrupt.

See also:

- **Exception during a singleword load operation on page B3-95**.
B3.28 Vector tables

In a PE with the Security Extension, two vector tables are implemented, the Secure Vector table and the Non-secure Vector table, and it is IMPLEMENTATION DEFINED which of the following is true:

- The PE supports configurability of each vector table base, and two Vector Table Offset Registers, VTOR_S and VTOR_NS, are provided for this purpose.
- The PE does not support configurability of either vector table base, and VTOR_S and VTOR_NS are RAZ/WI.

If the PE supports configurability of each vector table base:

- Exceptions that target Secure state use VTOR_S to determine the base address of the Secure vector table.
- Exceptions that target Non-secure state use VTOR_NS to determine the base address of the Non-secure vector table.

In a PE without the Security Extension, a single vector table is implemented, and it is IMPLEMENTATION DEFINED which of the following is true:

- The PE supports configurability of the vector table base, and a single Vector Table Offset Register, VTOR, is provided for this purpose.
- The PE does not support configurability of the vector table base, and VTOR is RAZ/WI.

ARM recommends that VTOR_S points to memory that is Secure and not Non-secure callable.

A vector table contains both:

- The initialization value for the main stack pointer on reset.
- The start address of each exception handler.

The exception number defines the order of entries.

<table>
<thead>
<tr>
<th>Word offset in vector table</th>
<th>Value held at offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initial value for the main stack pointer on reset</td>
</tr>
<tr>
<td>Exception number</td>
<td>Start address for the handler for the exception with that number</td>
</tr>
<tr>
<td>Exception number</td>
<td>Start address for the handler for the exception with that number</td>
</tr>
</tbody>
</table>

In a PE with a configurable vector table base, the vector table must be naturally aligned to a power of two, with an alignment value that is:

- A minimum of 128 bytes.
- Greater than or equal to (Number of Exceptions supported x4).

For all vector table entries other than the entry at offset 0, if bit[0] is not set to 1, the first instruction in the exception results in an INVSTATE UsageFault.

For all vector table entries other than the entry at offset 0, bit[0] defines EPSR.T on exception entry. Setting bit[0] to 1 indicates that the exception handler is in the T32 instruction set state.

Vector fetches for entries beyond the natural alignment of the associated VTOR occur from an UNKNOWN entry within the vector table.
ARM recommends that software ensures that the vector table and VTOR are aligned so that the entry for the highest taken exception falls within the natural alignment of the table, and at a minimum that the vector table is 128 byte aligned. A PE might impose further restrictions on the VTOR.

If a vector fetch causes a Security attribution unit (SAU) on page B8-178 or IMPLEMENTATION DEFINED Attribution Unit (IDAU) on page B8-179 violation, a secure VECTTBL HardFault is raised. If the exception priority prevents any secure VECTTBL HardFault pre-empting, one of the following occurs:

- The PE enters lockup at the priority of the original exception.
- The original exception transitions from the pending to the active state.
- If the original exception and the VECTTBL HardFault are different, or target different security states, the VECTTBL HardFault becomes pending.

See also:
- Exception numbers and exception priority numbers on page B3-47.
- Execution Program Status Register (EPSR) on page B3-43.
B3.29 Hardware-controlled priority escalation to HardFault

RGNVS When current execution has a priority number ≥0:
  • If a synchronous exception with an equal or lower priority is pending, the PE hardware escalates it to become a HardFault. This rule applies to all synchronous exceptions and DebugMonitor exceptions that are caused by the BKPT instruction. This rule does not apply to asynchronous exceptions and all other DebugMonitor exceptions.

RPBJQ When current execution has a priority number >= 0, if a disabled software configurable priority exception occurs:
  • If it is a synchronous exception, the PE hardware escalates the exception to become a HardFault.
  • If it is an interrupt, the PE does not escalate the interrupt. The interrupt remains pending.

See also:
  • Exception numbers and exception priority numbers on page B3-47.
B3.30 Special-purpose mask registers, PRIMASK, BASEPRI, FAULTMASK, for software-controlled priority boosting

In a PE with the Main Extension, software can use the PRIMASK, FAULTMASK, and BASEPRI registers as follows. A PE without the Main Extension implements PRIMASK, but does not implement FAULTMASK and BASEPRI.

**PRIMASK**

In a PE without the Security Extension:
- Setting this bit to one boosts the current execution priority to 0, masking all exceptions with a lower priority.

In a PE with the Security Extension:
- Setting PRIMASK\_S to one boosts the current execution priority to 0.
- If AIRCR.PRIS is:
  - 0 Setting PRIMASK\_NS to one boosts the current execution priority to 0.
  - 1 Setting PRIMASK\_NS to one boosts the current execution priority to \(0x80\).

In a PE with the Security Extension, when the current execution priority is boosted to a particular value, all exceptions with a lower priority are masked.

**FAULTMASK**

In a PE without the Security Extension:
- Setting this bit to one boosts the current execution priority to -1, masking all exceptions with a lower priority.

In a PE with the Security Extension, if AIRCR.BFHFNMIN is:
- 0 Setting FAULTMASK\_S to one boosts the current execution priority to -1.
  - If AIRCR.PRIS is:
    - 0 Setting FAULTMASK\_NS to one boosts the current execution priority to 0.
    - 1 Setting FAULTMASK\_NS to one boosts the current execution priority to \(0x80\).
  - 1 Setting FAULTMASK\_S to one boosts the current execution priority to -3.
  - Setting FAULTMASK\_NS to one boosts the current execution priority to -1.

In a PE with the Security Extension, when the current execution priority is boosted to a particular value, all exceptions with a lower priority are masked.

**BASEPRI**

In a PE without the Security Extension:
- Software can set this field to a priority number between 1 and the maximum supported priority number. This boosts the current execution priority to that number, masking all exceptions with a lower priority.

In a PE with the Security Extension:
- Software can set BASEPRI\_S to a priority number between 1 and the maximum supported priority number.
- If AIRCR.PRIS is:
  - 0 Software can set BASEPRI\_NS to a priority number between 1 and the maximum supported priority number.
  - 1 Software can set BASEPRI\_NS to a priority number between 1 and the maximum supported priority number. The value in BASEPRI\_NS is then mapped to the bottom half of the priority range, so that the current execution priority is boosted to the mapped-to value in the bottom half of the priority range.

In a PE with the Security Extension, when the current execution priority is boosted to a particular value, all exceptions with a lower priority are masked.

The PRIMASK, FAULTMASK, and BASEPRI priority boosting mechanisms only boost the group priority, not the subpriority.
Without the Security Extension:

- An exception return other than from an NMI sets `FAULTMASK` to 0.

With the Security Extension:

- An exception return other than from an NMI sets `FAULTMASK` to 0 if the raw execution priority is greater than or equal to 0. `EXC_RETURN.ES` indicates which banked instance of `FAULTMASK` is set to 0.

The raw execution priority is:

- The execution priority minus the effects of `AIRCR.PRIS == 1`, and minus any software-controlled `PRIMASK`, `FAULTMASK`, or `BASEPRI` priority boosting.

The requested execution priority is negative when any of the following are true:

- The banked `FAULTMASK` bit for the current Security state is 1, including when `AIRCR.PRIS` is also 1.
- HardFault for the current Security state is active.
- `AIRCR.BFHFNMINS`.

See also:

- Priority model on page B3-57.
- Exception numbers and exception priority numbers on page B3-47.
B3.31 Lockup

IRKJB

Lockup is a PE state where the PE stops executing instructions in response to an error for which escalation to an appropriate HardFault handler is not possible because of the current execution priority. An example is a synchronous exception that would escalate to a Secure HardFault, but that cannot escalate to a Secure HardFault because Secure HardFault is already active.

IFSFR

ARM recommends that an implementation provides a LOCKUP signal that, when the PE is in lockup, signals to the external system that the PE is in lockup.

RMBTM

When the PE is in lockup:
- DHCSR.S_LOCKUP reads as 1.
- The PC reads as 0xEFFFFFFE. This is an XN address.
- The PE stops fetching and executing instructions.
- If the implementation provides an external LOCKUP signal, LOCKUP is asserted HIGH.

RJRJC

Exit from lockup is by any of the following:
- A Cold reset.
- A Warm reset.
- Entry to Debug state.
- Preemption by a higher priority exception.

RHJNP

Exit from lockup causes both DHCSR.S_LOCKUP and, if implemented, the external LOCKUP signal, to be deasserted.

RSPPN

On an exit from lockup by entry to Debug state, or by preemption by a higher priority exception, the return address is 0xEFFFFFFE.

ICRHJ

After exit from lockup by entry to Debug state, or by preemption by a higher priority exception, a subsequent return from Debug state or that exception without modifying the return address attempts to execute from 0xEFFFFFFE. Execution from this address is guaranteed to generate an IACCVIOL MemManage fault, causing the PE to reenter lockup if the execution priority has not been modified. Modification of the return address would enable execution to be resumed, however ARM recommends treating entry to lockup as fatal and requiring the PE to be reset.

- Integrity checks on exception return on page B3-93.
- Errors when unstacking state on exception return on page B3-94.
- Chapter B11 Debug

B3.31.1 Instruction-related lockup behavior

Instruction execution

RVGMR

A synchronous exception results in lockup when:
- The synchronous exception would escalate to a Secure HardFault and any of the following is true:
  - Secure HardFault is already active.
  - NMI is active and AIRCR.BFHFNMINS is 0.
  - FAULTMASK_S.FM is 1.
  - Non-secure HardFault is active and AIRCR.BFHFNMINS is 0.
The synchronous exception would escalate to a Non-secure HardFault and any of the following is true:
- Non-secure HardFault or Secure HardFault is already active.
- NMI is active.
- FAULTMASK_NS.FM or FAULTMASK_S.FM is 1.

If the Security Extension is not implemented and the Main Extension is implemented, a synchronous exception results in lockup when:
- The synchronous exception would escalate to HardFault and any of the following is true:
  - HardFault is already active.
  - NMI is active.
  - FAULTMASK.FM is 1.

If the Main Extension and Security Extension are not implemented a synchronous exception results in lockup when:
- The synchronous exception would escalate to HardFault and any of the following is true:
  - HardFault is already active.
  - NMI is active.

Entry to lockup from an exception causes:
- Any Fault Status Registers associated with the exception to be updated.
- No update to the exception state, pending or active.
- The PC to be set to 0xEFFFFFFE.
- EPSR.IT to be become UNKNOWN.

In addition, HFSR.FORCED is not set to 1.

Asynchronous BusFaults never cause lockup. The standard rules for asynchronous BusFaults are applied.

When a BusFault does not cause lockup, the value that is read or written to the location that generated the BusFault is UNKNOWN.

### Floating-point lazy FP context preservation

When FPCCR.LSPACT is 1, a NOCP UsageFault, AU violation, MPU violation, or synchronous bus error during lazy FP context preservation causes lockup if any of the following is true:

- FPCCR.HFRDY is 0.
- The exception would escalate to a Secure HardFault and any of the following is true:
  - Secure HardFault is already active.
  - NMI is active and AIRCR.BFHFNMINS is 0.
  - FAULTMASK_S.FM is 1.
  - Non-secure HardFault is active and AIRCR.BFHFNMINS is 0.
- The exception would escalate to a Non-secure HardFault and any of the following is true:
  - Non-secure HardFault or Secure HardFault is already active.
  - NMI is active.
  - FAULTMASK_NS.FM or FAULTMASK_S.FM is 1.

When FPCCR.LSPEN is 0, any faults that are caused by floating-point register reads or writes during exception entry or exception return are handled as faults on stacking or unstacking respectively.

When FPCCR.LSPEN is 1 and a NOCP UsageFault, AU violation, MPU violation, or synchronous bus error during FP context stacking causes lockup, that entry to lockup causes:
- Any Fault Status Registers associated with the exception to be updated.
- No update to the exception state, pending or active.
- The PC to be set to 0xEFFFFFFE.
- EPSR.IT to be become UNKNOWN.
In addition, \texttt{HFSR.FORCED} is not set to 1.

\begin{longtable}{l}
\textbf{B3.31.2 Exception-related lockup behavior} \\

\textbf{Vector or stack pointer error on reset} \\

\textbf{RPBHV} \\

On reset, if reading the vector table to obtain either the vector for the reset handler or the initialization value for the main stack pointer causes a bus error, the PE enters lockup in HardFault with the following behavior:

- \texttt{HFSR.VECTTBL} is set to 1.
- In a PE with the Security Extension, Secure HardFault is made active. That is, \texttt{SHCSR.S.HARDFULTACT} is set to 1.
- In a PE without the Security Extension, HardFault is made active. That is, \texttt{SHCSR.HARDFULTACT} is set to 1.
- An \texttt{UNKNOWN} value is loaded into the main stack pointer.
- The \texttt{IPSR} is set to 0.
- \texttt{EPSR.T} is \texttt{UNKNOWN}.
- \texttt{EPSR.IT} is set to zero.
- The PC is set to \texttt{0xEFFFFFFE}.

\textbf{IXPNL} \\

Because the PE always resets into Secure state and the highest privilege, SAU and MPU violations are not possible on accesses to the reset vector.

\textbf{Errors on preemption and stacking for exception entry} \\

\textbf{RVKTX} \\

An AU violation, MPU violation, NOCP UsageFault, STKOF UsageFault, LSERR SecureFault, or synchronous bus error during context stacking causes lockup when:

- The exception would escalate to a Secure HardFault and any of the following is true:
  - Secure HardFault is already active.
  - NMI is active and \texttt{AIRCR.BFHFNMINS} is 0.
  - \texttt{FAULTMASK_S.FM} is 1.
- The exception would escalate to a Non-secure HardFault and any of the following is true:
  - Non-secure HardFault or Secure HardFault is already active.
  - NMI is active.
  - \texttt{FAULTMASK_NS.FM} or \texttt{FAULTMASK_S.FM} is 1.

In these cases, the point of PE lockup is when, after the exception to be taken has been chosen, the handler for that exception is entered. These cases do not in themselves cause any additional exception to become pending.

\textbf{RQSSB} \\

When an AU violation, MPU violation, NOCP UsageFault, STKOF UsageFault, LSERR SecureFault, or synchronous bus error occurs during context stacking, it is \texttt{IMPLEMENTATION DEFINED} whether the PE continues to stack any of the remaining context.

\textbf{RGIIG} \\

At the point of encountering an AU violation, MPU violation, NOCP UsageFault, STKOF UsageFault, LSERR SecureFault, or synchronous bus error during context stacking, the PE:

- Updates any Fault Status Registers associated with the error.
- Does not set \texttt{HFSR.FORCED} to 1.

At the point of lockup:

- All state, including the LR, \texttt{IPSR}, and active and pending bits, is modified as though the fault on context stacking had never occurred, other than the following:
  - \texttt{EPSR.T} becomes \texttt{UNKNOWN}.
  - \texttt{EPSR.IT} is set to zero.
  - The PC is set to \texttt{0xEFFFFFFE}.
\end{longtable}
Vector read error on NMI or HardFault entry

On entry to an NMI or HardFault, if reading the vector table to obtain the vector for the NMI or HardFault handler causes a bus error, the PE enters lockup with the following behavior:

- **HFSR.VECTTBL** is set to 1.
- The **IPSR** is updated to hold the exception number of the exception taken.
- The active bit of the exception that is taken is set to 1.
- The pending bit of the exception that is taken is cleared to 0.
- **EPSR.T** is **UNKNOWN**.
- **EPSR.IT** is set to zero.
- The **LR** is set to the **EXC_RETURN** value that would have been used had the fault not occurred.
- The **PC** is set to 0xEFFFFFFE.

Because **AU** violations on vector reads are required to be treated as late-arriving, they cannot cause lockup, instead resulting in a higher priority exception being taken. Vector reads always use the default memory map and cannot generate MPU violations.

Integrity checks on exception return

A fault that is generated by a failed **integrity check on exception return** is generated after either the active bit for the returning exception, or the active bit for NMI or HardFault, has been cleared to 0, and if applicable, after **FAULTMASK** has also been cleared to 0. A fault that is generated by a failed integrity check on exception return causes lockup when:

- The exception would escalate to a Secure HardFault and any of the following is true:
  - Secure HardFault is already active.
  - NMI is active and **AIRCRR.BFHFNMINS** is 0.
  - **FAULTMASK_S.FM** is 1.
  - Non-secure HardFault is active and **AIRCRR.BFHFNMINS** is 0.
- The exception would escalate to a Non-secure HardFault and any of the following is true:
  - Non-secure HardFault or Secure HardFault is already active.
  - NMI is active.
  - **FAULTMASK_NS.FM** or **FAULTMASK_S.FM** is 1.

The target **Security state** of an INVPC UsageFault generated because of a failed integrity check on exception return is either the Security state the exception return was executed in or the **Background state** dependent on when the INVPC UsageFault was generated.

When the PE enters lockup because of a fault that is generated by a failed integrity check, the PE:

- Updates any Fault Status Registers associated with the error.
- Sets **IPSR** to 0, if **EXC_RETURN** for the returning exception indicated a return to Thread mode.
- Sets **IPSR** to 3, if **EXC_RETURN** for the returning exception indicated a return to Handler mode.
- Sets the stack pointer that is used for unstacking to the value it would have had if the fault had not occurred.
  - If the **XPSR** load faults, the **SP** is 64-bit aligned.
- Updates **CONTROL.FPCA**, based on **EXC_RETURN.FType**.
- Sets the **PC** to 0xEFFFFFEE.

In addition, the **APSR**, **EPSR**, **FPSCR**, R0-R12, LR, and S0-S31 are **UNKNOWN**.
Errors when unstacking state on exception return

Context unstacking is performed after any clearing of exception active bits or FAULTMASK, that is required by the exception return, has been made visible. An AU violation, MPU violation, or synchronous bus error during context unstacking causes lockup when:

- The exception would escalate to a Secure HardFault and any of the following is true:
  - Secure HardFault is already active.
  - FAULTMASK_S.FM is 1.
  - Non-secure HardFault is active and AIRCR.BFHFNMINS is 0.
- The exception would escalate to a Non-secure HardFault and any of the following is true:
  - Non-secure HardFault or Secure HardFault is already active.
  - NMI is active.
  - FAULTMASK_NS.FM or FAULTMASK_S.FM is 1.

When an AU violation, MPU violation, or synchronous bus error during context unstacking causes lockup, the PE:

- Updates any Fault Status Registers associated with the error.
- Sets IPSR to 0, if EXC_RETURN for the returning exception indicated a return to Thread mode.
- Sets IPSR to 3, if EXC_RETURN for the returning exception indicated a return to Handler mode.
- Sets the stack pointer that is used for unstacking to the value it would have had if the fault had not occurred.
  - If the XPSR load faults, the SP is 64-bit aligned.
- Updates CONTROL.FPCA, based on EXC_RETURN.FType.
- Sets the PC to 0xFFFFFFFF.

In addition, the APSR, EPSR, FPSCR, R0-R12, LR, and S0-S31 are UNKNOWN.

Lockup on breakpoint instructions

A BKPT instruction executed when the PE cannot halt or generate a DebugMonitor exception will result in lockup.

See also:

- Breakpoint instructions on page B11-208.
- FPB unit operation on page B12-236.
B3.32 Exception during a singleword load operation

To support *instruction restart*, singleword load instructions must not update the destination register when the PE takes an exception during execution.

See also:

- *Exceptions, instruction resume, or instruction restart* on page B3-83.
B3.33 Special-purpose CONTROL register

Software can use MRS and MSR instructions to access the CONTROL register.

Privileged execution can write to the CONTROL register. The PE ignores unprivileged writes to the CONTROL register. All reads of the CONTROL register, regardless of privilege, are allowed.

The architecture requires a Context synchronization event to guarantee visibility of a change to the CONTROL register.

The PE automatically updates CONTROL.SPSEL on exception entry and exception return.

CONTROL.SPSEL selects the stack pointer when the PE is in Thread mode.

See also:

- Context Synchronization Event on page B3-98.
- CONTROL, Control Register on page D1-837.
B3.34 Saving context on process switch

When switching between different processes, software must save all context for the old process, including its associated EXC_RETURN value, before switching to the new process, and restore that context before returning to the old process.
B3.35 Context Synchronization Event

The architecture requires a Context synchronization event to guarantee visibility of any change to any memory-mapped register described in the architecture. Following a Context synchronization event a completed write to a memory-mapped register must be visible to an indirect read by an instruction appearing in program order after the context synchronization event.

Between any change to a memory-mapped register and a subsequent Context synchronization event, it is UNPREDICTABLE whether an indirect read of the register by the PE uses the old or new values.
B3.36 Coprocessor support

IQRRH If the Main Extension is implemented, coprocessor support is OPTIONAL.

IJBMG When coprocessors are not supported, CPACR and NSACR are RAZ/WI.

RXSQH The architecture supports 0-16 coprocessors, CP0 to CP15.

RHJDH CP0 to CP7 are IMPLEMENTATION DEFINED.

RXPRQ It is IMPLEMENTATION DEFINED whether CP0 to CP7 can be used from both Secure and Non-secure states or whether the coprocessor is enabled for only Secure or Non-secure state.

RQSRC ARM reserves CP8 to CP15.

RCRMD CP10 to CP11 are reserved to support the Floating-point Extension.

RXDG Instructions issued to unimplemented or disabled coprocessors result in a NOCP UsageFault.

RBMLV If a coprocessor cannot complete an instruction, an UNDEFINSTR UsageFault is generated.

B3.36 Coprocessor support
Chapter B4
Floating-point Support

This chapter specifies the ARMv8-M floating-point support rules. It contains the following sections:

- The optional Floating-point Extension, FPv5 on page B4-102.
- About the Floating-point Status and Control Register (FPSCR) on page B4-103.
- Registers for floating-point data processing, S0-S31 or D0-D15 on page B4-104.
- Floating-point standards and terminology on page B4-105.
- Floating-point data representable on page B4-106.
- Floating-point encoding formats, half-precision, single-precision, and double-precision on page B4-107.
- The IEEE 754 floating-point exceptions on page B4-109.
- The Flush-to-zero mode on page B4-110.
- The Default NaN mode, and NaN handling on page B4-111.
- The Default NaN on page B4-112.
- Combinations of floating-point exceptions on page B4-113.
- Priority of floating-point exceptions relative to other floating-point exceptions on page B4-114.
B4.1 The optional Floating-point Extension, FPv5

The optional Floating-point Extension defines a Floating Point Unit (FPU). Coprocessors 10 and 11 support the Extension.

Floating-point is sometimes abbreviated to FP.

The version of Floating-point Extension that is supported is FPv5.

FPv5 provides all of the following:

- Single-precision arithmetic operations.
- Optional double-precision arithmetic operations.
- Conversions between integer, double-precision, single-precision, and half-precision formats.
- Registers for floating-point processing, S0-S31 or D0-D15.
- Data transfers, between ARM general-purpose registers and FPv5 Extension registers S0-S31 or D0-D15, of single-precision and double-precision values.
- A Flush-to-zero mode that software can enable or disable.
- A Default NaN mode that software can enable or disable.
- An optional alternative half-precision interpretation of the IEEE 754 half-precision encoding format.

FPv5 adds the following system registers:

- The FPSCR, to the CP10 and CP11 system register space.
- The FPCAR, FPCCR, FPDSR, MVFR0, MVFR1, and MVFR2, to the System Control Block (SCB).

When the Floating-point Extension is implemented, some software tools might require the following information:

When the Floating-point Extension is implemented, software can interrogate MVFR0, MVFR1, and MVFR2 to discover the floating-point features that are implemented.

To use the Floating-point Extension, software must enable access to CP10, by programming CPACR.CP10.

The value of CPACR.CP11 is unknown if it is not programmed to the same value as CPACR.CP10.

See also:

- The System Control Space (SCS) on page B7-172.
- About the Floating-point Status and Control Register (FPSCR) on page B4-103.
- Registers for floating-point data processing, S0-S31 or D0-D15 on page B4-104.
- The Flush-to-zero mode on page B4-110.
- The Default NaN mode, and NaN handling on page B4-111.
- Floating-point encoding formats, half-precision, single-precision, and double-precision on page B4-107.
B4.2 About the Floating-point Status and Control Register (FPSCR)

CP10 and CP11 are used for floating-point control, and many coprocessor instruction encodings targeting CP10 and CP11 are used as floating-point instruction encodings.

The register map of the CP10 and CP11 system register space shows the location of the FPSCR:

<table>
<thead>
<tr>
<th>Location</th>
<th>Register</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b0000</td>
<td>Reserved</td>
<td>All accesses UNPREDICTABLE</td>
</tr>
<tr>
<td>0b0001</td>
<td>FPSCR</td>
<td>-</td>
</tr>
<tr>
<td>0b0010-0b1111</td>
<td>Reserved</td>
<td>All accesses UNPREDICTABLE</td>
</tr>
</tbody>
</table>

Software can use VMRS and VMSR instructions to access the FPSCR. The FPSCR holds configurable control fields to control the Floating-point Extension, and also status information fields.

Execution of floating-point instructions that generate floating-point exceptions update the appropriate status fields of FPSCR.

See also:
- The optional Floating-point Extension, FPv5 on page B4-102.
- FPSCR, Floating-point Status and Control Register on page D1-941.
The registers that FPv5 adds for floating-point processing are visible as either:

- 16 double-precision registers, D0-D15.

These map as follows:

<table>
<thead>
<tr>
<th>S0-S31</th>
<th>D0-D15</th>
</tr>
</thead>
<tbody>
<tr>
<td>S0</td>
<td></td>
</tr>
<tr>
<td>S1</td>
<td></td>
</tr>
<tr>
<td>S2</td>
<td></td>
</tr>
<tr>
<td>S3</td>
<td></td>
</tr>
<tr>
<td>S4</td>
<td></td>
</tr>
<tr>
<td>S5</td>
<td></td>
</tr>
<tr>
<td>S6</td>
<td></td>
</tr>
<tr>
<td>S7</td>
<td></td>
</tr>
<tr>
<td>S28</td>
<td></td>
</tr>
<tr>
<td>S29</td>
<td></td>
</tr>
<tr>
<td>S30</td>
<td></td>
</tr>
<tr>
<td>S31</td>
<td></td>
</tr>
<tr>
<td>D0</td>
<td></td>
</tr>
<tr>
<td>D1</td>
<td></td>
</tr>
<tr>
<td>D2</td>
<td></td>
</tr>
<tr>
<td>D3</td>
<td></td>
</tr>
<tr>
<td>D14</td>
<td></td>
</tr>
<tr>
<td>D15</td>
<td></td>
</tr>
</tbody>
</table>

After a reset, the values of S0-S31 or D0-D15 are **UNKNOWN**.

See also:

- *The optional Floating-point Extension, FPv5 on page B4-102.*
- *Exception handling on page B3-64.*
B4.4 Floating-point standards and terminology

There are two editions of the IEEE 754 standard:

In this manual, references to IEEE 754 that do not include the year apply to either edition.

The floating-point terminology that this manual uses differs from that used in IEEE 754-2008 as follows:

<table>
<thead>
<tr>
<th>This manual</th>
<th>IEEE 754-2008</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normalized</td>
<td>Normal</td>
</tr>
<tr>
<td>Denormal, or denormalized</td>
<td>Subnormal</td>
</tr>
<tr>
<td>Round towards Minus Infinity (RM)</td>
<td>roundTowardsNegative</td>
</tr>
<tr>
<td>Round towards Plus Infinity (RP)</td>
<td>roundTowardsPositive</td>
</tr>
<tr>
<td>Round towards Zero (RZ)</td>
<td>roundTowardZero</td>
</tr>
<tr>
<td>Round to Nearest (RN)</td>
<td>roundTiesToEven</td>
</tr>
<tr>
<td>Round to Nearest with Ties to Away</td>
<td>roundTiesToAway</td>
</tr>
<tr>
<td>Rounding mode</td>
<td>Rounding-direction attribute</td>
</tr>
</tbody>
</table>

The following is called ARM standard floating-point operation:

- IEEE 754-2008 plus the following FPSCR configuration:
  - Flush-to-zero mode enabled.
  - Default NaN mode enabled.
  - Round to Nearest mode selected.
  - Alternative half-precision interpretation not selected.

See also:

- *The Flush-to-zero mode* on page B4-110.
- *The Default NaN mode, and NaN handling* on page B4-111.
- *Floating-point encoding formats, half-precision, single-precision, and double-precision* on page B4-107.
B4.5 Floating-point data representable

FPv5 supports the following, as defined by IEEE 754:

- Normalized numbers.
- Denormalized numbers.
- Zeros, +0 and -0.
- Infinities, +\(\infty\) and -\(\infty\).
- NaNs, signaling NaN and quiet NaN.

See also:

- Floating-point standards and terminology on page B4-105.
- Floating-point encoding formats, half-precision, single-precision, and double-precision on page B4-107.
B4.6 Floating-point encoding formats, half-precision, single-precision, and double-precision

RPHRC The half-precision, single-precision, and double-precision encoding formats are those defined by IEEE 754-2008.

ILGTJ The half-precision encoding format defined by IEEE 754-2008 is:

ICWBP The single-precision encoding format defined by IEEE 754-2008 is:

IFVWV The double-precision encoding format defined by IEEE 754-2008 is:

RRWRW The interpretations of the IEEE 754-2008 half-precision, single-precision, and double-precision encoding formats are as follows.

Half-precision
The interpretation depends on the setting of FPSCR.AHP. It is either:
• The interpretation defined by IEEE 754-2008.
• An alternative half-precision interpretation.

Single-precision
The interpretation defined by IEEE 754-2008.

Double-precision
The interpretation defined by IEEE 754-2008.

See the following table:

<table>
<thead>
<tr>
<th>E (biased exponent)</th>
<th>T (trailing significand)</th>
<th>S (Sign bit)</th>
<th>MSB of T*</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zero, for all formats.</td>
<td>Non-zero</td>
<td>-</td>
<td>-</td>
<td>A denormalized number</td>
</tr>
<tr>
<td>Zero</td>
<td>0</td>
<td>-</td>

<td>-</td>
<td>-</td>
<td>-</td>
<td></td>
</tr>
</tbody>
</table>
### Floating-point Support

#### B4.6 Floating-point encoding formats, half-precision, single-precision, and double-precision

<table>
<thead>
<tr>
<th>E (biased exponent)</th>
<th>T (trailing significand)</th>
<th>S (Sign bit)</th>
<th>MSB of T&lt;sup&gt;a&lt;/sup&gt;</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x1F, if half-precision format, IEEE interpretation.</td>
<td>Non-zero</td>
<td>-</td>
<td>0</td>
<td>A signaling NaN</td>
</tr>
<tr>
<td>0xFF, if single-precision format.</td>
<td></td>
<td>-</td>
<td>1</td>
<td>A quiet Nan</td>
</tr>
<tr>
<td>0x7FF, if double-precision format.</td>
<td>Zero</td>
<td>0</td>
<td>-</td>
<td>Infinity, +∞</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
<td>-</td>
<td>Infinity, -∞</td>
</tr>
<tr>
<td>0x1F, if half-precision, alternative half-precision interpretation.</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>A normalized number</td>
</tr>
</tbody>
</table>

---

a. MSB = most significant bit.

#### RDPHH

The value of a normalized number is equal to:

**Half-precision IEEE 754-2008 interpretation**

\((-1)^S \times 2^{(E-15)} \times (1.T)\)

**Half-precision alternative half-precision interpretation**

\((-1)^S \times 2^{16} \times (1.T)\)

**Single-precision**

\((-1)^S \times 2^{(E-127)} \times (1.T)\)

**Double-precision**

\((-1)^S \times 2^{(E-1023)} \times (1.T)\)

#### IMHVP

The value of a denormalized number is equal to:

**Half-precision**

\((-1)^S \times 2^{-14} \times (0.T)\)

**Single-precision**

\((-1)^S \times 2^{-126} \times (0.T)\)

**Double-precision**

\((-1)^S \times 2^{-1022} \times (0.T)\)

#### IGBBJ

Denormalized numbers can be flushed to zero. FPv5 provides a Flush-to-zero mode that software can enable.

See also:

- *Floating-point data representable on page B4-106.*
B4.7 The IEEE 754 floating-point exceptions

The IEEE 754 floating-point exceptions are:

Invalid Operation
This exception is as IEEE 754-2008 (7.2) describes.

Division by zero
This exception is as IEEE 754-2008 (7.3) describes, with the following assumption:
• For the reciprocal and reciprocal square root estimate functions the dividend is assumed to be +1.0.

Overflow
This exception is as IEEE 754-2008 (7.4) describes.

Underflow
This exception is as IEEE 754-2008 (7.5) describes, with the additional clarification that:
• Assessing whether a result is tiny and non-zero is done before rounding.

Inexact
This exception is as IEEE 754-2008 (7.6) describes.

The criteria for the Underflow exception to be generated are different in Flush-to-zero mode.

The corresponding status flags for the IEEE 754 floating-point exceptions are FPSCR. {IOC, DZC, OFC, UFC, IXC}.

See also:
• *The Flush-to-zero mode on page B4-110.*
B4.8 The Flush-to-zero mode

Software can enable Flush-to-zero mode by setting FPSCR.FZ to 1.

Using Flush-to-zero mode is a deviation from IEEE 754.

Half-precision floating-point numbers are exempt from Flush-to-zero mode.

When Flush-to-zero mode is enabled, all single-precision denormalized inputs and double-precision denormalized inputs to floating-point operations are treated as though they are zero, that is they are flushed to zero.

When an input to a floating-point operation is flushed to zero, the PE generates an Input Denormal exception.

Input Denormal exceptions are only generated in Flush-to-zero mode.

When Flush-to-zero mode is enabled, the sequence of events for an input to a floating-point operation is:
1. Flush to zero processing takes place. If appropriate, the input is flushed to zero and the PE generates an Input Denormal exception.
2. Tests for the generation of any other floating-point exceptions are done after flush to zero processing.

When Flush-to-zero mode is enabled, the result of a floating-point operation is treated as if it is zero if, before rounding, it satisfies the condition:

\[ 0 < \text{Abs(result)} < \text{MinNorm}, \]

- MinNorm is \(2^{-126}\) for single-precision.
- MinNorm is \(2^{-1022}\) for double-precision.

The result is said to be flushed to zero.

When the result of a floating-point operation is flushed to zero, the PE generates an Underflow exception.

In Flush-to-zero mode, the PE generates Underflow exceptions only when a result is flushed to zero. The is different criteria than when Flush-to-zero mode is disabled.

When a floating-point number is flushed to zero, the sign is preserved. That is, the sign bit of the zero matches the sign bit of the number being flushed to zero.

The PE does not generate an Inexact exception when a floating-point number is flushed to zero.

The corresponding status flag for the Input Denormal exception is FPSCR.IDC.

See also:

- The IEEE 754 floating-point exceptions on page B4-109.
B4.9 The Default NaN mode, and NaN handling

IFGPN Software can enable Default NaN mode by setting FPSCR.DN to 1.

IDJVH Using Default NaN mode is a deviation from IEEE 754.

RQMOC When Default NaN mode is enabled, the Default NaN is the result of both:
• All floating-point operations that produce an untrapped Invalid Operation exception.
• All floating-point operations whose inputs include at least one quiet NaN but no signaling NaNs.

RNPRJ IEEE 754 specifies that:
• An operation that produces an untrapped Invalid Operation exception returns a quiet NaN as its result.
When Default NaN mode is disabled, behavior complies with this and adds:
• If the Invalid Operation exception was generated because one of the inputs to the operation was a signaling NaN, the quiet NaN result is equal to the first signaling NaN input with its most significant bit set to 1.
• The quiet NaN result is the Default NaN otherwise.
The first signaling NaN input means the first argument, in the left-to-right ordering of arguments, that is passed to the pseudocode function describing the operation.

RVCSB IEEE 754 specifies that:
• An operation using a quiet NaN as an input, but no signaling NaNs as inputs, returns one of its quiet NaN inputs as its result.
When Default NaN mode is disabled, behavior complies with this and adds:
• The quiet NaN result is the first quiet NaN input.
The first quiet NaN input means the first argument, in the left-to-right ordering of arguments, that is passed to the pseudocode function describing the operation.

ILXLF Depending on the floating-point operation, the exact value of a quiet NaN result might differ in both sign and the number of T bits from its source.

See also:
• The Default NaN on page B4-112.
• Floating-point encoding formats, half-precision, single-precision, and double-precision on page B4-107.
B4.10 The Default NaN

The Default NaN is:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>E</td>
<td>0x1F</td>
<td>0xFF</td>
<td>0x7FF</td>
</tr>
</tbody>
</table>

See also:
- Floating-point encoding formats, half-precision, single-precision, and double-precision on page B4-107.
- The Default NaN mode, and NaN handling on page B4-111.
B4.11 Combinations of floating-point exceptions

IBTTH In compliance with IEEE 754:
  • An Inexact floating-point exception can occur with an Overflow floating-point exception.
  • An Inexact floating-point exception can occur with an Underflow floating-point exception.

RLFVH An Input Denormal exception can occur with other floating-point exceptions.

See also:
  • The IEEE 754 floating-point exceptions on page B4-109.
  • The Flush-to-zero mode on page B4-110.
B4.12 Priority of floating-point exceptions relative to other floating-point exceptions

Some floating-point instructions specify more than one floating-point operation. In these cases, an exception on one operation is higher priority than an exception on another operation when generation of the second exception depends on the result of the first operation. Otherwise, it is UNPREDICTABLE which exception is higher priority.

See also:
• The IEEE 754 floating-point exceptions on page B4-109.
Chapter B5
Memory Model

This chapter specifies the ARMv8-M memory model architecture rules. It contains the following sections:

- Memory accesses on page B5-117.
- Address space on page B5-118.
- Endianness on page B5-119.
- Alignment behavior on page B5-121.
- Atomicity on page B5-122.
- Concurrent modification and execution of instructions on page B5-123.
- Access rights on page B5-124.
- Observability of memory accesses on page B5-125.
- Completion of memory accesses on page B5-126.
- Ordering requirements for memory accesses on page B5-127.
- Ordering of implicit memory accesses on page B5-128.
- Ordering of explicit memory accesses on page B5-129.
- Memory barriers on page B5-130.
- Normal memory on page B5-133.
- Cacheability attributes on page B5-134.
- Device memory on page B5-135.
- Device memory attributes on page B5-136.
- Shareability domains on page B5-139.
- Shareability attributes on page B5-140.
- Memory access restrictions on page B5-141.
- Mismatched memory attributes on page B5-142.
- Load-Exclusive and Store-Exclusive accesses to Normal memory on page B5-144.
- Load-Acquire and Store-Release accesses to memory on page B5-145.
- Caches on page B5-147.
• Cache identification on page B5-148.
• Cache visibility on page B5-149.
• Cache coherency on page B5-150
• Cache enabling and disabling on page B5-151.
• Cache behavior at reset on page B5-152.
• Behavior of Preload Data (PLD) and Preload Instruction (PLI) instructions with caches on page B5-153.
• Branch predictors on page B5-154.
• Cache maintenance operations on page B5-155.
• Ordering of cache maintenance operations on page B5-157.
• Branch predictor maintenance operations on page B5-158.
B5.1 Memory accesses

The memory accesses that are referred to in describing the memory model are instruction fetches from memory and load or store data accesses.

The instruction operation uses the `MemA[]` or `MemU[]` helper functions. If the Main Extension is not implemented unaligned accesses using the `MemU[]` helper functions generate an alignment fault.

A memory access is governed by whether the access is a read or write, its address alignment, data endianness, and memory attributes.

See also:
- Ordering of implicit memory accesses on page B5-128.
- Ordering of explicit memory accesses on page B5-129.
- Normal memory on page B5-133.
- Device memory on page B5-135.
- Memory access restrictions on page B5-141.
B5.2 Address space

The address space is a single, flat address space of $2^{32}$ bytes.

In the address space, byte addresses are unsigned numbers in the range $0-2^{32}-1$.

If an address calculation overflows or underflows the address space, it wraps around. Address calculations are modulo $2^{32}$.

Normal sequential execution cannot overflow the top of the address space, because the top of memory always has the Execute Never (XN) memory attribute.

LDC, LDM, LDRD, POP, PUSH, STC, STRD, STM, VLDM, VPOP, VPUSH, VSTM, VLD, and VSTR.64 instructions access a sequence of words at increasing memory addresses, effectively incrementing the address by 4 for each load or store. If this calculation overflows the top of the address space, the result is UNPREDICTABLE.

See also:
- In Chapter B7 The System Address Map:
  - System address map on page B7-170.
**B5.3 Endianness**

*In memory:*
- The following figures show the relationship between:
  - The word at address A.
  - The halfwords at addresses A and A+2.
  - The bytes at addresses A, A+1, A+2, and A+3.

*a) Bits[15:0]: this is hw1 for a T32 instruction with a 16-bit encoding*

*b) Bits[31:0]: this is hw1 and hw2 for a T32 instruction with a 32-bit encoding*

---

**RJJQL**

Instruction fetches are always little-endian, which means that the PE assumes a little-endian arrangement of instructions in memory.

**RMNSB**

All accesses to the Private Peripheral Bus (PPB) are always little-endian, which means that the PE assumes a little-endian arrangement of the PPB registers.

**RTFKG**

The endianness of data accesses is IMPLEMENTATION DEFINED, as indicated by AIRCR.ENDIANNESS.

**RKPCF**

AIRC.R.ENDIANNESS is either:
- Implemented with a static value.
• Configured by a hardware input on reset.

For data accesses, the following table shows the data element size that endianness applies to, for endianness conversion purposes.

<table>
<thead>
<tr>
<th>Instruction class</th>
<th>Instructions</th>
<th>Element size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load or store byte</td>
<td>LDR(S)B(T), LDAB, LDAEXB, STLB, STLEXB, STRB(T), TBB, LDREXB, STREXB</td>
<td>Byte</td>
</tr>
<tr>
<td>Load or store halfword</td>
<td>LDR(S)H(T), LDH, LDAEXH, STLH, STLEXH, STRH(T), TBB, LDREXH, STREXH</td>
<td>Halfword</td>
</tr>
<tr>
<td>Load or store word</td>
<td>LDR(T), LDA, LDAEX, STL, STLEX, and STR(T), LDREX, STREX, VLDR.F32, VSTR.F32</td>
<td>Word</td>
</tr>
<tr>
<td>Load or store two words</td>
<td>LDRD, STRD, VLDR.F64, VSTR.F64</td>
<td>Word</td>
</tr>
<tr>
<td>Load or store multiple words</td>
<td>LDM[IA, DB], STM[IA, DB], PUSH, POP, LDC, STC, VLDM, VSTM, VPUSH, VPOP, BLX, BLXNS, BX, BXNS, VLLDM, VLSTM.</td>
<td>Word</td>
</tr>
</tbody>
</table>

The following instructions change the endianness of data that is loaded or stored:

- REV     Reverse word (four bytes) register, for transforming 32-bit representations.
- REVSH    Reverse halfword and sign extend, for transforming signed 16-bit representations.
- REV16    Reverse packed halfwords in a register for transforming unsigned 16-bit representations.
B5.4 Alignment behavior

All instruction fetches are halfword-aligned.

The following are unaligned data accesses that always generate an alignment fault:

- Non halfword-aligned `LDREXH`, `LDAEXH`, `STLEXH`, and `STREXH`.
- Non word-aligned `LDREX`, `LDAEX`, `STLEX`, and `STREX`.
- Non word-aligned `LDR (literal)`, `LDRD`, `LDMIA`, `LMDB`, `POP`, `LDC`, `VLDR`, `VLDM`, and `VPOP`.
- Non word-aligned `STMIA`, `STMDB`, `PUSH`, `STC`, `VSTR`, `VSTM`, `VPUSH`, `VLDM`, and `VLSTM`.

If `CCR.UNALIGN_TRP` is set to 1, the following are unaligned data accesses that generate an alignment fault:

- Non halfword-aligned `LDR(S)(T)`, `LDAH`, `STLH`, and `STRH(T)`.
- Non halfword-aligned `TBH`.
- Non word-aligned `LDR(T)`, `LDA`, `STL`, and `STR(T)`.

Unaligned accesses are only supported if the Main Extension is implemented. If the Main Extension is not implemented unaligned access generate an alignment fault.

Accesses to Device memory are always aligned.

Alignment faults are synchronous and generate an UNALIGNED UsageFault.

See also:

- Normal memory on page B5-133.
- Device memory on page B5-135.
B5.5 Atomicity

There are two types of atomicity:

- **Single-copy atomicity.**
- **Multi-copy atomicity.**

B5.5.1 Single-copy atomicity

Store operations are *single-copy atomic* if, when they overlap bytes in memory:

1. All of the writes from one of the stores are inserted into the coherence order of each overlapping byte.
2. All of the writes from another of the stores are inserted into the coherence order of each overlapping byte.
3. Step 2 repeats, for each single-copy store atomic operation that overlaps.

The following data accesses are single-copy atomic:

- All byte accesses.
- All halfword accesses to halfword-aligned locations.
- All word accesses to word-aligned locations.

Instruction fetches are single-copy atomic at halfword granularity.

For instructions that access a sequence of word-aligned words, each word access is single-copy atomic.

For instructions that access a sequence of word-aligned words, the architecture does not require two or more subsequent word accesses to be single-copy atomic.

B5.5.2 Multi-copy atomicity

In a multiprocessing environment, writes to memory are *multi-copy atomic* if all of the following are true:

- All writes to the same location are observed in the same order by all observers, although some of the observers might not observe all of the writes.
- A read of a location does not return the value of a write to that location until all observers have observed that write.

 Writes to Normal memory are not required to be multi-copy atomic.

 Writes to Device memory with the Gathering attribute are not required to be multi-copy atomic.

 Writes to Device memory with the non-Gathering attribute that are single-copy atomic are also multi-copy atomic.

See also:

- *Device memory on page B5-135.*
- *Normal memory on page B5-133.*
- *Load-Acquire and Store-Release accesses to memory on page B5-145.*
B5.6 Concurrent modification and execution of instructions

ITFGC The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

RKMZG The hw1 of a 32-bit BL immediate instruction can be concurrently modified to the most significant halfword of another BL immediate instruction.

RHKGPR The hw1 of a 32-bit BL immediate or BLX immediate instruction can be concurrently modified to a 16-bit B, BL, BLX, BKPT, or SVC instruction. This modification also works in reverse.

RFGBT The hw2 of a 32-bit BL immediate instruction can be concurrently modified to the least significant halfword of another BL instruction with a different immediate.

RNTVD The hw2 of a 32-bit B immediate instruction with a condition field can be concurrently modified to the least significant halfword of another 32-bit B immediate instruction with a condition field with a different immediate.

RCMZXR The hw2 of a 32-bit B immediate instruction without a condition field can be concurrently modified to the least significant halfword of another 32-bit B immediate instruction without a condition field.

See also:
- Endianness on page B5-119.
- B on page C2-342.
- BL on page C2-350.
- BLX, BLXNS on page C2-351.
B5.7 Access rights

IJHGH An instruction fetch or memory access is subject to the following checks in the following order:
1. Alignment.
2. SAU.
3. MPU.

RTQJS An exception is generated, instead of normal execution of the fetching and decoding process, if one of the following occurs.

<table>
<thead>
<tr>
<th>Priority</th>
<th>Fault type</th>
<th>Cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highest</td>
<td>One of the following Secure faults: AU violation</td>
<td></td>
</tr>
<tr>

</tr>
<tr>
<td>↓</td>
<td>One of the following: FPB hit</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• DebugMonitor</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Halted Debug Entry</td>
<td></td>
</tr>
<tr>
<td>↓</td>
<td>The following SecureFault: SG check</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• INVEP</td>
<td></td>
</tr>
<tr>
<td>↓</td>
<td>The following UsageFault: T32 state check</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• INVSTATE</td>
<td></td>
</tr>
<tr>
<td>Lowest</td>
<td>One of the following UsageFaults: Undefined instruction</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• UNDEFINSTR</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• NOCP</td>
<td></td>
</tr>
</tbody>
</table>

RKPNQ If a memory access fails its alignment check, the fetch is not presented to the SAU.

RSDMQ If an instruction fetch or memory access fails its AU check, the fetch is not presented to the relevant MPU for comparison.

RFLLN If an instruction fetch or memory access fails its MPU check, it is not issued to the memory system.

See also:
• Exception numbers and exception priority numbers on page B3-47.
• Chapter B8 The ARMv8-M Protected Memory System Architecture.
B5.8 Observability of memory accesses

For a PE, the following mechanisms are treated as independent observers:
- The mechanism that performs reads from or writes to memory.
- The mechanism that causes an instruction cache to be filled from memory or that fetches instructions to be executed directly from memory. These accesses are treated as reads.

The set of observers that can observe a memory access is defined by the system.

In the context of observability, subsequent means whichever of the following descriptions is appropriate:
- After the point in time where the location is observed by the observer.
- After the point in time where the location is globally observed.

A write to a location in memory is observed by an observer when:
- A subsequent read of the location by the same observer returns the value that was written by the observed write or written by a write to that location by any observer that is sequenced in the coherence order of the location after the observed write.
- A subsequent write of the location by the same observer is sequenced in the coherence order of the location after the observed write.

A write to a location in memory is globally observed for a Shareability domain or set of observers when:
- A subsequent read of the location by any observer in that Shareability domain that is capable of observing the write returns the value that is written by the globally observed write or by a write to that location by any observer that is sequenced in the coherence order of the location after the globally observed write.
- A subsequent write to the location by any observer in that Shareability domain is sequenced in the coherence order of the location after the globally observed write.

For Device-nGnRnE memory, a read or write of a memory-mapped location in a peripheral is observed, and globally observed, only when the read or write:
- Meets the general observability conditions.
- Can begin to affect the state of the memory-mapped peripheral.
- Can trigger all associated side-effects, whether they affect other peripheral devices, PEs, or memory.

A read of a location in memory is observed by an observer when a subsequent write to the location by the same observer has no effect on the value that is returned by the read.

A read of a location in memory is globally observed for a Shareability domain when a subsequent write to the location by any observer in that Shareability domain that is capable of observing the write has no effect on the value that is returned by the read.

See also:
- Device memory on page B5-135.
- Device memory attributes on page B5-136.
B5.9 Completion of memory accesses

RXCTL
A read or write is complete for a Shareability domain when the following conditions are true:

• The read or write is globally observed for that Shareability domain.
• All instruction fetches by observers within the Shareability domain have observed the read or write.

RWCMQ
A cache or branch predictor maintenance instruction is complete for a Shareability domain when the effects of the instruction are globally observed for that Shareability domain.

RSFLM
The completion of a memory access to Device memory other than Device-nGnRnE does not guarantee the visibility of the side-effects of the access to all observers.

RMWBK
The mechanism that ensures the visibility of the side-effects of the access to all observers is IMPLEMENTATION DEFINED.

See also:

• Shareability domains on page B5-139.
• Device memory on page B5-135.
• Device memory attributes on page B5-136.
B5.10 Ordering requirements for memory accesses

ARMv8-M defines access restrictions in the permitted ordering of memory accesses. These restrictions depend on the memory attributes of the accesses involved.

For all accesses to all memory types, the only stores by an observer that can be observed by another observer are those stores that have been architecturally executed.

Reads and writes can be observed in any order provided that, if an address dependency exists between two reads or between a read and a write, then those memory accesses are observed in program order by all observers within the common Shareability domain of the memory addresses being accessed.

Speculative writes by an observer cannot be observed by another observer.

For Device memory with the non-Reordering attribute, memory accesses arrive at a single peripheral in program order.

Memory accesses caused by instruction fetches are not required to be observed in program order, unless they are separated by a Context synchronization event.

A register data dependency between the value that is returned by a load instruction and the address that is used by a subsequent memory transaction creates order between that load instruction and the subsequent memory transaction.

See also:
- Ordering of implicit memory accesses on page B5-128.
- Ordering of explicit memory accesses on page B5-129.
- Normal memory on page B5-133.
- Device memory on page B5-135.
- Shareability domains on page B5-139.
B5.11 Ordering of implicit memory accesses

There are no ordering requirements for implicit accesses to any type of memory.

See also:

- Memory accesses on page B5-117.
**B5.12 Ordering of explicit memory accesses**

**R_{BMNM}**
For all memory types, for accesses from a single observer, the requirements of uniprocessor semantics are maintained.

**R_{WTRP}**
For all types of memory, if there is a **control dependency** between a direct read and a subsequent direct write, the two accesses are observed in program order by any observer in the common Shareability domain of the two accesses.

**R_{XGNP}**
For all types of memory, if the value returned by a direct read computes data that is written by a subsequent direct write, the two accesses are observed in program order by any observer in the common Shareability domain of the two accesses.

**R_{MBNW}**
It is impossible for an observer to observe a write from a store that both:
- Has not been executed.
- Will not be executed.

See also:
- *Memory accesses* on page B5-117.
- *Normal memory* on page B5-133.
- *Device memory* on page B5-135.
- *Device memory attributes* on page B5-136.
- *Shareability domains* on page B5-139.
- *Shareability attributes* on page B5-140.
B5.13 Memory barriers

The ARM architecture supports out-of-order completion of instructions.

ARMv8 supports the following memory barriers:

- **Instruction Synchronization Barrier (ISB).**
- **Data Memory Barrier (DMB).**
- **Data Synchronization Barrier (DSB).**

The DMB and DSB memory barriers affect reads and writes to the memory system that are generated by Load/Store instructions and data or unified cache maintenance instructions that are executed by the PE. Instruction fetches are not explicit accesses.

### B5.13.1 Instruction Synchronization Barrier

An ISB instruction flushes the pipeline in the PE, so that all instructions that come after the ISB instruction in program order are fetched from the cache or memory only after the ISB instruction has completed.

See also:

- [InstructionSynchronizationBarrier()](#).
- [Context Synchronization Event on page B3-98](#).

### B5.13.2 Data Memory Barrier

The required Shareability for a DMB is *Full system*, and applies to all observers in the Shareability domain.

A DMB only affects memory accesses and the operation of data cache and unified cache maintenance instructions, and has no effect on the ordering of any other instructions.

A DMB that ensures the completion of cache maintenance instructions has an access type of both loads and stores.

A DMB instruction creates two groups of memory accesses, Group A and Group B, and does not affect memory accesses that are in not in Group A or Group B:

**Group A** Contains:

- All explicit memory accesses of the required access types from observers in the same Shareability domain as PEe that are observed by PEe before the DMB instruction.
- All loads of required access types from an observer PEx in the same required Shareability domain as PEe that have been observed by any given different observer, PEy, in the same required Shareability domain as PEe before PEy has performed a memory access that is a member of Group A.

**Group B** Contains:

- All explicit memory accesses of the required access types by PEe that occur in program order after the DMB instruction.
- All explicit memory accesses of the required access types by any given observer PEx in the same required Shareability domain as PEe that can only occur after a load by PEx has returned the result of a store that is a member of Group B.

Any observer with the same required Shareability domain as PEe observes all members of Group A before it observes any member of Group B to the extent that those group members are required to be observed, as determined by the Shareability and Cacheability of the memory addresses accessed by the group members.

If members of Group A and members of Group B access the same memory-mapped peripheral of arbitrary system-defined size, then members of Group A that are accessing Device or Normal Non-cacheable memory arrive at that peripheral before members of Group B that are accessing Device or Normal Non-cacheable memory. Where the members of Group A and Group B that must be ordered are from the same PE, a DMB provides for this guarantee.
B5.13.3 Data Synchronization Barrier

The **DSB** is a memory barrier that synchronizes the execution stream with memory accesses.

The required Shareability for a **DSB** is Full system and applies to all observers in the Shareability domain.

A **DSB** instruction creates two groups of memory accesses, Group A and Group B, and does not affect memory accesses that are in not in Group A or Group B:

**Group A** Contains:

- All explicit memory accesses of the required access types from observers in the same Shareability domain as PEe that are observed by PEe before the **DSB** instruction.
- All loads of required access types from an observer PEx in the same required Shareability domain as PEe that have been observed by any given different observer, PEy, in the same required Shareability domain as PEe before PEy has performed a memory access that is a member of Group A.

**Group B** Contains:

- All explicit memory accesses of the required access types by PEe that occur in program order after the **DSB** instruction.
- All explicit memory accesses of the required access types by any given observer PEx in the same required Shareability domain as PEe that can only occur after a load by PEx has returned the result of a store that is a member of Group B.

Any observer with the same required Shareability domain as PEe observes all members of Group A before it observes any member of Group B to the extent that those group members are required to be observed, as determined by the Shareability and Cacheability of the memory addresses accessed by the group members.

If members of Group A and members of Group B access the same memory-mapped peripheral of arbitrary system-defined size, then members of Group A that are accessing Device or Normal Non-cacheable memory arrive at that peripheral before members of Group B that are accessing Device or Normal Non-cacheable memory. Where the members of Group A and Group B that must be ordered are from the same PE, a **DSB** provides for this guarantee.

A **DSB** completes when all of the following conditions apply:

- All explicit memory accesses that are observed by PEe before the **DSB** is executed and are of the required access types, and are from observers in the same required Shareability domain as PEe, are complete for the set of observers in the required Shareability domain.
- If the required access types of the **DSB** is reads and writes, then all cache and branch predictor maintenance instructions that are issued by PEe before the **DSB** are complete for the required Shareability domain.
- All explicit accesses to the System Control Space that result in a context altering operation issued by PEe before the **DSB** are complete.

No instruction that appears in program order after the **DSB** instruction can execute until the **DSB** completes.

See also:

- **DataSynchronizationBarrier()**.
- **Shareability domains on page B5-139.**

B5.13.4 Synchronization requirements for System Control Space

A **DSB** guarantees that all writes to the System Control Space have been completed.

A **DSB** does not guarantee that the side-effects of writes to the System Control Space are visible.
A ISB that follows a DSB guarantees that the side-effects of any completed writes to the System Control Space will be visible.

See also:

- *The System Control Space (SCS)* on page B7-172.
B5.14 Normal memory

In memory locations that are idempotent have the following properties:

- Read accesses can be repeated with no side-effects.
- Repeated read accesses return the last value that is written to the resource being read.
- Read accesses can fetch additional memory locations with no side-effects.
- Write accesses can be repeated with no side-effects, if the contents of the location that is accessed are unchanged between the repeated writes or as the result of an exception.
- Unaligned accesses can be supported.
- Accesses can be merged before accessing the target memory system.

Normal memory is a memory type that is assigned to regions of memory that are idempotent.

Normal memory can be marked as Cacheable or Non-cacheable. Normal memory must be assigned Cacheability attributes.

Normal Non-cacheable memory is always treated as shareable.

Speculative data accesses to Normal memory are permitted.

A write to Normal memory completes in finite time.

A write to a Non-cacheable Normal memory location must reach the endpoint for that location in the memory system in finite time.

A completed write to Normal memory is globally observed for the Shareability domain in finite time without the requirement for cache maintenance instructions or memory barriers.

For multi-register Load/Store instructions that access Normal memory, the architecture does not define the order in which the registers are accessed.

There is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed.

See also:
- Memory accesses on page B5-117.
- Shareability domains on page B5-139.
- Cacheability attributes on page B5-134.
- Load-Exclusive and Store-Exclusive accesses to Normal memory on page B5-144.
- MAIR_ATTR, Memory Attribute Indirection Register Attributes on page D1-1024.
B5.15 Cacheability attributes

The architecture provides Cacheability attributes that are defined independently for each of two conceptual levels of cache:

- The Inner cache.
- The Outer cache.

The Cacheability attributes are:

- Non-cacheable.
- Write-Through Cacheable.
- Write-Back Cacheable.

It is IMPLEMENTATION DEFINED whether Write-Through Cacheable and Write-Back Cacheable can have the additional attribute Transient or Non-transient.

The Transient attribute is a memory hint that indicates that the benefit of caching is for a short period. The architecture does not define what is meant by a short period.

Cacheability attributes other than Non-cacheable can be complemented by the following cache allocation hints, which are independent for read and write accesses:

- Read-Allocate, Transient Read-Allocate, or No Read-Allocate.
- Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

The architecture does not require an implementation to make any use of cache allocation hints.

Any cacheable Normal memory region is treated as Read-Allocate, No Write-Allocate unless it is explicitly assigned other cache allocation hints.

A Cacheable location with no Read-Allocate and no Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply to a location that is Cacheable, no Read-Allocate, no Write-Allocate.

All data accesses to Non-cacheable Normal memory locations are data coherent to all observers.

See also:

- Normal memory on page B5-133.
B5.16 Device memory

Device memory is a memory type that is assigned to regions of memory where accesses can have side-effects.

Device memory is not cacheable.

Device memory is always treated as shareable.

Speculative data accesses cannot be made to Device memory. However, for instructions that access a sequence of word-aligned words, the accesses might occur multiple times.

Speculative instruction fetches can be made to Device memory, unless the location is marked as Execute-never.

Any unaligned access to Device memory generates an UNALIGNED UsageFault exception.

Device memory is assigned a combination of Device memory attributes.

A write to Device memory completes in finite time.

A write to a Device memory location reaches the endpoint for that location in the memory system in finite time.

A completed write to a Device memory location is globally observed for the Shareability domain in finite time without the requirement for cache maintenance instructions or barriers.

If the content of a Device memory location changes without a direct write to the location, the change must be observed for the Shareability domain in finite time.

For an instruction fetch from Device memory, if a branch causes the program counter to point to an area of memory that is not marked as Execute-never, the implementation can either:

- Treat the fetch as if it is to a location in Normal Non-cacheable memory.
- Take an IACCVIOLL MemManage fault.

There is no requirement for the memory system beyond the PE to be able to identify the size of the elements that are accessed, for instructions that load the following from Device memory:

- More than one general-purpose register.
- One or more registers from the floating-point register file.

For an LDM, STM, LDRO, or STRD instruction with a register list that includes the PC, the architecture does not define the order in which the registers are accessed.

For a LDM, STM, VLDM, or VSTM instruction with a register list that does not include the PC, all registers are accessed in the order that they appear in the register list, for Device memory with the non-Reordering attribute.

See also:

- Memory accesses on page B5-117.
- Shareability attributes on page B5-140.
- Device memory attributes on page B5-136.
- Shareability domains on page B5-139.
B5.17 Device memory attributes

Each Device memory region is assigned a combination of Device memory attributes. The attributes are:

Gathering, G and nG
The Gathering and non-Gathering attributes.

Reordering, R and nR
The Reordering and non-Reordering attributes.

Early Write Acknowledgement, E and nE
The Early Write Acknowledgement and no Early Write Acknowledgement attributes.

Each Device memory region is assigned one of the combinations in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>nG</th>
<th>nR</th>
<th>nE</th>
<th>G</th>
<th>R</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device-nGnRnE</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Device-nGnRE</td>
<td>Y</td>
<td>Y</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>Y</td>
</tr>
<tr>
<td>Device-nGRE</td>
<td>Y</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>Device-GRE</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>
</tr>
</tbody>
</table>

Device-nGnRnE is the most constrained, so it is the strongest. Device-GRE is the least constrained, so it is the weakest. Going down the table, the combinations are described as getting weaker.

Weaker memory can be accessed according to the rules specified for stronger memory:

- Memory with the:
  - G attribute can be accessed according to the rules specified for the nG attribute.
  - nG attribute cannot be accessed according to the rules specified for the G attribute.

- Memory with the:
  - R attribute can be accessed according to the rules specified for the nR attribute.
  - nR attribute cannot be accessed according to the rules specified for the R attribute.

Because the nE attribute is a hint:

- An implementation is permitted to perform an access with the E attribute in a manner consistent with the requirements specified by the nE attribute.
- An implementation is permitted to perform an access with the nE attribute in a manner consistent with the relaxations allowed by the E attribute.

For Device-GRE and Device-nGRE memory, the use of barriers is required to order accesses.

See also:

- Gathering and non-Gathering Device memory attributes.
- Reordering and non-Reordering Device memory attributes on page B5-137.
- Early Write Acknowledgement and no Early Write Acknowledgement Device memory attributes on page B5-138.
- Device memory on page B5-135.
G attribute

RDBSX

If multiple accesses of the same type, read or write, are to:

- The same location, with the G attribute, they can be merged into a single transaction.
- Different locations, all with the G attribute, they can be merged into a single transaction.

RKCMX

Gathering of accesses that are separated by a memory barrier is not permitted.

RJSRD

Gathering of accesses that are generated by a Load-Acquire/Store-Release is not permitted.

RMGKJ

A read can come from intermediate buffering of a previous write if:

- The accesses are not separated by a DMB or DSB barrier.
- The accesses are not separated by any other ordering construction that requires that the accesses are in order, for example a combination of Load-Acquire and Store-Release.
- The accesses are not generated by a Store-Release instruction.

ISRDS

The architecture only defines programmer visible behavior. Therefore, if a programmer cannot tell whether gathering has occurred, gathering can be performed.

nG attribute

RGVTF

Multiple accesses to a memory location with the nG attribute cannot be merged into a single transaction.

RBTWD

A read of a memory location with the nG attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system.

See also:

- Load-Acquire and Store-Release accesses to memory on page B5-145.

B5.17.2 Reordering and non-Reordering Device memory attributes

R attribute

RRPTB

This attribute imposes no restrictions or relaxations.

nR attribute

RDFXL

If the access is to a:

- Peripheral, it must arrive at the peripheral in program order. If there is a mixture of accesses to Device nGnRE and Device-nGnRnE in the same peripheral, these accesses must occur in program order.
- Non-peripheral, this attribute imposes no restrictions or relaxations.

IBDWB

The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee that is provided by the DMB instruction.

RNDHC

The non-Reordering attribute does not require any additional ordering, other than the ordering that applies to Normal memory, between:

- Accesses with the non-Reordering attribute and accesses with the Reordering attribute.
- Accesses with the non-Reordering attribute and accesses to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.
B5.17.3 Early Write Acknowledgement and no Early Write Acknowledgement Device memory attributes

E attribute

RPVSH

This attribute imposes no restrictions or relaxations.

nE attribute

RFWFR

Assigning the nE attribute recommends that only the endpoint of the write access returns a write acknowledgement of the access, and that no earlier point in the memory system returns a write acknowledgement.

IFQWQ

The E attribute is treated as a hint. ARM strongly recommends that this hint is not ignored by a PE, but is made available for use by the system.
B5.18 Shareability domains

There are two conceptual Shareability domains:

- The Inner Shareability domain.
- The Outer Shareability domain.

The following diagram shows the Shareability domains:

All observers in an Inner Shareability domain are data coherent for data accesses to memory that has the Inner-shareable Shareability attribute.

All observers in an Outer Shareability domain are data coherent for data accesses to memory that has the Outer-shareable Shareability attribute.

Each observer is a member of only a single Inner Shareability domain.

Each observer is a member of only a single Outer Shareability domain.

All members of the same Inner Shareability domain are always members of the same Outer Shareability domain.

Accesses to a shareable memory location are coherent within the Shareability domain of that location.

An Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Hardware is required to ensure coherency and ordering within the Shareability domain if all of the following apply:

- Before writing to a location not using the Write-Back attribute, a location in the caches that might have been written with the Write-Back attribute by an agent has been invalidated or cleaned.
- After writing the location with the Write-Back attribute, the location has been cleaned from the caches to make the write visible to external memory.
- Before reading the location with a cacheable attribute, the location has been invalidated from the caches, to ensure that any value that is held in the caches reflects the last value made visible in external memory.
- A DMB barrier instruction has been executed, with a scope that applies to the common Shareability of the accesses, between any accesses to the same memory location that use different attributes.

See also:

- Observability of memory accesses on page B5-125.
- Shareability attributes on page B5-140.
B5.19 Shareability attributes

Each Normal cacheable memory region is assigned one of the following Shareability attributes:

- Non-shareable.
- Inner-shareable.
- Outer-shareable.

For Non-shareable memory, hardware is not required to make data accesses by different observers coherent. If a number of observers share the memory, cache maintenance instructions, in addition to the barrier operations that are required to ensure memory ordering, can ensure that the presence of caches does not lead to coherency issues.

Non-cacheable Normal memory locations are always treated as Outer Shareable.

See also:
- Memory accesses on page B5-117.
- Normal memory on page B5-133.
- Device memory on page B5-135.
- Shareability domains on page B5-139.
- Cache maintenance operations on page B5-155.
B5.20 Memory access restrictions

**RKXT**
For accesses to any two bytes that are accessed by the same instruction, the two bytes must have the same memory type and Shareability attributes, otherwise the behavior is a **CONSTRAINED UNPREDICTABLE** choice of the following:

- All memory accesses that were generated by the instruction use the memory type and Shareability attributes that are associated with the first address that is accessed by the instruction.
- All memory accesses that were generated by the instruction use the memory type and Shareability attributes that are associated with the last address that is accessed by the instruction.
- Each memory access that is generated by the instruction uses the memory type and Shareability attribute that is associated with its own address.
- The instruction executes as a NOP.
- The instruction generates an alignment fault caused by the memory type.

**IWRBT**
Except for possible differences in cache allocation hints, ARM deprecates having different Cacheability attributes for accesses to any two bytes that are generated by the same instruction.

**RBFS**
If the accesses of an instruction that cause multiple accesses to any type of Device memory cross the boundary of a memory region then the behavior is a **CONSTRAINED UNPREDICTABLE** choice of the following:

- All memory accesses that are generated by the instruction are performed as if the presence of the boundary had no effect on memory accesses.
- All memory accesses that are generated by the instruction are performed as if the presence of the boundary had no effect on memory accesses, except that there is no guarantee of ordering between memory accesses,
- The instruction executes as a NOP.
- The instruction generates an alignment fault caused by the memory type.

See also:

- *Memory accesses on page B5-117.*
B5.21 Mismatched memory attributes

Memory locations are accessed with mismatched attributes if all accesses to the location do not use a common definition of all the following memory attributes of that location:

- Memory type - Device or Normal.
- Shareability.
- Cacheability, for the same level of the Inner or Outer cache, but excluding any cache allocation hints.

When a memory location is accessed with mismatched attributes, the only permitted effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory location might be lost. This means:
  - A read of the memory location by one agent might not return the value that was most recently written to that memory location by the same agent.
  - Multiple writes to the memory location by one agent with different memory attributes might not be ordered in program order.
- There might be a loss of coherency when multiple agents attempt to access a memory location.
- There might be a loss of the properties that are derived from the memory type.
- If all Load-Exclusive/Store-Exclusive instructions that are executed across all threads to access a given memory location do not use consistent memory attributes, the exclusive monitor state becomes UNKNOWN.
- Bytes that are written without the Write-Back cacheable attribute and that are within the same Write-Back granule as bytes that are written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of the properties that are associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of speculative read accesses.
- Prohibition on Gathering.
- Prohibition on Re-ordering.

If the only memory type mismatch that is associated with a memory location across all users of the memory location is between different types of Device memory, then all accesses might take the properties of the weakest Device memory type.

Any agent that reads a memory location with mismatched attributes using the same common definition of the Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all the following conditions are met:

- All aliases to the memory location with write permission both use a common definition of the Shareability and Cacheability attributes for the memory location, and have the Inner Cacheability attribute the same as the Outer Cacheability attribute.
- All aliases to a memory location use a definition of the Shareability attributes that encompasses all the agents with permission to access the location.

The possible permitted effects that are caused by mismatched attributes for a memory location are defined more precisely if all the mismatched attributes define the memory location as one of:

- Any Device memory type.
- Normal Inner Non-cacheable, Outer Non-cacheable memory.

In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:

- Possible loss of properties that are derived from the memory type when multiple agents attempt to access the memory location.
- Possible reordering of memory transactions to the same memory location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting DMB barrier instructions between accesses to the same memory location that might use different attributes.
If the mismatched attributes for a location mean that multiple cacheable accesses to the location might be made with different Shareability attributes, then ordering and coherency are guaranteed only if:

- Each PE that accesses the location with a cacheable attribute performs a clean and invalidate of the location before and after accessing that location.
- A DMB barrier with scope that covers the full Shareability of the accesses is placed between any accesses to the same memory location that use different attributes.

If multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a location, and the accesses from the different agents have different memory attributes associated with the location, the exclusive monitor state becomes UNKNOWN.

ARM strongly recommends that software does not use mismatched attributes for aliases of the same location. An implementation might not optimize the performance of a system that uses mismatched aliases.

See also:
- Chapter B8 The ARMv8-M Protected Memory System Architecture.
- Shareability domains on page B5-139.
- Cacheability attributes on page B5-134.
- Device memory on page B5-135.
- Normal memory on page B5-133.
- Load-Exclusive and Store-Exclusive accesses to Normal memory on page B5-144.
B5.22 Load-Exclusive and Store-Exclusive accesses to Normal memory

For Normal memory that is:

- Non-shareable, it is IMPLEMENTATION DEFINED whether Load-Exclusive and Store-Exclusive instructions take account of the possibility of accesses by more than one observer.
- Shareable, Load-Exclusive, and Store-Exclusive instructions take account of the possibility of accesses by more than one observer.

See also:

- Normal memory on page B5-133.
- Memory accesses on page B5-117.
B5.23 Load-Acquire and Store-Release accesses to memory

The following table summarizes the Load-Acquire/Store-Release instructions.

<table>
<thead>
<tr>
<th>Data type</th>
<th>Load-Acquire</th>
<th>Store-Release</th>
<th>Load-Acquire Exclusive</th>
<th>Store-Release Exclusive</th>
</tr>
</thead>
<tbody>
<tr>
<td>32-bit word</td>
<td>LDA</td>
<td>STL</td>
<td>LDAEX</td>
<td>STLEX</td>
</tr>
<tr>
<td>16-bit halfword</td>
<td>LDAH</td>
<td>STLH</td>
<td>LDAEXH</td>
<td>STLEXH</td>
</tr>
<tr>
<td>8-bit byte</td>
<td>LDAB</td>
<td>STLB</td>
<td>LDAEXB</td>
<td>STLEXB</td>
</tr>
</tbody>
</table>

A Store-Release followed by a Load-Acquire is observed in program order by each observer within the Shareability domain of the memory address being accessed by the Store-Release and the memory address being accessed by the Load-Acquire.

For a Load-Acquire, observers in the Shareability domain of the address that is accessed by the Load-Acquire observe accesses in the following order:
1. The read caused by the Load-Acquire.
2. Reads and writes caused by loads and stores that appear in program order after the Load-Acquire for which the Shareability of the address that is accessed by the load or store requires that the observer observes the access.

There are no other ordering requirements on loads or stores that appear before the Load-Acquire.

For a Store-Release, observers in the Shareability domain of the address that is accessed by the Store-Release observe accesses in the following order:
1. All of the following for which the Shareability of the address that is accessed requires that the observer observes the access:
   - Reads and writes caused by loads and stores that appear in program order before the Store-Release.
   - Writes that were observed by the PE executing the Store-Release before it executed the Store-Release.
2. The write caused by the Store-Release.

There are no other ordering requirements on loads or stores that appear in program order after the Store-Release.

All Store-Release instructions must be multi-copy atomic when they are observed with Load-Acquire instructions.

A Load-Acquire to an address in a memory-mapped peripheral of an arbitrary system-defined size that is defined as any type of Device memory access ensures that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed after the Load-Acquire will arrive at the memory-mapped peripheral after the memory access of the Load-Acquire.

A Store-Release to an address in a memory-mapped peripheral of an arbitrary system-defined size that is defined as any type of Device memory access ensures that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed before the Store-Release will arrive at the memory-mapped peripheral before the memory access of the Store-Release.

If a Load-Acquire to a memory address in a memory-mapped peripheral of an arbitrary system-defined size that is defined as any type of Device memory access has observed the value that is stored to that address by a Store-Release, then any memory access to the memory-mapped peripheral that is architecturally required to be ordered before the memory access of the Store-Release will arrive at the memory-mapped peripheral before any memory access to the same peripheral that is architecturally required to be ordered after the memory access of the Load-Acquire.

Load-Acquire and Store-Release access only a single data element.

Load-Acquire and Store-Release accesses are single-copy atomic.

If a Load-Acquire or Store-Release instruction accesses an address that is not aligned to the size of the data element being accessed, the access generates an alignment fault.
A Store-Release Exclusive instruction only has the release semantics if the store is successful.

See also:
• *Shareability domains* on page B5-139.
• *Device memory* on page B5-135.
B5.24 Caches

When a memory location is marked with a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache can depend on many aspects of the implementation, such as the following factors:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

An implementation can include multiple levels of cache, up to a maximum of seven levels, in a hierarchical memory system.

The lower the cache level, the closer the cache is to the PE.

Entries for addresses with a Normal cacheable attribute can be allocated to an enabled cache at any time.

The allocation of a memory address to a cache location is IMPLEMENTATION DEFINED.

A cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to its size.

Where a breakdown in coherency can occur, data coherency of the caches is controlled in an IMPLEMENTATION DEFINED manner.

The architecture cannot guarantee whether:

- A memory location that is present in the cache remains in the cache.
- A memory location that is not present in the cache is brought into the cache.

If the cache is disabled, no new allocation of memory locations into the cache occurs.

The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer, if it had previously been visible to that observer.

If the cache is enabled, it is guaranteed that no memory location that does not have a cacheable attribute is allocated into the cache.

If the cache is enabled, it is guaranteed that no memory location is allocated to the cache if the access permissions for that location are so that the location cannot be accessed by reads and cannot be accessed by writes.

Any cached memory location is not guaranteed to remain incoherent with the rest of memory.

It is IMPLEMENTATION DEFINED whether an access can generate a cache hit when the cache is disabled.

It is UNPREDICTABLE whether the location is returned from cache or from memory when:

- The location is not marked as cacheable but is contained in the cache. This situation can occur if a location is marked as Non-cacheable after it has been allocated into the cache.
- The location is marked as cacheable and might be contained in the cache, but the cache is disabled.

See also:

- Cache identification on page B5-148.
- Cache enabling and disabling on page B5-151.
- Cacheability attributes on page B5-134.
- Cache behavior at reset on page B5-152.
- Ordering of cache maintenance operations on page B5-157.
- Mismatched memory attributes on page B5-142.
B5.25 Cache identification

A PE controls the implemented caches using:

- A single Cache Type Register, CTR.
- A single Cache Level ID Register, CLIDR.
- A single Cache Size Selection Register, CSSLR.
- For each implemented cache, across all levels of caching, a Cache Size Identification Register, CCSIDR.

The number of levels of cache is IMPLEMENTATION DEFINED and can be determined from the Cache Level ID Register.

Cache sets and Cache ways are numbered from 0. Usually the set number is an IMPLEMENTATION DEFINED function of an address.
B5.26 Cache visibility

\textbf{RQLVB} A completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.

\textbf{RRCHC} A completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.

See also:
- Cacheability attributes on page B5-134.
B5.27 Cache coherency

RNNDJ Data coherency of caches is ensured:
• When caches are not used.
• As a result of cache maintenance operations.
• By the use of hardware coherency mechanisms to ensure coherency of data accesses to memory for cacheable locations by observers in different Shareability domains.

RCPGW Hardware is not required to ensure coherency between instruction caches and memory, even for regions of memory with the Shareability attribute.

IQXXC An ISB and a DSB can ensure coherency where this is required.

See also:
• Cache maintenance operations on page B5-155.
• Memory barriers on page B5-130.
• Shareability attributes on page B5-140.
B5.28 Cache enabling and disabling

IPPLL The Configuration and Control Register, CCR, enables and disables caches across all levels of cache that are visible to the PE.

RHTLD It is IMPLEMENTATION DEFINED whether the CCR.DC and CCR.IC bits affect the memory attributes that are generated by an enabled MPU.

ITNHX An implementation can use control bits in the Auxiliary Control Register, ACTLR, for finer-grained control of cache enabling.

RDSTQ If the MPU is disabled, MPU_CTRL.ENABLE == 0, the CCR.DC and CCR.IC bits determine the cache state for cacheable regions of the default address map.

See also:
- Cache identification on page B5-148.
- Caches on page B5-147.
- Cache behavior at reset on page B5-152.
B5.29 Cache behavior at reset

RKCFK All caches are disabled at reset.

RJMBT An implementation can require the use of a specific cache initialization routine to invalidate its storage array before it is enabled:
• The exact form of any required cache initialization routine is IMPLEMENTATION DEFINED.
• If a required initialization routine is not performed, the state of an enabled cache is UNPREDICTABLE.

RTVKQ If an implementation permits cache hits when the cache is disabled, the cache initialization routine provides a mechanism to ensure the correct initialization of the caches.

RCJGV If an implementation permits cache hits when the cache is disabled and the cache contents are not invalidated at reset, the initialization routine avoids any possibility of running from an uninitialized cache.

IJSSQ An initialization routine can require a fixed instruction sequence to be placed in a restricted range of memory.

IJCTD ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8-M cache maintenance operations.

See also:
• Caches on page B5-147.
• Cache enabling and disabling on page B5-151.
• Cache maintenance operations on page B5-155.
B5.30 Behavior of Preload Data (PLD) and Preload Instruction (PLI) instructions with caches

ICQLR
The instructions are memory system hints and their effect is IMPLEMENTATION DEFINED.

ITPPK
The instructions do not generate exceptions but the memory system operations might generate an imprecise fault (asynchronous exception) because of the memory access.

RQNGJ
A PLD instruction does not cause any effect to the caches or memory other than the effects that, for permission or other reasons, can be caused by the equivalent load from the same location with the same context and at the same privilege level and Security state.

RSFNK
A PLD instruction does not access Device-nGnRnE or Device-nGnRE memory.

RHLNL
A PLI instruction does not cause any effect to the caches or memory other than the effects that, for permission or other reasons, can be caused by the fetch resulting from changing the PC to the location specified by the PLI instruction with the same context and at the same privilege level and Security state.

RMRFG
A PLI instruction cannot access memory that has the Device-nGnRnE or Device-nGnRE attribute.

See also:
- PLD (immediate).
- PLD (literal).
- PLD (register).
- PLI (immediate, literal).
- PLI (register).
B5.31 Branch predictors

\( I_{GTPB} \) Branch predictor hardware typically uses a form of cache to hold branch information.

\( R_{MTBD} \) Branch predictors are not architecturally visible.

\( I_{CVCV} \) The BPIALL operation is provided for timing and determinism

See also:

- Branch predictor maintenance operations on page B5-158.
B5.32 Cache maintenance operations

Cache maintenance operations act on particular memory locations.

Following a Clean operation, updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the operation is performed.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the Shareability domain of that memory location.

Following an invalidate operation, updates made visible by observers that access memory at the point to which the invalidate is defined are made visible to an observer that controls the cache.

An invalidate operation might result in the loss of updates to the locations affected by the operation that have been written by observers that access the cache.

If the address of an entry on which the invalidate operates does not have a Normal cacheable attribute, or if the cache is disabled, then an invalidate operation ensures that this address is not present in the cache.

If the address of an entry on which the invalidate operates has the Normal cacheable attribute, the cache invalidate operation cannot ensure that the address is not present in an enabled cache.

A clean and invalidate operation behaves as the execution of a clean operation followed immediately by an invalidate operation. Both operations are performed to the same location.

The clean operation cleans from the level of cache that is specified through at least the next level of cache away from the PE.

The invalidate operation invalidates only at the level specified.

For set/way operations and for All (entire cache) operations, the cache maintenance operation is to the next level of caching.

For address operations, the cache maintenance operation is to the point of coherency (PoC) or to the point of unification (PoU) depending on the settings in CLIDR.LoC and CLIDR.LOUU.

Data cache maintenance operations affect data caches and unified caches.

Instruction cache maintenance operations only affect instruction caches.

Cache maintenance operations are memory mapped, 32-bit write-only operations.

Cache maintenance operations can have one of the following side-effects:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

The ICMVAll, DCIMVAC, DCCMVAll, DCCMVAC, and DCCIMVAC operations require the physical address in the memory map but it does not have to be cache-line aligned.

For DCISw, DCCSw, and DCCISw, the STR operation identifies the cache line to which it applies by specifying the following:

- The cache set the line belongs to.
- The way number of the line in the set.
- The cache level.

The format of the register data for a set/way operation is:

<table>
<thead>
<tr>
<th>31</th>
<th>31-A</th>
<th>32-A</th>
<th>B-1</th>
<th>L-1</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Way</td>
<td>SBZ</td>
<td>Set</td>
<td>SBZ</td>
<td>Level</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Where:

\[ A = \log_2(\text{ASSOCIATIVITY}), \text{rounded up to the next integer if necessary.} \]

\[ B = (L + S). \]

\[ L = \log_2(\text{LINELEN}). \]

\[ S = \log_2(\text{NSETS}), \text{rounded up to the next integer if necessary. ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on.} \]

The values of A and S are rounded up to the next integer.

**Level** 
(\text{(Cache level to operate on)} - 1). For example, this field is 0 for operations on an L1 cache, or 1 for operations on an L2 cache.

**Set** 
The number of the set to operate on.

**Way** 
The number of the way to operate on.

- If \( L = 4 \) then there is no SBZ field between the set and level fields in the register.
- If \( A = 0 \) there is no way field in the register, and register bits[31:B] are SBZ.
- If the level, set, or way field in the register is larger than the size implemented in the cache, then the effect of the operation is UNPREDICTABLE.

After the completion of an instruction cache maintenance operation, a Context synchronization event guarantees that the effects of the cache maintenance operation are visible to all instruction fetches that follow the Context synchronization event.

ARM recommends that, wherever possible, all caches that require maintenance to ensure coherency are included in the caches affected by the architecturally-defined cache maintenance operations.

When the Security Extension is implemented, it is IMPLEMENTATION DEFINED whether the DCIMVAC and DCISW operations, when performed from Non-secure state either:

- Clean any data that might be Secure data before invalidating it.
- Do not invalidate Secure data.

When the Security Extension is implemented, ICIALLU, ICIMVAU, DCOMVAC, DCCSW, DCCIMVAC, DCCISW, and BPIALL operations on Secure data might be ignored if the operation was performed from Non-secure state.

The following is the sequence of cache cleaning operations for a line of self-modifying code.

\[
\begin{align*}
; \text{Enter this code with } & \langle Rx \rangle \text{ containing the new 32-bit instruction and } \langle Ry \rangle; \\
& \text{containing the address of the instruction.} \\
; \text{Use STRH in the first line instead of STR for a 16-bit instruction.} \\
\text{STR } & \langle Rx \rangle, [\langle Ry \rangle]; \text{ Write instruction to memory} \\
\text{DSB } & \text{; Ensure write is visible} \\
\text{MOV } & \langle Rt \rangle, 0x80000000; \text{ Create pointer to base of System Control Space} \\
\text{STR } & \langle Ry \rangle, [\langle Rt \rangle, #0xF64]; \text{ Clean data cache by address to point of unification} \\
\text{DSB } & \text{; Ensure visibility of the data cleaned from the cache} \\
\text{STR } & \langle Ry \rangle, [\langle Rt \rangle, #0xF58]; \text{ Invalidate instruction cache by address to PoU} \\
\text{STR } & \langle Ry \rangle, [\langle Rt \rangle, #0xF78]; \text{ Invalidate branch predictor} \\
\text{DSB } & \text{; Ensure completion of the invalidations} \\
\text{ISB } & \text{; Synchronize fetched instruction stream}
\end{align*}
\]

In a PE with the Security Extension, if the Security attribution of memory is changed, it is IMPLEMENTATION DEFINED whether cache maintenance operations are required to keep the system state valid.

See also:

- Cache Maintenance Operations on page D1-809.
- Cache Maintenance Operations (NS alias) on page D1-814.
- Observability of memory accesses on page B5-125.
- Cacheability attributes on page B5-134.
- Out of range values of the Set/Way/Index fields in cache maintenance instructions on page G1-1337.
B5.33 Ordering of cache maintenance operations

RGCNB All cache and branch predictor maintenance operations that do not specify an address execute, relative to each other, in program order.

RGXNL All cache maintenance operations that specify an address:
• Execute in program order relative to all cache operations that do not specify an address.
• Execute in program order relative to all cache maintenance operations that specify the same address.
• Can execute in any order relative to cache maintenance operations that specify a different address.

RRTJG There is no restriction on the ordering of data or unified cache maintenance operation by address relative to any explicit load or store.

RMIJJ There is no restriction on the ordering of a data or unified cache maintenance operation by set/way relative to any explicit load or store.

IVXXZ A DSB instruction can be inserted to enforce ordering as required.

RSWBG For the ICAI\(u\) operation, the value in the register specified by the STR instruction that performs the operation is ignored.

IZQQZ In a PE with the Security Extension, if cache maintenance operations are required when the security attribution of memory is changed, the following sequence of steps can be followed:
1. If the attribution of the address range is changing from Secure to Non-secure, ensure that memory does not contain any data that must remain secure.
2. Execute a DSB instruction.
3. Clean the affected lines in data or unified caches using the DCC\(^*\) instruction.
4. Execute a DSB instruction.
5. Change the security attribution of the address range.
6. Execute a DSB instruction.
7. Invalidate the affected lines in all caches using the DCI\(^*\) and ICI\(^*\) instructions.
8. Execute a Context synchronization event.

See also:
• Data Synchronization Barrier on page B5-131.
• Security attribution on page B8-176.
• Cache maintenance operations on page B5-155.
• Security attribution on page B8-176.
B5.34  Branch predictor maintenance operations

RHVXX  Branch predictor maintenance operations are independent of cache maintenance operations.

RNSRK  A Context synchronization event that follows a branch predictor maintenance operation guarantees that the effects of the branch predictor maintenance operation are visible to all instructions after the context synchronization event.

HRXF   For the BPIALL operation, the value in the register specified by the STR instruction that performs the operation is ignored.

RLXHX  As a side-effect of a branch predictor maintenance operation, any entry in the branch predictor might be invalidated.

See also:
- Cache Maintenance Operations on page D1-809.
- Cache Maintenance Operations (NS alias) on page D1-814.

- Memory barriers on page B5-130.
- DSB on page C2-371.
Chapter B6
Synchronization and Semaphores

This chapter specifies the ARMv8-M architecture rules for exclusive access instructions and non-blocking synchronization of shared memory. It contains the following sections:

- Exclusive access instructions on page B6-160.
- The local monitors on page B6-161.
- The global monitor on page B6-162.
- Exclusive access instructions and the monitors on page B6-165
- Load-Exclusive and Store-Exclusive instruction constraints on page B6-166.
B6.1 Exclusive access instructions

Armv8 provides non-blocking synchronization of shared memory, using synchronization primitives for accesses to both Normal and Device memory.

The synchronization primitives and associated instructions are as follows:

<table>
<thead>
<tr>
<th>Function</th>
<th>T32 instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load-Exclusive</td>
<td></td>
</tr>
<tr>
<td>Byte</td>
<td>LDREXB, LDAEXB</td>
</tr>
<tr>
<td>Halfword</td>
<td>LDREXH, LDAEXH</td>
</tr>
<tr>
<td>Word</td>
<td>LDREX, LDAEX</td>
</tr>
<tr>
<td>Store-Exclusive</td>
<td></td>
</tr>
<tr>
<td>Byte</td>
<td>STREXB, STLEXB</td>
</tr>
<tr>
<td>Halfword</td>
<td>STREXH, STLEXH</td>
</tr>
<tr>
<td>Word</td>
<td>STREX, STLEX</td>
</tr>
<tr>
<td>Clear-Exclusive</td>
<td>CLREX</td>
</tr>
</tbody>
</table>

A Load-Exclusive instruction performs a load from memory, and:
- The executing PE marks the memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

The size of the marked memory block is called the Exclusives reservation granule (ERG), and is an implementation defined value that is of a power of 2 size, in the range 4 - 512 words.

A marked block of the ERG is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block.

In some implementations the CTR identifies the Exclusives reservation granule. Where this is not the case, the Exclusives reservation granule is treated as having the maximum of 512 words.

See also:
- *The local monitors on page B6-161.*
- *The global monitor on page B6-162.*
- *Exclusive access instructions and the monitors on page B6-165.*
- *Load-Exclusive and Store-Exclusive instruction constraints on page B6-166.*
B6.2 The local monitors

RQTFP Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

RNJWC When a PE writes using any instruction other than a Store-Exclusive instruction:
- If the write is to a physical address that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a physical address that is marked as Exclusive Access by its local monitor, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

RPFFT It is IMPLEMENTATION DEFINED whether a store to a marked physical address causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the physical address to be marked.

RKXNM The state machine for the local monitor is shown here.

The local monitor does not hold any physical address, but instead treats any access as matching the address of the previous Load-Exclusive instruction.

A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.

The architecture does not require a load instruction by another PE that is not a Load-Exclusive instruction to have any affect on the local monitor.

It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the Store or StoreExcl is from another observer.

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause.

An exception return clears the local monitor.

See also:
- Exclusive access instructions and the monitors on page B6-165.
**B6.3 The global monitor**

For each PE in the system, the global monitor:
- Can hold at least one marked block.
- Maintains a state machine for each marked block it can hold.

For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is CONSTRAINED UNPREDICTABLE.

The global monitor can either reside in a block that is part of the hardware on which the PE executes or exist as a secondary monitor at the memory interfaces.

The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and the local monitor can be combined into a single unit, provided that the unit performs the global monitor and the local monitor functions defined in this manual.

For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:
- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:
- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

The only memory types for which it is architecturally guaranteed that a global exclusive monitor is implemented are:
- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hint and not transient.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hints and not transient.

The set of memory types that support atomic instructions includes all of the memory types for which a global monitor is implemented.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive/Store-Exclusive instruction to such a location has one or more of the following effects:
- The instruction generates BusFault.
- The instruction generates a DACCCVIOL MemManage fault.
- The instruction is treated as a NOP.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

For write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global monitor and the local monitor that are used by an ARM PE is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:
- Some address ranges.
- Some memory types.

A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the physical address of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other physical address that has been marked by the requesting PE.

The global monitor only supports a single outstanding exclusive access to shareable memory for each PE.
A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the physical address accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  - A status value of 0 is returned to a register to acknowledge the successful store.
  - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  - A status value of 1 is returned to a register to indicate that the store failed.
  - The global monitor is not affected and remains in Open Access state for the requesting PE.
- If a different physical address is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
  - If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it.

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism.

The state machine for PE(n) in a global monitor is as follows.

![State machine diagram](image)

\*Operations marked * are possible alternative IMPLEMENTATION DEFINED options.

\‡StoreExcl(Marked_address,!,n) clears the monitor only if the StoreExcl updates memory.

Any LoadExcl operation updates the marked address to the most significant bits of the address x used for the operation.
Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local monitor and the global monitor are in the exclusive state.

A Load-Exclusive instruction can only update the marked shareable memory address for the PE issuing the Load-Exclusive instruction.

When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.

It is IMPLEMENTATION DEFINED:

- Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
- Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

See also:

- Appendix G1 Architectural Constraints on UNPREDICTABLE behaviors.
- Exclusive access instructions and the monitors on page B6-165.
B6.4 Exclusive access instructions and the monitors

The Store-Exclusive instruction defines the register to which the status value of the monitors is returned.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor

If the local monitor is in the **Exclusive Access state**

- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  - If the store took place the status value is 0.
  - Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

If the local monitor is in the **Open Access state**

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

A Store-Exclusive instruction performs a store to Shareable memory that depends on the state of both the local monitor and the global monitor:

If both the local monitor and the global monitor are in the **Exclusive Access state**

- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  - If the store took place the status value is 0.
  - Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

If either the local monitor or the global monitor is in the **Open Access state**

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor of the executing PE transitions to the Open Access state.
- The global monitor that is associated with the executing PE transitions to the Open Access state.

- *The local monitors on page B6-161.*
- *The global monitor on page B6-162.*
### B6.5 Load-Exclusive and Store-Exclusive instruction constraints

**IRTHW** The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a LDRX/STREX pair or a LDRXB/STREXB pair.

**RBHPN** The architecture does not require an address or size check as part of the IsExclusiveLocal() function.

**RLHLG** If two StoreExcl instructions are executed without an intervening LoadExcl instruction the second StoreExcl instruction returns a status value of 1.

**RDVRQ** The architecture does not require every LoadExcl instruction to have a subsequent StoreExcl instruction.

**RJXXS** If the transaction size of a StoreExcl instruction is different from the preceding LoadExcl instruction in the same thread of execution, behavior is a CONSTRAINED UNPREDICTABLE choice of:

- The StoreExcl either passes or fails, and the status value returned by the StoreExcl is UNKNOWN.
- The block of data of the size of the larger of the transaction sizes used by the LoadExcl/StoreExcl pair at the address accessed by the LoadExcl/StoreExcl pair, is UNKNOWN.

**RGVWN** The hardware only ensures that a LoadExcl/StoreExcl pair succeeds if the LoadExcl and the StoreExcl have the same transaction size.

**RXLSK** Forward progress can only be made using LoadExcl/StoreExcl loops if, for any LoadExcl/StoreExcl loop within a single thread of execution if both of the following are true:

- There are no explicit memory accesses, pre-loads, direct or indirect register writes, cache maintenance instructions, SVC instructions, or exception returns between the Load-Exclusive and the Store-Exclusive.
- The following conditions apply between the Store-Exclusive having returned a fail result and the retry of the Load-Exclusive:
  - There are no stores to any location within the same Exclusives reservation granule that the Store-Exclusive is accessing.
  - There are no direct or indirect register writes, other than changes to the flag fields in APSR or FPSCR, caused by data processing or comparison instructions.
  - There are no direct or indirect cache maintenance instructions, SVC instructions, or exception returns.

The exclusive monitor can be cleared at any time without an application-related cause, provided that such clearing is not systematically repeated so as to prevent the forward progress in finite time of at least one of the threads that is accessing the exclusive monitor.

**IRFXR** Keeping the LoadExcl and the StoreExcl operations close together in a single thread of execution minimizes the chance of the exclusive monitor state being cleared between the LoadExcl instruction and the StoreExcl instruction. Therefore, for best performance, ARM strongly recommends a limit of 128 bytes between LoadExcl and StoreExcl instructions in a single thread of execution.

**RPKQF** The architecture sets an upper limit of 2048 bytes on the Exclusives reservation granule that can be marked as exclusive.

**IPGGN** Forward progress can only be made using LoadExcl/StoreExcl loops if, for any LoadExcl/StoreExcl loop within a single thread of execution if both of the following are true:

- There are no explicit memory accesses, pre-loads, direct or indirect register writes, cache maintenance instructions, SVC instructions, or exception returns between the Load-Exclusive and the Store-Exclusive.
- The following conditions apply between the Store-Exclusive having returned a fail result and the retry of the Load-Exclusive:
  - There are no stores to any location within the same Exclusives reservation granule that the Store-Exclusive is accessing.
  - There are no direct or indirect register writes, other than changes to the flag fields in APSR or FPSCR, caused by data processing or comparison instructions.
  - There are no direct or indirect cache maintenance instructions, SVC instructions, or exception returns.

The exclusive monitor can be cleared at any time without an application-related cause, provided that such clearing is not systematically repeated so as to prevent the forward progress in finite time of at least one of the threads that is accessing the exclusive monitor.

**RDMJW** For performance reasons, ARM recommends that objects that are accessed by exclusive accesses are separated by the size of the exclusive reservations granule.

**RXPON** After taking a BusFault or a MemManage fault, the state of the exclusive monitors is UNKNOWN.

**RFCRN** For the memory location accessed by a LoadExcl/StoreExcl pair, if the memory attributes for a StoreExcl instruction are different from the memory attributes for the preceding LoadExcl instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE.

**RDMJW** The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local exclusive monitor or a global exclusive monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE, and the instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same Shareability domain as the PE executing the cache maintenance instruction, as determined by the Shareability domain of the address being maintained.
ARM strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

In the event of repeatedly-contending LoadExcl/StoreExcl instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

Chapter B7
The System Address Map

This chapter specifies the ARMv8-M system address map rules. It contains the following sections:

- System address map on page B7-170.
- The System region of the system address map on page B7-171.
- The System Control Space (SCS) on page B7-172.
## B7.1 System address map

The address space is divided into the following regions:

<table>
<thead>
<tr>
<th>Address</th>
<th>Region</th>
<th>Memory type</th>
<th>XN?</th>
<th>Cache</th>
<th>Shareability</th>
<th>Example usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00000000-0x1FFFFFFF</td>
<td>Code</td>
<td>Normal</td>
<td>-</td>
<td>WTbRA</td>
<td>Non-shareable</td>
<td>Typically ROM or flash memory.</td>
</tr>
<tr>
<td>0x20000000-0x3FFFFFFF</td>
<td>SRAM</td>
<td>Normal</td>
<td>-</td>
<td>WBWAbRA</td>
<td>Non-shareable</td>
<td>SRAM region typically used for on-chip RAM.</td>
</tr>
<tr>
<td>0x40000000-0x5FFFFFFF</td>
<td>Peripheral</td>
<td>Device, nGnRE</td>
<td>XNd</td>
<td>-</td>
<td>Shareable</td>
<td>On-chip peripheral address space.</td>
</tr>
<tr>
<td>0x60000000-0x7FFFFFFF</td>
<td>RAM</td>
<td>Normal</td>
<td>-</td>
<td>WBWARA</td>
<td>Non-shareable</td>
<td>Memory with write-back, write allocate cache attribute for L2/L3 cache support.</td>
</tr>
<tr>
<td>0x80000000-0x9FFFFFFF</td>
<td>RAM</td>
<td>Normal</td>
<td>-</td>
<td>WTRA</td>
<td>Non-shareable</td>
<td>Memory with write-through cache attribute.</td>
</tr>
<tr>
<td>0xA0000000-0x8FFFFFFF</td>
<td>Device</td>
<td>Device, nGnRE</td>
<td>XN</td>
<td>-</td>
<td>Shareable</td>
<td>Peripherals accessible to all masters.</td>

<td>XN</td>
<td>-</td>
<td>Shareable</td>
<td>Peripherals accessible only to this PE.</td>
</tr>
<tr>
<td>0xE0000000-0xEFFFFF</td>
<td>System PPB</td>
<td>Device, nGnRnE</td>
<td>XN</td>
<td>-</td>
<td>Shareable</td>
<td>1 MB region reserved as the PPB. This supports key resources, including the System Control Space, and debug features.</td>
</tr>
<tr>
<td>0xE0100000-0xFFFFFFFF</td>
<td>System Vendor_SYS</td>
<td>Device, nGnRE</td>
<td>XN</td>
<td>-</td>
<td>Shareable</td>
<td>Vendor System Region.</td>
</tr>
</tbody>
</table>

- a. Write-through.
- b. Read-allocate.
- c. Write-back, write allocate.
- d. Memory with the Execute Never (XN) memory attribute.

An access that crosses a boundary is UNPREDICTABLE. This rule also applies to the 0xFFFFFFFF - 0x00000000 boundary.

See also:
- *The System region of the system address map on page B7-171.*
- In Chapter B5 Memory Model:
  - Address space on page B5-118.
  - Memory accesses on page B5-117.
  - Caches on page B5-147.
B7.2 The System region of the system address map

In a PE with the Security Extension, the system region of the system address map is as follows:

- **0xE0100000 - 0xEFFFFFFF** is reserved.
- **Vendor resources start at 0xF0000000**.

Unprivileged access to the PPB causes BusFault errors unless otherwise stated. Unprivileged accesses can be enabled to the Software Trigger Interrupt Register in the System Control Space by programming a control bit in the Configuration and Control Register.

See also:
- *System address map* on page B7-170.
- *The System Control Space (SCS)* on page B7-172.
- *STIR, Software Triggered Interrupt Register* on page D1-1084.
- *CCR, Configuration and Control Register* on page D1-829.
- *Debug resources* on page B11-188.
B7.3 The System Control Space (SCS)

The System Control Space (SCS) provides registers for control, configuration, and status reporting.

The Secure view of the NS alias is identical to the Non-secure view of normal addresses unless otherwise stated.

Privileged accesses to unimplemented registers are RES0.

Unprivileged accesses to unimplemented registers will generate a BusFault unless otherwise stated.

Chapter B8
The ARMv8-M Protected Memory System Architecture

This chapter specifies the ARMv8-M Protected Memory System Architecture (PMSAv-8) rules, and in particular the rules for the optional Memory Protection Unit (MPU) and the optional Security Attribution Unit (SAU). It contains the following sections:

- Memory protection unit on page B8-174.
- Security attribution on page B8-176.
- Security attribution unit (SAU) on page B8-178.
- IMPLEMENTATION DEFINED Attribution Unit (IDAU) on page B8-179.
B8.1 Memory protection unit

In an implementation that includes the Protected Memory System Architecture (PMSA), system address space is protected by a memory protection unit (MPU).

PMSAv8-M only supports a unified memory model. All enabled regions support instruction and data accesses.

Memory attributes are determined from the default system address map or by using an MPU.

The default memory map can be configured to provide a background region for privileged accesses.

MPU support in ARMv8-M is optional.

When the MPU is enabled, the PE can be configured to use the default system map when it processes NMI and HardFault exceptions.

When the MPU is disabled or not present, accesses use memory attributes from the default system address map.

The MPU divides the memory into regions.

An individual MPU region is defined by:

Address >= MPU_RBAR.BASE:'00000' && Address <= MPU_RLAR.LIMIT:'11111'

The number of supported MPU regions is IMPLEMENTATION DEFINED.

Because the MPU_TYPE register is banked, an implementation can have a different number of MPU regions, including no MPU regions, for each Security state.

All MPU regions are aligned to a multiple of 32 bytes.

The PE can fetch and execute instructions from each MPU region according to the value of MPU_RBAR.XN. The value of MPU_RBAR.XN can be used by privileged software.

Accesses to the Private Peripheral Bus (PPB) always use memory attributes from the default system address map.

Exception vector reads from the Vector Address Table always use the default system address map.

The MPU is restricted in how it can change the default memory map attributes associated with System space, that is, for addresses 0xE0000000 and higher, in the following ways:

- System space is always XN.
- The MPU can map system space regions that default to Device-nGnRE to Device-nGnRnE.
- The effect of remapping a System space region that defaults to Device memory as Normal memory is UNPREDICTABLE.

The following accesses generate a MemManage fault:

- An access to an address that matches in more than one region.
- An access that does not match all access conditions for that region.
- An access that matches a background region or default memory map if the MPU is enabled.

However, privileged accesses are permitted if either:

- MPU_CTRL PRIVDEFENA ==1.
- Executing at a priority less than zero when MPU_CTRLHFNMIENA is set.

A memory access to an address that matches in more than one region, or does not match all access conditions of a region address match, with the MPU enabled, or a background or default memory map match, generates a precise fault.

For data accesses, the MPU memory attribution and privilege checking uses the configuration registers that correspond to the current executing Security state of the PE.
For instruction fetches, the MPU memory attribution and privilege checking uses the configuration registers associated with the address that is fetched.

Setting `MPU_CTRL.HFNMIENA` to zero disables the MPU if the requested priority for the handler of the HardFault, NMI and exceptions that the MPU is associated with is negative.

See also:
- *System address map* on page B7-170.
- *MPU_CTRL, MPU Control Register* on page D1-1029.
B8.2 Security attribution

The Security Extension defines three levels of memory security attribution. In ascending order of security, these are:

1. Non-secure.
2. Secure and Non-secure callable.
3. Secure and not Non-secure callable.

The following units can provide security attribution information:

- A security attribution unit (SAU) inside the PE.
- An implementation defined attribution unit (IDAU) external to the PE. The presence of such a unit is IMPLEMENTATION DEFINED.

The attribution information from the SAU is used unless the IDAU specifies attributes with a higher security, in which case the IDAU attributes override the SAU attributes. This rule does not apply to architecturally defined ranges exempt from memory attribution.

An attribution unit (AU) violation is defined as being a violation raised by either the SAU or the IDAU.

All boundaries between address ranges with different security attributes must be aligned to 32-byte boundaries.

The behavior of the following address ranges is fixed, so they are exempt from memory attribution by both the SAU and IDAU:

0xF0000000 - 0xFFFFFFFF

If the PE implements the Security Extension, this memory range is always marked as Secure and not Non-secure callable for instruction fetches.

If the Security Extension is not present, this range is marked as Non-secure.

Ranges exempt from checking security violation

The following address ranges are marked with the Security state indicated by NS-Req, that is, the current state of the PE for non-debug accesses. This marking sets the NS-Attr to NS-Req:

- 0xE0000000 - 0xE0002FFF: ITM, DWT, FPB.
- 0xE000E000 - 0xE000EFFF: SCS range.
- 0xE002E000 - 0xE002EFFF: SCS NS alias range.
- 0xE0040000 - 0xE0041FFF: TPIU, ETM.
- 0xE00FF000 - 0xE00FFFFF: ROM table.
- 0xE0000000 - 0xEFFFFFFF: for instruction fetch only.

Additional address ranges specified by the IDAU.
The Security attribution and MPU check sequence is shown in the following diagram.

See also:
- [Security attribution unit (SAU)](page B8-178).
- [IMPLEMENTATION DEFINED Attribution Unit (IDAU)](page B8-179).
B8.3 Security attribution unit (SAU)

RVFLR The SAU configuration defines an IMPLEMENTATION DEFINED number of memory regions. The number of regions is indicated by SAU_TYPE.SREGION.

IPPLK The memory regions defined by the SAU configuration are referred to as SAU_REGIONn, where n is a number from 0 - (SAU_TYPE.SREGION-1).

RRVFP The SAU region configuration fields can only be accessed indirectly using the window registers shown in the following table.

<table>
<thead>
<tr>
<th>SAU region configuration field</th>
<th>Associated window register field</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAU_REGIONn.Enable</td>
<td>SAU_RLAR.ENDABLE</td>
</tr>
<tr>
<td>SAU_REGIONn.NSC</td>
<td>SAU_RLAR.NSC</td>
</tr>
<tr>
<td>SAU_REGIONn.BADDR</td>
<td>SAU_RBAR.BADDR</td>
</tr>
<tr>
<td>SAU_REGIONn.LADDR</td>
<td>SAU_RLAR.LADDR</td>
</tr>
</tbody>
</table>

RNBFD When the SAU is enabled, an address is defined as matching a region in the SAU if the following is true:

SAU_REGIONn.BADDR <= Address <= SAU_REGIONn.LADDR.

RMPJC Memory is marked as Secure by default. However, if the address matches a region with SAU_REGIONn.ENABLE set to 1 and SAU_REGIONn.NSC set to 0, then memory is marked as Non-secure.

RWGDK An address that matches multiple SAU regions is marked as Secure and not Not-secure callable regardless of the attributes specified by the regions that matched the address.

RGVFQ When the SAU is not enabled:

• Addresses are not checked against the SAU regions.
• The attribution of the address space is determined by the SAU_CTRL.ALLNS field.

RMBJN To permit lockdown of the SAU configuration, it is IMPLEMENTATION DEFINED whether the SAU registers are writeable.
B8.4 IMPLEMENTATION DEFINED Attribution Unit (IDAU)

The IDAU can provide the following security attribution information for an address:

- Security attribution exempt. This specifies that the address is exempt from security attribution. This information is combined with the address ranges that are architecturally required to be exempt from attribution.
- Non-secure. This specifies if the address is Secure or Non-secure.
- Non-secure callable. This specifies if code at the address can be called from Non-secure state. This attribute is only valid if the address is marked as Secure.
- Region number. This is the region number that matches the address, and is only used by the TT instruction.
- Region number valid. This specifies that the region number is valid. This field has no effect on the attribution of the address, and is only used by the TT instruction.

The Non-secure and the Non-secure callable attributes from the IDAU are combined with the results from the SAU. The resulting attribution is the most restrictive of the two.

See also:
- TT, TTT, TTA, TTAT on page C2-649.
- Security attribution on page B8-176.
B8 The ARMv8-M Protected Memory System Architecture

B8.4 IMPLEMENTATION DEFINED Attribution Unit (IDAU)
Chapter B9
The System Timer, SysTick

This chapter specifies the ARMv8-M system timer rules. It contains the following section:

• The system timer, SysTick on page B9-182.
B9.1 The system timer, SysTick

RBQRG In a PE without the Main and Security Extensions, either:
- No system timers are implemented.
- One system timer, SysTick, is implemented.

RFPDDL In a PE without the Main Extension but with the Security Extension, one of the following is true:
- No system timers are implemented.
- One system timer, SysTick, is implemented. ICSR.STTNS determines which Security state owns the SysTick.
- Two system timers are implemented:
  - SysTick, Secure instance.
  - SysTick, Non-secure instance.

RCNFG In a PE with the Main Extension but without the Security Extension, one system timer, SysTick, is implemented.

RXPCW In a PE with the Main and Security Extensions, two system timers are implemented:
- SysTick, Secure instance.
- SysTick, Non-secure instance.

IDXSQ There are the following SysTick registers:
- SysTick Control and Status Register (SYST_CSR).
- SysTick Reload Value Register (SYST_RVR).
- SysTick Current Value Register (SYST_CVR).
- SysTick Calibration Value Register (SYST_CALIB).

In a PE with the Security Extension and a SysTick instance dedicated to each Security state, these registers are banked.

IVHDT Each implemented SysTick is a 24-bit decrementing, wrap-on-zero, clear-on-write counter:
- When enabled, the counter counts down from the value in SYST_CVR. When it reaches zero, SYST_CVR is reloaded with the value held in SYST_RVR on the next clock edge.
- Reading SYST_CVR returns the value of the counter at the time of the read access.
- When the counter reaches zero, it sets SYST_CSR.COUNTFLAG to 1. Reading SYST_CSR.COUNTFLAG clears it to 0.
- A write to SYST_CVR clears both SYST_CVR and SYST_CSR.COUNTFLAG to 0. SYST_CVR is then reloaded with the value held in SYST_RVR on the next clock edge.

RTLKG Writing the value zero to SYST_RVR disables the SysTick on the next wrap-on-zero. The value zero is held by the counter after the wrap. This is true even when SYST_CSR.ENABLE is 1.

RTTFT A write to SYST_CVR does not cause a SysTick exception.

IVDJQ Setting SYST_CSR.TICKINT to 1 causes the SysTick exception to become pending on the SysTick reaching zero.

IPPGV ARM recommends that before enabling a SysTick by SYST_CSR.ENABLE, software writes the required counter value to the SYST_RVR, and then writes to the SYST_CVR to clear the SYST_CVR to zero.

IMMRQ Software can optionally use SYST_CALIB.TENMS to scale the counter to other clock rates within the dynamic range of the counter.

RQSKV When the PE is halted in Debug state, any implemented SysTicks do not decrement.

IRWFQ Each implemented SysTick is clocked by a reference clock, either the PE clock or an external system clock. It is IMPLEMENTATION DEFINED which clock is used as the external reference clock. ARM recommends that if an external system clock is used, the relationship between the PE clock and the external clock is documented, so that system timings can be calculated taking into account metastability, clock skew, jitter.
Chapter B10

Nested Vectored Interrupt Controller

This chapter specifies the ARMv8-M Nested Vectored Interrupt Controller (NVIC) rules. It contains the following sections:

- *NVIC definition* on page B10-184.
- *NVIC operation* on page B10-185.
B10.1 NVIC definition

RXJJQ An ARMv8-M PE includes an integral interrupt controller.

RFSGP The NVIC behavior aligns with the behavior that is described in the ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0.

RWQHG The Interrupt Controller Type Register (ICTR) defines the number of external interrupt lines that are supported.

See also:

• ICTR, Interrupt Controller Type Register on page D1-977.
B10.2 NVIC operation

RSNVK It is IMPLEMENTATION DEFINED which NVIC interrupts are implemented.

RSGCR When a particular NVIC interrupt line is not implemented, its associated registers are reserved.

RWTFs ARMv8-M supports level-sensitive and pulse-sensitive interrupts.

RHVQq Pulse interrupt sources must be held long enough so that the PE clock can sample them reliably to ensure they are latched and become pending.

RRLCp A subsequent pulse can add the pending state to an active interrupt, making the status of the interrupt active and pending.

RRKFC Multiple pulses that occur during the active period only register as a single event for interrupt scheduling.

RPDPq Pulses held for a clock period act like edge-sensitive interrupts.

RLWBW Edge-sensitive interrupts can become pending again while the interrupt is active.

RXVWM A pulse must be cleared before the assertion of AIRCR.VECTORACTIVE or the associated exception return. Otherwise the interrupt signal behaves as a level-sensitive input and the pending bit is asserted again.

RQDDK Level-based interrupts first become pending then make the interrupt active. The Interrupt Service Routine (ISR) then accesses the peripheral to cause it to deassert the interrupt.

RBQQq If the interrupt is still asserted on return from the ISR, it becomes pending again.

RQKFw All NVIC interrupts have a programmable priority value and an associated exception number.

RXNWq NVIC interrupts can be enabled and disabled by writing to their corresponding Interrupt Set-Enable or Interrupt Clear-Enable register bit field.

RCCVj When an interrupt is disabled, interrupt assertion causes the interrupt to become pending but the interrupt cannot become active.

RXCLJ If an interrupt is active when it is disabled, it remains in the active state until this is cleared by a reset or an exception return.

IWGDj An implementation can hard-wire interrupt enable bits to zero if the associated interrupt line does not exist.

IRSDj An implementation can hard-wire interrupt enable bits to one if the associated interrupt line cannot be disabled.

RNRJV It is IMPLEMENTATION DEFINED for each NVIC interrupt line supported whether an NVIC interrupt supports either or both setting and clearing of the associated pending state under software control.

Chapter B11
Debug

This chapter specifies the ARMv8-M debug rules. It contains the following sections:

- About debug on page B11-188.
- Accessing debug features on page B11-192.
- Debug authentication interface on page B11-195.
- Debug event behavior on page B11-201.
- Multiprocessor support on page B11-211.
B11.1 About debug

B11.1.1 Debug feature overview

The debug architecture supports the following features:

- High-level trace using the ITM.
- Profiling various system events, including associated timing information.
- PC sampling and event counts associated with load and store operations, instruction folding, and performance statistics that are based on cycles-per-instruction (CPI) counts.
- Instruction trace, using an Embedded Trace Macrocell (ETM).
- Warm reset functionality to reset the PE and support debug of reset events.
- A control register that a debugger can write to halt the PE.
- An external signal to asynchronously halt the PE, which might be connected to a Cross Trigger Interface (CTI).
- Step functionality, with or without interrupt masking.
- Run functionality, with or without interrupt masking.
- For register access, reading and writing PE registers when software execution is halted.
- Access to exception-related information through the System Control Space (SCS) resources.
- The BKPT instruction to provide software breakpoints.
- Hardware breakpoints, and remapping of code memory locations.
- Hardware watchpoints.
- Access to all memory through the Debug Access Port (DAP).
- The ability to add other system debug features such as a bus monitor or cross-trigger facility.
- Application and data trace, typically through either a low pin-count Serial Wire Viewer (SWV) or a parallel trace port.

B11.1.2 Debug mechanisms

ARMv8-M supports a range of invasive and non-invasive debug mechanisms.

The invasive debug mechanisms are:
- The ability to halt the PE. This provides a run-stop debug model.
- Debugging code using the DebugMonitor exception. This provides less intrusive debug than halting the PE.

The non-invasive debug techniques are:
- Generating application trace by writing to the Instrumentation Trace Macrocell (ITM), causing a low level of intrusion.
- Non-intrusive program trace and profiling.

When the PE is halted, it is in Debug state.
When the PE is not halted, it is in Non-debug state.

See also:
- Accessing debug features on page B11-192.

B11.1.3 Debug resources

In the system address map, debug resources are in the Private Peripheral Bus (PPB) region.
Except for the resources in the SCS, each debug component occupies a fixed 4KB address region.

The debug resources in the SCS are:

- The Debug Control Block (DCB).
- Debug controls in the System Control Block (SCB).

The ARMv8-M debug components are:

- The Instrumentation Trace Macrocell on page B12-214, only available if the Main Extension is implemented.
- The Data Watchpoint and Trace unit on page B12-220.
- The Flash Patch and Breakpoint unit on page B12-236.
- The Embedded Trace Macrocell on page B12-234.
- The Trace Port Interface Unit on page B12-235.
- The ROM table.

The following debug components are not part of the ARMv8-M architecture:

- The Cross-Trigger Interface (CTI).
- The CoreSight basic trace router (MTB).

The debug configuration of an implementation is IMPLEMENTATION DEFINED. Support for Halting debug is optional. All debug components are optional.

If the Main Extension is implemented then support for DebugMonitor must be implemented. If the Main Extension is not implemented DebugMonitor is not supported.

ROM table entries identify which optional debug components are implemented.

The addresses of the optional debug resources are:

<table>
<thead>
<tr>
<th>Address range</th>
<th>Debug resource</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xE0000000-0xE0000FFF</td>
<td>Instrumentation Trace Macrocell (ITM)</td>
</tr>
<tr>
<td>0xE0001000-0xE0001FFF</td>
<td>Data Watchpoint and Trace unit (DWT) unit</td>
</tr>
<tr>

B11.1.4 Trace

RLJVL

Trace can be generated by using the:
- Embedded Trace Macrocell (ETM).
- Instrumentation Trace Macrocell (ITM), only available if the Main Extension is implemented.
- Data Watchpoint and Trace (DWT) unit, trace is only available if the Main Extension is implemented.

RNJSL

A debug implementation that generates trace must include a trace sink, such as a TPIU, which exports the trace data from the device.

A TPIU can be either the ARMv8-M TPIU implementation, or an external system resource.

<td>Adds ETM and TPIU.</td>
</tr>
</tbody>
</table>
B11.2 Accessing debug features

The mechanism by which an external debugger accesses the PE and system is IMPLEMENTATION DEFINED.

A debugger can use a Debug Access Port (DAP) interface, such as that provided by the ARM® Debug Interface v5 Architecture Specification (ADIv5), to interrogate a system for memory access ports (MEM-APs). The base register in a memory access port provides the address of the ROM table, or the first of a series of ROM tables in a ROM table hierarchy. The memory access port can then be used to fetch the ROM table entries. ARM recommends implementation of an ADIv5 DAP for compatibility with tools.

 Writes from a DAP are complete when the DAP reports them as complete.

For SCS registers, a write from a DAP is complete when the write has completed and the SCS register has been updated.

 Software configures and controls the debug model through memory-mapped registers.

See also:
- ROM table.
- DAP access permissions on page B11-198.
- The ARM® Debug Interface v5 Architecture Specification.

B11.2.1 ROM table

The ROM table is a table of entries providing a mechanism to identify the debug infrastructure that is supported by the implementation.

The ROM table indicates the implemented debug components, and the position of those components in the memory map. See the ARM® Debug Interface v5 Architecture Specification for the format of a ROM table entry.

For an ARMv8-M ROM table, all address offsets are negative.

The entry 0x00000000 is the end-of-table marker.

The ROM table must be implemented if any other debug component is implemented or a Debug Access Port is implemented.

Bit[0] of the ROM table entries indicates whether the corresponding debug component is implemented and is accessible through the PPB at the indicated address. If the corresponding debug component is not implemented, this bit has a value of 0.

If a debug component is implemented, debug registers can provide additional information about the implemented features of that debug component.

The format of the ROM table is:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Value</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x000</td>
<td>0xFFF0F003</td>
<td>ROMSCS</td>
<td>Points to the SCS at 0xE000E000.</td>
</tr>
<tr>
<td>0x004</td>
<td>0xFFF20002 or 0xFFF20003</td>
<td>ROMDWT</td>
<td>Points to the Data Watchpoint and Trace unit at 0xE0001000.</td>
</tr>
<tr>
<td>0x008</td>
<td>0xFFF30002 or 0xFFF30003</td>
<td>ROMFPB</td>
<td>Points to the Flash Patch and Breakpoint unit at 0xE0002000.</td>
</tr>
<tr>
<td>0x00C</td>
<td>0xFFF10002 or 0xFFF10003</td>
<td>ROMITM麻</td>
<td>Points to the Instrumentation Trace unit at 0xE0000000.</td>
</tr>
</tbody>
</table>
B11.2.2 Debug System registers

The debug provision in the System Control Block (SCB) comprises:

- Two handler-related flag bits, ICSR.ISRPREEMPT and ICSR.ISRPENDING.
- The DFSR.

</tbody>
</table>

See also:

- **CoreSight and identification registers on page B11-194.**

---

<sup>a.</sup> Accesses cannot cause a non-existent memory exception.

<sup>b.</sup> It is IMPLEMENTATION DEFINED whether a shared resource is managed by the local PE or a different resource.
See also:

- Chapter D1 Register Specification.
- Debug Control Block on page D1-808.

### B11.2.3 CoreSight and identification registers

**ICMLH**

ARM recommends that CoreSight-compliant ID registers are implemented to allow identification and discovery of the components to a debugger.

**RCBCM**

The address spaces that are reserved in each of the debug components for IMPLEMENTATION DEFINED ID registers and CoreSight compliance are:

<table>
<thead>
<tr>
<th>Debug component</th>
<th>Space reserved for ID registers</th>
<th>Space reserved for CoreSight compliance</th>
</tr>
</thead>
<tbody>
<tr>
<td>ITM</td>
<td>0xE000FD0-0xE000FFC</td>
<td>0xE000FA0-0xE000FCC</td>
</tr>
<tr>
<td>DWT</td>
<td>0xE001FD0-0xE001FFC</td>
<td>0xE001FA0-0xE001FCC</td>
</tr>
<tr>
<td>FPB</td>
<td>0xE002FD0-0xE002FFC</td>
<td>0xE002FA0-0xE002FCC</td>
</tr>
<tr>
<td>SCS</td>
<td>0xE003FD0-0xE003FFC</td>
<td>0xE003FA0-0xE003FCC</td>
</tr>
<tr>
<td>TPIU</td>
<td>0xE004FD0-0xE004FFC</td>
<td>0xE004FA0-0xE004FCC</td>
</tr>
<tr>
<td>ETM</td>
<td>0xE005FD0-0xE005FFC</td>
<td>0xE005FA0-0xE005FCC</td>
</tr>
<tr>
<td>ROM table</td>
<td>0xE006FD0-0xE006FFC</td>
<td>0xE006FA0-0xE006FCC</td>
</tr>
</tbody>
</table>

**RVWSX**

For the ROM table, the ID register space must be used for a set of CoreSight-compliant ID registers.

**RHXDK**

For all components other than the ROM table, if the registers in the ID register space are not used for ID registers they must be RAZ.

**RVQPM**

If CoreSight-compliant ID registers are implemented, the Class field in Component ID Register 1 must be:

- 0x1 for the ROM table.
- 0x9 for other components.

**IHQSR**

The Part number in the PIDR registers should be assigned a unique value for each implementation, as with all other CoreSight components.

CoreSight permits that two or more functionally different components are permitted to share the same Part number, so long as they have different values of the DEVTYPE or DEVARCH registers.

**ICTBF**

The Part number in the PIDR registers do not need to be unique for different implementation options of the same part.
B11.3 Debug authentication interface

The following pseudocode functions provide an abstracted description of the authentication interface:

- `ExternalInvasiveDebugEnabled()`.
- `ExternalSecureInvasiveDebugEnabled()`.
- `ExternalNoninvasiveDebugEnabled()`.
- `ExternalSecureNoninvasiveDebugEnabled()`.

For an implementation using the CoreSight signals `DBGEN`, `NIDEN`, `SPIDEN`, and `SPNIDEN`:

- `ExternalInvasiveDebugEnabled()` returns TRUE if `DBGEN` is asserted.
- `ExternalSecureInvasiveDebugEnabled()` returns TRUE if both `DBGEN` and `SPIDEN` are asserted.
- `ExternalNoninvasiveDebugEnabled()` returns TRUE if either `NIDEN` or `DBGEN` is asserted.
- `ExternalSecureNoninvasiveDebugEnabled()` returns TRUE if both of the following conditions apply:
  - Either `NIDEN` or `DBGEN` is asserted.
  - Either `SPNIDEN` or `SPIDEN` is asserted.

For any implementation of the authentication interface, if `ExternalInvasiveDebugEnabled()` is FALSE, then `ExternalSecureInvasiveDebugEnabled()` must be FALSE.

For any implementation of the authentication interface, if `ExternalNoninvasiveDebugEnabled()` is FALSE, then `ExternalSecureNoninvasiveDebugEnabled()` must be FALSE.

For any implementation of the authentication interface, if `ExternalInvasiveDebugEnabled()` is TRUE, then `ExternalNoninvasiveDebugEnabled()` must be TRUE.

For any implementation of the authentication interface, if `ExternalSecureInvasiveDebugEnabled()` is TRUE, then `ExternalSecureNoninvasiveDebugEnabled()` must be TRUE.

Secure self-hosted debug is controlled by the authentication interface. The pseudocode function `ExternalSecureSelfHostedDebugEnabled()` provides an abstracted description of this authentication interface.

Between a change to the debug authentication interface and a following Context synchronization event, it is UNPREDICTABLE whether the PE uses the old or the new values.

See also:
- `Halting debug authentication`.
- `DebugMonitor authentication` on page B11-196.
- `Non-invasive debug authentication` on page B11-197.
- `DAP access permissions` on page B11-198.

B11.3.1 Halting debug authentication

Halting debug authentication is controlled by the IMPLEMENTATION DEFINED authentication interface function `ExternalInvasiveDebugEnabled()`, and if the Security Extension is implemented, the IMPLEMENTATION DEFINED authentication interface function `ExternalSecureInvasiveDebugEnabled()`.

Halting is prohibited in all states if the function `ExternalInvasiveDebugEnabled()` returns FALSE.

When the PE is halted, the PE behaves as if `ExternalInvasiveDebugEnabled()` is TRUE. The pseudocode function `HaltingDebugAllowed()` describes this.
If the Security Extension is not implemented, there are two Halting debug authentication modes:

<table>
<thead>
<tr>
<th>ExternalInvasiveDebugEnabled()</th>
<th>DHCSR.S_HALT</th>
<th>Halting debug authentication mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>FALSE</td>
<td>0</td>
<td>Halting is prohibited</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>Halting is allowed</td>
</tr>
<tr>
<td>TRUE</td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

If the Security Extension is implemented, halting is prohibited in Secure state if any of:

- ExternalInvasiveDebugEnabled() returns FALSE.
- DAUTHCTRL.SPIDENSEL is set to 1 and DAUTHCTRL.INTSPIDEN is set to 0.
- DAUTHCTRL.SPIDENSEL is set to 0 and ExternalSecureInvasiveDebugEnabled() returns FALSE.

The pseudocode function SecureHaltingDebugAllowed() describes this.

If the Security Extension is implemented, DHCSR.S_SDE has a value of 0 if one or more of the following conditions are true:

- The PE is halted and the PE entered Debug state from Non-secure state when SecureHaltingDebugAllowed() was FALSE.
- The PE is not halted and SecureHaltingDebugAllowed() returns FALSE.

If the Security Extension is implemented, DHCSR.S_SDE has a value of 1 if any of the following conditions are true:

- The PE is halted and the PE entered Debug state from either:
  - Secure state.
  - Non-secure state when SecureHaltingDebugAllowed() was TRUE.
- The PE is not halted and SecureHaltingDebugAllowed() returns TRUE.

If the Security Extension is implemented, there are three Halting debug authentication modes:

<table>
<thead>
<tr>
<th>HaltingDebugAllowed()</th>
<th>DHCSR.S_SDE</th>
<th>Halting debug authentication mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>FALSE</td>
<td>X</td>
<td>Halting is prohibited.</td>
</tr>
<tr>
<td>TRUE</td>
<td>0</td>
<td>Halting is allowed in Non-secure state.</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>Halting is prohibited in Secure state.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Halting is allowed.</td>
</tr>
</tbody>
</table>

When DHCSR.C_DEBUGEN == 0 or the PE is in a state in which halting is prohibited, the PE must not enter Debug state.

When the PE is in a state in which halting is prohibited, if DHCSR.C_HALT == 1 and DHCSR.C_DEBUGEN == 1, then DHCSR.C_HALT remains set unless it is cleared by a direct write to DHCSR. If the PE enters a state in which halting is allowed while DHCSR.C_HALT is set to 1, then the PE enters Debug state.

See also:

- CanHaltOnEvent().

**B11.3.2 DebugMonitor authentication**

DebugMonitor authentication is only available if the Main Extension is implemented.

If the Security Extension is implemented, DebugMonitor authentication is controlled by the IMPLEMENTATION DEFINED authentication interface function ExternalSecureSelfHostedDebugEnabled().
If the Security Extension is implemented, DebugMonitor exceptions are never generated for secure operations if any of:

- \texttt{DAUTHCTRL.SPIDENSEL} is set to 1 and \texttt{DAUTHCTRL.INTSPIDEN} is set to 0.
- \texttt{DAUTHCTRL.SPIDENSEL} is set to 0 and \texttt{ExternalSecureSelfHostedDebugEnabled()} returns FALSE.

The pseudocode function \texttt{SecureDebugMonitorAllowed()} describes this.

If the Security Extension is implemented \texttt{DEMCR.SDME} is set to zero if any of:

- DebugMonitor is pending or active and \texttt{SecureDebugMonitorAllowed()} returned FALSE when DebugMonitor became pending or active.
- DebugMonitor is not pending and not active and \texttt{SecureDebugMonitorAllowed()} returns FALSE.

If the Security Extension is implemented \texttt{DEMCR.SDME} is set to one if any of:

- DebugMonitor is pending or active and \texttt{SecureDebugMonitorAllowed()} returned TRUE when DebugMonitor became pending or active.
- DebugMonitor is not pending and not active and \texttt{SecureDebugMonitorAllowed()} returns TRUE.

If the Security Extension is implemented, there are two DebugMonitor authentication modes, which are controlled by \texttt{DEMCR.SDME}:

<table>
<thead>
<tr>
<th>DEMCR.SDME</th>
<th>Target state for DebugMonitor exception</th>
<th>DebugMonitor authentication mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Non-secure</td>
<td>Non-secure DebugMonitor</td>
</tr>
<tr>
<td>1</td>
<td>Secure</td>
<td>Secure DebugMonitor</td>
</tr>
</tbody>
</table>

If the Security Extension is implemented and \texttt{DEMCR.SDME == 1}, \texttt{SHPR3_PRI_12} behaves as \texttt{RES0} when accessed from Non-secure state.

A direct write to \texttt{DEMCRI} can set \texttt{DEMCRI.MON_PEND} to 1 at any time to make the DebugMonitor exception pending or can set \texttt{DEMCRI.MON_PEND} to 0 to remove a pending DebugMonitor exception.

If the DebugMonitor group priority is greater than the current execution priority and \texttt{DEMCRI.MON_EN == 1}, an External debug request that does not generate an entry to Debug state sets \texttt{DEMCRI.MON_PEND} to 1.

When \texttt{DEMCRI.MON_PEND == 1}, the PE takes the DebugMonitor exception according to the exception prioritization rules, regardless of the value of \texttt{DEMCRI.SDME} and \texttt{DEMCRI.MON_EN}.

When set to 1, \texttt{DEMCRI.MON_PEND} remains set to 1 until either the DebugMonitor exception is taken or a write sets the field to 0.

- \texttt{CanPendMonitorOnEvent()}.

\textbf{B11.3.3 Non-invasive debug authentication}

Non-invasive authentication is controlled by the \texttt{IMPLEMENTATION DEFINED} function \texttt{ExternalNoninvasiveDebugEnabled()}, and if the Security Extension is implemented, the \texttt{IMPLEMENTATION DEFINED} function \texttt{ExternalSecureNoninvasiveDebugEnabled()}.

When \texttt{HaltingDebugEnabled()} is TRUE, the PE behaves as if \texttt{ExternalNoninvasiveDebugEnabled()} returns TRUE. The pseudocode function \texttt{NoninvasiveDebugEnabled()} describes this.

Non-invasive debug is prohibited if the function \texttt{NoninvasiveDebugEnabled()} returns FALSE.
**If the Security Extension is not implemented, there are two non-invasive debug authentication modes:**

<table>
<thead>
<tr>
<th>ExternalNoninvasiveDebugEnabled()</th>
<th>HaltingDebugAllowed()</th>
<th>Non-invasive debug authentication mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>FALSE</td>
<td>FALSE</td>
<td>Non-invasive debug prohibited</td>
</tr>
<tr>
<td>TRUE</td>
<td>TRUE</td>
<td>Non-invasive debug allowed</td>
</tr>
</tbody>
</table>

**If the Security Extension is implemented, non-invasive debug of Secure operations is prohibited if any of:**

- `NoninvasiveDebugAllowed()` returns FALSE.
- `DCHSR.S_SDE` is set to 0, `DAUTHCTRL.SPNIDENSEL` is set to 1 and `DAUTHCTRL.INTSPNIDEN` is set to 0.
- `DCHSR.S_SDE` is set to 0, `DAUTHCTRL.SPNIDENSEL` is set to 0 and `ExternalSecureNoninvasiveDebugEnabled()` returns FALSE.

The pseudocode function `SecureNoninvasiveDebugAllowed()` shows this.

**If the Security Extension is implemented, there are three non-invasive debug authentication modes:**

<table>
<thead>
<tr>
<th>NoninvasiveDebugAllowed()</th>
<th>SecureNoninvasiveDebugAllowed()</th>
<th>Non-invasive debug authentication mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>FALSE</td>
<td>FALSE</td>
<td>Non-invasive debug prohibited</td>
</tr>
<tr>
<td>TRUE</td>
<td>FALSE</td>
<td>Non-invasive debug of only Non-secure operations allowed. Non-invasive debug of Secure operations prohibited.</td>
</tr>
<tr>
<td>TRUE</td>
<td>TRUE</td>
<td>Non-invasive debug allowed</td>
</tr>
</tbody>
</table>

The PE must not generate any trace or profiling data when non-invasive debug is prohibited in all states.

If the Security Extension is implemented and non-invasive debug of Secure operations is prohibited, the PE must not generate any trace or profiling data that contains secure information.

If non-invasive debug is prohibited in the current Security state, an ETM must behave as if it is disabled.

- `NoninvasiveDebugAllowed()`.
- `SecureNoninvasiveDebugAllowed()`.
- `DWT unit operation` on page B12-220.

**DAP access permissions**

When `HaltingDebugAllowed()` returns TRUE, regardless of the value of `DHCSR.S_SDE`, the external debugger can access the whole physical address space.
If `HaltingDebugAllowed()` = FALSE the DAP access permissions are:

<table>
<thead>
<tr>
<th>Address range</th>
<th>Region or registers</th>
<th>NoninvasiveDebugAllowed()</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00000000-0xFFFFFFFF</td>
<td>Rest of memory</td>
<td>FALSE TRUE</td>
</tr>
<tr>

</tr>
</tbody>
</table>

a. For each debug component implementing the CoreSight Software Lock registers. These registers are optional.
b. For each debug component implementing the CoreSight ID registers. These registers are optional.

If the Security Extension is implemented, the DAP must be capable of requesting Secure and Non-secure accesses.

The architecture does not describe how a DAP requests Secure or Non-secure memory accesses. In the recommended ADIV5 Memory Access Port (MEM-AP), ARM recommends that:

- CSW[30], CSW.Prot[6], selects a Secure or Non-secure access:
  - 0 Request a Secure access.
  - 1 Request a Non-secure access.

- CSW[23], CSW.SPIDEN, is Read-As-One. This is because the DAP can always request a Secure access.

In a CoreSight DAP, the SPIDEN input to the ARMv8-M MEM-AP is independent of the SPIDEN input of the PE, and should be tied HIGH.

If the Security Extension is implemented, DHCSR.S_SDE == 1, and the DAP requests a Secure access, NS-Req is set to Secure.

If the Security Extension is implemented and either DHCSR.S_SDE == 0 or the DAP requests a Non-secure access, NS-Req set to Non-secure.
If the Security Extension is implemented, DAP accesses are checked by the IDAU and the SAU, if applicable. That is, if NS-Req on a DAP access specifies Non-secure access, and the IDAU or SAU prohibits Non-secure access to the address, an error response is returned to the DAP.

DAP accesses are not checked by the MPU.

If the Security Extension is implemented, permitted DAP accesses to banked SCS registers in the range 0xE000E000-0xE000EFFF are affected by the values of DHCSR.S_SDE, DSCSR.SBRSELEN, and DSCSR.SBRSEL, as well as by the current Security state of the PE. The following table shows the effect of these factors on the banked register that is accessed.

<table>
<thead>
<tr>
<th>DHCSR.S_SDE</th>
<th>DSCSR.SBRSELEN</th>
<th>DSCSR.SBRSEL</th>
<th>Current Security state of the PE</th>
<th>Banked register accessed</th>
</tr>
</thead>
<tbody>

<td>Secure</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Permitted DAP accesses to the region 0xE002E000-0xE002EFFF are RAZ/WI if the access is privileged and return an error if the access is unprivileged.
B11.4 Debug event behavior

B11.4.1 About debug events

An event that is triggered for debug reasons is known as a debug event.

A debug event that is not ignored causes one of the following to occur:

- If Halting debug is implemented, entry to Debug state.
- If the Main Extension is implemented, a DebugMonitor exception.
- A HardFault exception.
- An unrecoverable error.

The HardFault exceptions or unrecoverable errors that are caused by debug events are generated by:

- A \texttt{BKPT} instruction that is executed when the PE can neither halt nor generate a DebugMonitor exception.
- In some circumstances, the FPB.

The debug events are:

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
Debug event & Actions \\
\hline
Step & Halt or DebugMonitor \\
Halt request & Halt \\
Breakpoint & Halt, DebugMonitor, or HardFault \\
Watchpoint & Halt or DebugMonitor \\
Vector catch & Halt only \\
External & Halt or DebugMonitor \\
\hline
\end{tabular}
\caption{Table B11-2 Debug events}
\end{table}

The DFSR contains status bits for each debug event. These bits are set to 1 when a debug event causes the PE to halt or generate a DebugMonitor exception, and are then write-one-to-clear.

The following table shows which bit is set for each debug event.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
Event cause & DFSR bit \\
\hline
Step & HALTED \\
Halt request & HALTED \\
Breakpoint & BKPT \\
Watchpoint & DWTTRAP \\
Vector catch & VCATCH \\
External & EXTERNAL \\
\hline
\end{tabular}
\caption{Table B11-3 Debug events}
\end{table}

It is IMPLEMENTATION DEFINED whether the DFSR debug event bits are updated when an event is ignored.

Debug events are either synchronous or asynchronous.
The synchronous debug events are:

- Breakpoint debug events, caused by execution of a `BKPT` instruction or by a match in the FPB.
- Vector catch debug events, caused when one or more `DEMCR.VC_*` bits are set to 1, and the PE takes the corresponding exception.
- Step debug events, caused by `DHCSR.C_STEP` or `DEMCR.MON_STEP`.

A single instruction can generate several synchronous debug events.

Synchronous debug events are associated with the instruction that generated them and are taken instead of executing the instruction. The PE does not generate any other synchronous exception or debug event that might have occurred as a result of executing the instruction.

The Step debug event is taken on the instruction following the instruction being stepped. This means that prioritization of the event applies relative to any other exception or debug event for the following instruction, not for the instruction being stepped.

If multiple synchronous debug events and exceptions are generated on the same instruction, they are prioritized as follows:

1. Halt request (halting only), including where `DHCSR.C_HAL` is set by `DHCSR.C_STEP` of the previous instruction.
2. Highest-priority pending exception that is eligible to be taken. If the Main Extension is implemented, this might be a DebugMonitor exception, if `DEMCR.MON_PEND` == 1. This includes where `DEMCR.MON_PEND` is set by `DEMCR.MON_STEP` of the previous instruction.
3. Vector catch.
4. Fault from an instruction fetch, including synchronous BusFault error.
5. Breakpoint that is signaled by an FPB unit.
6. `BKPT` instruction or other exception that results from decoding the instructions. This includes the cases where exceptions from the instruction are UNDEFINED, an unimplemented or disabled coprocessor is targeted, or the `EPSR.T` bit has a value of 1.
7. Other synchronous exception that is generated by executing the instruction, including an exception that is generated by a memory access that is generated by the instruction.

The highest-priority synchronous debug event is reported in the DFSR.

It is UNPREDICTABLE whether synchronous debug events that occur on the same instruction as a debug event with a higher priority are reported in the DFSR.

The asynchronous debug events are:

- Watchpoint debug events caused by a match in the DWT, including instruction address match watchpoints.
- Halt request debug events, where either
  - A debugger write that has set `DHCSR.C_HAL` to 1 and `C_DEBUGEN` set to 1.
  - A software write that sets `DHCSR.C_HAL` to 1 when `C_DEBUGEN` was set to 1.
- External debug request debug events caused by assertion of an IMPLEMENTATION DEFINED external debug request.

When `DHCSR.C_DEBUGEN` == 0 or the PE is in a state in which halting is prohibited, `DHCSR.C_HAL` and `DHCSR.C_STEP` are ignored, and the PE behaves as if these bits are zero.

See also:

- Halting debug on page B11-203.
- DebugMonitor exception on page B11-204.
- Vector catch on page B11-208.
- BKPTIntrDebugEvent().
Halting debug

Setting the DHCSR.C_DEBUGEN bit to 1 enables Halting debug.

A debug event sets DHCSR.C_HALT to 1 if all of the following conditions apply:

- The debug event supports generating entry to Debug state and DHCSR.C_DEBUGEN == 1.
- Unless otherwise stated, halting is allowed.

If DHCSR.C_HALT has a value of 1 and halting is allowed, the PE halts and enters Debug state.

A debug event that sets DHCSR.C_HALT to 1 pends entry to Debug state.

If the Security Extension is implemented, a debug event might set DHCSR.C_HALT and remain pending through execution in Secure state, which might not be a finite time. If halting is prohibited in Secure state and allowed in Non-secure state, then on transition from Secure to Non-secure state by an exception entry, exception return, Non-secure function call or function return, if DHCSR.C_HALT has a value of 1, the PE must halt and enter Debug state before the first instruction executed in Non-secure state completes its execution.

If DHCSR.C_HALT has a value of 1 or EDBGRQ is asserted before a context synchronization event, and halting is allowed after the context synchronization event, then the PE must halt and enter Debug state before the first instruction following the context synchronization event completes its execution.

DFSR is updated at the same time as the PE sets DHCSR.C_HALT to 1.

If an instruction that is being stepped or an instruction that generates a debug event reads DFSR or DHCSR, the value that is read for the relevant DFSR bit or for DHCSR.C_HALT is UNKNOWN.

For asynchronous debug events, if halting is allowed, the PE must enter Debug state in finite time.

Entering Debug state has no architecturally defined effect on the Event Register and exclusive monitors.

DHCSR.C_SNAPSTALL allows imprecise entry into the Debug state, for example by forcing any stalled load or store instructions to be abandoned.

If DHCSR.C_DEBUGEN == 0 or HaltingDebugAllowed() == FALSE, DHCSR.C_SNAPSTALL is ignored and the PE behaves as if this bit is zero.

If the Security extension is implemented and if DHCSR.S_SDE == 0, DHCSR.C_SNAPSTALL ignores writes from the debugger.

Before leaving Debug state caused by an imprecise entry the system must be reset.

The PE is not permitted to report the PC (R15) as either EXC_RETURN or FNC_RETURN when in Debug state.

To transfer a word to a general-purpose register, to a Special-purpose register, or to a Floating-point Extension register, a debugger:

1. Writes the required word to DCRDR.
2. Writes to the DCRSR, with the REGSEL value indicating the required register, and the REGWnR bit set to one to indicate a write access. This clears the DHCSR.S_REGRDY bit to zero.
3. If required, polls DHCSR until DHCSR.S_REGRDY reads-as-one. This shows that the PE has transferred the DCRDR value to the selected register.

To transfer a word from a general-purpose register, Special-purpose register, or Floating-point Extension register, a debugger:

1. Writes to DCRSR, with the REGSEL value indicating the required register, and the REGWnR bit as zero to indicate a read access. This clears the DHCSR.S_REGRDY bit to zero.
2. Polls DHCSR until DHCSR.S_REGRDY reads-as-one. This shows that the PE has transferred the value of the selected register to DCRDR.
3. Reads the required value from DCRDR.
RQDCP
In Debug state, writing to DCRDR clears the DHCSR.S_REGRDY bit to zero, and the PE then sets the bit to 1 when the transfer between the DCRDR and R0 to R12, special-purpose register, or Floating-point Extension register completes.

RJKBB
When using this mechanism to write all bits of the XPSR registers are fully accessible. The effect of writing an illegal value is UNPREDICTABLE.

IRXQB
This mechanism differs from the behavior of MSR or MRS instruction accesses to the XPSR, where some bits are ignored on writes.

RQLRN
The debugger can write to the EPSR.IT/ICI bits. If the debugger does this, it must write a value consistent with the instruction to be executed on exiting Debug state, otherwise instruction execution will be UNPREDICTABLE.

IRRNFN
The debugger can always set FAULTMASK to one, but doing so might cause unexpected behavior on exit from Debug state. An MSR instruction cannot set FAULTMASK to 1 when the execution priority is -1 or higher.

RXRRQ
The debugger can write to the ESPR.ICI bits, and on exiting Debug state any interrupted LDM or STM instruction will use these new values. Clearing the ICI bits to zero will cause the interrupted LDM or STM instruction to restart or continue.

RRRTST
The Debugger can write to the DebugReturnAddress, and on exiting Debug state the PE starts executing from the updated address. The Debugger must ensure the EPSR.IT bits and the EPSR.ICI bits are consistent with the new DebugReturnAddress.

RGGMJ
DebugReturnAddress is the address of the first instruction to be executed on exit from Debug state. This address indicates the point in the execution stream where the debug event was invoked. For a breakpoint this is the address of the debug event was invoked. For all other debug events DebugReturnAddress is the address of the first instruction that both:

• In a simple sequential execution of the program, executes after the instruction that caused the debug event.
• Has not been executed, where the PE has executed all instructions that are earlier in a simple sequential execution of the program than the instruction indicated by DebugReturnAddress.

RXXCB
Bit[0] of a DebugReturnAddress value is RAZ/SBZ. When writing a DebugReturnAddress, writing bit [0] of the address does not affect the EPSR.T bit.

RVVJB
When the PE is in Debug state, an indirect write to a Special-purpose register caused by an access by the debugger to a register within the System Control Block on page D1-806 is guaranteed to be visible to a subsequent read of the Special-purpose register through DCRDR, if the corresponding write to DCRSR was made after the access to the register within the System Control Block completed.

RPXNX
A first write to a Special-purpose register made by the debugger through the DCRDR is guaranteed to be visible to a second read or write of any Special-purpose register through DCRDR, if the corresponding second write to DCRSR was made after the first write is observed to be completed in DHCSR.S_REGRDY.

• DHCSR, Debug Halting Control and Status Register on page D1-876.
• Debug stepping on page B11-205.
• DCRDR, Debug Core Register Data Register on page D1-863.
• DCRSR, Debug Core Register Select Register on page D1-864.

DebugMonitor exception

IDPCC
The DebugMonitor exception is only available if the Main Extension is implemented.

RZBSJ
The DebugMonitor exception is enabled when the DEMCR.MON_EN bit is set to 1.

RPPLF
A debug event sets DEMCR.MON_PEND to 1 if all of the following conditions apply:

• The debug event supports generating DebugMonitor exceptions and does not generate an entry to Debug state.
• DEMCR.MON_EN == 1.
• The DebugMonitor group priority is greater than the current execution priority.

If a Debug event does not generate an entry to Debug state, DEMCR.MON_EN is set to 1 and the DebugMonitor group priority is less than or equal to the current execution priority:
• The PE escalates a breakpoint debug event that is generated by executing a 
  BKPT instruction to a HardFault.
• There are UNPREDICTABLE circumstances in which the breakpoint generated by the FPB can be escalated to a HardFault.
• The PE might set DEMCR.MON_PEND to 1 for a watchpoint debug event.
• The PE ignores the other debug events.

A debug event that sets DEMCR.MON_PEND to 1 pends a DebugMonitor exception.

DEMCR.MON_PEND is cleared to 0 when the PE takes a DebugMonitor exception. This means that a value of 1 for DEMCR.MON_PEND might never be observed for a synchronous DebugMonitor exception.

DFSR is updated at the same time as the PE sets DEMCR.MON_PEND to 1.

If an instruction that is being stepped or that generates a debug event reads DFSR or DEMCR, the value that is read for the relevant DFSR bit or for DEMCR.MON_PEND is UNKNOWN.

For asynchronous debug events, if taken as a DebugMonitor exception, and if the current priority is lower than the DebugMonitor group priority, a DebugMonitor exception must be taken in finite time.

See also:
• DWT unit operation on page B12-220.
• FPB unit operation on page B12-236.

B11.4.2 Debug stepping

The ARMv8-M architecture supports debug stepping in both Halting debug and monitor debug.

It is IMPLEMENTATION DEFINED whether stepping a WFE or WFI instruction causes the WFE or WFI instruction to:
• Retire and take the debug event.
• Go into a sleep state and take the debug event only when another wake up event occurs.

If a debug event wakes a WFE or WFI instruction, then on taking the debug event, the instruction has retired.

See also:
• Halting debug stepping.
• Debug monitor stepping on page B11-207.

Halting debug stepping

A debugger can use Halting debug stepping to exit from Debug state, execute a single instruction, and then reenter Debug state.

Halting debug stepping is active when all of the following apply:
• DHCSR.C_DEBUGEN is set to 1, Halting debug is enabled, and halting is allowed.
• DHCSR.C_STEP is set to 1, halting stepping is enabled.
• The PE is in Non-debug state.
When the PE exits Debug state and Halting debug stepping becomes active, the PE performs a Halting debug step as follows:

1. Performs one of the following:
   - Completes the next instruction without generating any exception.
   - Takes any pending exception entry of sufficient priority, without completing the next instruction. The PE performs an exception entry sequence that stacks the next instruction context. This context might include instruction continuation bits if the next instruction was partly executed and supports instruction resume. The exception might be a pending exception, or an exception generated by the execution of the next instruction.
   - Completes the execution of the next instruction, and then takes any pending exception of sufficient priority. The PE performs an exception entry sequence that stacks the following instruction context.
   - If the next instruction is an exception return instruction, completes the next instruction, tail-chaining to enter a new exception handler.

   In each case where the PE performs an exception entry sequence it does so according to the exception priority and late-arrival rules, meaning derived and late-arriving exceptions might preempt the exception entry sequence.

   The exception behavior is not recursive. Only a single PushStack() update can occur in a step sequence.

2. Sets DFSR.HALTED and DHCSR.C_HALT to 1. A read of the DFSR.HALTED or the DHCSR.C_HALT bit performed by the stepped instruction returns an UNKNOWN value.

3. After the Halting debug step, before executing the following instruction, because DHCSR.C_HALT is set the PE will halt and enter Debug state if halting is still allowed. However, if halting is prohibited after the Halting debug step then the PE does not enter Debug state and DHCSR.C_HALT remains set.

The debugger can optionally set the DHCSR.C_MASKINTS bit to 1 to prevent PendSV, SysTick, and external configurable interrupts from being taken. When DHCSR.C_MASKINTS is set to 1, if a permitted exception becomes active, the PE steps into the exception handler and halts before executing the first instruction of the associated exception handler.

If DHCSR.C_DEBUGEN == 0 or HaltingDebugAllowed() == FALSE, DHCSR.C_MASKINTS is ignored and the PE behaves as if this bit is zero.

If the Security Extension is implemented and if DHCSR.S_SDE == 0, DHCSR.C_MASKINTS is ignored for exceptions targeting Secure state.

DHCSR.{C_HALT, C_STEP, C_MASKINTS} can be written in a single write to DHCSR, as follows:

<table>
<thead>
<tr>
<th>DHCSR write</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>C_HALT C_STEP C_MASKINTS</td>
<td>Exit Debug state and start instruction execution. Exceptions can become active.</td>
</tr>
<tr>
<td>0 0 0</td>
<td>Exit Debug state and start instruction execution. PendSV, SysTick and, external configurable interrupts are disabled, otherwise exceptions can become active.</td>
</tr>
<tr>
<td>0 0 1</td>
<td>Exit Debug state, step an instruction and halt. Exceptions can become active.</td>
</tr>
<tr>
<td>0 1 0</td>
<td>Exit Debug state, step an instruction and halt. PendSV, SysTick and, external configurable interrupts are disabled, otherwise exceptions can become active.</td>
</tr>
<tr>
<td>0 1 1</td>
<td>Exit Debug state, step an instruction and halt. PendSV, SysTick and, external configurable interrupts are disabled, otherwise exceptions can become active.</td>
</tr>
<tr>
<td>1 X X</td>
<td>Remain in Debug state</td>
</tr>
</tbody>
</table>
When `DHCSR.C_DEBUGEN` is 1 and `DHCSR.S_HALT` is 0, meaning the PE is in Non-debug state with Halting debug enabled, the effect of modifying `DHCSR.C_STEP` or `DHCSR.C_MASKINTS` is UNPREDICTABLE.

When `DHCSR.C_DEBUGEN` is 0, the PE ignores the values of `DHCSR.C_HALT`, `DHCSR.C_STEP` and `DHCSR.C_MASKINTS`, and these values are UNKNOWN on `DHCSR` reads.

### Debug monitor stepping

A debugger can use debug monitor stepping to return from the DebugMonitor exception handler, execute a single instruction, and then reenter the DebugMonitor exception handler.

Debug monitor stepping is active when all of the following apply:
- `DHCSR.C_DEBUGEN` is set to 0 or the PE is in a state in which halting is prohibited.
- `DEMCR.MON_EN` is set to 1, that is monitor debug is enabled.
- `DEMCR.MON_STEP` is set to 1, that is monitor stepping is enabled.
- `DEMCR.SDME` == 1 or the instruction was executed in Non-secure state or the exception was taken from Non-secure state.
- Execution priority is below the priority of the DebugMonitor exception when the instruction was executed or below the exception taken.

When the PE returns from an exception and debug monitor stepping becomes active, the PE performs a debug monitor step by one of the following:
- Completing the next instruction.
- Taking an exception without completing the next instruction.

If the PE completes the next instruction, it performs the debug monitor step as follows:
1. If the PE executes the next instruction the PE performs one of the following:
   - Executes the next instruction without generating any exception.
   - Executes a SVC instruction generating an SVCall exception.
   - Executes an exception return instruction, tail-chaining to enter a new exception handler according to the normal exception priority and late-arrival rules.
2. If the PE performs an exception entry as part of the execution of the next instruction, it stacks the following instruction context.
3. Sets `DEMCR.MON_PEND` and `DFSR.HALTED` bits to one. A read of `DEMCR.MON_PEND` or `DFSR.HALTED` bit by the stepped instruction returns an UNKNOWN value.

If the PE takes an exception without completing the next instruction it performs the debug monitor step as follows:
1. If the PE takes an exception without completing the next instruction the PE performs one of the following:
   - Takes a pending exception with sufficient priority without executing the next instruction.
   - Starts execution of the next instruction, generating a synchronous exception other than an SVCall exception.
2. The PE performs an exception entry sequence that stacks the next instruction context. This context might include instruction continuation bits if the next instruction was partly executed and supports instruction resume.
3. If the execution priority is below the priority of the DebugMonitor exception after taking the exception, sets `DEMCR.MON_PEND` and `DFSR.HALTED` bits to one.

After the debug monitor step, before executing the following instruction, the PE takes any pending exception with sufficient priority. If the debug monitor step sets `DEMCR.MON_PEND` to one, this might be the DebugMonitor exception. However, if any exceptions other than the DebugMonitor exception are pending, the normal rules for exception prioritization apply. This means that another exception with a higher priority than the DebugMonitor exception might preempt execution.
In all other cases, the DebugMonitor exception preemption execution returns control to the DebugMonitor handler. Unless that handler clears DEMCR.MON_STEP to 0, returning from the handler performs the next debug monitor step.

If, after the debug monitor stepping process, the taking of an exception means that the execution priority is no longer below that of the DebugMonitor exception, the values of DEMCR.MON_STEP and DEMCR.MON_PEND mean that debug monitor stepping process continues when execution priority falls back below the priority of the DebugMonitor exception.

### B11.4.3 Vector catch

Vector catch is the mechanism for generating a debug event and entering Debug state on entry to a particular exception handler or reset.

Vector catching is only supported by Halting debug.

The conditions for a vector catch, other than reset vector catch, are:

- DHCSR.C_DEBUGEN == 1 and halting is allowed.
- The associated vector catch enable bit, one of DEMCR[11:4] in the Main Extension or DEMCR[10] without the Main Extension, is set to 1.
- An exception is taken to the relevant exception handler. The associated fault status register status bit is set to 1.

When these conditions are met, the PE sets DHCSR.C_HALT to 1 and enters Debug state before executing the first instruction of the exception handler.

Late arrival and derived exceptions might occur, postponing when the PE halts.

If the Security Extension is implemented, then when DHCSR.C_DEBUGEN == 0 or the PE is in a state in which halting is prohibited, all DEMCR.VC_* bits, other than DEMCR.VC_CORERESET, are ignored.

If debug is enabled, DHCSR.C_DEBUGEN == 1, and DEMCR.VC_CORERESET == 1 when the PE resets, the PE pends a Vector Catch debug event, even if the Security Extension is implemented, debug is prohibited in Secure state, and the PE has reset into Secure state. The PE does not halt until either it enters Non-secure state or debug is allowed in Secure state.

See also:

- Exception numbers and exception priority numbers on page B3-47.
- Exceptions during exception entry on page B3-79.
- Exceptions during exception return on page B3-80.
- Resets, Cold reset and Warm reset on page B1-32.

### B11.4.4 Breakpoint instructions

If the Security Extension is implemented, then is when DHCSR.C_DEBUGEN == 0 or when the PE is in a state in which halting is prohibited, the BKPT instruction does not generate an entry to Debug state. If no DebugMonitor exception is generated, the BKPT instruction generates a HardFault exception or enters Lockup state.

A BKPT instruction halts the PE if all of the following conditions apply:

- HaltingDebugAllowed() == TRUE.
- DHCSR.C_DEBUGEN == 1.
- The Security Extension is not implemented, the instruction is executed in Non-secure state, or DHCSR.S_SDE == 1.

A BKPT instruction generates a DebugMonitor exception if it does not halt the PE and all of the following conditions apply:

- DEMCR.MON_EN == 1.
• The DebugMonitor group priority is greater than the current execution priority.
• The Security Extension is not implemented, the instruction is executed in Non-secure state, or \texttt{DEMCR.SDME == 1}.

### B11.4.5 External debug request

**\texttt{RXZCP}** When the PE is in Non-debug state, an external agent can signal an external debug request.

**\texttt{RGTX}** An external debug request can cause a debug event, that causes either:
- Entry to Debug state.
- If the Main Extension is implemented, a DebugMonitor exception.

**\texttt{RFGCV}** The PE ignores external debug requests when it is in Debug state.

**\texttt{RBXRD}** If the Security Extension is implemented, then when \texttt{DHCSR.C_DEBUGEN == 0} or the PE is in a state in which halting is prohibited, an External debug request does not generate an entry to Debug state and is ignored if no DebugMonitor exception is generated.

See also:
- *Debug event behavior* on page B11-201.
- *DFSR.EXTERNAL.*
B11.5 Exiting Debug state

RMQWL  The PE exits Debug state:
  • When the debugger writes 0 to DHCSR.C_HALT.
  • On receipt of an external restart request.

RHKKB  Exiting Debug state has no architecturally defined effect on the Event Register and exclusive monitors.

RWKSD  If software clears DHCSR.C_HALT to 0 when the PE is in Debug state, a subsequent read of the DHCSR that returns 1 for both DHCSR.C_HALT and DHCSR.S_HALT indicates that the PE has reentered Debug state because it has detected a new debug event.
B11.6 Multiprocessor support

Systems that support debug of more than one PE, either within a single device or as heterogeneous PEs in a more complex system, require each PE to support all of the following to enable cross-triggering of debug events between PEs:

- An external debug request.
- A cross-halt event.
- An external restart request.

Support for these features is OPTIONAL in other systems.

B11.6.1 Cross-halt event

When the PE enters Debug state, it signals to an external agent that it is entering Debug state.

B11.6.2 External restart request

When the PE is in Debug state, an external agent can signal an external restart request that causes the PE to exit Debug state.

An external restart request is not ordered with respect to accesses to memory-mapped registers. It is UNPREDICTABLE whether an access to a memory-mapped register from a DAP completes before an external restart request. Therefore, a debugger must ensure that any read or write of a memory-mapped register by the DAP completes before issuing an external restart request.

The PE ignores external restart requests when it is in Non-debug state.

B12.1 Instrumentation Trace Macrocell

See also:
• Data Watchpoint and Trace unit on page B12-220.

B12.1.1 About the ITM

The Instrumentation Trace Macrocell (ITM) provides a memory-mapped register interface that applications can use to generate Instrumentation packets.

The ITM is only available if the Main Extension is implemented.

The ITM generates Instrumentation packets, Synchronization packets, and the following protocol packets:
• Overflow packets.
• Local timestamp packets.
• Global timestamp packets.
• Extension packets.

The ITM combines the following packets into a single trace stream:
• Instrumentation packets.
• Synchronization packets.
• Protocol packets.
• Hardware source packets that are generated by the DWT.

The following figure shows how the ITM relates to other debug components.

When multiple sources are generating data at the same time, the ITM arbitrates using the following priorities:

**Synchronization, when required**

- Priority level -1, highest.

**Instrumentation**

- Priority level 0.

**Hardware source**

- Priority level 1.

**Local timestamps**

- Priority level 2.

**Global timestamp 1**

- Priority level 3.

**Global timestamp 2**

- Priority level 4.

See also:
• Global timestamping on page B12-217.
• Data Watchpoint and Trace unit on page B12-220.
• Chapter F1 ITM and DWT Packet Protocol Specification.
B12.1.2 ITM operation

The ITM consists of:
• Up to 256 stimulus port registers, ITM_STIM<n>.
• Up to eight enable registers, ITM_TER<n>.
• An access control register, ITM_TPR.
• A general control register, ITM_TCR.

The number of ITM_STIM<n> registers is an IMPLEMENTATION DEFINED multiple of eight. Software can discover the number of supported stimulus ports by writing all ones to the ITM_TPR, and then reading how many bits are set to 1.

If the ITM is disabled or not implemented, any Secure or Non-secure write to ITM_STIM<n> is ignored.

Unprivileged and privileged software can always read all ITM registers. If the ITM is not implemented, these registers are RAZ/WI.

The ITM_TPR defines whether each group of eight ITM_STIM<n> registers, and their corresponding ITM_TER<n> bits, can be written by an unprivileged access.

ITM_STIM<n> registers are 32-bit registers that support the following word-aligned accesses:
• Byte accesses, to access register bits[7:0].
• Halfword accesses, to access register bits[15:0].
• Word accesses, to access register bits[31:0].

Non-word-aligned accesses are UNPREDICTABLE.

ITM_TCR.ITMENA is a global enable bit for the ITM. A Cold reset clears this bit to 0, disabling the ITM.

The ITM_TER<n> registers provide an enable bit for each stimulus port.

When software writes to an enabled ITM_STIM<n> register, the ITM combines the identity of the port, the size of the write access, and the data that is written, into an Instrumentation packet that it writes to a stimulus port output buffer. The ITM transmits packets from the output buffer to a trace sink.

If DEMCR.TRCENA == 0 or NoninvasiveDebugAllowed() == FALSE, the ITM does not generate trace.

The size of the stimulus port output buffer is IMPLEMENTATION DEFINED, but must have at least one entry. The stimulus port output buffer is shared by all ITM_STIM<n> registers.

When the stimulus port output buffer is full, if software writes to any ITM_STIM<n> register, the ITM discards the write data, and generates an Overflow packet.

Reading the ITM_STIM<n> register of any enabled stimulus port returns a value indicating the output buffer status and that the port is enabled.

Reading an ITM_STIM<n> register when the ITM is disabled, or when the individual stimulus port is disabled in the corresponding ITM_TER<n> register, returns the value indicating that the output buffer cannot accept data because the port is disabled.

Hardware source packets that are generated by the DWT unit use a separate output buffer. The output buffer status that is obtained by reading an ITM_STIM<n> register is not affected by trace that is generated by the DWT unit.

Stalling is supported through an optional control, ITM_TCR.STALLENA. When implemented and set to 1, the ITM can stall the PE to guarantee delivery of data trace packets.

Stalling does not affect the DWT counters.

The ITM might generate an Overflow packet while the PE is stalled, if the DWT generates:
• A Hardware source packet other than a Data trace packet.
• A Data trace PC value packet or Data trace match packet from a Cycle Counter comparator.
The ITM must not stall the PE in Secure state if `SecureHaltingDebugAllowed()` == FALSE.

The ITM must not stall the PE if `HaltingDebugAllowed()` == FALSE.

The ITM must not stall the PE in such a way as to deadlock the system.

The ITM must not stall the PE if the trace output is disabled.

The ITM must not stall for writes to the `ITM_STIM<n>` registers.

Instrumentation trace packets must appear in the trace output in the order in which writes arrive at the `ITM_STIM<n>` registers.

It is IMPLEMENTATION DEFINED whether an ITM requires flushing of trace data to guarantee that data is output.

If periodic flushing is required, the ITM must flush trace data:

- When a Synchronization packet is generated.
- When trace is disabled, meaning that either `DEMCR.TRCENA` is cleared to 0 or one or more of `ITM_TCR.{TXENA, SYNCENA, TSENA, SYNCENA}` is cleared to 0, and the buffered trace includes at least one corresponding packet type.
- In response to other IMPLEMENTATION DEFINED flush requests from the system.

If a system supports multiple trace streams, the debugger must write a unique nonzero trace ID value to the `ITM_TCR.TraceBusID` field. The system uses this value to identify the ITM and DWT trace stream. To avoid trace stream corruption, before modifying the `ITM_TCR.TraceBusID` a debugger must:

- Clear the `ITM_TCR.ITMENA` bit to zero, to disable the ITM.
- Poll the `ITM_TCR.BUSY` bit until it returns to zero, indicating that the ITM is inactive.

### B12.1.3 Timestamp support

Timestamps provide information on the timing of event generation regarding their visibility at a trace output port.

An ARMv8-M PE can implement either or both of the following types of timestamp:

- Local timestamps.
- Global timestamps.

### Local timestamping

Local timestamps provide delta timestamp values, meaning each local timestamp indicates the elapsed time since generating the previous local timestamp.

The ITM generates the local timestamps from the timestamp counter in the ITM unit.

The timestamp counter size is an IMPLEMENTATION DEFINED value that must be less than or equal to 28 bits.

It is IMPLEMENTATION DEFINED whether the ITM supports synchronous clocking of the timestamp counter mode.

It is IMPLEMENTATION DEFINED whether the ITM and TPIU support asynchronous clocking of the timestamp counter mode.

`ITM_TCR.TSENA` enables Local timestamp packet generation.

When local timestamping is enabled and the DWT or ITM transfers a Hardware source or instrumentation trace packet to the appropriate output FIFO, and the timestamp counter is non-zero, the ITM:

- Generates a Local timestamp packet.
- Resets the timestamp counter to zero.
If the timestamp counter overflows, it continues counting from zero and the ITM generates an Overflow packet and transmits an associated Local timestamp packet at the earliest opportunity. If higher priority trace packets delay transmission of this Local timestamp packet, the timestamp packet has the appropriate non-zero local timestamp value.

The ITM can generate a Local timestamp packet relating to a single event packet, or to a stream of back-to-back packets if multiple events generate a packet stream without any idle time.

Local timestamp packets include status information that indicates any delay in one or both of:
- Transmission of the timestamp packet relative to the corresponding event packet.
- Transmission of the corresponding event packet relative to the event itself.

If the ITM cannot generate a Local timestamp packet synchronously with the corresponding event packet, the timestamp count continues to increment until the ITM can generate a Local timestamp packet.

The ITM compresses the count value in the timestamp packet by removing leading zeroes, and transmits the smallest packet that can hold the required count value.

See also:
- Local timestamp clocking options.

**Local timestamp clocking options**

If the implementation supports both synchronous and asynchronous clocking of the local timestamp counter, ITM_TCR.SWOENA selects the clocking mode.

When software selects synchronous clocking, when local timestamping is enabled, the PE clock drives the timestamp counter, and the counter increments on each PE clock cycle.

When software selects synchronous clocking, whether local timestamps are generated in Debug state is IMPLEMENTATION DEFINED. ARM recommends that entering Debug state must disable local timestamping, regardless of the value of the ITM_TCR.TSENA bit.

When software selects asynchronous clocking, and enables local timestamping, the TPIU output interface clock drives the timestamp counter, through a configurable prescaler. The rate of asynchronous clocking depends on the output encoding scheme. This clock might be asynchronous to the PE clock.

When asynchronous clocking is implemented, whether the incoming clock signal can be divided before driving the local timestamping counter is IMPLEMENTATION DEFINED.

If the implementation supports division of the incoming asynchronous clock signal, ITM_TCR.TSPrescale sets the prescaler divide value.

Software must only select asynchronous clocking when the TPIU is configured to use an output mode that supports asynchronous clocking.

When software selects asynchronous clocking and the TPIU asynchronous interface is idle, the ITM holds the timestamp counter at zero. This means that the ITM does not generate a local timestamp on the first packet after an idle on the asynchronous interface.

See also:
- Trace Port Interface Unit on page B12-235.

**Global timestamping**

Global timestamps provide absolute timestamp values, which are based on a system global timestamp clock. They provide synchronization between different trace sources in the system.
If an implementation includes global timestamping, the ITM generates *Global timestamp* (GTS) packets, which are based on a global timestamp clock.

The size of the global timestamp is either 48 bits or 64 bits. The choice between these two options is **IMPLEMENTATION DEFINED**.

To transfer the global timestamp, two formats of Global timestamp packets are defined:

- The first packet format, Global timestamp 1 packet, holds the value of the least significant timestamp bits[25:0], and wrap and clock change indicators.
- The second packet format, Global timestamp 2 packet, holds the value of the high-order timestamp bits:
  - Bits[47:26], if a 48-bit global timestamp is supported.
  - Bits[63:26], if a 64-bit global timestamp is supported.

The global timestamp that is generated by the ITM must be a full global timestamp:

- When software first enables global timestamps, by changing the value of the ITM_TCR.GTSFREQ field from zero to a nonzero value.
- When the system asserts the clock ratio change signal in the external ITM timestamp interface.
- In response to a Synchronization packet request, even if ITM_TCR.SYNCENA == 0 meaning it does not generate a Synchronization packet.
- If, when it has to generate a global timestamp, it detects that the values of the high-order bits of the global timestamp have changed.

If the global timestamp generated by the ITM does not have to be a full global timestamp, the ITM generates only a single Global timestamp 1 packet. The ITM might compress the packet by omitting significant bits, if they are unchanged from the previous timestamp value.

When the ITM must generate a full global timestamp:

1. The ITM first generates the Global timestamp 1 packet with timestamp bits[25:0], with the applicable bit of the Wrap and ClockCh bits in that packet set to 1 to indicate that the high-order bits of the timestamp will also be output. This is the packet that the ITM outputs immediately after a non-delayed trace packet.
2. Because of packet prioritization, the ITM might have to transmit other trace packets before it can output the Global timestamp 2 packet that contains the high-order bits of the timestamp. It might also have to transmit another Global timestamp packet. If so, it outputs the Global timestamp 1 packet with timestamp bits[25:0] and the Wrap bit set to 1.
3. The ITM later generates the Global timestamp 2 packet with the high-order timestamp bits for the most recently transmitted Global timestamp 1 packet.

See also:

- *Synchronization support*.
- *Continuation bits on page B12-219*.
- *Chapter F1 ITM and DWT Packet Protocol Specification*.

### B12.1.4 Synchronization support

An external debugger uses *Synchronization packets* to recover bit-to-byte alignment information in a serial data stream.

Synchronization packets are independent of timestamp packets.

ARM recommends that software disables Synchronization packets when using an asynchronous serial trace port, to reduce the data stream bandwidth.

If ITM_TCR.SYNCENA == 1, the ITM outputs a Synchronization packet:

- When it is first enabled.
• If DWT_CYCCNT is implemented and DWT_CTRL.SYNCTAP is nonzero, in response to a
  Synchronization packet request from the DWT unit.
• If TPIU_PSCR is implemented, in response to a Synchronization packet request from the TPIU:
  — If DWT_CYCCNT is not implemented, TPIU_PSCR must be implemented.
  — If DWT_CYCCNT is implemented, it is IMPLEMENTATION DEFINED whether TPIU_PSCR is
    implemented.
• In response to other IMPLEMENTATION DEFINED Synchronization packet requests from the system.

See also:
• DWT_CTRL.SYNCTAP.

### B12.1.5 Continuation bits

| IBFMX | A Synchronization packet consists of a bit stream of at least 47 zero bits followed by a one bit. The final bit is the
| RJNVH | byte alignment marker, and therefore bit [7] of the last byte of a Synchronization packet is always one.
| RXFTL | The longest Extension packet is always 5 bytes. In an Extension packet, bit [7] of each byte, including the header
| RBBSF | byte, but not including the last byte of a 5-byte packet, is a continuation bit, C. Bit [7] of the last byte of a 5-byte
| RDPJG | Extension packet is part of the extension field. Bit [7] of the last byte of a fewer-than-5-byte Extension packet is
|       | always zero.
|       | For all other protocol packets, bit [7] of each byte, including the header byte, but not including the last byte of a
|       | 7-byte packet, is a continuation bit, C. Bit [7] of the last byte of a packet is always zero.
|       | The continuation bit, C, is defined as:
|       | 0  This is the last byte of the packet.
|       | 1  This is not the last byte of the packet.
B12.2 Data Watchpoint and Trace unit

B12.2.1 About the DWT

The Data Watchpoint and Trace (DWT) unit provides the following features:

- Comparators that support:
  - Use as a single comparator for instruction address matching or data address matching.
  - Use in linked pairs for instruction address range matching or data address range matching.
- Generation, on a comparator match, of:
  - A debug event that causes the PE either to enter Debug state or, if the Main Extension is implemented, to take a DebugMonitor exception.
  - Signaling a match to an ETM, if implemented.
  - Signaling a match to another external resource.
- External PC sampling using a PC sample register.

If the Main Extension is implemented, the DWT provides the following features:

- An optional cycle counter.
- Comparators that support:
  - Use as a single comparator for cycle counter matching, if the cycle counter is implemented.
  - Use as a single comparator for data value matching.
  - Use in linked pairs for data value matching at a specific data address.

If the Main Extension and the ITM are implemented, the DWT provides the following trace generation features:

- Generating one or more trace packets on a comparator match.
- Generating periodic trace packets for software profiling.
- Exception trace.
- Performance profiling counters that generate trace.

If DWT_CTRL.NOTRCPKT is 1, there is no DWT trace support.

If DWT_CTRL.NOCYCCNT is 1, there is no cycle counter support.

If DWT_CTRL.NOPRFCNT is 1, there is no profiling counter support.

The DWT_CTRL.NUMCOMP field indicates the number of implemented DWT comparators, which must be in the range 0-15.

If the Main Extension is not implemented, Cycle counter, Data value, Linked data value, and Data address with value comparators and all trace features are not supported.

Data trace packets are only generated for comparators 0-3.

When a DWT implementation includes one or more comparators, which comparator features are supported, and by which comparators, is IMPLEMENTATION DEFINED.

B12.2.2 DWT unit operation

For each implemented comparator, a set of registers defines the comparator operation. For comparator $n$:

- $\text{DWT\_COMP}<n>$ holds a value for the comparison.
- $\text{DWT\_FUNCTION}<n>$ defines the operation of the comparator.

A Secure match is a match that is generated by:

- Vector fetches where NS-Req has a value of Secure for the operation.
• The hardware stacking or unstacking of registers, where NS-Req has a value of Secure for the operation, on any of:
  — Exception entry.
  — Exception exit.
  — Function call entry.
  — Function return.
  — Lazy state preservation.
• When the Main Extension is implemented, a cycle counter match in Secure state if DWT_CTRL.CYCDISS == 1.
• An operation that is generated by an instruction that is executed in Secure state, including:
  — An Instruction address match for an instruction that is executed in Secure state.
  — A Data address or Data value match for a load or store that is generated by an instruction that is executed in Secure state.

RMGGT For a comparator <n>, all matches are prohibited if one or more of the following conditions apply:
• DEMCR.TRCENA == 0 or NoninvasiveDebugAllowed() == FALSE.
• DWT_FUNCTION.ACTION specifies a debug event and all the following conditions apply:
  — HaltingDebugAllowed() == FALSE or DHCSR.C_DEBUGEN == 0.
  — The Main Extension is not implemented or DEMCR.MON_EN == 0.

RGFLN If the Security Extension is implemented, Secure matches are prohibited for a comparator if one of the following conditions applies:
• DWT_FUNCTION.ACTION specifies a trace or trigger event and SecureNoninvasiveDebugAllowed() == FALSE.
• DWT_FUNCTION.ACTION specifies a debug event and all of the following conditions apply:
  — DHCSR.S_SDE == 0.
  — The Main Extension is not implemented or DEMCR.SDME == 0.

RHCFP For address and value comparisons, the control register values and the current execution priority and Security state relate to the state of the PE when it generated the transaction that is being matched against.

RMVFK Between a change to the debug authentication interface, DHCSR or DEMCR, that disables debug and a following Context synchronization event, it is UNPREDICTABLE whether the DWT uses the old values or the new values.

RVTNJ Where the DWT operation rules prohibit a match being generated, a match must not be generated, even if the programmer’s model defines it as being UNPREDICTABLE whether a comparator generates a match as the result of the way in which the DWT is programmed.

RPKRK If DEMCR.TRCENA == 0 or NoninvasiveDebugAllowed() == FALSE, DWT_CTRL.FOLDEVTENA, DWT_CTRL.LSUEVTENA, DWT_CTRL.SLEEPEVTENA, DWT_CTRL.EXCEVTENA, and DWT_CTRL.CPIEVTENA are ignored, and the PE behaves as if they have a value of zero.

RGDMN If DEMCR.TRCENA == 0 or NoninvasiveDebugAllowed() == FALSE, the DWT does not generate any trace packets.

RFHWV If the Security Extension is implemented and SecureNoninvasiveDebugAllowed() == FALSE, DWT_CTRL.FOLDEVTENA, DWT_CTRL.LSUEVTENA, DWT_CTRL.SLEEPEVTENA, DWT_CTRL.EXCEVTENA, and DWT_CTRL.CPIEVTENA are ignored and the PE behaves as if they have a value of zero in Secure state.

RWSRR If the Security Extension is implemented and SecureNoninvasiveDebugAllowed() == FALSE, Exception trace packets are not generated if the exception number in the packet represents a Secure exception:
• Exception entry packets are not generated for exceptions that are taken to Secure state.
• Exception exit packets are not generated for exits from Secure state.
• Exception return packets are not generated for returns to Secure state.
Exception trace packets must appear in the same order as for a simple sequential execution of the exception handling.

The cycle counter, DWT_CYCCNT, and the POSTCNT counter are disabled when DEMCR.TRCENA == 0, but are not otherwise affected by debug authentication.

If the Security Extension is implemented, the cycle counter does not count in Secure state when DWT_CTRL.CYCDISS is set to 1. This is independent of Secure debug authentication.

When the DWT generates a match, DWT_FUNCTION.MATCHED is set to 1, unless the comparator is a Data address limit or Instruction address limit comparator, in which case DWT_FUNCTION.MATCHED is UNKNOWN.

When the DWT generates a match, then if DWT_FUNCTION.ACTION specifies a debug event, then DHCSR.C_HALT is set to 1 if all of the following conditions are true:

- HaltingDebugAllowed() == TRUE.
- DHCSR.C_DEBUGEN == 1.
- DHCSR.S_HALT == 0.
- Either the match is not a Secure match or DHCSR.S_SDE == 1.

When the DWT generates a match, then if DWT_FUNCTION.ACTION specifies a debug event, and the Main Extension is implemented, then DEMCR.MON_PEND is set to 1 if all of the following conditions apply:

- HaltingDebugAllowed() == FALSE, DHCSR.C_DEBUGEN == 0, or the match is a Secure match and DHCSR.S_SDE == 0.
- DEMCR.MON_EN == 1.
- Either the DebugMonitor group priority is greater than the current execution priority and the watchpoint was not generated by a lazy state preservation access, or FPCCR.MONRDY has a value of 1 and the watchpoint was generated by lazy state preservation.

When the DWT generates a match, then if the Main Extension is implemented, a Data trace match packet is generated, if all of the following conditions apply:

- The Security Extension is implemented.
- SecureNoninvasiveDebugAllowed() == FALSE.
- DWT_FUNCTION.ACTION specifies generating a Data trace PC value packet.
- The PC value that would be included in the packet refers to an instruction that was executed in Secure state.

Otherwise, the type of trace packet that is specified by DWT_FUNCTION.ACTION is generated.

An access that results in a MemManage fault or SecureFault exception because of the alignment, SAU, IDAU, or MPU checks, is not observed by the DWT, and cannot generate a match.

The DWT treats hardware accesses to the stack as data accesses:

- For registers pushed to the stack by hardware as part of an exception entry or lazy state preservation.
- For registers popped from the stack by hardware as part of an exception return.
- If the Security Extension is implemented:
  — For registers pushed to the stack by hardware as part of a Non-secure function call.
  — For registers popped from the stack by hardware as part of a Non-secure function.

### Constraints on programming DWT comparators

If a DWT comparator, <n>, or pair of comparators, <n> and <n+1>, is programmed with a reserved combination of DWT_FUNCTION.MATCH and DWT_FUNCTION.ACTION, then it is UNPREDICTABLE whether any comparator:

- Behaves as if disabled.
- Generates a match, setting `DWT_FUNCTION.MATCHED` bit to an `UNKNOWN` value, and any of the following:
  - Asserts `CMPMATCH`.
  - Generates a debug event.
  - Generates one or more trace packets.

**RGPLQ**

Combinations of `DWT_FUNCTION.MATCH` and `DWT_FUNCTION.ACTION` that are not specified as valid combinations are reserved.

**RCNHN**

The valid combinations of `DWT_FUNCTION.MATCH` and `DWT_FUNCTION.ACTION` for a single comparator, and the events and Data trace packets that the comparator can generate from matching a single access, are identified in the following table.

In the table:
- `-` means that the packet or event is not generated.
- `Yes` means that the packet or event is generated on a comparator match.
- `x` means that the Action is ignored.

a. Only if the Main Extension is implemented.
**Instruction address range**

To match an instruction that is in an instruction address range, the following conditions must be met:

- The first comparator, \(<n-1>\), must be programmed for *Instruction address*.
- The second comparator, \(<n>\), must be programmed for *Instruction address limit*.

The valid combinations of `DWT_FUNCTION.MATCH` and `DWT_FUNCTION.ACTION` for an instruction address range, and the events and data trace packets that matching a single access can generate, are specified in the following table.

In the table:
- means that the packet or event is not generated.
- *First* means that the packet or event is generated by the first comparator match.
- *Second* means that the packet or event is generated by the second comparator match.

<table>

a. Only if the Main Extension is implemented.

**Data address range**

To match a data access in a data address range, the following conditions must be met:

- The first comparator, \(<n-1>\), must be programmed for either *Data address* or *Data address with value*.
- The second comparator, \(<n>\), must be programmed for *Data address limit*.

The valid combinations of `DWT_FUNCTION.MATCH` and `DWT_FUNCTION.ACTION` for a data address range, and the events and data trace packets that matching a single access can generate, are specified in the following table.

In the table:
- means that the packet or event is not generated.
- *First* means that the packet or event is generated by the first comparator match.
- *Second* means that the packet or event is generated by the second comparator match.

a. Only if the Main Extension is implemented.
### Data value at specific address

Matching data values at specific data addresses is possible only if the Main Extension is implemented.

To match a data value at a specific data address, the following conditions must be met:

- The first comparator, <n-1>, must be programmed for either Data address or Data address with value.
- The second comparator, <n>, must be programmed for Linked data value.

The first comparator matches any access that matches the address. The second matches only accesses that match the address and the data value.

The valid combinations of DWT_FUNCTION.MATCH and DWT_FUNCTION.ACTION for a linked data value, and the events and data trace packets that matching a single access can generate, are specified in the following table.

In the table:
- means that the packet or event is not generated.
- First means that the packet or event is generated by the first comparator match.
- Second means that the packet or event is generated by the second comparator match.
- Both means that a first packet is generated by a first comparator match, even if the Linked data value comparator does not match, and a second packet is generated by the second comparator match, if both comparators match.

### B12.2.4 CMPMATCH trigger events

#### IVNCC

The **CMPMATCH** events signal watchpoint matches.

#### RPRJG

The implementation of **CMPMATCH** is IMPLEMENTATION DEFINED.

#### RFTWC

If an ETM is implemented, **CMPMATCH** events are output to the ETM.

#### RTMZX

If an ETM is not implemented, the effect of **CMPMATCH** is IMPLEMENTATION DEFINED, including whether the trigger event has any observable effect or whether observable effects are visible to other components in the system.

#### RXXKM

For all enabled watchpoints, if **DWT_FUNCTION<n>** is not programmed as an Instruction address limit comparator and is not programmed as a Data address limit comparator, **CMPMATCH[n]** is triggered on a comparator match.

#### RGVHS

For all enabled watchpoints, if **DWT_FUNCTION<n>** is programmed as an Instruction address limit or Data address limit comparator, it is UNPREDICTABLE whether **CMPMATCH[n]** is triggered on a comparator match.
B12.2.5 Matching in detail

Instruction address matching in detail

The DWT checks all instructions that are executed by a simple sequential execution of the program and do not generate any exception for an instruction address match, including conditional instructions that fail their condition code check.

An instruction might be checked by the DWT for an instruction address match if it either:

- Is executed by a simple sequential execution of the program and generates a synchronous exception.
- Would be executed by the sequential execution of the program but is abandoned because of an asynchronous exception.

Speculative instruction prefetches, other than those that would be executed by the sequential execution of the program but that are abandoned because of asynchronous exceptions, must not generate matches.

For all instruction address matches, if bit[0] of the comparator address has a value of 1, it is UNPREDICTABLE whether a match is generated when the other address bits match.

For single instruction address matches, an instruction matches if the address of the first byte of the instruction matches the comparator address.

For single address matches, if the instruction is a 4-byte T32 instruction, and the address of the first byte of the upper halfword matches but the address of the first byte of the lower halfword does not match, it is UNPREDICTABLE whether a match is generated.

For instruction address range matches, an instruction matches if the address of the first byte of the instruction lies between the lower comparator address, which is specified by comparator <n-1>, and the limit comparator address, which is specified by comparator <n>. Both addresses are inclusive to the range.

For instruction address range matches, if the instruction is a 4-byte T32 instruction, and the address of the first byte of the upper halfword lies in the range but the address of the first byte of the lower halfword does not lie in the range, it is UNPREDICTABLE whether a match is generated.

For instruction address range matches, if so configured, a Data trace PC value packet or Data trace match packet is generated for the first instruction that is executed in the range.

For instruction address range matches, if so configured, a branch or sequential execution that stays within the range does not necessarily generate a new packet.

For instruction address range matches, if so configured, CMPMATCH[n-1] is triggered for each instruction that is executed inside the range, where n-1 is the lower of the two comparators that configure the range.

Data address matching in detail

For all Data Address matches, all bits of the comparator address are considered.

Speculative reads might generate data address matches.

Speculative writes must not generate data address matches.

Prefetches into a cache must not generate data address matches.

For single data address matches, an access matches if any accessed byte lies between the comparator address and a limit that is defined by DWT_FUNCTION.DATAVSIZE.

For single data address matches, the comparator address must be naturally aligned to DWT_FUNCTION.DATAVSIZE otherwise generation of watchpoint events is UNPREDICTABLE.

For data address range matches, an access matches if any accessed byte lies between the lower comparator address, which is specified by comparator <n-1>, and the limit comparator address, which is specified by comparator <n>. Both addresses are inclusive to the range.
For data address range matches, **DWT_FUNCTION.DATASIZE** must be set to \( \emptyset 0 0 \) for both the lower comparator address and the limit comparator address otherwise it is UNPREDICTABLE whether or not a match is generated.

### Data value matching in detail

**RBMSM**

Data value matching is only possible if the Main Extension is implemented.

**RFVFQ**

Speculative reads might generate data value matches.

**RVGJF**

Speculative writes must not generate data value matches.

**RMLFK**

Prefetches into a cache must not generate data value matches.

**RRMDB**

For data value matches, if the access size is smaller than **DWT_FUNCTION.DATASIZE**, there is no match.

**RZDPM**

For unlinked data value matches, an access matches if all bytes of any naturally-aligned subset of the access of the size that is specified by **DWT_FUNCTION.DATASIZE** match the data value in **DWT_COMP<n>**. The data value in **DWT_COMP<n>** is in little-endian order with respect to memory.

**IHMS**

If the access is unaligned then this might generate a higher priority alignment fault, depending on the instruction type, profile, and configuration. In these cases no match is generated.

**RSQKS**

For unlinked data value matches, if an access is unaligned, it is IMPLEMENTATION DEFINED whether it either treated as:

- A sequence of byte accesses.
- A sequence of naturally-aligned accesses covering the accessed bytes. For a read, this access might access more bytes than the original access.

**RQRPW**

For linked data value matching, if an access is larger than **DWT_FUNCTION.DATASIZE**, then only the naturally-aligned subset of the access of size **DWT_FUNCTION.DATASIZE** at the matching address is compared for a match.

**RQVRK**

For linked data value matching, the data address comparator address must be naturally aligned to **DWT_FUNCTION.DATASIZE**, and the **DWT_FUNCTION.DATASIZE** values for both comparators must be the same.

**RKRCV**

A Data value comparator that is linked to a Data address comparator does not change the behavior of the address comparator.

See also:

- **DWT_AddressCompare()**.
- **DWT_ValidMatch()**.
- **DWT_InstructionAddressMatch()**.
- **DWT_DataAddressMatch()**.
- **DWT_DataValueMatch()**.

### DWT match restrictions and relaxations

**RKBHM**

It is IMPLEMENTATION DEFINED whether the DWT treats a fetch from the exception vector table as part of an exception entry as a data access or ignores these accesses, for the purposes of DWT comparator matches.

**RDTTHW**

A fetch by the DWT from the exception vector table as part of an exception entry must never be treated as an instruction fetch.

**RFDKL**

If the Main Extension and the Flash Patch function of the FPB are implemented, and if an FPB comparator remaps one word-aligned address onto another, then if an instruction fetch is remapped by the FPB comparator, the PE might check for an instruction address match for any or none of the two addresses.
If the Main Extension and Flash Patch function of the FPB are implemented, and if an FPB comparator remaps one word-aligned address onto another, then if a literal load is remapped by the FPB comparator, the PE might check for a data address match for any or none of the two addresses.

If a return is tail-chained, it is IMPLEMENTATION DEFINED whether hardware accesses the stack and therefore IMPLEMENTATION DEFINED whether the DWT can generate events or trace.

The DWT does not match accesses from the DAP.

Any executed NOP or IT that matches an appropriately configured instruction address watchpoint must cause a match.

For the Main Extension only, it is IMPLEMENTATION DEFINED whether a failed STREX instruction can generate a data access match.

If an instruction or operation makes multiple or unaligned data accesses, then it is UNPREDICTABLE whether any nonmatching access generated by an instruction that generated a matching access is treated as a matching access.

If an instruction or operation makes multiple or unaligned data accesses, then CMPMATCH is triggered for each matching access.

If the Main Extension is implemented and an instruction or operation makes multiple or unaligned data accesses, then, if so configured, only a data value match of at least a part of the value that is guaranteed to be single-copy atomic can generate a match.

If an instruction or operation makes multiple or unaligned data accesses, then, if so configured, for a matching data access that generates a debug event, if permitted, DHCSR.C_HALT or DEMCR.MON_PEND, as applicable, is set to 1.

A pending DebugMonitor exception does not interrupt the multiple accesses, but another interrupt might, which means that the debug event might be taken before the multiple operations complete.

The DWT can match on the address of an access that generates a BusFault.

In the Main Extension, it is IMPLEMENTATION DEFINED whether a stored value for an access that generates a BusFault:

- Can generate a data value match.
- Can be traced.

In the Main Extension, for a load access that returns a BusFault, any data that is returned by the memory system is invalid, and the DWT must not:

- Generate a data value match.
- Generate a Data trace data value packet.

A data access that generates any fault other than a BusFault does not generate a data address or data value match at the DWT and is not traced.

DWT matches are generated asynchronously.

A DSB barrier guarantees that the effect of a DWT match is visible to a subsequent read of DWT_FUNCTION.MATCHED, DHCSR, or DEMCR. In the absence of a DSB barrier, the effect is only guaranteed to be visible in finite time.

The effects of a DWT match never affect instructions appearing in program order before the operation that generates the match.

See also:

- Tail-chaining on page B3-81.
B12.2.7 DWT trace restrictions and relaxations

RHDKK Where a single instruction or operation, or multiple instructions, generate multiple accesses that each one or more trace packets, then if the architecture guarantees the order in which a pair of these accesses is observed by the PE, the first trace packets that are generated for each of those accesses must appear in the trace output in the same order.

RWSKK Where a single instruction or operation, or multiple instructions, generate multiple accesses that each generate one or more trace packets, then if the architecture does not guarantee the order of the accesses, the order of trace packets in the trace output is not defined.

RXCNB If a single instruction or operation makes multiple or unaligned data accesses, then, if so configured, only the first access is guaranteed to generate a Data trace PC value packet, Data trace data address packet, or Data trace match packet. If the architecture does not guarantee the order of the accesses, the first access might be any of the accesses.

RxVBT If a single instruction or operation makes multiple or unaligned data accesses, then, if so configured, a Data trace data value packet is generated for each matching access.

RQSCF If a single instruction or operation makes multiple or unaligned data accesses, then, if so configured, it is UNPREDICTABLE how many Data trace data value packets are generated for each unaligned matching access. An implementation might over-read, meaning that more data outside the access might be traced.

RXXBL If a single instruction or operation makes multiple or unaligned data accesses, then, if so configured, for a matching data access that generates a Data trace data value packet, at least that part of the value that is guaranteed to be single-copy atomic is traced.

RQWQS Duplicate Data trace PC value packets, Data trace data address packets, and Data trace data value packets from a single access are not generated for a single access.

RCPXW Where a comparator or linked pair of comparators generates multiple packet types for a single access, the packets must appear in the trace output in the following order:

1. Data trace PC value packet.
2. Data trace match packet, generated by a Data address or Data address with value comparator match.
3. Data trace data address packet.
4. Data trace match packet, generated by a Data value comparator match.
5. Data trace data value packet.

RQXBC Where a comparator or linked pair of comparators generates multiple packet types for a single access, packets must not be interleaved with packets that are generated by other accesses by the same comparator or linked pair of comparators.

RRHNF Where a comparator or linked pair of comparators generates a trace packet for a single access, if a comparator other than this comparator or this linked pair of comparators generates a trace packet of the same type for the same access, then only one of these packets is output. It is IMPLEMENTATION DEFINED which comparator is chosen.

IMXG ARM recommends that the packet from the lowest-numbered comparator is output.

RDVW Where a comparator or linked pair of comparators generates multiple packet types for a single access, if any of the packets cannot be output and an Overflow packet is generated, then the remaining packets for that access are not generated.

RLNDW Where a comparator or linked pair of comparators generates multiple packet types for a single access, packets might be interleaved with packets that are generated for the same access by comparators other than this comparator or this linked pair of comparators.

B12.2.8 CYCCNT cycle counter and related timers

RSVPW CYCCNT is an optional free-running 32-bit cycle counter. If the DWT unit implements CYCCNT then DWT_CTRL.NOCYCCNT is RAZ.

RKRFP When implemented and enabled, CYCCNT increments on each cycle of the PE clock.
When the counter overflows it transparently wraps to zero.

**DWT_CTRL.CYCCNTENA** enables the CYCCNT counter.

POSTCNT is a 4-bit countdown counter derived from CYCCNT, that acts as a timer for the periodic generation of Periodic PC sample packets or Event counter packets, when these packets are enabled.

Periodic PC sample packets are not the same as the Data trace PC value packets that are generated by the DWT comparators.

The DWT does not support the generation of Periodic PC sample packets or Event packets if it does not implement the CYCCNT timer and **DWT_CTRL.NOTRCPKT** is RAO.

The DWT_CTRL.CYCTAP bit selects the CYCCNT tap bit for POSTCNT. Table B12-1 shows the effect of this bit:

<table>
<thead>
<tr>
<th>CYCTAP bit</th>
<th>CYCCNT tap at</th>
<th>POSTCNT clock rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Bit[6]</td>
<td>(PE clock)/64</td>
</tr>
<tr>
<td>1</td>
<td>Bit[10]</td>
<td>(PE clock)/1024</td>
</tr>
</tbody>
</table>

A write to DWT_CTRL will initialize POSTCNT to the previous value of **DWT_CTRL.POSTINIT** if all of:

- **DWT_CTRL.PCSAMPELENA** was set to 0 prior to the write.
- **DWT_CTRL.CYCEVTENAA** was set to 0 prior to the write.
- The write sets either **DWT_CTRL.PCSAMPLEENA** or **DWT_CTRL.CYCEVTENA** to 1.

It is UNPREDICTABLE whether any other write to DWT_CTRL that alters the value of either **DWT_CTRL.PCSAMPLEENA** and **DWT_CTRL.CYCEVTENA** sets POSTCNT to **DWT_CTRL.POSTINIT** or leaves POSTCNT unchanged.

When either **DWT_CTRL.CYCEVTENA** or **DWT_CTRL.PCSAMPLEENA** is set to 1, and the CYCCNT tap bit transitions, either from 0 to 1 or from 1 to 0:

- If POSTCNT is nonzero, POSTCNT decrements by 1.
- If POSTCNT is zero, the DWT:
  - Reloads POSTCNT from **DWT_CTRL.POSTRESET**.
  - Generates a Periodic PC Sample packets if **DWT_CTRL.PCSAMPLEENA** is set to 1.
  - Generates an Event Counter packet with the Cyc bit set to 1 if **DWT_CTRL.CYCEVTENA** is set to 1.

The enable bit for the POSTCNT counter underflow event is **DWT_CTRL.CYCCNTENA**. There is no overflow event for the CYCCNT counter. When CYCCNT overflows it wraps to zero transparently. Software cannot access the POSTCNT value directly, or change this value.

This means that, to initialize POSTCNT, software must:

1. Ensure that **DWT_CTRL.CYCCNTENA** and **DWT_PCSAMPLEENA** are set to 0. This can be achieved with a single write to DWT_CTRL. This is also the reset value of these bits.
2. Write the required initial value of POSTCNT to the **DWT_CTRL.POSTINIT** field, leaving **DWT_CTRL.CYCCNTENA** and **DWT_CTRL.PCSAMPLEENA** set to 0.
3. Set either **DWT_CTRL.CYCEVTENA** or **DWT_CTRL.PCSAMPLEENA** to 1 to enable the POSTCNT counter.

Each of these must be separate writes to DWT_CTRL.

Disabling CYCCNT stops POSTCNT.

Writes to **DWT_CTRL.POSTINIT** are ignored if either **DWT_CTRL.PCSAMPLEENA** was set to 1 or **DWT_CTRL.CYCEVTENA** was set to 1 prior to the write.
B12.2.9 Profiling counter support

Profiling counter support is an optional debug feature.

If Profiling counter support is implemented the DWT provides five 8-bit Event counters for software profiling:

- **DWT_FOLDCNT.**
- **DWT_LSUCNT.**
- **DWT_EXCCNT.**
- **DWT_SLEEPCNT.**
- **DWT_CPICNT.**

The DWT_CPICNT is a general counter for instruction cycle count estimation.

The DWT_CPICNT counter increments on each additional cycle to execute a multicycle instruction, including each cycle of any instruction fetch stall, but does not increment for those instructions recorded by DWT_LSUNCT.

The DWT_EXCCNT is the exception overhead counter. DWT_EXCCNT increments on each cycle associated with entry stacking, return unstacking, preemption, and other exception-related processes.

The DWT_LSUCNT is the sleep overhead counter. DWT_LSUCNT increments on each cycle associated with power saving, whether initiated by a WFI or WFE instruction or sleep-on-exit functionality. It is IMPLEMENTATION DEFINED whether the counter advances in SLEEPDEEP.

The DWT_SLEEPCNT is the sleep overhead counter. DWT_SLEEPCNT increments on each cycle associated with power saving, whether initiated by a WFI or WFE instruction or sleep-on-exit functionality. It is IMPLEMENTATION DEFINED whether the counter advances in SLEEPDEEP.

The DWT_LSUCNT is the load-store counter. DWT_LSUCNT increments on each additional cycle required to execute a multicycle load-store instruction. It does not count the first cycle required to execute any instruction.

The DWT_FOLDCNT is the folded instruction counter. DWT_FOLDCNT increments on any instruction that executes in zero cycles.

Counters do not increment when the PE is halted. In Debug state the overhead associated with **STEP** and **RUN** commands from and to the halt condition is IMPLEMENTATION DEFINED.

A counter overflows on every 256th cycle counted and then wraps to 0. If the appropriate counter overflow event is enabled in **DWT_CTRL** the DWT outputs an Event counter packet with the appropriate counter flag set to 1.

Setting one of the enable bits to one clears the corresponding counter to zero.

If the Main extension is implemented the following equation must hold:

\[\text{ICNT} = \text{CNTCYCLES} + \text{CNTFOLD} - (\text{CNTLSU} + \text{CNTEXC} + \text{CNTSLEEP} + \text{CNTCP})\]

Where:

- **ICNT** is the total number of instructions architecturally executed.
- **CNTCYCLES** is the number of cycles counted by **DWT_CYCCNT**.
- **CNTFOLD** is the number of instructions counted by **DWT_FOLDCNT**.
- **CNTLSU** is the number of cycles counted by **DWT_LSUCNT**.
- **CNTEXC** is the number of cycles counted by **DWT_EXCCNT**.
- **CNTSLEEP** is the number of cycles counted by **DWT_SLEEPCNT**.
- **CNTCP** is the number of cycles counted by **DWT_CPICNT**.

See also:

- **Trace Port Interface Unit** on page B12-235.
Generating overflow packets from event counters

RKWDH If a counter value wraps round to zero and the previous Event Counter packet has been delayed and has not yet been output, then it is IMPLEMENTATION DEFINED whether:

• The DWT attempts to generate a second Event counter packet.
• The DWT updates the delayed Event counter packet to include the new wrap event.

RHKL If a counter value wraps round to zero and the previous Event counter packet has been delayed and has not yet been output but has the bit for the counter value set, the DWT must attempt to generate a second Event counter packet.

RVPK If the DWT unit attempts to generate a packet when its output buffer is full, an Overflow packet is output.

RSFL The size of the DWT output buffer is IMPLEMENTATION DEFINED.
B12.3 Embedded Trace Macrocell

An Embedded Trace Macrocell (ETM) is an optional feature of an ARMv8-M implementation.

An ETM implementation must comply with one of the following versions of the ETM architecture:

<table>
<thead>
<tr>
<th>Data trace</th>
<th>Security Extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implemented</td>
<td>ETMv3 not permitted</td>
</tr>
<tr>
<td></td>
<td>ETMv4, version 4.2 or later</td>
</tr>
<tr>
<td>Not implemented</td>
<td>ETMv3, version 3.5 or later</td>
</tr>
<tr>
<td></td>
<td>ETMv4, version 4.2 or later</td>
</tr>
</tbody>
</table>

If an ETM is implemented a trace sink must also be implemented. If the trace sink implemented is the TPIU it must be CoreSight compliant, and must comply with the TPIU architecture for compatibility with ARM and other CoreSight-compatible debug solutions.

When an ARMv8-M implementation includes an ETM, the CMPMATCH[N] signals from the DWT unit are available as control inputs to the ETM unit.

If the Main Extension is not implemented, it is IMPLEMENTATION DEFINED whether the ETM is accessible only to the debugger and is RES0 to software.

If the ETM is implemented the debugger must program the TRC_TRACEIDR with a unique nonzero Trace ID for the ETM trace stream.

See also:

- ARM® CoreSight™ Architecture Specification.
- CMPMATCH trigger events on page B12-226.
**B12.4 Trace Port Interface Unit**

The Trace Port Interface Unit (TPIU) support for ARMv8-M provides an output path for trace data from the DWT, ITM, and ETM. The TPIU is a trace sink.

It is IMPLEMENTATION DEFINED whether the TPIU supports a parallel trace port output.

It is IMPLEMENTATION DEFINED whether the TPIU supports low-speed asynchronous serial port output using NRZ encoding. This operates as a traditional UART.

It is IMPLEMENTATION DEFINED whether the TPIU supports medium-speed asynchronous serial port output using Manchester encoding.

ARM recommends that the TPIU provides both parallel and asynchronous serial ports, for maximum flexibility with external capture devices.

Whether the trace port clock is synchronous to the PE clock is IMPLEMENTATION DEFINED.

Software must ensure that all trace is output and flushed to the trace sink before setting the DEMCR.TRCENA bit to 0.

The TPIU is not directly affected by DEMCR.TRCENA being set to 0 or NoninvasiveDebugAllowed() being FALSE.

The output formatting modes that are supported by the TPIU are IMPLEMENTATION DEFINED. They are:

- Bypass.
- Continuous.

Bypass mode is only supported if a serial port output is supported.

Continuous mode must be supported if the parallel trace port is implemented. Software must select Continuous mode when the parallel trace port is used.

Continuous mode must be supported if the ETM is implemented. Software must select Continuous mode when the ETM is used.

See also:
- TPIU_FFCR, TPIU Formatter and Flush Control Register on page D1-1098.
- Instrumentation Trace Macrocell on page B12-214.
- Embedded Trace Macrocell on page B12-234.
## B12.5 Flash Patch and Breakpoint unit

### B12.5.1 About the FPB unit

The **Flash Patch and Breakpoint** (FPB) unit supports setting breakpoints on instruction fetches.

In the Main Extension, if the Security Extension is not implemented, it is IMPLEMENTATION DEFINED whether the FPB unit supports:

- Remapping data accesses from specific locations from the Code region of system memory to addresses in the SRAM region. This is referred to as **literal remapping**.
- Remapping instruction fetches from specific addresses from the Code region of system memory to addresses in the SRAM region. This is referred to as **instruction remapping**.

The number of implemented instruction address comparators is IMPLEMENTATION DEFINED. Software can discover the number of implemented instruction address comparators from `FP_CTRL.NUM_CODE`.

If literal remapping is supported, the number of implemented literal address comparators is IMPLEMENTATION DEFINED. Software can discover the number of implemented literal address comparators from `FP_CTRL.NUM_LIT`.

If the Main Extension is not implemented or the Security Extension is implemented, the FPB unit does not support remapping functions.

If the FPB does not support remapping functions, the `FP_REMAP.RMPSPT` and `FP_CTRL.NUM_LIT` fields have a value of 0.

See also:

- Chapter B7 *The System Address Map*.
- *DWT trace restrictions and relaxations* on page B12-230.
- Chapter D1 *Register Specification*.

### B12.5.2 FPB unit operation

The FPB contains the following register types:

- A general control register, `FP_CTRL`.
- A remap address register, `FP_REMAP`, if instruction or literal remapping is supported.
- Comparator registers.

The FPB uses separate comparators for instruction address comparison and for literal address comparison.

Each implemented instruction address comparator must support breakpoint generation.

If instruction remapping is supported, each implemented instruction address comparator must support instruction remapping.

The `FP_CTRL` register provides a global enable bit for the FPB, and ID fields that indicate the numbers of instruction address comparison and literal comparison registers implemented.

If instruction or literal remapping is supported, `FP_REMAP` provides the base address for the remapped accesses.

If remapping is supported, software can configure an instruction address comparator to remap the instruction, or to generate a breakpoint.

If literal remapping is supported, each implemented literal address comparator must support literal remapping.

The literal address comparators only support remapping of data read accesses. Each comparator has its own enable bit that enables operation of the comparator only when the global enable bit is also set to 1.
When configured for breakpoint generation, instruction address comparators can be configured to match any halfword-aligned addresses in the whole address map.

When configured for instruction remapping, instruction address comparators can be configured to match any word-aligned address in the Code memory region, by ignoring bits[1:0] of each instruction fetch.

Instruction address comparators match only on instruction fetches.

Bit[0] of each instruction fetch address is always zero.

Literal address comparators can be configured to match any word-aligned address in the Code memory region, by ignoring bits[1:0] of each access.

Literal address comparators match only on data reads and ignore data writes. Data writes always access the original location.

When configured for remapping, a match causes the instruction or data to be read from the remapped location.

Comparator $n$ remaps to address \((FP \_REMAP\_REMAP\_00000 + 4n)\) when it is configured for remapping and a match occurs.

If a remapped instruction reads the PC, then the value that is returned is calculated from the original instruction address and not the remapped address.

Literal address matching can remap word, halfword, or byte data accesses. A match fetches the appropriate-sized data item from the remapped location.

It is IMPLEMENTATION DEFINED how remapping affects unaligned literal accesses.

When an MPU is enabled, it performs its checks on the original address, and applies the attributes for that address to the remapped location. The MPU does not check the remapped address.

The FPB can remap a Load exclusive accesses, but whether the remapped access is performed as an exclusive access is UNPREDICTABLE.

When an Instruction address matching comparator is configured for breakpoint generation, a match on the address of a 32-bit instruction must be configured to match the first halfword or both halfwords of the instruction.

If a Breakpoint debug event is generated by the FPB on the second halfword of a 32-bit T32 instruction, it is UNPREDICTABLE whether the breakpoint generates a debug event.

An FPB match specifying a Breakpoint debug event generates a Breakpoint debug event that halts the PE if all of the following conditions are true:

- \(\text{HaltingDebugAllowed}() \equiv \text{TRUE}\).
- \(\text{DHCSR\_C\_DEBUGEN} \equiv 1\).
- \(\text{DHCSR\_S\_HALT} \equiv 0\).
- The Security Extension is not implemented, the matching instruction is executed in Non-secure state, or \(\text{DHCSR\_S\_SDE} \equiv 1\).

If the Main Extension is implemented, an FPB match specifying a Breakpoint debug event generates a DebugMonitor exception if it does not halt the PE and all of the following conditions are true:

- \(\text{DEMCR\_MON\_EN} \equiv 1\).
- \(\text{DHCSR\_S\_HALT} \equiv 0\).
- The DebugMonitor group priority is greater than the current execution priority.
- The Security Extension is not implemented, the matching instruction is executed in Non-secure state, or \(\text{DEMCR\_SDME} \equiv 1\).

An FPB match that specifies a Breakpoint debug event is ignored if it does not meet the conditions for generating either:

- A Breakpoint debug event that halts the PE.
• A DebugMonitor exception.

Between a change to the debug authentication interface, DHCSR or DEMCR, that disables debug, and a following context synchronization event, it is UNPREDICTABLE whether any breakpoints generated by the FPB:

• Generate a Breakpoint debug event based on the old values and either:
  — If the Main Extension is implemented, generate a DebugMonitor exception.
  — Halts the PE.
• Are escalated to HardFault.
• Are ignored.

The FPB treats hardware accesses to the stack as data accesses for registers that are pushed to the stack by hardware as part of an exception entry or lazy state preservation.

The FPB treats hardware accesses to the stack as data accesses for registers popped from the stack by hardware as part of an exception return.

If the Security Extension is implemented, the FPB treats hardware accesses to the stack as data accesses for registers that are pushed to the stack by hardware as part of a Non-secure function return.

If the Security Extension is implemented, the FPB treats hardware accesses to the stack as data accesses for registers popped from the stack by hardware as part of a Non-secure function call.

It is IMPLEMENTATION DEFINED whether the FPB treats a fetch from the exception vector table as part of an exception entry as a data access, or ignores these accesses, for the purposes of FPB address comparator matches. The fetch must never be treated as an instruction fetch.

The FPB does not match access from the DAP.

• FPB_BreakpointMatch().

Multiple FPB comparators

In this section, A, B, and C are word-aligned addresses and comparators n and m are different FPB comparators.

If instruction address comparator n remaps A to B, and instruction address comparator m specifies a breakpoint on A, then, for an instruction that is executed from A, the PE generates a breakpoint.

If instruction address comparator n remaps A to B, and instruction address comparator m specifies a breakpoint on A+2, then, for an instruction that is executed from A+2, the PE generates a breakpoint.

If instruction address comparator n remaps A to B, and instruction address comparator m specifies a breakpoint on A, then, for an instruction that is to be executed from A+2, the PE does one of the following:

• Executes the instruction from A+2.
• Executes the instruction from B+2.

If instruction address comparator n remaps A to B, and instruction address comparator m specifies a breakpoint on A+2, then, for an instruction to be executed from A, the PE does one of the following:

• Executes the instruction from A.
• Executes the instruction from B.

If instruction address comparator n remaps A to B, and instruction address comparator m specifies a breakpoint on either B, then, for an instruction that is to be executed from A, the PE does one of the following:

• Executes the instruction from A.
• Executes the instruction from B.
• Generates a breakpoint.

**RPDRR**

If instruction address comparator \( n \) remaps A to B, and instruction address comparator \( m \) specifies a breakpoint at B+2, then, for an instruction that is to be executed from A+2, the PE does one of the following:

• Executes the instruction from A+2.
• Executes the instruction from B+2.
• Generates a breakpoint.

**RLGSL**

If instruction address comparator \( n \) remaps A to B, and instruction address comparator \( m \) remaps A to C, then, for an instruction that is executed from A or A+2, the PE does one of the following:

• Executes the instruction from A.
• Executes the instruction from A+2.
• Executes the instruction from B.
• Generates a breakpoint.

**RCCFF**

If instruction address comparator \( n \) specifies a breakpoint on A or A+2, and instruction address comparator \( m \) also has a breakpoint on A or A+2 then, for all combinations of A and A+2 in comparators \( n \) and \( m \), for an instruction that is executed from either A or A+2, the PE does one of the following:

• Executes the instruction from A.
• Executes the instruction from A+2.
• Generates a breakpoint.

**I\_\text{xxxD}**

The following table shows multiple instruction address comparator cases on instruction fetches. In this table, an outcome of A, B, or C means the instruction from A, B, or C, respectively, is executed.

<table>
<thead>

</tbody>
</table>

**RNHIHW**

If literal address comparator \( n \) remaps A to B and literal address comparator \( m \) remaps A to C, then, for a literal access from A, A+1, A+2, or A+3, the PE does one of the following:

• Uses data from A, A+1, A+2, or A+3, respectively.
• Uses data from B, B+1, B+2, or B+3, respectively.
• Uses data from C, C+1, C+2, or C+3, respectively.
The following table shows multiple comparator cases on literal fetches.

<table>
<thead>
<tr>
<th>Comparator n</th>
<th>Comparator m</th>
<th>Literal fetched from</th>
<th>Permitted outcomes</th>

<td>A+x, B+x, C+x</td>
</tr>
</tbody>
</table>

**Cache maintenance**

**RGVTv**

Instruction and data caches are permitted to cache the results of the Flash Patch remap function. This means that software must perform cache maintenance operations when enabling, disabling, or modifying a Flash Patch remap.

**RBWSW**

Instruction caches are not permitted to cache breakpoints that are generated by a Flash Patch and Breakpoint unit.
Part C
ARMv8-M Instruction Set
Chapter C1
Instruction Set Overview

This chapter provides a definition of the instruction descriptions contained in Chapter C2 Instruction Specification. It contains the following sections:

• Instruction set on page C1-244.
• Format of instruction descriptions on page C1-245.
• Pseudocode for instruction descriptions on page C1-248.
• Unified Assembler Language on page C1-250.
• Standard assembler syntax fields on page C1-252.
• Conditional execution on page C1-253.
• Instruction set encoding information on page C1-256.
• Modified immediate constants on page C1-259.
• NOP-compatible hint instructions on page C1-260.
• Instruction set, interworking support on page C1-261.
• Instruction set, interstating support on page C1-262.
C1 Instruction Set Overview
C1.1 Instruction set

C1.1 Instruction set

There is one instruction set, called T32.

For more information about the T32 instruction set encoding, see Top level T32 instruction set encoding on page C2-264.

See also:

• Instruction set encoding information on page C1-256.
• Chapter C2 Instruction Specification. See this for descriptions of each T32 instruction.
C1.2 Format of instruction descriptions

Each instruction description in Chapter C2 has the following content:
1. A title.
3. The instruction encoding or encodings.
4. Any alias conditions, if applicable.
5. A list of the assembler symbols for the instruction.
6. Pseudocode describing how the instruction operates.
7. Notes, if applicable.

C1.2.1 The title

The title of an instruction description includes the base mnemonic or mnemonics for the instruction. This is part of the assembler syntax, for example SUB.

If different forms of an instruction use the same base mnemonic, each form has its own description. In this case, the title is the mnemonic followed by a short description of the instruction form in parentheses. This is most often used when an operand is an immediate value in one instruction form, but is a register in another form.

For example, in Chapter C2 there are the following titles for different forms of the ADD instruction:

- ADD (SP plus immediate) on page C2-316.
- ADD (SP plus register) on page C2-318.
- ADD (immediate) on page C2-321.
- ADD (immediate, to PC) on page C2-324.
- ADD (register) on page C2-326.

Where an instruction has more than one variant, the descriptions might be combined, for example for CDP and CDP2.

C1.2.2 A short description

This briefly describes the function of the instruction. The description is not a complete description of the instruction and must be read in conjunction with the rest of the instruction description.

C1.2.3 The instruction encoding or encodings

This shows the instruction encoding diagram, or, if the instruction has multiple encodings, shows all of the encoding diagrams. The heading for each encoding is the letter T followed by an arbitrary number, usually between 1 and 5.

The instruction alignment and byte ordering figure in Endianness on page B5-119 shows the alignment for both 16-bit encodings and 32-bit encodings. The left-hand halfword in the diagram is called hw1 for a 16-bit encoding. The left-hand halfword in the diagram is called hw1 and the right-hand halfword is called hw2 for a 32-bit encoding.

Between each encoding diagram and its T<n> heading, there is an italicized statement that describes which ARMv8-M variant the encoding is present in. For example, "ARMv8-M Main Extension only."

Below each encoding diagram is the assembler syntax prototype for that encoding, written in typewriter font. The assembler syntax prototype describes the syntax that can be used in the assembler to select this encoding, and also the syntax that is used when disassembling this encoding.

In some cases an encoding has multiple variants of assembler syntax prototype, when the prototype differs depending on the value in one or more of the encoding fields. In these cases, the correct variant to use can be identified by either:

- Its subheading.
- An annotation to the syntax.

Each encoding diagram, and its associated assembler syntax prototypes, is followed by encoding-specific pseudocode that translates the fields of that encoding into inputs for the encoding-independent pseudocode that describes the operation of the instruction. See Pseudocode describing how the instruction operates on page C1-246.
In the assembler syntax prototypes, the following conventions are used:

< >     Angle brackets. Any symbol enclosed by these is mandatory. For each symbol, there is a description of what the symbol represents. The description usually also specifies which encoding field or fields encodes the symbol.

{}     Brace brackets. Any symbol enclosed by these is optional. For each optional symbol, there is a description of what the symbol represents and how its presence or absence is encoded.

C1.2.4   Any alias conditions, if applicable

This is an optional part of an instruction description. If included, it describes the set of conditions for which an alternative mnemonic and its associated assembler syntax prototypes are preferred for disassembly by a disassembler. It includes a link to the alias instruction description that defines the alternative syntax. The alias syntax and the original syntax can be used interchangeably in the assembler source code.

ARM recommends that if a disassembler outputs the alias syntax, it consistently outputs the alias syntax.

C1.2.5   A list of the assembler symbols for the instruction

The Assembler symbols subsection of an instruction description contains a list of the symbols that the assembler syntax prototype or prototypes use.

The following conventions are used:

{}     In some assembler syntax prototypes, some brace brackets are mandatory, for example if they surround a register list. When the use of brace brackets is mandatory, they are separated from other syntax items by one or more spaces.

{}     Brace brackets. Any symbol enclosed by these is optional. For each optional symbol, there is a description of what the symbol represents and how its presence or absence is encoded.

#      Usually precedes a numeric constant. All uses of # are optional in assembler source code. ARM recommends that disassemblers output the # where the assembler syntax prototype includes it.

+/-     Indicates an optional + or - sign. If neither is coded, + is assumed.
!

Indicates that the result address is written back to the base register.

Single spaces are used for clarity, to separate syntax items. Where a space is mandatory, the assembler syntax prototype shows two or more consecutive spaces.

Any characters not shown in this conventions list must be coded exactly as shown in the assembler syntax prototype. Apart from brace brackets, these characters are used as part of a meta-language to define the architectural assembler syntax prototype for an instruction encoding, but have no architecturally defined significance in the input to an assembler or in the output from a disassembler.

Some assembler syntax prototype fields are standardized across all or most instructions.

See also:

• Standard assembler syntax fields on page C1-252.

C1.2.6   Pseudocode describing how the instruction operates

The Operation subsection of the instruction description contains this pseudocode.

It is encoding-independent pseudocode that provides a precise description of what the instruction does.
C1.2 Format of instruction descriptions

Note

For a description of ARM pseudocode, see Chapter E1 ARM Pseudocode Definition.

C1.2.7 Exceptions

The Exceptions subsection contains a list of the exceptional conditions that can be caused by execution of the instruction. For a list of the possible exceptions, see:

• Exception numbers and exception priority numbers on page B3-47.
• The IEEE 754 floating-point exceptions on page B4-109.

C1.2.8 Notes

Where appropriate, additional notes about the instruction appear under further subheadings.
C1.3 Pseudocode for instruction descriptions

Each instruction description includes pseudocode that provides a precise description of what the instruction does, subject to the limitations described in General limitations of ARM pseudocode on page E1-1130 and Limitations of the instruction pseudocode.

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction. Instruction encoding diagrams and instruction pseudocode gives more information about the pseudocode provided for each instruction.

C1.3.1 Instruction encoding diagrams and instruction pseudocode

Instruction descriptions in this manual contain:

- An encoding section, containing one or more encoding diagrams, each followed by some decode pseudocode that:
  1. Picks out any encoding-specific special cases.
  2. Translates the fields of the encoding into inputs for the common pseudocode of the instruction.
- An operation section, containing common pseudocode that applies to all of the encodings being described. The Operation section pseudocode contains a call to the EncodingSpecificOperations() function, either at its start or only after a condition code check performed by if ConditionPassed() then.

An encoding diagram specifies each bit of the instruction as one of the following:

- A mandatory 0 or 1, represented in the diagram as 0 or 1. If this bit does not have this value, the encoding corresponds to a different instruction.
- A should be 0 or 1, represented in the diagram as (0) or (1). If this bit does not have this value, the instruction is CONSTRAINED UNPREDICTABLE. For more information, see the ARM® Architecture Reference Manual, ARMv8, for ARMv8-A architecture profile.
- A named single bit or a bit in a named multi-bit field.

An encoding diagram matches an instruction if all mandatory bits are identical in the encoding diagram and the instruction.

C1.3.2 Pseudocode descriptions of operations on general-purpose registers and PC

In pseudocode, the uses of the R[] function are:

- Reading or writing R0-R12, SP, and LR, using n = 0-12, 13, and 14 respectively.
- Reading the PC, using n = 15.

R on page E2-1261 shows the function prototypes.

C1.3.3 Limitations of the instruction pseudocode

The pseudocode descriptions of instruction functionality have a number of limitations.

These limitations include:

- Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses. For a description of the ordering requirements on memory accesses see Ordering requirements for memory accesses on page B5-127.

- Pseudocode does not describe the exact rules when an UNDEFINED instruction fails its condition code check. In such cases, the UNDEFINED pseudocode statement lies inside the if ConditionPassed() then ... structure, either directly or in the EncodingSpecificOperations() function call, and so the pseudocode indicates that the instruction executes as a NOP. Conditional execution of undefined instructions on page C1-254 describes the exact rules.
• Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped. *Priority of floating-point exceptions relative to other floating-point exceptions* on page B4-114 describes the exact rules.

• An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function, or implicitly, for example if an interrupt is taken during execution of an LDM instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs. To determine that, see the descriptions of the exceptions in *Exception handling* on page B3-64 and *Exception return* on page B3-75.
C1.4 Unified Assembler Language

This manual uses the ARM Unified Assembler Language (UAL). This assembly language syntax provides a canonical form for all T32 instructions.

UAL describes the syntax for the mnemonic and the operands of each instruction. For example:

\[ \text{BX } \{<c>\}{<q>}<Rm> \]

In this example, BX is the mnemonic, and \{<c>\}{<q>}<Rm> are the operands.

--- Note ---
Operands can also be referred to as assembler symbols.

In addition, UAL assumes that instructions and data items can be given labels. It does not specify the syntax to be used for labels, see your assembler documentation for these details.

UAL includes instruction selection rules that specify which instruction encoding is selected when more than one can provide the required functionality, see the definition of \(<c>\) in Standard assembler syntax fields on page C1-252.

Syntax options exist to override the normal instruction selection rules and ensure that a particular encoding is selected. These are useful when disassembling code, to ensure that subsequent assembly produces the original code, and in some other situations.

C1.4.1 Conditional instructions

The instructions that are made conditional by an IT instruction must be written with a condition after the mnemonic. These conditions must match the conditions imposed by the IT instruction.

For example:

\[ \text{ITTEE EQ} \]
\[ \text{ADDEQ R0, R1} \]
\[ \text{SUBEQ R2, R3} \]
\[ \text{ADDNE R4, R5} \]
\[ \text{SUBNE R6, R7} \]

Some instructions cannot be made conditional by an IT instruction. Some instructions can be conditional if they are the last instruction in the IT block, but not otherwise, see the individual instruction descriptions for details.

If the assembler syntax indicates a conditional branch that correctly matches a preceding IT instruction, it is assembled using a branch instruction encoding that does not include a condition field.

For more information, see IT on page C2-380.

C1.4.2 Use of labels in UAL instruction syntax

The UAL syntax for some instructions includes the label of an instruction or a literal data item that is at a fixed offset from the instruction being specified. The assembler must:

1. Calculate the PC or Align(PC,4) value of the instruction. The PC value of an instruction is its address plus 4 for a T32 instruction. The Align(PC,4) value of an instruction is its PC value ANDed with 0xFFFFFFFF to force it to be word-aligned.

2. Calculate the offset from the PC or Align(PC,4) value of the instruction to the address of the labeled instruction or literal data item.

3. Assemble a PC-relative encoding of the instruction, that is, one that reads its PC or Align(PC,4) value and adds the calculated offset to form the required address.
Note

For instructions that encode a subtraction operation, if the instruction cannot encode the calculated offset, but can encode minus the calculated offset, the instruction encoding specifies a subtraction of minus the calculated offset.

The following instructions include a label:

- B and BL.
- CBNZ and CBZ.
- LDC, LDC2, LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLI, and VLDR:
  
  When the assembler calculates an offset of 0 for the normal syntax of these instructions, it must assemble an encoding that adds 0 to the Align(PC,4) value of the instruction. Encodings that subtract 0 from the Align(PC,4) value cannot be specified by the normal syntax.

  There is an alternative syntax for these instructions that specifies the addition or subtraction and the immediate offset explicitly. In this syntax, the label is replaced by [PC, #/+/-<imm>], where:

  - +/- is + or omitted to specify that the immediate offset is to be added to the Align(PC,4) value, or - if it is to be subtracted.

  - <imm> is the immediate offset.

  This alternative syntax makes it possible to assemble the encodings that subtract 0 from the Align(PC,4) value, and to disassemble them to a syntax that can be re-assembled correctly.

- ADR:

  When the assembler calculates an offset of 0 for the normal syntax of this instruction, it must assemble the encoding that adds 0 to the Align(PC,4) value of the instruction. The encoding that subtracts 0 from the Align(PC,4) value cannot be specified by the normal syntax.

  There is an alternative syntax for this instruction that specifies the addition or subtraction and the immediate value explicitly, by writing them as additions ADD <Rd>,PC,#<imm> or subtractions SUB <Rd>,PC,#<imm>. This alternative syntax makes it possible to assemble the encoding that subtracts 0 from the Align(PC,4) value, and to disassemble it to a syntax that can be re-assembled correctly.

Note

ARM recommends that where possible, the alias is used.

C1.4.3 Using syntax information

For a particular encoding:

- There is usually more than one assembler syntax prototype variant that assembles to it.

- The exact set of prototype variants that assemble to it usually depends on the operands to the instruction, for example the register numbers or immediate constants. As an example, for the AND (register) instruction, the syntax AND R0, R0, R8 selects a 32-bit encoding, but AND R0, R0, R1 selects a 16-bit encoding.

For each instruction encoding that belongs to a target instruction set, an assembler can use the information in the encoding to determine whether it can use that particular encoding to encode the instruction requested by the UAL source. If multiple encodings can encode the instruction, then:

- If both a 16-bit encoding and a 32-bit encoding can encode the instruction, the architecturally preferred encoding is the 16-bit encoding. This means that the assembler must use the 16-bit encoding instead of the 32-bit encoding.

- If multiple encodings of the same width can encode the instruction, the assembler syntax indicates the preferred encoding, and how software can select other encodings if required. Each encoding also documents UAL syntax that selects it in preference to any other encoding. If no encodings of the target instruction set can encode the instruction requested by the UAL source, the assembler normally generates an error that indicates that the instruction is not available in that instruction set.
C1.5 Standard assembler syntax fields

The following assembler syntax prototype fields are standard across all or most instructions:

- `<c>` Specifies the condition under which the instruction is executed. If `<c>` is omitted, it defaults to `always (AL)`. For details see Conditional instructions on page C1-250.

- `<q>` Specifies one of the following optional assembler qualifiers on the instruction:
  - `.N` Meaning narrow. The assembler must select a 16-bit encoding for the instruction. If this is not possible, an assembler error is produced.
  - `.W` Meaning wide. The assembler must select a 32-bit encoding for the instruction. If this is not possible, an assembler error is produced.

If neither `.W` nor `.N` is specified, the assembler can select either a 16-bit or 32-bit encoding. If both encoding lengths are available, it must select a 16-bit encoding. In the few cases where more than one encoding of the same length is available for an instruction, the rules for selecting between them are instruction-specific and are part of the instruction description.
C1.6 Conditional execution

*Conditionally executed* means that the instruction only has its normal effect on the programmers’ model operation, memory and coprocessors if the N, Z, C, and V flags in the APSR satisfy a condition specified in the instruction. If the flags do not satisfy this condition, the instruction acts as a NOP, that is, execution advances to the next instruction as normal, including any relevant checks for exceptions being taken, but has no other effect.

Most T32 instructions are unconditional. Conditional execution in T32 code can be achieved using any of the following instructions:

- A 16-bit conditional branch instruction, with a branch range of −256 to +254 bytes. See B on page C2-342 for details.
- A 32-bit conditional branch instruction, with a branch range of approximately ± 1MB. See B on page C2-342 for details.
- 16-bit Compare and Branch on Zero and Compare and Branch on Nonzero instructions, with a branch range of +4 to +130 bytes. See CBNZ, CBZ on page C2-355 for details.
- A 16-bit If-Then instruction that makes up to four following instructions conditional. See IT on page C2-380 for details. The instructions that are made conditional by an IT instruction are called its IT block. Instructions in an IT block must either all have the same condition, or some can have one condition, and others can have the inverse condition.

In T32 instructions, the condition (if it is not AL) is encoded in a preceding IT instruction, other than B, CBZ, and CBNZ. Some conditional branch instructions do not require a preceding IT instruction, and include a condition code in their encoding.

Table C1-1 shows the conditions that are available for conditionally executed instructions.

Table C1-1 Condition codes

---

**Notes:**
- ^b Carry set and Carry clear do not support floating-point arithmetic.
- ^c Carry clear and Carry set do not support floating-point arithmetic.
- ^d None (AL) is always unconditional.
C1.6 Conditional execution

C1.6.1 Pseudocode details of conditional execution

The `CurrentCond()` pseudocode function prototype returns a 4-bit condition specifier as follows:

- For the T1 and T3 encodings of the Branch instruction shown in B on page C2-342, it returns the 4-bit `cond` field of the encoding.
- For all other T32 instructions:
  - If `ITSTATE.IT<3:0>` != '0000' it returns `ITSTATE.IT<7:4>`
  - If `ITSTATE.IT<7:0>` == '00000000' it returns '1110'
  - Otherwise, execution of the instruction is UNPREDICTABLE.

For more information, see `ITSTATE`.

The `ConditionPassed()` function uses this condition specifier and the APSR condition flags to determine whether the instruction must be executed.

C1.6.2 Conditional execution of undefined instructions

If an undefined instruction fails a condition check in ARMv8-M, the instruction behaves as a NOP and does not cause an exception.

C1.6.3 ITSTATE

ITSTATE is held in EPSR, see Execution Program Status Register (EPSR) on page B3-43.

The bit assignments of the ITSTATE register are:

```
7 6 5 4 3 2 1 0
```

```
\begin{array}{c}
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
\hline
\text{IT}[7:0]
\end{array}
```

This register holds the If-Then Execution state bits for the T32 IT instruction. See IT on page C2-380 for a description of the IT instruction and the associated IT block.

ITSTATE divides into two subfields:

- **IT[7:5]**
  - Holds the base condition for the current IT block. The base condition is the top 3 bits of the condition specified by the IT instruction.
  - This subfield is 0b000 when no IT block is active.

- **IT[4:0]**
  - Encodes:
    - The size of the IT block. This is the number of instructions that are to be conditionally executed. The size of the block is indicated by the position of the least significant 1 in this field which is bit[4-size of the block].
    - The value of the least significant bit, bit[0], of the condition code for each instruction in the block.
  
  **Note**
  - Changing the value of the least significant bit of a condition code from 0 to 1 inverts the condition code. For example cond 0000 is EQ, and cond 0001 is NE.

  This subfield is 0b0000 when no IT block is active.
When an IT instruction is executed, IT bits[7:0] are set according to the condition in the instruction, and the *Then* and *Else* (T and E) parameters in the instruction. See *IT* on page C2-380 for more information.

An instruction in an IT block is conditional. See *Conditional instructions* on page C1-250. The condition used is the current value of IT[7:4]. When an instruction in an IT block completes its execution normally, ITSTATE is advanced by shifting IT bits[4:0] left by 1 bit.

For example:

<table>
<thead>
<tr>
<th>IT[7:5]</th>
<th>IT[4:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>ITTEE EQ 000</td>
<td>00111</td>
</tr>
<tr>
<td>ADDEQ R0, R1 000</td>
<td>01110</td>
</tr>
<tr>
<td>SUBEQ R2, R3 000</td>
<td>11100</td>
</tr>
<tr>
<td>ADDNE R4, R5 000</td>
<td>11000</td>
</tr>
<tr>
<td>SUBNE R6, R7 000</td>
<td>10000</td>
</tr>
</tbody>
</table>

**Note**

Instructions that can complete their normal execution by branching are only permitted in an IT block as its last instruction, and so always result in ITSTATE advancing to normal execution.

In Table C1-2, *P* represents the base condition or the inverse of the base condition.

| IT Advance() describes how ITSTATE advances after normal execution. |
| InITBlock and LastInITBlock test whether the current instruction is in an IT block, and whether it is the last instruction of an IT block. |

**C1.6.4 Branching into and out of an IT block**

Execution of an instruction outside of an IT block with ITSTATE set to a non-zero IT value is UNPREDICTABLE. Execution of an instruction inside an IT block with ITSTATE set to zero, an ICI value, or a value that is inconsistent with the IT block is UNPREDICTABLE.

See also:

- *Instructions in IT blocks and EPSR.IT* on page G1-1334.
C1.7 Instruction set encoding information

C1.7.1 UNDEFINED and UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE.
- An UNDEFINSTR Usage Fault. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description in Chapter C2.

An instruction is UNPREDICTABLE if:

- A bit marked (0) or (1) in the encoding diagram of an instruction is not 0 or 1, respectively, and the pseudocode for that encoding does not indicate that a different special case applies
- It is declared as UNPREDICTABLE in an instruction description in Chapter C2.

Unless otherwise specified, a T32 instruction that is provided by one or more of the architecture extensions is either UNPREDICTABLE or UNDEFINED in an implementation that does not include those extensions. See the individual instruction descriptions for details.

For information about the CONSTRAINED UNPREDICTABLE behavior that can be generated by an instruction, see Appendix G1 Architectural Constraints on UNPREDICTABLE behaviors.

C1.7.2 Use of 0b1111 as a register specifier

The use of 0b1111 as a register specifier is not normally permitted in T32 instructions. When a value of 0b1111 is permitted, as indicated in the individual instruction descriptions, a variety of meanings is possible. For register reads, these meanings are:

- Read the PC value, that is, the address of the current instruction + 4. The base register of the table branch instructions TBB and TBH can be the PC. This enables branch tables to be placed in memory immediately after the instruction. (Some instructions read the PC value implicitly, without the use of a register specifier, for example the conditional branch instruction B<cond>.)
- Read the word-aligned PC value, that is, the address of the current instruction + 4, with bits [1:0] forced to zero. The base register of LDC, LDR, LDRB, LDRD (pre-indexed, no write-back), LDRH, LDRSB, and LDRSH instructions can be the word-aligned PC. This enables PC-relative data addressing. In addition, some encodings of the ADD and SUB instructions permit their source registers to be 0b1111 for the same purpose.
- Read zero. This is done in some cases when one instruction is a special case of another, more general instruction, but with one operand zero. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page. An example of this is the descriptions of MOV (register) and ORR (register).

For register writes, these meanings are:

- The PC can be specified as the destination register of an LDR instruction. This is done by encoding Rt as 0b1111. The loaded value is treated as an address, and the effect of execution is a branch to that address. bit [0] of the loaded value selects the Execution state after the branch and must have the value 1.
- Discard the result of a calculation. This is done in some cases when one instruction is a special case of another, more general instruction, but with the result discarded. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page. An example of this is the descriptions of TST (register) and AND (register).
- If the destination register specifier of an LDRB, LDRH, LDRSB, or LDRSH instruction is 0b1111, the instruction is a memory hint instead of a load operation.
- If the destination register specifier of an MRC instruction is 0b1111, bits [31:28] of the value transferred from the coprocessor are written to the N, Z, C, and V flags in the APSR, and bits [27:0] are discarded.
C1.7.3 Use of 0b1101 as a register specifier

R13 is defined in the T32 instruction set so that its use is primarily as a stack pointer, and R13 is normally identified as SP in T32 instructions.

The following subsections describe the restrictions that apply to using SP:

- **SP[1:0] definition.**
- **32-bit T32 instruction support for SP.**
- **16-bit T32 instruction support for SP.**

### SP[1:0] definition

Bits [1:0] of SP must be treated as SBZP (Should Be Zero or Preserved). Writing a non-zero value to bits [1:0] results in UNPREDICTABLE behavior. Reading bits[1:0] returns zero.

### 32-bit T32 instruction support for SP

32-bit T32 instruction support for SP is restricted to the following cases:

- SP as the source or destination register of a MOV instruction. Only register to register transfers without shifts are supported, with no flag setting:
  
  \[
  \text{MOV} \quad \text{SP}, Rm \\
  \text{MOV} \quad Rn, \text{SP}
  \]

- Adjusting SP up or down by a multiple of its alignment:
  
  \[
  \text{ADD}[\text{W}] \quad \text{SP}, SP, #N \quad \text{; For N a multiple of 4} \\
  \text{SUB}[\text{W}] \quad \text{SP}, SP, #N \quad \text{; For N a multiple of 4} \\
  \text{ADD} \quad \text{SP}, SP, Rm, \text{LSL #shft} \quad \text{; For shft=0,1,2,3} \\
  \text{SUB} \quad \text{SP}, SP, Rm, \text{LSL #shft} \quad \text{; For shft=0,1,2,3}
  \]

- SP as a base register, Rn, of any load or store instruction. This supports SP-based addressing for load, store, or memory hint instructions, with positive or negative offsets, with and without write-back.

- SP as the first operand, Rn, in any ADD(S), CMN, CMP, or SUB(S) instruction. The add and subtract instructions support SP-based address generation, with the address going into a general-purpose register. CMN and CMP can check the stack pointer.

- SP as the transferred register, Rt, in any LDR or STR instruction.

- SP as the address in a POP or PUSH instruction.

Use of the SP as a general-purpose register in any other case is UNPREDICTABLE.

### 16-bit T32 instruction support for SP

For 16-bit data processing instructions that affect general-purpose registers R8-R15, SP can only be used as described in **32-bit T32 instruction support for SP.** ARM deprecates any other use. This affects the high register forms of CMP and ADD, where ARM deprecates the use of SP as Rm.

C1.7.4 Branching

Writing an address to the PC causes either a simple branch to that address or an interworking branch.

A simple branch is performed by BranchWritePC.

An interworking branch is performed by BXWritePC.

Branching can occur in cases where 0b1111 is not a register specifier.

In these cases, instructions write the PC either:

- Implicitly, for example, B<cond>.
- By using a register mask rather than a register specifier, for example LDM.
The address to branch to can be:

- A loaded value, for example LDM.
- A register value, for example BX.
- The result of a calculation, for example TBB or TBH.

Table C1-3 summarizes the branch instructions in the T32 instruction set. In addition to providing for changes in the flow of execution, some branch instructions can change the Security state.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>See</th>
<th>Range, T32</th>
</tr>
</thead>
<tbody>
<tr>
<td>Branch to target address</td>
<td>$B$ on page C2-342</td>
<td>±16MB</td>
</tr>
<tr>
<td>Compare and Branch on Nonzero,</td>
<td>$CBNZ, CBZ$ on page C2-355</td>
<td>0-126 bytes</td>
</tr>
<tr>
<td>Compare and Branch on Zero</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Call a subroutine</td>
<td>$BL$ on page C2-350</td>
<td>±16MB</td>
</tr>
<tr>
<td>Call a subroutine, optionally change Security state</td>
<td>$BLX, BLXNS$ on page C2-351</td>
<td>Any</td>
</tr>
<tr>
<td>Branch to target address, change to Non-secure state</td>
<td>$BX, BXNS$ on page C2-353</td>
<td>Any</td>
</tr>
<tr>
<td>Table Branch (byte offsets)</td>
<td>$TBB, TBH$ on page C2-641</td>
<td>0-510 bytes</td>
</tr>
<tr>
<td>Table Branch (halfword offsets)</td>
<td></td>
<td>0-131070 bytes</td>
</tr>
</tbody>
</table>

Branches to loaded and calculated addresses can be performed by LDR, LDM and data-processing instructions. For details, see Chapter C2 Instruction Specification.

In addition to the branch instructions shown in Table C1-3, a load instruction that targets the PC behaves as a branch instruction.
C1.8 Modified immediate constants

The encoding of modified immediate constants in T32 instructions is:

<table>
<thead>
<tr>
<th>i:imm3:a</th>
<th>&lt;const&gt; a</th>
<th>Carry flag setb</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000x</td>
<td>00000000 00000000 00000000 abcdefgh</td>

#### C1.8.1 Operation of modified immediate constants

*T32ExpandImm on page E2-1279 and T32ExpandImm_C on page E2-1280* show the operation of modified immediate constants.
C1.9  NOP-compatible hint instructions

A hint instruction only provides an indication to the PE. It is not required that the PE perform an operation on a hint instruction.

A NOP-compatible hint instruction either:

• Acts as a NOP (No Operation) instruction.
• Performs some IMPLEMENTATION DEFINED behavior.

A PE without the Main Extension only supports the 16-bit encodings of the ARMv8-M NOP-compatible hint instructions. A PE with the Main Extension supports both the 16-bit and the 32-bit encodings of the ARMv8-M NOP-compatible hint instructions.

• For information on the 16-bit encodings see Hints on page C2-273.
• For information on the 32-bit encodings see Hints on page C2-288.
C1.10 Instruction set, interworking support

In the A profile version of the ARMv8 architecture, ARMv8-A, the AArch32 Execution state supports two instruction sets, T32 and A32, and software can use interworking branches to select which of these to execute.

In ARMv8-M, the following instructions are interworking branches:

- BX and BLX.
- POP and all forms of LDM, when the register list includes the PC.
- LDR (immediate), LDR (literal), and LDR (register), with <Rt> equal to the PC.

This means that the value of bit[0] for these instructions is not stored in the PC. Instead, it selects the instruction set that is executed after the branch.

In ARMv8-M, if bit [0] of an interworking address is:

0  EPSR.T is assigned the value 0b0, causing the PE to take an INVSTATE UsageFault on the next instruction it attempts to execute.

1  EPSR.T is assigned the value 0b1. The instruction set state is T32 state and all instructions are decoded as T32 instructions.

Bit[0] of the PC is always 0.

See also:

- Instruction set on page C1-244.
- BXWritePC on page E2-1159.
C1.11 Instruction set, interstating support

In ARMv8-M, the following instructions are interstating branches:

- BXNS and BLXNS.

This means that the value of bit[0] for these instructions is not stored in the PC. Instead, it selects the target Security state.

When an interstating branch is executed in Secure state, bit[0] of the target address indicates the target Security state:

<table>
<thead>
<tr>
<th>Bit[0]</th>
<th>Security State</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The target Security state is Non-secure state.</td>
</tr>
<tr>
<td>1</td>
<td>The target Security state is Secure state.</td>
</tr>
</tbody>
</table>

Bit[0] of the PC is always 0.

Interstating branches are UNDEFINED when executing in Non-secure state.

See also:

- In Chapter B3 Programmers’ Model:
  — Security state transitions on page B3-61.
Chapter C2
Instruction Specification

This chapter specifies the ARMv8-M instruction set. It contains the following sections:

• Top level T32 instruction set encoding on page C2-264.
• 16-bit T32 instruction encoding on page C2-265.
• 32-bit T32 instruction encoding on page C2-276.
• Alphabetical list of instructions on page C2-312.

In this chapter:

• In the decode tables, an entry of - for a field value means that the value of the field does not affect the decoding.
• In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.
C2.1 Top level T32 instruction set encoding

The T32 instruction stream is a sequence of halfword-aligned halfwords. Each T32 instruction is either a single 16-bit halfword in that stream, or a 32-bit instruction consisting of two consecutive halfwords in that stream.

If the value of bits[15:11] of the halfword being decoded is one of the following, the halfword is the first halfword of a 32-bit instruction:

- 0b11101
- 0b11110
- 0b11111

Otherwise, the halfword is a 16-bit instruction.

C2.4 Alphabetical list of instructions

Every ARMv8-M instruction is listed in this section. See Chapter C1 Instruction Set Overview for the format of the instruction descriptions.
C2.4.1   ADC (immediate)

Add with Carry (immediate) adds an immediate value and the carry flag value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

T1

ARMv8-M Main Extension only

ADC variant

Applies when $S = 0$.

ADCS variant

Applies when $S = 1$.

Decode for all variants of this encoding

if !HaveMainExt() then UNDEFINED;

$ d = \text{UInt}(Rd); \ n = \text{UInt}(Rn); \ \text{setflags} = (S == '1'); \ \text{imm32} = \text{T32ExpandImm}(i:imm3:imm8);

if $d \ \text{IN} \{13,15\} || n \ \text{IN} \{13,15\}$ then UNPREDICTABLE;

Assembler symbols

<

See Standard assembler syntax fields on page C1-252.

>

See Standard assembler syntax fields on page C1-252.

<Rd>

Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn>

Is the general-purpose source register, encoded in the "Rn" field.

<const>

An immediate value. See Modified immediate constants on page C1-259 for the range of values.

Operation

if ConditionPassed() then

EncodingSpecificOperations();

(result, carry, overflow) = AddWithCarry(R[n], imm32, APSR.C);

R[d] = result;

if setflags then

APSR.N = result<31>;

APSR.Z = IsZeroBit(result);

APSR.C = carry;

APSR.V = overflow;

Exceptions

None.
### C2.4.2 ADC (register)

Add with Carry (register) adds a register value, the carry flag value, and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

#### T1

*ARMv8-M*

\[
\begin{array}{c|c|c|c|c|c|c}
15 & 14 & 13 & 12 & 11 & 10 & 9 \10 & 8 & 7 & 6 & 5 & 3 & 2 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & Rm & Rdn \\
\end{array}
\]

**T1 variant**

ADC\{<c>}{<q>} {<Rdn>,} <Rdn>, <Rm> // Inside IT block
ADC{<q>} {<Rdn>,} <Rdn>, <Rm> // Outside IT block

**Decode for this encoding**

\[

Assembler symbols
<
See Standard assembler syntax fields on page C1-252.
>
See Standard assembler syntax fields on page C1-252.

<iimm7>
Is an unsigned immediate, a multiple of 4 in the range 0 to 508, encoded in the "imm7" field as <iimm7>/4.

<Rd>
For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.
For encoding T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<iimm8>
Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <iimm8>/4.

<iimm12>
Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const>
An immediate value. See Modified immediate constants on page C1-259 for the range of values.

Operation for all encodings

if ConditionPassed() then
EncodingSpecificOperations();
(result, carry, overflow) = AddWithCarry(SP, imm32, '0');
RSPCheck[d] = result;
if setflags then
  APSR.N = result<31>;

if (d == 15 && S == '0') || m IN {13,15} then UNPREDICTABLE;

**Assembler symbols**

\(<c>\)  See *Standard assembler syntax fields on page* C1-252.

\(<q>\)  See *Standard assembler syntax fields on page* C1-252.

\(<Rdm>\)  Is the general-purpose destination and second source register, encoded in the "Rdm" field. If omitted, this register is the SP. ARM deprecates using the PC as the destination register, but if the PC is used, the instruction is a simple branch to the address calculated by the operation.

\(<Rd>\)  Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

\(<Rm>\)  For encoding T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T3: is the second general-purpose source register, encoded in the "Rm" field.

\(<shift>\)  Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- \( LSL \)  when type = 00
- \( LSR \)  when type = 01
- \( ASR \)  when type = 10
- \( ROR \)  when type = 11

\(<amount>\)  Is the shift amount, in the range 1 to 31 (when \( <shift> = LSL \) or \( ROR \)) or 1 to 32 (when \( <shift> = LSR \) or \( ASR \)) encoded in the "imm3:imm2" field as \( <amount> \) modulo 32.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();
  shifted = Shift(R[m], shift_t, shift_n, APSR.C);
  (result, carry, overflow) = AddWithCarry(SP, shifted, '0');
  if d == 15 then
    ALUWritePC(result); // setflags is always FALSE here
  else
    RSPCheck[d] = result;
    if setflags then
      APSR.N = result<31>;

APSR.Z = IsZeroBit(result);
APSR.C = carry;
APSR.V = overflow;

Exceptions

UsageFault.
C2.4.5 ADD (immediate)

Add (immediate) adds an immediate value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD (SP plus immediate).
For encoding T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD (SP plus immediate). If the PC is used, see ADR.
\(<imm3>\)  Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.
\(<imm12>\)  Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.
\(<const>\)  An immediate value. See Modified immediate constants on page C1-259 for the range of values.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry, overflow) = AddWithCarry(R[n], imm32, '0');
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        APSR.V = overflow;

Exceptions

None.
C2.4.6   ADD (immediate, to PC)

Add to PC adds an immediate value to the Align(PC, 4) value to form a PC-relative address, and writes the result

to the destination register. ARM recommends that, where possible, software avoids using this alias.

This instruction is a pseudo-instruction of the ADR instruction. This means that:

- The encodings in this description are named to match the encodings of ADR.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of ADR gives the operational pseudocode for this instruction.

T1

ARMv8-M

|15 14 13 12|11 10  8  7 |0|
|---|---|---|---|
|1 0 1 0 0 | Rd | imm8 |

T1 variant

ADD{<c>}{<q>} <Rd>, PC, #<imm8>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is never the preferred disassembly.

T3

ARMv8-M Main Extension only

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is never the preferred disassembly.

ADD{<c>}{<q>} <Rd>, PC, #<imm12>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is never the preferred disassembly.

Assembler symbols

<>

See Standard assembler syntax fields on page C1-252.

<q>

See Standard assembler syntax fields on page C1-252.
<Rd>  Is the general-purpose destination register, encoded in the "Rd" field.

<label>  For encoding T1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. If the offset is zero or positive, encoding T3 is used, with imm32 equal to the offset. If the offset is negative, encoding T2 is used, with imm32 equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are 0-4095.

<imm8>  Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4.

<imm12>  Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

**Operation for all encodings**

The description of ADR gives the operational pseudocode for this instruction.
C2.4.7 ADD (register)

ADD (register) adds a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

\end{align*}
\]

Assembler symbols

\(<c>\>

See Standard assembler syntax fields on page C1-252.

\(<c>\)

See Standard assembler syntax fields on page C1-252.

\(<\text{Rdn}>\)

Is the general-purpose source and destination register, encoded in the "DN:Rdn" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch. The assembler language allows \(<\text{Rdn}>\) to be specified once or twice in the assembler syntax. When used inside an IT block, and \(<\text{Rdn}>\) and \(<\text{Rm}>\) are in the range R0 to R7, \(<\text{Rdn}>\) must be specified once so that encoding T2 is preferred to encoding T1. In all other cases there is no difference in behavior when \(<\text{Rdn}>\) is specified once or twice.

\(<\text{Rd}>\)

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. When used inside an IT block, \(<\text{Rd}>\) must be specified. When used outside an IT block, \(<\text{Rd}>\) is optional, and:

- If omitted, this register is the same as \(<\text{Rn}>\).
- If present, encoding T1 is preferred to encoding T2.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as \(<\text{Rn}>\).

\(<\text{Rn}>\)

For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.

For encoding T3: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD (SP plus register).

\(<\text{Rm}>\)

For encoding T1 and T3: is the second general-purpose source register, encoded in the "Rm" field.

For encoding T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

\(<\text{shift}>\)

Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- LSL \quad when \text{type} = 00
LSR  when type = 01
ASR  when type = 10
ROR  when type = 11

<amount>  Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

**Operation for all encodings**

if ConditionPassed() then
  EncodingSpecificOperations();
  shifted = Shift(R[m], shift_t, shift_n, APSR.C);
  (result, carry, overflow) = AddWithCarry(R[n], shifted, '0');
  if d == 15 then
    ALUWritePC(result);  // setflags is always FALSE here
  else
    R[d] = result;
    if setflags then
      APSR.N = result<31>;
      APSR.Z = IsZeroBit(result);
      APSR.C = carry;
      APSR.V = overflow;

**Exceptions**

None.
C2.4.8 ADR

Address to Register adds an immediate value to the PC value, and writes the result to the destination register.

This instruction is used by the pseudo-instructions ADD (immediate, to PC) and SUB (immediate, from PC). The pseudo-instruction is never the preferred disassembly.

MOV, shift or rotate by value variant

ASR<.W {<Rd>,} <Rm>, #<imm> // Inside IT block, and <Rd>, <Rm>, <imm> can be represented in T2

is equivalent to

MOV<{<op>,} <Rd>, <Rm>, ASR #<imm>

and is always the preferred disassembly.

ASR<\{<op>,} {<Rd>,} <Rm>, #<imm>

is equivalent to

MOV<\{<op>,} <Rd>, <Rm>, ASR #<imm>

and is always the preferred disassembly.

Assembler symbols

- \(<c>\) See Standard assembler syntax fields on page C1-252.
- \(<q>\) See Standard assembler syntax fields on page C1-252.
- \(<Rd>\) Is the general-purpose destination register, encoded in the "Rd" field.
<Rm> Is the general-purpose source register, encoded in the "Rm" field.

<imm> For encoding T2: is the shift amount, in the range 1 to 32, encoded in the "imm5" field as <imm> modulo 32.
For encoding T3: is the shift amount, in the range 1 to 32, encoded in the "imm3:imm2" field as <imm> modulo 32.

**Operation for all encodings**

The description of MOV (register) gives the operational pseudocode for this instruction.
C2.4.12 ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination registers. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted register).
- The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

Notes for all encodings

Related encodings: Branches and miscellaneous control on page C2-287.

Assembler symbols

\(<c>\)

For encoding T1: see Standard assembler syntax fields on page C1-252. Must not be AL or omitted.
For encoding T2 and T4: see Standard assembler syntax fields on page C1-252.
For encoding T3: see Standard assembler syntax fields on page C1-252. \(<c>\) must not be AL or omitted.

\(<q>\)

See Standard assembler syntax fields on page C1-252.

\(<label>\)

For encoding T1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets \text{imm32} to that offset. Permitted offsets are even numbers in the range –256 to 254.
For encoding T2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets \text{imm32} to that offset. Permitted offsets are even numbers in the range –2048 to 2046.
For encoding T3: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets \text{imm32} to that offset. Permitted offsets are even numbers in the range –1048576 to 1048574.
For encoding T4: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets \text{imm32} to that offset. Permitted offsets are even numbers in the range –16777216 to 16777214.

Operation for all encodings

\( \text{if ConditionPassed()} \text{ then} \)
\( \text{EncodingSpecificOperations();} \)
\( \text{BranchWritePC(PC + imm32);} \)

Exceptions

None.

\]

T1 variant

BKPT\{<q>\} \{#\}<imm>

Decode for this encoding

\[
\text{imm32} = \text{ZeroExtend}(\text{imm8}, 32);
\]

// imm32 is for assembly/disassembly only and is ignored by hardware.

Assembler symbols

\(<q>\) See Standard assembler syntax fields on page C1-252. A BKPT instruction must be unconditional.

\(<\text{imm}>\) Is an 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. The PE ignores this value, but a debugger might use it to store additional information about the breakpoint.

Operation

EncodingSpecificOperations();

BKPTInstrDebugEvent();

Exceptions

DebugMonitor.
C2.4.21   BL

Branch with Link (immediate) calls a subroutine at a PC-relative address.

BL{<c>}{<q>} {<label>}

*Decode for this encoding*

I1 = NOT(J1 EOR S); I2 = NOT(J2 EOR S); imm32 = SignExtend(S:I1:I2:imm10:imm11:'0', 32);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;

*Assembler symbols*

{<c>} See *Standard assembler syntax fields* on page C1-252.
{<q>} See *Standard assembler syntax fields* on page C1-252.
<label> The label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are even numbers in the range −16777216 to 16777214.

*Operation*

if ConditionPassed() then
    EncodingSpecificOperations();
    next_instr_addr = PC;
    LR = next_instr_addr<31:1> : '1';
    BranchWritePC(PC + imm32);

*Exceptions*

None.
C2.4.22   BLX, BLXNS

Branch with Link and Exchange calls a subroutine at an address, with the address and instruction set specified by a register. Bit[0] complies with the ARM architecture interworking rules for switching between the A32 and T32 instruction sets. However, ARMv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

Branch with Link and Exchange Non-secure calls a subroutine at an address specified by a register, and if bit[0] of the target address is 0 then the instruction causes a transition from Secure to Non-secure state. This variant of the instruction must only be used when the additional steps required to make such a transition safe have been taken.

BLXNS is UNDEFINED if executed in Non-secure state, and is only implemented if the Security Extensions have been implemented.

See GVBB for further details of register and stack changes as a result of BLXNS causing a transition from Secure to Non-secure state.

T1

if n == 15 || m IN {13,15} then UNPREDICTABLE;
```

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields* on page C1-252.
- `<q>` See *Standard assembler syntax fields* on page C1-252.
- `<Rn>` For encoding T1 and T3: is the first general-purpose source register, encoded in the "Rn" field.
  For encoding T2: is the first general-purpose source register, encoded in the "N:Rn" field.
- `<Rm>` Is the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
  - LSL when type = 00
  - LSR when type = 01
  - ASR when type = 10
  - ROR when type = 11
- `<amount>` Is the shift amount, in the range 1 to 31 (when `<shift>` = LSL or ROR) or 1 to 32 (when `<shift>` = LSR or ASR) encoded in the "imm3:imm2" field as `<amount>` modulo 32.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations();
  shifted = Shift(R[m], shift_t, shift_n, APSR.C);
  (result, carry, overflow) = AddWithCarry(R[n], NOT(shifted), '1');
  APSR.N = result<31>;
  APSR.Z = IsZeroBit(result);
  APSR.C = carry;
  APSR.V = overflow;
```

**Exceptions**

None.
C2.4.32  CPS

Change PE State. The instruction modifies the PRIMASK and FAULTMASK special-purpose register values.

All other encodings of option are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    InstructionSynchronizationBarrier(option);

Exceptions

None.
C2.4.41 IT

If Then makes up to four following instructions (the IT block) conditional. The conditions for the instructions in the IT block can be the same, or some of them can be the inverse of others.

IT does not affect the condition code flags. Branches to any instruction in the IT block are not permitted, apart from those performed by exception returns.

16-bit instructions in the IT block, other than CMP, CMN, and TST, do not set the condition code flags. The AL condition can be specified to get this changed behavior without conditional execution.

Notes for all encodings

Assembler symbols

L If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.

<c> See Standard assembler syntax fields on page C1-252.

<q> See Standard assembler syntax fields on page C1-252.

<coproc> Is the name of the coprocessor, encoded in the "coproc" field. The valid coprocessor names are p10, p11, p14, and p15.

<CRd> Is the coprocessor register to be transferred, encoded in the "CRd" field.

<label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE (encoded as U == 1). If the offset is negative, imm32 is equal to minus the offset and add == FALSE (encoded as U == 0).

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
+ when U = 1

<imm> Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();
   ExecuteCPCheck(cp);
   if !Coproc_Accepted(cp, ThisInstr()) then
      GenerateCoprocessorException();
   else

      address = if index then offset_addr else Align(PC,4);
      repeat
         Coproc_SendLoadedWord(MemA[address,4], cp, ThisInstr());
      until Coproc_DoneLoading(cp, ThisInstr());

Exceptions

C2.4.50   LDM, LDMIA, LDMFD

Load Multiple loads multiple registers from consecutive memory locations using an address from a base register. The sequential memory locations start at this address, and the address just above the last of those locations can optionally be written back to the base register.

The registers loaded can include the PC. If they do, the word loaded for the PC is treated as a branch address, a function return value, or an exception return value. Bit[0] of the address in the PC complies with the ARM architecture interworking rules for switching between the A32 and T32 instruction sets. However, ARMv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] of the target address is 0, and the target address is not FNC_RETURN or EXC_RETURN, the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

This instruction is used by the alias POP. The alias is always the preferred disassembly.

if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;

Assembler symbols

IA  
Is an optional suffix for the Increment After form.

<
See Standard assembler syntax fields on page C1-252.

>
See Standard assembler syntax fields on page C1-252.

Rn
Is the general-purpose base register, encoded in the "Rn" field.

!
For encoding T1: the address adjusted by the size of the data loaded is written back to the base register. It is omitted if <Rn> is included in <registers>, otherwise it must be present.

For encoding T2: the address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

registers
For encoding T1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field.

For encoding T2: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0.

If the PC is in the list:
• The LR must not be in the list.
• The instruction must be either outside any IT block, or the last instruction in an IT block.

For encoding T3: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the PC. If the PC is in the list, the "P" field is set to 1, otherwise this field defaults to 0. If the PC is in the list, the instruction must be either outside any IT block, or the last instruction in an IT block.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if n == 13 && wback then
        (limit, applylimit) = LookUpSPLim(LookUpSP());
    else
        applylimit = FALSE;

// If memory operation is not performed as a result of a stack limit violation,
// and the write-back of the SP itself does not raise a stack limit violation, it
// is UNKNOWN whether a SPLIM exception is raised.
// ARM recommends that any instruction which discards a memory access as
// a result of a stack limit violation, and where the write-back of the SP itself
// does not raise a stack limit violation, generates an SPLIM exception.
for i = 0 to 14
    // If R[n] is the SP, memory operation only performed if limit not violated
    if registers<i> == '1' && (!applylimit || (UInt(address) >= UInt(limit))) then
        if i != n then
            R[i] = MemA[address,4];
        else
            newBaseVal = MemA[address,4];
            address = address + 4;
        if registers<i> == '1' && (!applylimit || (UInt(address) >= UInt(limit))) then
            newPCVal = MemA[address,4];
    // If the register list contains the register that holds the base address it
    // must be updated after all memory reads have been performed. This prevents
    // the base address being overwritten if one of the memory reads generates a
    // fault.
    if registers<i> == '1' then
        wback = TRUE;
    else
        newBaseVal = R[n] + 4*BitCount(registers);
    // If the PC is in the register list update that now, which may raise a fault
    // Likewise if R[n] is the SP writing back may raise a fault due to SP limit violation
    if registers<i> == '1' then
        loadWritePC(newPCVal, n, newBaseVal, wback, FALSE);
    elsif wback then
        RSPCheck[n] = newBaseVal;

Exceptions
C2.4.51 LDMDB, LDMEA

Load Multiple Decrement Before (Load Multiple Empty Ascending) loads multiple registers from sequential memory locations using an address from a base register. The sequential memory locations end just below this address, and the address of the first of those locations can optionally be written back to the base register.

The registers loaded can include the PC. If they do, the word loaded for the PC is treated as a branch address or an exception return value. Bit[0] complies with the ARM architecture interworking rules for switching between the A32 and T32 instruction sets. However, ARMv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

        LoadWritePC(newPCVal, n, newBaseVal, wback, TRUE);
    elsif wback then
        RSPCheck[n] = newBaseVal;

Exceptions

C2.4.52   LDR (immediate)

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing.

The register loaded can be the PC. If it is, the word loaded for the PC is treated as a branch address or an exception return value. Bit[0] complies with the ARM architecture interworking rules for switching between the A32 and T32 instruction sets. However, ARMv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

This instruction is used by the alias POP. See Alias conditions on page C2-399 for details of when each alias is preferred.

Assembler symbols

<

See Standard assembler syntax fields on page C1-252.

>

See Standard assembler syntax fields on page C1-252.

<

For encoding T1 and T2: is the general-purpose register to be transferred, encoded in the "Rt" field.
For encoding T3: is the general-purpose register to be transferred, encoded in the "Rt" field. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC.
For encoding T4: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC.

\(<Rn>\)

For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

For encoding T3 and T4: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDR (literal).

\(+/-\)

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when \(U = 0\)
+ when \(U = 1\)

\(+\)

Specifies the offset is added to the base register.

\(<imm>\)

For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.

For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 4 in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as \(<imm>/4\).

For encoding T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as \(<imm>/4\).

For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T4: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

### Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];

    // Determine if the stack pointer limit should be checked
    if n == 13 && wback then
        (limit, applylimit) = LookUpSPLim(LookUpSP());
    else
        applylimit = FALSE;

    // Memory operation only performed if limit not violated
    if !applylimit || (UInt(offset_addr) >= UInt(limit)) then
        data = MemU[address,4];

    // If the stack pointer is being updated update a fault will be raised if
    // the limit is violated
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data, n, offset_addr, wback, TRUE);
        else
            UNPREDICTABLE;
    else
        if wback then RSPCheck[n] = offset_addr;
        R[t] = data;
```

### Exceptions

C2.4.53 LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register.

The register loaded can be the PC. If it is, the word loaded for the PC is treated as a branch address or an exception return value. Bit[0] complies with the ARM architecture interworking rules for switching between the A32 and T32 instruction sets. However, ARMv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

**Decode for this encoding**

if !HaveMainExt() then UNDEFINED;
\( t = \text{UInt}(Rt); \ imm32 = \text{ZeroExtend}(\text{imm12}, 32); \ add = (U == '1');\)
if \( t == 15 \) && InITBlock() \&\& LastInITBlock() then UNPREDICTABLE;

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields* on page C1-252.
- `<q>` See *Standard assembler syntax fields* on page C1-252.
- `<Rt>` For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field. For encoding T2: is the general-purpose register to be transferred, encoded in the "Rt" field. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC.
For encoding T1: the label of the literal data item that is to be loaded into \(<Rt>\). The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are Multiples of four in the range 0 to 1020.

For encoding T2: the label of the literal data item that is to be loaded into \(<Rt>\). The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, \(\text{imm32}\) is equal to the offset and \(\text{add} == \text{TRUE}\), encoded as \(U == 1\). If the offset is negative, \(\text{imm32}\) is equal to minus the offset and \(\text{add} == \text{FALSE}\), encoded as \(U == 0\).

\(<label>\) specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when \(U = 0\)
+ when \(U = 1\)

\(<\text{imm}>\) is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + \(\text{imm32}\)) else (base - \(\text{imm32}\));
    data = MemU[address,4];
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data, 0, Zeros(32), FALSE, FALSE);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
```

Exceptions

C2.4.54   LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits.

The register loaded can be the PC. If it is, the word loaded for the PC is treated as a branch address or an exception return value. Bit[0] complies with the ARM architecture interworking rules for switching between the A32 and T32 instruction sets. However, ARMv8-M only supports the T32 instruction set, so bit[0] must be 1. Assembler symbols

\(<c>\)  See Standard assembler syntax fields on page C1-252.
\(<p>\)  See Standard assembler syntax fields on page C1-252.
\(<Rt>\)  For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.
For encoding T2: is the general-purpose register to be transferred, encoded in the "Rt" field. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.
+ Specifies the index register is added to the base register.
<Rm> Is the general-purpose index register, encoded in the "Rm" field.
<imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

**Operation for all encodings**

```plaintext
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[n], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    // Determine if the stack pointer limit should be checked
    if n == 13 && wback then
        (limit, applylimit) = LookUpSPLim(LookUpSP());
    else
        applylimit = FALSE;
    // Memory operation only performed if limit not violated
    if !applylimit || (UInt(offset_addr) >= UInt(limit)) then
        data = MemU[address,4];
    // If the stack pointer is being updated update a fault will be raised if
    // the limit is violated
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data, n, offset_addr, wback, TRUE);
        else
            UNPREDICTABLE;
    else
        if wback then RSPCheck[n] = offset_addr;
        R[t] = data;
```

**Exceptions**

C2.4.55   LDRB (immediate)

Load Register Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing.

if t == 13 then UNPREDICTABLE;

Assembler symbols

<>
See Standard assembler syntax fields on page C1-252.

<op>
See Standard assembler syntax fields on page C1-252.

<Rt>
Is the general-purpose register to be transferred, encoded in the "Rt" field.

<label>
The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

<+->
Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

<imm>
Is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  base = Align(PC,4);
  address = if add then (base + imm32) else (base - imm32);
  R[t] = ZeroExtend(MemU[address,1], 32);

Exceptions

C2.4.57 LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits.

- `+/-`: Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
  - `-` when \( U = 0 \)
  - `+` when \( U = 1 \)
- `<imm>`: For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.
  
  For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
  
  For encoding T2: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

### Operation for all encodings

\[
\text{if } \text{ConditionPassed() then}
\]
\[
\text{EncodingSpecificOperations();}
\]
\[
\text{offset_addr} = \text{if add then } (R[n] + \text{imm32}) \text{ else } (R[n] - \text{imm32});
\]
\[
\text{address} = \text{if index then offset_addr else } R[n];
\]

// Determine if the stack pointer limit should be checked
\[
\text{if } n == 13 \&\& \text{wback then}
\]
\[
\text{(limit, applylimit) = LookUpSPLim(LookUpSP());}
\]
\[
\text{else applylimit = FALSE;}
\]

// Memory operation only performed if limit not violated
\[
\text{if !applylimit || (UInt(offset_addr) >= UInt(limit)) then}
\]
\[
R[t] = \text{SignExtend(MemU[address,1], 32)};
\]

// If the stack pointer is being updated update a fault will be raised if
// the limit is violated
\[
\text{if wback then RSPCheck[n] = offset_addr;}
\]

### Exceptions

C2.4.69   LDRSB (literal)

Load Register Signed Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register.

T1

ARMv8-M Main Extension only

\text{LSL}\{<c>\}\{<q>\} \{<Rd>,\} <Rm>, \#<imm> \text{ // Inside IT block}
\]

is equivalent to

\[
\text{MOV}\{<c>\}\{<q>\} <Rd>, <Rm>, \text{LSL} \#<imm>
\]

and is the preferred disassembly when \( \text{InITBlock}() \).

### T3

**ARMv8-M Main Extension only**

\[
\begin{array}{cccccccc}
| 15 & 14 & 13 & 12 | 11 & 10 & 9 & 8 & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 |
\end{array}
\]

- \( \text{S} \)
- \( \text{imm3} \)
- \( \text{Rd} \)
- \( \text{imm2} \)
- \( \text{Rm} \)

**MOV, shift or rotate by value variant**

\[
\text{LSL}\{<c>\}.W \{<Rd>,\} <Rm>, \#<imm> \text{ // Inside IT block, and } <Rd>, <Rm>, <imm> \text{ can be represented in T2}
\]

is equivalent to

\[
\text{MOV}\{<c>\}\{<q>\} <Rd>, <Rm>, \text{LSL} \#<imm>
\]

and is always the preferred disassembly.

\[
\text{LSL}\{<c>\}\{<q>\} \{<Rd>,\} <Rm>, \#<imm>
\]

is equivalent to

\[
\text{MOV}\{<c>\}\{<q>\} <Rd>, <Rm>, \text{LSL} \#<imm>
\]

and is always the preferred disassembly.

### Assembler symbols

- \(<c>\) See Standard assembler syntax fields on page C1-252.
- \(<q>\) See Standard assembler syntax fields on page C1-252.
- \(<Rd>\) Is the general-purpose destination register, encoded in the "Rd" field.
Is the general-purpose source register, encoded in the "Rm" field.

For encoding T2: is the shift amount, in the range 1 to 31, encoded in the "imm5" field.

For encoding T3: is the shift amount, in the range 1 to 31, encoded in the "imm3:imm2" field.

**Operation for all encodings**

The description of MOV (register) gives the operational pseudocode for this instruction.
C2.4.78   LSL (register)

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted register).
- The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

### Assembler symbols

- **<c>**
  - See [Standard assembler syntax fields](#) on page C1-252.

- **<q>**
  - See [Standard assembler syntax fields](#) on page C1-252.

- **<Rd>**
  - For encoding T1: is the general-purpose destination register, encoded in the "D:Rd" field. If the PC is used:
    - The instruction causes a simple branch to the address moved to the PC.
    - The instruction must either be outside an IT block or the last instruction of an IT block.

- **<Rm>**
  - For encoding T1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used.
  - For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

- **<shift>**
  - For encoding T2: is the type of shift to be applied to the source register, encoded in the "op" field. It can have the following values:
    - LSL when op = 00
    - LSR when op = 01
    - ASR when op = 10
  - For encoding T3: is the type of shift to be applied to the source register, encoded in the "type" field. It can have the following values:
    - LSL when type = 00
    - LSR when type = 01
    - ASR when type = 10
    - ROR when type = 11

- **<amount>**
  - For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
  - For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

### Operation for all encodings

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    if d == 15 then
        ALUWritePC(result); // setflags is always FALSE here
    else
        RSPCheck[d] = result;
        if setflags then
```

**Notes for all encodings**

Floating-point: *Floating-point 32-bit move* on page C2-308.

**Assembler symbols**

- `<c>` See Standard assembler syntax fields on page C1-252.
- `<q>` See Standard assembler syntax fields on page C1-252.
- `<coproc>` Is the name of the coprocessor, encoded in the "coproc" field. The valid coprocessor names are p10, p11, p14, and p15.
- `<opc1>` Is a coprocessor-specific opcode in the range 0 to 7, encoded in the "opc1" field.
<Rt> Is the general-purpose register to be transferred or APSR\_nzcv (encoded as 0b1111), encoded in the "Rt" field. If APSR\_nzcv is used, bits [31:28] of the transferred value are written to the APSR condition flags.

<CRn> Is the first coprocessor register, encoded in the "CRn" field.

<CRm> Is the second coprocessor register, encoded in the "CRm" field.

<opc2> Is a coprocessor-specific opcode in the range 0 to 7, defaulting to 0 and encoded in the "opc2" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    ExecuteCPCheck(cp);
    if !Coproc\_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        value = Coproc\_GetOneWord(cp, ThisInstr());
        if t != 15 then
            R[t] = value;
        else
            APSR.N = value<31>;
            APSR.Z = value<30>;
            APSR.C = value<29>;
            APSR.V = value<28>;
            // value<27:0> are not used.

Exceptions

UsageFault.
C2.4.94 MRRC, MRRC2

Move to two Registers from Coprocessor causes a coprocessor to transfer values to two general-purpose registers. If no coprocessor can execute the instruction, a UsageFault exception is generated.

Exceptions

UsageFault.
C2.4.97 MUL

Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether signed or unsigned calculations are performed.

It can optionally update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

T1

Assembler symbols

See Standard assembler syntax fields on page C1-252.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

- LSL when type = 00
- LSR when type = 01
- ASR when type = 10
- ROR when type = 11

<amount> Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();
   (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
   result = R[n] OR shifted;
   R[d] = result;

if d \text{ IN } \{13,15\} \(||\ n \text{ IN } \{13,15\} \(||\ m \text{ IN } \{13,15\} \) then UNPREDICTABLE;

Assembler symbols

\(<c>\)  See Standard assembler syntax fields on page C1-252.
\(<q>\)  See Standard assembler syntax fields on page C1-252.
\(<Rd>\)  Is the general-purpose destination register, encoded in the "Rd" field.
\(<Rn>\)  Is the first general-purpose source register, encoded in the "Rn" field.
\(<Rm>\)  Is the second general-purpose source register, encoded in the "Rm" field.
\(<imm>\)  The shift to apply to the value read from \(<Rm>\), encoded in imm3:imm2. For PKHBT, it is one of:
\text{omitted}  No shift, encoded as 0b00000.
1-31  Left shift by specified number of bits, encoded as a binary number.
For PKHTB, it is one of:
\text{omitted}  Instruction is a pseudo-instruction and is assembled as though PKHBT{<c>}{<q>} <Rd>,
\(<Rm>\), <Rn> had been written.
1-32  Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.

Note

An assembler can permit \(<imm> = 0\) to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.
Operation

if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = Shift(R[m], shift_t, shift_n, APSR.C);  // APSR.C ignored
    result<32> = if tbform then operand2<15:0> else R[n]<15:0>
    result<31:16> = if tbform then R[n]<31:16> else operand2<31:16>
    R[d] = result;

Exceptions

None.

   offset = Shift(R[m], shift_t, shift_n, APSR.C);
   address = if add then (R[n] + offset) else (R[n] - offset);
   Hint_PreloadInstr(address);

Exceptions

None.
C2.4.111   POP

Pop registers from stack loads one or more general-purpose registers from the stack, loading from consecutive
memory locations starting at the address in SP, and updates SP to point above the loaded data.

If the registers loaded include the PC, the word loaded for the PC is treated as a branch address or an exception
return value. Bit[0] complies with the ARM architecture interworking rules for switching between the A32 and T32
instruction sets. However, ARMv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE
takes an INVSTATE UsageFault exception on the instruction at the target address.

This instruction is an alias of LDM, LDMIA, LDMFD and LDR (immediate). This means that:

• The encodings in this description are named to match the encodings of LDM, LDMIA, LDMFD and LDR
  (immediate).

• The descriptions of LDM, LDMIA, LDMFD and LDR (immediate) give the operational pseudocode for this
  instruction.

T2 - alias of LDM

T3 variant

POP{<c>}{<q>} <registers>

is equivalent to

LDM{<c>}{<q>} SP!, <registers>

and is always the preferred disassembly.

T4 - alias of LDR (immediate)

ARMv8-M Main Extension only
Post-indexed variant

POP{<c>}{<q>} <single_register_list>

is equivalent to

LDR{<c>}{<q>} <Rt>, [SP], #4

and is always the preferred disassembly.

Assembler symbols

<

See Standard assembler syntax fields on page C1-252.

>

See Standard assembler syntax fields on page C1-252.

<registers>

For encoding T2: is a list of two or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0. The PC can be in the list. If it is, the instruction branches to the address loaded to the PC, and:

If the PC is in the list:

• The LR must not be in the list.
• The instruction must be either outside any IT block, or the last instruction in an IT block.

For encoding T3: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the PC. If the PC is in the list, the "P" field is set to 1, otherwise this field defaults to 0. If the PC is in the list, the instruction must be either outside any IT block, or the last instruction in an IT block.

<single_register_list>

Is the general-purpose register <Rt> to be loaded surrounded by { and }.

<Rt>

Is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC.

Operation for all encodings

The descriptions of LDM, LDMIA, LDMFD and LDR (immediate) give the operational pseudocode for this instruction.
C2.4.112 PUSH

Push registers to stack stores one or more general-purpose registers to the stack, storing to consecutive memory locations ending below the address in SP, and updates SP to point to the start of the stored data.

This instruction is an alias of STMDB, STMFD and STR (immediate). This means that:

- The encodings in this description are named to match the encodings of STMDB, STMFD and STR (immediate).
- The descriptions of STMDB, STMFD and STR (immediate) give the operational pseudocode for this instruction.

**T1 - alias of STMD**

<td>P U W</td>
<td>imm8</td>
<td></td>
</tr>
</tbody>
</table>

**Pre-indexed variant**

PUSH{<c>}{<q>} <single_register_list> // Standard syntax
is equivalent to

```
STR{<c>}{<q>} <Rt>, [SP, #-4]!
```

and is always the preferred disassembly.

**Assembler symbols**

- `<c>` See *Standard assembler syntax fields on page C1-252.*
- `<q>` See *Standard assembler syntax fields on page C1-252.*
- `<registers>` For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

For encoding T2: is a list of one or more registers to be stored, separated by commas and surrounded by `{` and `}`. The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the LR. If the LR is in the list, the "M" field is set to 1, otherwise this field defaults to 0.

- `<single_register_list>`
  - Is the general-purpose register `<Rt>` to be stored surrounded by `{` and `}`.

- `<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

**Operation for all encodings**

The descriptions of STMDB, STMFD and STR (immediate) give the operational pseudocode for this instruction.
C2.4.113   QADD

Saturating Add adds two register values, saturates the result to the 32-bit signed integer range $-2^{31}$ to $2^{31}-1$, and writes the result to the destination register. If saturation occurs, it sets the Q flag in the APSR.

T1

*ARMv8-M DSP Extension only*

C2.4.127 ROR (immediate)

Rotate Right (immediate) rotates a register value by a constant number of bits, inserting the bits that are rotated off the right end into the vacated bit positions on the left, and writes the result to the destination register.

This instruction is an alias of the MOV (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV (register).
- The description of MOV (register) gives the operational pseudocode for this instruction.

T3

ARMv8-M Main Extension only

MOV, shift or rotate by value variant

Applies when !(imm3 == 000 & imm2 == 00).

ROR{<c>}{<q>} {<Rd>,} <Rm>, #<imm>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ROR #<imm>

and is always the preferred disassembly.

Assembler symbols

- `<c>` See Standard assembler syntax fields on page C1-252.
- `<q>` See Standard assembler syntax fields on page C1-252.
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<Rm>` Is the general-purpose source register, encoded in the "Rm" field.
- `<imm>` Is the shift amount, in the range 1 to 31, encoded in the "imm3:imm2" field.

Operation

The description of MOV (register) gives the operational pseudocode for this instruction.
C2.4.128   ROR (register)

Rotate Right (register) rotates a register value by a variable number of bits, inserting the bits that are rotated off the right end into the vacated bit positions on the left, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted register).
- The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

C2.4.144   SG

Secure Gateway marks a valid branch target for branches from Non-secure code that call Secure code.

This instruction sets the Security state to Secure if its address is in Secure memory. If the address of this instruction is in Non-secure memory, the instruction behaves as a NOP.

If the PE was previously in Non-secure state:

- This instruction sets bit[0] of LR to 0, to indicate that the return address will cause a transition from Secure to Non-secure state.
- If the Floating-point Extension is implemented, this instruction marks Secure floating-point state as inactive, by setting CONTROL.S.SFPA to 0. This indicates that the floating-point registers do not contain active state that belongs to the Secure state.

If the Security Extension is not implemented, this instruction behaves as a NOP.

______  Note  _______

SG is an unconditional instruction and executes as such both inside and outside an IT instruction block. ARM recommends that software does not place SG inside an IT instruction block.

C2.4.151  SMLABB, SMLABT, SMLATB, SMLATT

Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets the Q flag in the APSR. It is not possible for overflow to occur during the multiplication.

C2.4.158 SMLSLD, SMLSLDX

Signed Multiply Subtract Long Dual performs two signed 16-bit by 16-bit multiplications. It adds the difference of the products to a 64-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo $2^{64}$.

- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<imm>` Is the bit position for saturation, in the range 1 to 32, encoded in the "sat_imm" field as `<imm>-1`.
- `<Rn>` Is the general-purpose source register, encoded in the "Rn" field.
- `<amount>` For the arithmetic shift right variant: is the shift amount, in the range 1 to 31 encoded in the "imm3:imm2" field as `<amount>`.
  
  For the logical shift left variant: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm3:imm2" field.

**Operation**

```plaintext
if ConditionPassed() then
  EncodingSpecificOperations();
  operand = Shift(R[n], shift_t, shift_n, APSR.C);  // APSR.C ignored
  (result, sat) = SignedSatQ(SInt(operand), saturate_to);
```
R[d] = SignExtend(result, 32);
    if sat then
        APSR.Q = '1';

Exceptions

None.
C2.4.168   SSAT16

Signed Saturate 16 saturates two signed 16-bit values to a selected signed range.

The Q flag is set to 1 if the operation saturates.

```

Assembler symbols

IA  Is an optional suffix for the Increment After form.
<e>  See Standard assembler syntax fields on page C1-252.
<q>  See Standard assembler syntax fields on page C1-252.
<Rn>  Is the general-purpose base register, encoded in the "Rn" field.
!  The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
<registers> For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For encoding T2: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

Operation for all encodings

if ConditionPassed() then
   EncodingSpecificOperations();
   address = R[n];
   endAddress = R[n] + 4*BitCount(registers);

   // Determine if the stack pointer limit should be checked
   if n == 13 && wback && registers<0> == '0' then
      (limit, applyLimit) = LookUpSPLim(LookUpSP());
      doOperation = (!applyLimit || (UI32(endAddress) >= UI32(limit)));
   else
      doOperation = TRUE;
   
   for i = 0 to 14
      // Memory operation only performed if limit not violated
      if registers<i> == '1' && doOperation then
         if i == n && wback && i != LowestSetBit(registers) then
            MemA[address,4] = bits(32) UNKNOWN;  // encoding T1 only
         else
            MemA[address,4] = R[i];
            address = address + 4;
      
   // If the stack pointer is being updated update a fault will be raised if
   // the limit is violated
   if wback then RSPCheck[n] = endAddress;

Exceptions

STMDB, STMFD

Store Multiple Decrement Before stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the first of those locations can optionally be written back to the base register.

This instruction is used by the alias PUSH. The alias is always the preferred disassembly.

T1

ARMv8-M Main Extension only

```
15 14 13 12|11 10 9 8 |7 6 5 4|3 0 |15 14 13 12|   |   | 0 |

<<
Is the general-purpose register to be transferred, encoded in the "Rt" field.

<<
Is the general-purpose base register, encoded in the "Rn" field.
C2 Instruction Specification
C2.4 Alphabetical list of instructions

+/-  Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
    - when U = 0
    + when U = 1

+  Specifies the offset is added to the base register.

<imm>  For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.
    For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 4 in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4.
    For encoding T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4.
    For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
    For encoding T4: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];

Notes for all encodings

Related encodings: Load/store (multiple, dual, exclusive, acquire-release), table branch on page C2-276.

Assembler symbols

\(<c>\)
See Standard assembler syntax fields on page C1-252.

\(<q>\)
See Standard assembler syntax fields on page C1-252.

\(<Rt>\)
Is the first general-purpose register to be transferred, encoded in the "Rt" field.

\(<Rt2>\)
Is the second general-purpose register to be transferred, encoded in the "Rt2" field.

\(<Rn>\)
Is the general-purpose base register, encoded in the "Rn" field.

\(+/-\)
Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
+ when U = 1
<imm> For the offset variant: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4.

For the post-indexed and pre-indexed variant: is the unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm>/4.

Operation

if ConditionPassed() then
  EncodingSpecificOperations();
  offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
  address = if index then offset_addr else R[n];
  // Determine if the stack pointer limit should be checked
  if n == 13 && wback then
    (limit, applylimit) = LookUpSPLim(LookUpSP());
  else
    applylimit = FALSE;
  // Memory operation only performed if limit not violated
  if !applylimit || (UInt(offset_addr) >= UInt(limit)) then
    MemA[address,4] = R[t];
    MemA[address+4,4] = R[t2];
  // If the stack pointer is being updated update a fault will be raised if
  // the limit is violated
  if wback then RSPCheck[n] = offset_addr;

Exceptions

C2.4.187 STREX

Store Register Exclusive calculates an address from a base register value and an immediate offset, and stores a word from a register to memory if the executing PE has exclusive access to the memory addressed.

T1

ARMv8-M

STREX{<c>}{<q>} <Rd>, <Rt>, [<Rn> {, #<imm>}]  

Decode for this encoding

**Assembler symbols**

- $<c>$
  - See *Standard assembler syntax fields* on page C1-252.
- $<q>$
  - See *Standard assembler syntax fields* on page C1-252.
- $<Rdn>$
  - Is the general-purpose source and destination register, encoded in the "Rdn" field.
- $<\text{imm8}>$
  - Is an 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.
- $<\text{Rd}>$
  - Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as $<\text{Rn}>$.
- $<\text{Rn}>$
  - For encoding T1: is the general-purpose source register, encoded in the "Rn" field.
  - For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see **SUB (SP minus immediate)**.
  - For encoding T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see **SUB (SP minus immediate)**. If the PC is used, see **ADR**.
- $<\text{imm3}>$
  - Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.
- $<\text{imm12}>$
  - Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.
- $<\text{const}>$
  - An immediate value. See *Modified immediate constants* on page C1-259 for the range of values.
Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry, overflow) = AddWithCarry(R[n], NOT(imm32), '1');
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        APSR.V = overflow;

Exceptions

None.
C2.4.197   SUB (immediate, from PC)

Subtract from PC subtracts an immediate value from the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. ARM recommends that, where possible, software avoids using this alias.

This instruction is an alias of the ADR instruction. This means that:

- The encodings in this description are named to match the encodings of ADR.
- The description of ADR gives the operational pseudocode for this instruction.

T2

ARMv8-M Main Extension only

```
|15 14 13 12|11 10 9  8 |7 6 5  4|3 2 1  0|15 14|12|11 |  8 | 7 |  0 |
1 1 1 1 0 | i 1 0 |1 0 |1 1 1 1 | 0 | imm3 | Rd | imm8 |
```

**T2 variant**

SUB{<c>}{<q>} <Rd>, PC, #<imm12>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is the preferred disassembly when i:imm3:imm8 == '000000000000'.

**Assembler symbols**

- `<c>`       See Standard assembler syntax fields on page C1-252.
- `<q>`       See Standard assembler syntax fields on page C1-252.
- `<Rd>`     Is the general-purpose destination register, encoded in the "Rd" field.
- `<label>`  For encoding T1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

  For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. If the offset is zero or positive, encoding T3 is used, with imm32 equal to the offset. If the offset is negative, encoding T2 is used, with imm32 equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of imm32. Permitted values of the size of the offset are 0-4095.

- `<imm12>`   Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

**Operation**

The description of ADR gives the operational pseudocode for this instruction.
C2.4.198   SUB (register)

Subtract (register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Exceptions

C2.4.251 VCVT (between floating-point and fixed-point)

Floating-point Convert (between floating-point and fixed-point) converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point, and places the result in the destination register. You can specify the fixed-point value as either signed or unsigned.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

```

**T2**

*ARMv8-M Floating-point Extension only*

```
| 15 14 13 12| 11 10 9 8 | 7 6 5 4 | 3 0 | 15 12| 11 10 9 8 | 7 | 0 |
| 1 1 1 0 1 1 0 1 | U | D | 0 | 1 | Rn | Vd | 1 0 1 | 0 | imm8 |
```

**Literal variant**

Applies when Rn == 1111.

VLDR{<c>}{<q>}{.32} <Sd>, <label>
VLDR{<c>}{<q>}{.32} <Sd>, [PC, #{+/-}<imm>]

**Offset variant**

Applies when Rn != 1111.

VLDR{<c>}{<q>}{.32} <Sd>, [Rn] {, #{+/-}<imm>}

**Decode for all variants of this encoding**

```java
if !HaveFPExt() then UNDEFINED;
single_reg = TRUE; add = (U == '1'); imm32 = ZeroExtend(imm8:'00', 32);
d = UInt(Vd:D); n = UInt(Rn);
```
Assembler symbols

<
See Standard assembler syntax fields on page C1-252.

Q
See Standard assembler syntax fields on page C1-252.

.64
Optional data size specifiers.

Dd
The destination register for a doubleword load.

.32
Optional data size specifiers.

Sd
The destination register for a singleword load.

<label>
The label of the literal data item to be loaded. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

<Rn>
Is the general-purpose base register, encoded in the "Rn" field.

+/-
Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1

<imm>
The immediate offset used for forming the address. For the immediate forms of the syntax, <imm> can be omitted, in which case the #0 form of the instruction is assembled. Permitted values are multiples of 4 in the range 0 to 1020.

Operation for all encodings

if ConditionPassed() then
    EncodingSpecificOperations();
    ExecuteFPCheck();
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    if single_reg then
        S[d] = MemA[address,4];
    else
        word1 = MemA[address,4]; word2 = MemA[address+4,4];
        // Combine the word-aligned words in the correct order for current endianness.
        D[d] = if BigEndian() then word1:word2 else word2:word1;

Exceptions

C2.4.268  VLLDM

Floating-point Lazy Load Multiple restores the contents of the Secure floating-point registers that were protected by a VLSTM instruction, and marks the floating-point context as active.

If the lazy state preservation set up by a previous VLSTM instruction is active (FPCCR.LSPACT == 1), this instruction deactivates lazy state preservation and enables access to the Secure floating-point registers.

If lazy state preservation is inactive (FPCCR.LSPACT == 0), either because lazy state preservation was not enabled (FPCCR.LSPEN == 0) or because a floating-point instruction caused the Secure floating-point register contents to be stored to memory, this instruction loads the stored Secure floating-point register contents back into the floating-point registers.

If Secure floating-point is not in use (CONTROL_S.SFPA == 0), this instruction behaves as a NOP.

This instruction is only available in Secure state, and is UNDEFINED in Non-secure state.

If the Floating-point Extension is not implemented, this instruction is available in Secure state, but behaves as a NOP.

**T1**

*ARMv8-M Main Extension only*

- `<c>`  
  See Standard assembler syntax fields on page C1-252.
- `<q>`  
  See Standard assembler syntax fields on page C1-252.
- `<Rn>`  
  Is the general-purpose base register, encoded in the "Rn" field.

*Operation*

```c
if ConditionPassed() then
    EncodingSpecificOperations();
    if CONTROL_S.SFPA == '1' then
        // Check access to the co-processor is permitted
        exc = CheckCPEnabled(10);
        HandleException(exc);
    if FPCCR_S.LSPACT == '1' then // state in FP is still valid
        FPCCR_S.LSPACT = '0';
    else
        if !IsAligned(R[n],8) then
            UFSR.UNALIGNED = '1';
            exc = CreateException(UsageFault, FALSE, boolean UNKNOWN);
```
HandleException(exc);

for i = 0 to 15
  S[i] = MemA[R[n] + (4*i), 4];
  FPSCR = MemA[R[n] + 0x40, 4];
if FPCCR.S.TS == '1' then
  for i = 0 to 15
    S[i+16] = MemA[R[n] + 0x48 + (4*i), 4];
  CONTROL.FPCA = '1';

Exceptions
C2.4.269   VLSTM

Floating-point Lazy Store Multiple stores the contents of Secure floating-point registers to a prepared stack frame, and clears the Secure floating-point registers.

If floating-point lazy preservation is enabled (FPCCR.LSPEN == 1), then the next time a floating-point instruction other than VLSTM or VLLDM is executed:

- The contents of Secure floating-point registers are stored to memory.
- The Secure floating-point registers are cleared.

If Secure floating-point is not in use (CONTROL_S.SFPA == 0), this instruction behaves as a NOP.

This instruction is only available in Secure state, and is UNDEFINED in Non-secure state.

If the Floating-point Extension is not implemented, this instruction is available in Secure state, but behaves as a NOP.

**Exceptions**

C2.4.285 VNMLA

Floating-point Multiply Accumulate and Negate multiplies two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

--- Note ---
ARM recommends that software does not use the VNMLA instruction in the Round towards +Infinity and Round towards -Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

**Operation for all encodings**

if ConditionPassed() then
    EncodingSpecificOperations();
    WaitForInterrupt();

**Exceptions**

None.
C2.4.304  YIELD

Yield is a hint instruction. It enables software with a multithreading capability to indicate to the hardware that it is performing a task, for example a spinlock, that could be swapped out to improve overall system performance. Hardware can use this hint to suspend and resume multiple code threads if it supports the capability.

This is a NOP-compatible hint. For more information about NOP-compatible hints, see NOP-compatible hint instructions on page C1-260.

T1

ARMv8-M

\[ \begin{array}{cccccccccccccccc} |15|14|13|12|11|10|9|8|7|6|5|4|3|2|1|0| \\ 1|0|1|1|1|1|1|1|0|0|0|1|0|0|0|0| \end{array} \]

T1 variant

YIELD{<c>{<q>}

Decode for this encoding

// No additional decoding required

T2

ARMv8-M Main Extension only

\[ \begin{array}{cccccccccccccccc} |15|14|13|12|11|10|9|8|7|6|5|4|3|2|1|0| \\ 1|1|1|1|0|0|1|1|0|1|0|[(1)][(1)][(1)]1|0|0|0|0|0|0|0|1| \end{array} \]

T2 variant

YIELD{<c>}.W

Decode for this encoding

if !HaveMainExt() then UNDEFINED;
// No additional decoding required

Assembler symbols

<e>  See Standard assembler syntax fields on page C1-252.
<q>  See Standard assembler syntax fields on page C1-252.

Operation for all encodings

if ConditionPassed() then
  EncodingSpecificOperations();
  Hint_Yield();

Exceptions

None.
Part D
ARMv8-M Registers
Chapter D1
Register Specification

This chapter specifies the ARMv8-M registers. It contains the following sections:

• *Register index* on page D1-800.
• *Alphabetical list of registers* on page D1-816.
## D1.1 Register index

D1.2   Alphabetical list of registers
D1.2.1 ACTLR, Auxiliary Control Register

The ACTLR characteristics are:

**Purpose**
Provides IMPLEMENTATION DEFINED configuration and control options.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000E008.
Secure software can access the Non-secure view of this register via ACTLR_NS located at 0xE002E008. The location 0xE002E008 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The ACTLR bit assignments are:

![Field descriptions](image)

**IMPLEMENTATION DEFINED, bits [31:0]**
IMPLEMENTATION DEFINED. The contents of this field are IMPLEMENTATION DEFINED.
D1.2.2 AFSR, Auxiliary Fault Status Register

The AFSR characteristics are:

**Purpose**

Provides IMPLEMENTATION DEFINED fault status information.

**Usage constraints**

Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**

This register is always implemented.

**Attributes**

32-bit read/write register located at 0xE000ED3C.

Secure software can access the Non-secure view of this register via AFSR_NS located at 0xE002ED3C. The location 0xE002ED3C is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

**Field descriptions**

The AFSR bit assignments are:

![AFSR Bit Assignments](image)

**IMPLEMENTATION DEFINED, bits [31:0]**

IMPLEMENTATION DEFINED. The contents of this field are IMPLEMENTATION DEFINED.
D1.2.3 AIRCR, Application Interrupt and Reset Control Register

The AIRCR characteristics are:

**Purpose**
Sets or returns interrupt control and reset configuration.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000ED0C.

Secure software can access the Non-secure view of this register via AIRCR_NS located at 0xE002ED0C. The location 0xE002ED0C is RES0 to software executing in Non-secure state and the debugger.

This register is banked between Security states on a bit by bit basis.

**Field descriptions**

The AIRCR bit assignments are:

On a read:

On a write:

VECTKEY, bits [31:16], on a write

Vector key. Writes to the AIRCR must be accompanied by a write of the value 0x05FA to this field. Writes to the AIRCR fields that are not accompanied by this value are ignored for the purpose of updating any of the AIRCR values or initiating any AIRCR functionality.

This field is not banked between Security states.

The possible values of this field are:

- **0x05FA** Permit write to AIRCR fields.
- **Not 0x05FA**

Accompanying write to AIRCR fields ignored.

VECTKEYSTAT, bits [31:16], on a read

Vector key status. Returns the bitwise inverse of the value required to be written to VECTKEY.

This field is not banked between Security states.

This field reads as 0xFA05.

ENDIANNESS, bit [15]

Data endianness. Indicates how the PE interprets the memory system data endianness.
This bit is not banked between Security states.
The possible values of this bit are:
0 Little-endian.
1 Big-endian.
This bit is read-only.
This bit reads as an IMPLEMENTATION DEFINED value.

**PRIS, bit [14]**

Prioritize Secure exceptions. The value of this bit defines whether Secure exception priority boosting is enabled.
This bit is not banked between Security states.
The possible values of this bit are:
0 Priority ranges of Secure and Non-secure exceptions are identical.
1 Non-secure exceptions are de-prioritized.
To allow lock down of this bit, it is IMPLEMENTATION DEFINED whether this bit is writable.
This bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

**BFHFNMINS, bit [13]**

BusFault, HardFault, and NMI Non-secure enable. The value of this bit defines whether BusFault and NMI exceptions are Non-secure, and whether exceptions target the Non-secure HardFault exception.
This bit is not banked between Security states.
The possible values of this bit are:
0 BusFault, HardFault, and NMI are Secure.
1 BusFault and NMI are Non-secure and exceptions can target Non-secure HardFault.
If an implementation resets into Secure state, this bit resets to zero. If an implementation does not support Secure state, this bit is RAO/WI. To allow lock down of this field it is IMPLEMENTATION DEFINED whether this bit is writable. The effect of setting both BFHFNMINS and PRIS to 1 is UNPREDICTABLE.
This bit is read-only from Non-secure state.
This bit resets to zero on a Warm reset.

**Bits [12:11]**

Reserved, RES0.

**PRIGROUP, bits [10:8]**

Priority grouping. The value of this field defines the exception priority binary point position for the selected Security state.
This field is banked between Security states.
The possible values of this field are:
0b000 Group priority [7:1], subpriority [0].
0b001 Group priority [7:2], subpriority [1:0].
0b010 Group priority [7:3], subpriority [2:0].
0b011 Group priority [7:4], subpriority [3:0].
0b100 Group priority [7:5], subpriority [4:0].
0b101 Group priority [7:6], subpriority [5:0].
0b110 Group priority [7], subpriority [6:0].
0b111 No group priority, subpriority [7:0].
If the Main Extension is not implemented, this field is RES0.
This field resets to zero on a Warm reset.

Bits [7:4]

Reserved, RES0.

SYSRESETREQS, bit [3]

System reset request Secure only. The value of this bit defines whether the SYSRESETREQ bit is functional for Non-secure use.
This bit is not banked between Security states.
The possible values of this bit are:
0 SYSRESETREQ functionality is available to both Security states.
1 SYSRESETREQ functionality is only available to Secure state.
This bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

SYSRESETREQ, bit [2]

System reset request. This bit allows software or a debugger to request a system reset.
This bit is not banked between Security states.
The possible values of this bit are:
0 Do not request a system reset.
1 Request a system reset.
When SYSRESETREQS is set to 1, the Non-secure view of this bit is RAZ/WI.
This bit resets to zero on a Warm reset.

VECTCLRACTIVE, bit [1]

Clear active state.
A debugger write of one to this bit when the PE is halted in Debug state:
• IPSR is cleared to zero.
• The active state for all Non-secure exceptions is cleared.
• If DHCSR.S_SDE==1, the active state for all Secure exceptions are cleared.
This bit is not banked between Security states.
The possible values of this bit are:
0 Do not clear active state.
1 Clear active state.
Writes to this bit while the PE is in Non-debug state are ignored.
This bit reads as zero.

Bit [0]

Reserved, RES0.
**D1.2.4 APSR, Application Program Status Register**

The APSR characteristics are:

**Purpose**
Provides privileged and unprivileged access to the PE Execution state fields.

**Usage constraints**
Both privileged and unprivileged access permitted.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write special-purpose register.
This register is not banked between Security states.

**Field descriptions**

The APSR bit assignments are:

```
  31 30 29 28 27 26 20 19 16 15 0
N  Z  C  V  Q  RES0  GE  RES0
```

**N, bit [31]**
Negative condition flag. When updated by a flag setting instruction this bit indicates whether the result of the operation when treated as a two's complement signed integer is negative.

The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Result is positive or zero.</td>
</tr>
<tr>
<td>1</td>
<td>Result is negative.</td>
</tr>
</tbody>
</table>

See individual instruction pages for details.
This bit resets to an **UNKNOWN** value on a Warm reset.

**Z, bit [30]**
Zero condition flag. When updated by a flag setting instruction this bit indicates whether the result of the operation was zero.

The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Result is non-zero.</td>
</tr>
<tr>
<td>1</td>
<td>Result is zero.</td>
</tr>
</tbody>
</table>

See individual instruction pages for details.
This bit resets to an **UNKNOWN** value on a Warm reset.

**C, bit [29]**
Carry Condition flag. When updated by a flag setting instruction this bit indicates whether the operation resulted in an unsigned overflow or whether the last bit shifted out of the result was set.

The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No carry occurred, or last bit shifted was clear.</td>
</tr>
<tr>
<td>1</td>
<td>Carry occurred, or last bit shifted was set.</td>
</tr>
</tbody>
</table>

See individual instruction pages for details.
This bit resets to an **UNKNOWN** value on a Warm reset.

**V, bit [28]**
Overflow condition flag. When updated by a flag setting instruction this bit indicates whether a signed overflow occurred.

The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Signed overflow did not occur.</td>
</tr>
</tbody>
</table>
1  Signed overflow occurred.
See individual instruction pages for details.
This bit resets to an UNKNOWN value on a Warm reset.

Q, bit [27]

Sticky saturation flag. When updated by certain instructions this bit indicates either that an overflow occurred or that the result was saturated. This bit is cumulative and can only be cleared to zero by software.
The possible values of this bit are:
0  Saturation or overflow has not occurred since bit was last cleared.
1  Saturation or overflow has occurred since bit was last cleared.
See individual instruction pages for details.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to an UNKNOWN value on a Warm reset.

Bits [26:20]

Reserved, RES0.

GE, bits [19:16]

Greater than or equal flags. When updated by parallel addition and subtraction instructions these bits record whether the result was greater than or equal to zero. SEL instructions use these bits to determine which register to select a particular byte from.
See individual instruction pages for details.
If the DSP Extension is not implemented, this field is RES0.
This field resets to an UNKNOWN value on a Warm reset.

Bits [15:0]

Reserved, RES0.
D1.2.5   BASEPRI, Base Priority Mask Register

The BASEPRI characteristics are:

**Purpose**  Changes the priority level required for exception preemption.

**Usage constraints**  Privileged access only. Unprivileged access is RAZ/WI.

**Configurations**  Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**  32-bit read/write special-purpose register.
This register is banked between Security states.

**Field descriptions**

The BASEPRI bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | RES0 |
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | BASEPRI |

**Bits [31:8]**

Reserved, RES0.

**BASEPRI, bits [7:0]**

Base priority mask. BASEPRI changes the priority level required for exception preemption. It has an effect only when BASEPRI has a lower value than the unmasked priority level of the currently executing software.

The possible values of this field are:

- **0**  Disables masking by BASEPRI.

- **1-255**  Priority value.

The number of implemented bits in BASEPRI is the same as the number of implemented bits in each field of the priority registers, and BASEPRI has the same format as those fields.

This field resets to zero on a Warm reset.
D1.2.6  BFAR, BusFault Address Register

The BFAR characteristics are:

**Purpose**
Shows the address associated with a precise data access BusFault.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented. This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read/write register located at 0xE000ED38. Secure software can access the Non-secure view of this register via BFAR_NS located at 0xE002ED38. The location 0xE002ED38 is RES0 to software executing in Non-secure state and the debugger. This register is not banked between Security states.

**Preface**
The Non-secure version of this register is RAZ/WI if AIRCR.BFHFNMIN is set to 0.

**Field descriptions**
The BFAR bit assignments are:

```
ADDRESS, bits [31:0]
```

Data address for a precise BusFault. This register is updated with the address of a location that produced a BusFault. The BFSR shows the reason for the fault. This field is valid only when BFSR.BFARVALID is set, otherwise it is UNKNOWN.

In implementations without unique BFAR and MMFAR registers, the value of this register is UNKNOWN if MMFSR.MMARVALID is set.

If AIRCR.BFHFNMIN is zero this field is RAZ/WI from Non-secure state.

This field resets to an UNKNOWN value on a Warm reset.

--- Note ---
If an implementation shares a common BFAR and MMFAR it must not leak Secure state information to the Non-secure state. One possible implementation is that BFAR shares resource with the Secure MMFAR if AIRCR.BFHFNMIN is zero, and with the Non-secure MMFAR if AIRCR.BFHFNMIN is set.
D1.2.7 BFSR, BusFault Status Register

The BFSR characteristics are:

**Purpose**
Shows the status of bus errors resulting from instruction fetches and data accesses.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
- If the Main Extension is implemented, this register is word, halfword, and byte accessible.
- If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
- This register is RES0 if the Main Extension is not implemented.

**Attributes**
8-bit read/write-one-to-clear register located at 0xE000ED29.
Secure software can access the Non-secure view of this register via BFSR_NS located at 0xE002ED29. The location 0xE002ED29 is RES0 to software executing in Non-secure state and the debugger.
- This register is not banked between Security states.
- This register is part of CFSR.

**Preface**
The Non-secure version of this register is RAZ/WI if AIRCR.BFHFNMINS is set to 0.

**Field descriptions**
The BFSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Values</th>
<th>Accessible from Non-secure state</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>BFARVALID</td>
<td>0: BFAR content not valid. 1: BFAR content valid.</td>
<td>RAZ/WI</td>
</tr>
<tr>
<td>6</td>
<td>LSPERR</td>
<td>0: No BusFault occurred. 1: BusFault occurred.</td>
<td>RAZ/WI</td>
</tr>
<tr>
<td>5</td>
<td>STKERR</td>
<td>Reserved, RES0.</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>UNSTKERR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>IBUSERR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>PRECISERR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>IMPRECISERR</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**BFARVALID, bit [7]**
- BFAR valid. Indicates validity of the contents of the BFAR register.
- The possible values of this bit are:
  - 0: BFAR content not valid.
  - 1: BFAR content valid.
- If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.
- This bit resets to zero on a Warm reset.

**Bit [6]**
- Reserved, RES0.

**LSPERR, bit [5]**
- Lazy state preservation error. Records whether a BusFault occurred during FP lazy state preservation.
- The possible values of this bit are:
  - 0: No BusFault occurred.
  - 1: BusFault occurred.
- If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

**STKERR, bit [4]**
Stack error. Records whether a derived BusFault occurred during exception entry stacking.
The possible values of this bit are:
0 No derived BusFault occurred.
1 Derived BusFault occurred during exception entry.
If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

**UNSTKERR, bit [3]**
Unstack error. Records whether a derived BusFault occurred during exception return unstacking.
The possible values of this bit are:
0 No derived BusFault occurred.
1 Derived BusFault occurred during exception return.
If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

**IMPRECISERR, bit [2]**
Imprecise error. Records whether an imprecise data access error has occurred.
The possible values of this bit are:
0 No imprecise data access error has occurred.
1 Imprecise data access error has occurred.
If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

**PRECISERR, bit [1]**
Precise error. Records whether a precise data access error has occurred.
The possible values of this bit are:
0 No precise data access error has occurred.
1 Precise data access error has occurred.
When a precise error is recorded, the associated address is written to the BFAR and BFSR.BFARVALID bit is set.
If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

**IBUSERR, bit [0]**
Instruction bus error. Records whether a BusFault on an instruction prefetch has occurred.
The possible values of this bit are:
0 No BusFault on instruction prefetch has occurred.
1 A BusFault on an instruction prefetch has occurred.
An IBUSERR is only recorded if the instruction is issued for execution.
If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.
D1.2.8   BPIALL, Branch Predictor Invalidate All

The BPIALL characteristics are:

**Purpose**  
Invalidate all entries from branch predictors.

**Usage constraints**  
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**  
This register is always implemented.

**Attributes**  
32-bit write-only register located at 0xE000EF78.
Secure software can access the Non-secure view of this register via BPIALL_NS located at 0xE002EF78. The location 0xE002EF78 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**

The BPIALL bit assignments are:

```
#31  Ignored
```

Ignored, bits [31:0]  
Ignored. The value written to this field is ignored.
D1.2.9 CCR, Configuration and Control Register

The CCR characteristics are:

**Purpose**
Sets or returns configuration and control data.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000ED14.
Secure software can access the Non-secure view of this register via CCR_NS located at 0xE002ED14. The location 0xE002ED14 is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states on a bit by bit basis.

**Field descriptions**
The CCR bit assignments are:

![CCR Bit Assignments Diagram]

**Bits [31:19]**
Reserved, RES0.

**BP, bit [18]**
Branch prediction enable. Enables program flow prediction for the selected Security state.
This bit is banked between Security states.
The possible values of this bit are:

- **0** Program flow prediction disabled for the selected Security state.
- **1** Program flow prediction enabled for the selected Security state.

If program flow prediction cannot be disabled, this bit is RAO/WI. If the program flow prediction is not supported, this bit is RAZ/WI.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

**IC, bit [17]**
Instruction cache enable. This is a global enable bit for instruction caches in the selected Security state.
This bit is banked between Security states.
The possible values of this bit are:

- **0** Instruction caches disabled for the selected Security state.
- **1** Instruction caches enabled for the selected Security state.

If the PE does not implement instruction caches, this bit is RAZ/WI.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.
DC, bit [16]
Data cache enable. Enables data caching of all data accesses to Normal memory for the selected Security state.
This bit is banked between Security states.
The possible values of this bit are:
0 Data caching disabled for the selected Security state.
1 Data caching enabled for the selected Security state.
If the PE does not implement data caches, this bit is RAZ/WI.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

Bits [15:11]
Reserved, RES0.

STKOFHFNMIGN, bit [10]
Stack overflow in HardFault and NMI ignore. Controls the effect of a stack limit violation while executing at a requested priority less than 0 for the security state with which the stack limit register is associated.
This bit is banked between Security states.
The possible values of this bit are:
0 Stack limit faults not ignored.
1 Stack limit faults at requested priorities of less than 0 ignored.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

Bit [9]
Reserved, RES1.

BFHFNIGN, bit [8]
BusFault in HardFault or NMI ignore. Determines the effect of precise BusFaults on handlers running at a requested priority less than 0.
This bit is not banked between Security states.
The possible values of this bit are:
0 Precise BusFaults not ignored.
1 Precise BusFaults at requested priorities of less than 0 ignored.
If AIRCR.BFHNMINNS is 0, this bit is read only from Non-secure state.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

Bits [7:5]
Reserved, RES0.

DIV_0_TRP, bit [4]
Divide by zero trap. Controls the generation of a DIVBYZERO UsageFault when attempting to perform integer division by zero.
This bit is banked between Security states.
The possible values of this bit are:
0 DIVBYZERO UsageFault generation disabled.
1 DIVBYZERO UsageFault generation enabled.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

UNALIGN_TRP, bit [3]
Unaligned trap. Controls the trapping of unaligned word or halfword accesses.
This bit is banked between Security states.
The possible values of this bit are:
0 Unaligned accesses permitted from LDR, LDRH, STR, and STRH.
1 Any unaligned transaction generates an UNALIGNED UsageFault.
Unaligned load/store multiples and atomic/exclusive accesses always generate an UNALIGNED UsageFault.
If the Main Extension is not implemented, this bit is RES1.
This bit resets to zero on a Warm reset if the Main Extension is implemented.

Bit [2]
Reserved, RES0.

USERSETMPEND, bit [1]
User set main pending. Determines whether unprivileged accesses are permitted to pend interrupts via the STIR.
This bit is banked between Security states.
The possible values of this bit are:
0 Unprivileged accesses to the STIR generate a fault.
1 Unprivileged accesses to the STIR are permitted.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

Bit [0]
Reserved, RES1.
D1.2.10 CCSIDR, Current Cache Size ID register

The CCSIDR characteristics are:

**Purpose**
The CCSIDR provides information about the architecture of the currently selected cache.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If CSSELR points to an unimplemented cache, the value of this register is UNKNOWN.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read-only register located at 0xE000ED80.
Secure software can access the Non-secure view of this register via CCSIDR_NS located at 0xE002ED80. The location 0xE002ED80 is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.

**Preface**
Provides indirect read access to the architecture of the cache currently selected by CSSELR.

**Field descriptions**
The CCSIDR bit assignments are:

The CCSIDR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>WT</td>
<td>[0]</td>
<td>Write-through. Indicates whether the currently selected cache level supports write-through.</td>
</tr>
<tr>
<td>30</td>
<td>WB</td>
<td>[0]</td>
<td>Writeback. Indicates whether the currently selected cache level supports writeback.</td>
</tr>
<tr>
<td>29</td>
<td>RA</td>
<td>[0]</td>
<td>Read-allocate. Indicates whether the currently selected cache level supports read-allocation.</td>
</tr>
<tr>
<td>13</td>
<td>NumSets</td>
<td>[0]</td>
<td>Number of sets.</td>
</tr>
</tbody>
</table>

**WT, bit [31]**
Write-through. Indicates whether the currently selected cache level supports write-through.
The possible values of this bit are:
0 Not supported.
1 Supported.
This bit reads as an IMPLEMENTATION DEFINED value.

**WB, bit [30]**
Writeback. Indicates whether the currently selected cache level supports writeback.
The possible values of this bit are:
0 Not supported.
1 Supported.
This bit reads as an IMPLEMENTATION DEFINED value.

**RA, bit [29]**
Read-allocate. Indicates whether the currently selected cache level supports read-allocation.
The possible values of this bit are:
0 Not supported.
1 Supported.
This bit reads as an IMPLEMENTATION DEFINED value.
WA, bit [28]

Write-allocate. Indicates whether the currently selected cache level supports write-allocation.

The possible values of this bit are:

0   Not supported.
1   Supported.

This bit reads as an IMPLEMENTATION DEFINED value.

NumSets, bits [27:13]

Number of sets. Indicates (Number of sets in the currently selected cache) - 1. Therefore, a value of 0 indicates that 1 is set in the cache. The number of sets does not have to be a power of 2.

This field reads as an IMPLEMENTATION DEFINED value.

LineSize, bits [2:0]

Line size. Indicates (Log2(Number of words per line in the currently selected cache)) - 2.

This field reads as an IMPLEMENTATION DEFINED value.
D1.2.11 CFSR, Configurable Fault Status Register

The CFSR characteristics are:

**Purpose**
Contains the three Configurable Fault Status Registers.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
If the Main Extension is implemented, this register is word, halfword, and byte accessible.
If the Main Extension is not implemented, this register is word accessible only, halfword
and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read/write-one-to-clear register located at 0xE000ED28.
Secure software can access the Non-secure view of this register via CFSR_NS located at
0xE000ED28. The location 0xE000ED28 is RES0 to software executing in Non-secure state and
the debugger.
This register is banked between Security states on a bit by bit basis.

**Field descriptions**
The CFSR bit assignments are:

```
+-----------------+-----------------+-----------------+
| 31              | 30:16           | 15:0            |
| UFSR            | BFSR            | MMFSR           |
+-----------------+-----------------+-----------------+
```

**UFSR, bits [31:16]**
UsageFault Status Register. Provides information on UsageFault exceptions.
This field is banked between Security states.
See UFSR.
This field resets to zero on a Warm reset.

**BFSR, bits [15:8]**
BusFault Status Register. Provides information on BusFault exceptions.
This field is not banked between Security states.
See BFSR.
This field resets to zero on a Warm reset.

**MMFSR, bits [7:0]**
MemManage Fault Status Register. Provides information on MemManage exceptions.
This field is banked between Security states.
See MMFSR.
This field resets to zero on a Warm reset.
### D1.2.12 CLIDR, Cache Level ID Register

The CLIDR characteristics are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Purpose</strong></td>
<td>Identifies the type of caches implemented and the level of coherency and unification.</td>
</tr>
<tr>
<td><strong>Usage constraints</strong></td>
<td>Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.</td>
</tr>
<tr>
<td><strong>Configurations</strong></td>
<td>This register is always implemented.</td>
</tr>
<tr>
<td><strong>Attributes</strong></td>
<td>32-bit read-only register located at 0xE000ED78. Secure software can access the Non-secure view of this register via CLIDR_NS located at 0xE002ED78. The location 0xE002ED78 is RES0 to software executing in Non-secure state and the debugger. This register is not banked between Security states.</td>
</tr>
</tbody>
</table>

#### Field descriptions

The CLIDR bit assignments are:

<table>
<thead>
<tr>
<th>Field, bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 30 29 27 26 24-23 21 20 18 17 15 14 12 11 9 8 6 5 3 2 1</td>
<td><strong>ICB</strong> Inner cache boundary. This field indicates the boundary between inner and outer domain. The possible values of this field are: 0b00 Not disclosed in this mechanism. 0b01 L1 cache is the highest inner level. 0b10 L2 cache is the highest inner level. 0b11 L3 cache is the highest inner level. This field reads as an IMPLEMENTATION DEFINED value. <strong>LoUU</strong> Level of Unification Uniprocessor. This field indicates the Level of Unification Uniprocessor for the cache hierarchy. This field reads as an IMPLEMENTATION DEFINED value. <strong>LoC</strong> Level of Coherence. This field indicates the Level of Coherence for the cache hierarchy. This field reads as an IMPLEMENTATION DEFINED value. <strong>LoUIS</strong> Level of Unification Inner Shareable. This field indicates the Level of Unification Shareable for the cache hierarchy. This field reads as an IMPLEMENTATION DEFINED value. <strong>Ctype m</strong>, bits [3(m-1)+2:3(m-1)], for m = 1 to 7 Cache type field m. Indicates the type of cache implemented at level m. The possible values of this field are: 0b000 No cache. 0b001 Instruction cache only. 0b010 Data cache only.</td>
</tr>
</tbody>
</table>
0b011   Separate instruction and data caches.
0b100   Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 000, no caches exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 000, the values of Ctype4 to Ctype7 must be ignored.

This field reads as an IMPLEMENTATION DEFINED value.
D1.2.13  CONTROL, Control Register

The CONTROL characteristics are:

**Purpose**  Provides access to the PE control fields.

**Usage constraints**  Privileged access only. Unprivileged access is RAZ/WI.

**Configurations**  This register is always implemented.

**Attributes**  32-bit read/write special-purpose register.

This register is banked between Security states on a bit by bit basis.

**Field descriptions**

The CONTROL bit assignments are:

![CONTROL Register Bit Assignment Diagram](image)

**Bits [31:4]**

Reserved, RES0.

**SFPA, bit [3]**

Secure floating-point active. Indicates that the floating-point registers contain active state that belongs to the Secure state.

This bit is not banked between Security states.

The possible values of this bit are:

0  The floating-point registers do not contain state that belongs to the Secure state.
1  The floating-point registers contain state that belongs to the Secure state.

This bit is accessible from both privileged and unprivileged modes, but unprivileged writes are ignored.

This bit is RAZ/WI from Non-secure state.

If the Security Extension is not implemented, this bit is RES0.

If the Floating-point Extension is not implemented, this bit is RES0.

This bit resets to zero on a Warm reset.

**FPCA, bit [2]**

Floating-point context active. Defines whether the FP Extension is active in the current context.

This bit is not banked between Security states.

The possible values of this bit are:

0  FP Extension is not active.
1  FP Extension is active.

When NSACR.CP10 is set to zero, the Non-secure view of this bit is read-only. If FPCCR.ASPEN is set to 1, enabling automatic Floating-point state preservation, then the PE sets this bit to 1 on successful completion of any Floating-point instruction.

If the Floating-point Extension is not implemented, this bit is RES0.

This bit resets to zero on a Warm reset.

**SPSEL, bit [1]**

Stack-pointer select. Defines the stack pointer to be used.
This bit is banked between Security states.
The possible values of this bit are:

0 Use SP_main as the current stack.
1 In Thread mode use SP_process as the current stack.

This bit resets to zero on a Warm reset.

nPRIV, bit [0]

Not privileged. Defines the execution privilege in Thread mode.
This bit is banked between Security states.
The possible values of this bit are:

0 Thread mode has privileged access.
1 Thread mode has unprivileged access only.

If the Main Extension is not implemented, it is IMPLEMENTATION DEFINED whether this field is RW or RAZ/WI.

This bit resets to zero on a Warm reset.
D1.2.14 CPACR, Coprocessor Access Control Register

The CPACR characteristics are:

**Purpose**
Specifies the access privileges for coprocessors and the FP Extension.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented. This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read/write register located at 0xE000ED88. Secure software can access the Non-secure view of this register via CPACR_NS located at 0xE002ED88. The location 0xE002ED88 is RES0 to software executing in Non-secure state and the debugger. This register is banked between Security states.

**Field descriptions**

The CPACR bit assignments are:

| 31 | 24,23 | 22,21 | 20,19 | 16,15 | 14 | 13 | 12,11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|-------|-------|-------|-------|-----|----|-------|----|---|---|---|---|---|---|---|---|---|---|---|
| RES0 | CP11 | CP10 | RES0 | CP7 | CP6 | CP5 | CP4 | CP3 | CP2 | CP1 | CP0 |

**Bits [31:24]**
Reserved, RES0.

**CP11, bits [23:22]**
CP11 Privilege. The value in this field is ignored. If the implementation does not include the FP Extension, this field is RAZ/WI. If the value of this bit is not programmed to the same value as the CP10 field, then the value is UNKNOWN.

This field resets to an UNKNOWN value on a Warm reset.

**CP10, bits [21:20]**
CP10 Privilege. Defines the access rights for the floating-point functionality.

The possible values of this field are:

- **0b00**: All accesses to the FP Extension result in NOCP UsageFault.
- **0b01**: Unprivileged accesses to the FP Extension result in NOCP UsageFault.
- **0b11**: Full access to the FP Extension.

All other values are reserved.

The features controlled by this field are the execution of any floating-point instruction and access to any floating-point registers D0-D16. If the implementation does not include the FP Extension, this field is RAZ/WI. See individual floating-point instruction pages for details.

This field resets to an UNKNOWN value on a Warm reset.

**Bits [19:16]**
Reserved, RES0.

**CPlm, bits [2m+1:2m], for m = 0 to 7**
Coprocessor m privilege. Controls access privileges for coprocessor m.

The possible values of this field are:

- **0b00**: Access denied. Any attempted access generates a NOCP UsageFault.
- **0b01**: Privileged access only. An unprivileged access generates a NOCP UsageFault.
0b10  Reserved.
0b11  Full access.

If coprocessor \( m \) is not implemented, this field is RAZ/WI.
This field resets to an UNKNOWN value on a Warm reset.
D1.2.15 CPPWR, Coprocessor Power Control Register

The CPPWR characteristics are:

**Purpose**
Specifies whether coprocessors are permitted to enter a non-retentive power state.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.

This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read/write register located at 0xE000E00C.

Secure software can access the Non-secure view of this register via CPPWR_NS located at 0xE002E00C. The location 0xE002E00C is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

**Field descriptions**

The CPPWR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>

SU0...
This bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

**SU10, bit [20]**

State UNKNOWN 10. This bit indicates and allows modification of whether the state associated with the floating-point unit is permitted to become UNKNOWN. This can be used as a hint to power control logic that the floating-point unit might be powered down.

The possible values of this bit are:

0  The floating-point state is not permitted to become UNKNOWN.
1  The floating-point state is permitted to become UNKNOWN.

When SUS10 is set to 1, the Non-secure view of this bit is RAZ/WI. It is IMPLEMENTATION DEFINED whether this bit is always RAZ/WI.

This bit resets to zero on a Warm reset.

**Bits [19:16]**

Reserved, RES0.

**SUSm, bit [2m+1], for m = 0 to 7**

State UNKNOWN Secure only m. This field indicates and allows modification of whether the SU[m] field can be modified from Non-secure state.

The possible values of this field are:

0  The SU[m] field is accessible from both Security states.
1  The SU[m] field is only accessible from the Secure state.

If SUSm is always RAZ/WI this field is also RAZ/WI.

This field is RAZ/WI from Non-secure state.
This field resets to zero on a Warm reset.

**SUm, bit [2m], for m = 0 to 7**

State UNKNOWN m. This field indicates and allows modification of whether the state associated with coprocessor m is permitted to become UNKNOWN. This can be used as a hint to power control logic that the coprocessor might be powered down.

The possible values of this field are:

0  The coprocessor state is not permitted to become UNKNOWN.
1  The coprocessor state is permitted to become UNKNOWN.

When SUS[m] is set to 1, the Non-secure view of this bit is RAZ/WI. It is IMPLEMENTATION DEFINED whether this bit is always RAZ/WI.

This field resets to zero on a Warm reset.
D1.2.16   CPUID, CPUID Base Register

The CPUID characteristics are:

**Purpose**

Provides identification information for the PE, including an implementer code for the device and a device ID number.

**Usage constraints**

Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**

This register is always implemented.

**Attributes**

32-bit read-only register located at 0xE000ED00.

Secure software can access the Non-secure view of this register via CPUID_NS located at 0xE002ED00. The location 0xE002ED00 is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

**Field descriptions**

The CPUID bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>12</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Implementer, bits [31:24]**

Implementer code. This field must hold an implementer code that has been assigned by ARM.

The possible values of this field are:

0x41   'A' : ARM Limited.

**Not** 0x41   Implementer other than ARM Limited.

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

This field reads as an IMPLEMENTATION DEFINED value.

**Variant, bits [23:20]**

Variant number. IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

This field reads as an IMPLEMENTATION DEFINED value.

**Architecture, bits [19:16]**

Architecture version. Defines the Architecture implemented by the PE.

The possible values of this field are:

0b1100   ARMv8-M architecture without Main Extension.

0b1111   ARMv8-M architecture with Main Extension.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

**PartNo, bits [15:4]**

Part number. IMPLEMENTATION DEFINED primary part number for the device.

This field reads as an IMPLEMENTATION DEFINED value.

**Revision, bits [3:0]**

Revision number. IMPLEMENTATION DEFINED revision number for the device.
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.17 CSSELR, Cache Size Selection Register

The CSSELR characteristics are:

**Purpose**
Selects the current Cache Size ID Register, CCSIDR, by specifying the required cache level and the cache type (either instruction or data cache).

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000ED84.
Secure software can access the Non-secure view of this register via CSSELR_NS located at 0xE002ED84. The location 0xE002ED84 is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.

**Field descriptions**
The CSSELR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>30-24</td>
<td>Level, bits [3:1]</td>
</tr>
<tr>
<td>23-20</td>
<td>Level 1 cache.</td>

</tr>
<tr>
<td>31</td>
<td>InD, bit [0]</td>
</tr>
<tr>
<td>30</td>
<td>Instruction not data.</td>
</tr>
</tbody>
</table>

**Bits [31:4]**
Reserved, RES0.

**Level, bits [3:1]**
Cache level. Selects which cache level is to be identified. Permitted values are from 0b000, indicating Level 1 cache, to 0b110 indicating Level 7 cache.
The possible values of this field are:

- 0b000 Level 1 cache.
- 0b001 Level 2 cache.
- 0b010 Level 3 cache.
- 0b011 Level 4 cache.
- 0b100 Level 5 cache.
- 0b101 Level 6 cache.
- 0b110 Level 7 cache.
All other values are reserved.
This field resets to an UNKNOWN value on a Warm reset.

**InD, bit [0]**
Instruction not data. Selects whether the instruction or the data cache is to be identified.
The possible values of this bit are:

- 0 Data or unified cache.
- 1 Instruction cache.
This bit resets to an UNKNOWN value on a Warm reset.
D1.2.18  CTR, Cache Type Register

The CTR characteristics are:

**Purpose**
Provides information about the architecture of the caches. CTR is RES0 if CLIDR is zero.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.  
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read-only register located at 0xE000ED7C.  
Secure software can access the Non-secure view of this register via CTR_NS located at 0xE002ED7C. The location 0xE002ED7C is RES0 to software executing in Non-secure state and the debugger.  
This register is banked between Security states.

**Field descriptions**

The CTR bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Bits</th>
<th>Value</th>

```

**Bit [31]**
Reserved, RES1.

**Bits [30:28]**
Reserved, RES0.

**CWG, bits [27:24]**
Cache Writeback Granule. \( \log_2 \) of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

The possible values of this field are:
- 0b0000: Indicates that this register does not provide Cache Writeback Granule information and either the architectural maximum of 512 words (2KB) must be assumed, or the Cache Writeback Granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.
- 0b0001-0b1000: \( \log_2 \) of the number of words.
- All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

**ERG, bits [23:20]**
Exclusives Reservation Granule. \( \log_2 \) of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

The possible values of this field are:
- 0b0000: Indicates that this register does not provide Exclusives Reservation Granule information and the architectural maximum of 512 words (2KB) must be assumed.
- 0b0001-0b1000: \( \log_2 \) of the number of words.
- All other values are reserved.
This field reads as an IMPLEMENTATION DEFINED value.

**DminLine, bits [19:16]**

Data cache minimum line length. \( \log_2 \) of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

This field reads as an IMPLEMENTATION DEFINED value.

**Bits [15:14]**

Reserved, RES1.

**Bits [13:4]**

Reserved, RES0.

**IminLine, bits [3:0]**

Instruction cache minimum line length. \( \log_2 \) of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

This field reads as an IMPLEMENTATION DEFINED value.
D1.2.19   DAUTHCTRL, Debug Authentication Control Register

The DAUTHCTRL characteristics are:

**Purpose**  
This register allows the IMPLEMENTATION DEFINED authentication interface to be overridden from software.

**Usage constraints**  
Privileged access permitted only. Un privileged accesses generate a BusFault.  
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.  
This register is RES0 if accessed via the debugger.

**Configurations**  
Present only if Halting debug or the Main Extension is implemented.  
This register is RES0 if both Halting debug and Main Extension are not implemented.  
Present only if the Security Extension is implemented.  
This register is RES0 if the Security Extension is not implemented.

**Attributes**  
32-bit read/write register located at 0xE000EE04.  
This register is RAZ/WI when accessed as Non-secure.  
This register is not banked between Security states.

**Field descriptions**

The DAUTHCTRL bit assignments are:

```
+------------+------------+------------+------------+------------+
<table>
<thead>
<tr>
<th>Bit</th>
<th>Function</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>

<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
```

**INTSPNIDEN, bit [3]**

Internal Secure non-invasive debug enable. Overrides the external Secure non-invasive debug authentication interface.  
The possible values of this bit are:  
0  Secure Non-invasive debug prohibited.  
1  Secure Non-invasive debug allowed.  
Ignored if DAUTHCTRL.SPNIDENSEL == 0. See SecureNoninvasiveDebugAllowed().  
This bit resets to zero on a Cold reset.

**SPNIDENSEL, bit [2]**

Secure non-invasive debug enable select. Selects between DAUTHCTRL and the IMPLEMENTATION DEFINED external authentication interface for control of Secure non-invasive debug.  
The possible values of this bit are:  
0  Secure non-invasive debug controlled by the IMPLEMENTATION DEFINED external authentication interface. In the CoreSight authentication interface, this is controlled by the SPNIDEN signal.  
1  Secure non-invasive debug controlled by DAUTHCTRL.INTSPNIDEN.  
The PE ignores the value of this bit and Secure non-invasive debug is allowed if DHCSR.S_SDE == 1. See SecureNoninvasiveDebugAllowed().  
This bit resets to zero on a Cold reset.
INTSPIDEN, bit [1]
Internal Secure invasive debug enable. Overrides the external Secure invasive debug authentication interfaces.

The possible values of this bit are:
0 Secure halting and self-hosted debug prohibited.
1 Secure halting and self-hosted debug allowed.
Ignored if DAUTHCTRL.SPIDENSEL == 0. See SecureHaltingDebugAllowed() and SecureDebugMonitorAllowed().
This bit resets to zero on a Cold reset.

SPIDENSEL, bit [0]
Secure invasive debug enable select. Selects between DAUTHCTRL and the IMPLEMENTATION DEFINED external authentication interface for control of Secure invasive debug.

The possible values of this bit are:
0 Secure halting and self-hosted debug controlled by the IMPLEMENTATION DEFINED external authentication interface. In the CoreSight authentication interface, both are controlled by the SPIDEN signal.
1 Secure halting and self-hosted debug controlled by DAUTHCTRL.INTSPIDEN.
See SecureHaltingDebugAllowed() and SecureDebugMonitorAllowed().
This bit resets to zero on a Cold reset.
D1.2.20 DAUTHSTATUS, Debug Authentication Status Register

The DAUTHSTATUS characteristics are:

**Purpose**
Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if Halting debug is implemented.

This register is RES0 if Halting debug is not implemented.

**Attributes**
32-bit read-only register located at 0xE000EFB8.

Secure software can access the Non-secure view of this register via DAUTHSTATUS_NS located at 0xE002EFB8. The location 0xE002EFB8 is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

**Field descriptions**

The DAUTHSTATUS bit assignments are:

```
             31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0
            -----------------------------------------------
            | RES0 | SNID | SID | NSID |
            -----------------------------------------------
```

**Bits [31:8]**
Reserved, RES0.

**SNID, bits [7:6]**
Secure Non-invasive Debug. Indicates whether Secure non-invasive debug is implemented and allowed.

The possible values of this field are:
- 0b00: Security Extension not implemented.
- 0b01: Reserved.
- 0b10: Security Extension implemented and Secure non-invasive debug disabled.
- 0b11: Security Extension implemented and Secure non-invasive debug enabled.

**SID, bits [5:4]**
Secure Invasive Debug. Indicates whether Secure invasive debug is implemented and allowed.

The possible values of this field are:
- 0b00: Security Extension not implemented.
- 0b01: Reserved.
- 0b10: Security Extension implemented and Secure invasive debug disabled.
- 0b11: Security Extension implemented and Secure invasive debug enabled.

**NSNID, bits [3:2]**
Non-secure Non-invasive Debug. Indicates whether Non-secure non-invasive debug is implemented and allowed.
The possible values of this field are:

- 0b0x  Reserved.
- 0b10  Non-secure non-invasive debug disabled.
- 0b11  Non-secure non-invasive debug enabled.

**NSID, bits [1:0]**

Non-secure Invasive Debug. Indicates whether Non-secure invasive debug is implemented and allowed.

The possible values of this field are:

- 0b0x  Reserved.
- 0b10  Non-secure invasive debug disabled.
- 0b11  Non-secure invasive debug enabled.
D1.2.21  DCCIMVAC, Data Cache line Clean and Invalidate by Address to PoC

The DCCIMVAC characteristics are:

**Purpose**  
Clean and invalidate data or unified cache line by address to PoC.

**Usage constraints**  
Privileged access permitted only. Unprivileged accesses generate a BusFault.  
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**  
This register is always implemented.

**Attributes**  
32-bit write-only register located at 0xE000EF70.  
Secure software can access the Non-secure view of this register via DCCIMVAC_NS located at 0xE002EF70. The location 0xE002EF70 is RES0 to software executing in Non-secure state and the debugger.  
This register is not banked between Security states.

**Field descriptions**

The DCCIMVAC bit assignments are:

```
ADDRESS, bits [31:0]
```

Address. Writing to this field initiates the maintenance operation for the address written.
D1.2.22  DCCISW, Data Cache line Clean and Invalidate by Set/way

The DCCISW characteristics are:

**Purpose**  
Clean and invalidate data or unified cache line by set/way.

**Usage constraints**  
Privileged access permitted only. Unprivileged accesses generate a BusFault.  
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**  
This register is always implemented.

**Attributes**  
32-bit write-only register located at 0xE000EF74.  
Secure software can access the Non-secure view of this register via DCCISW_NS located at 0xE002EF74. The location 0xE002EF74 is RES0 to software executing in Non-secure state and the debugger.  
This register is not banked between Security states.

**Field descriptions**

The DCCISW bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td><strong>SetWay</strong>, bits [31:4]</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Cache set/way. Contains two fields: Way, bits[31:32-A], the number of the way to operate on. Set, bits[B-1:L], the number of the set to operate on. Bits[L-1:4] are RES0. A = Log2(ASSOCIATIVITY), L = Log2(LINELEN), B = (L + S), S = Log2(NSETS). ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.</td>
<td></td>
</tr>

</tbody>
</table>

Field descriptions

The DCCMVAC bit assignments are:

ADDRESS, bits [31:0]

Address. Writing to this field initiates the maintenance operation for the address written.
D1.2.24  DCCMVAU, Data Cache line Clean by address to PoU

The DCCMVAU characteristics are:

**Purpose**  
Clean data or unified cache line by address to PoU.

**Usage constraints**  
Privileged access permitted only. Unprivileged accesses generate a BusFault.  
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**  
This register is always implemented.

**Attributes**  
32-bit write-only register located at $0xE000EF64$.
Secure software can access the Non-secure view of this register via DCCMVAU_NS located at $0xE002EF64$. The location $0xE002EF64$ is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**

The DCCMVAU bit assignments are:

```
+------------+  +------------+  +------------+  +------------+
| 31         |  | 30         |  | 29         |  | 28         |
| ADDRESS    |  | ADDRESS    |  | ADDRESS    |  | ADDRESS    |
+------------+  +------------+  +------------+  +------------+  +------------+
```

**ADDRESS, bits [31:0]**

Address. Writing to this field initiates the maintenance operation for the address written.
D1.2.25 DCCSW, Data Cache Clean line by Set/Way

The DCCSW characteristics are:

Purpose
Clean data or unified cache line by set/way.

Usage constraints
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

Configurations
This register is always implemented.

Attributes
32-bit write-only register located at 0xE000EF6C.
Secure software can access the Non-secure view of this register via DCCSW_NS located at 0xE002EF6C. The location 0xE002EF6C is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

Field descriptions
The DCCSW bit assignments are:

SetWay, bits [31:4]
Cache set/way. Contains two fields: Way, bits [31:32-A], the number of the way to operate on. Set, bits [B-1:L], the number of the set to operate on. Bits [L-1:4] are RES0. A = \( \log_2(\text{ASSOCIATIVITY}) \), L = \( \log_2(\text{LINELEN}) \), B = (L + S), S = \( \log_2(\text{NSETS}) \).
ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]
Cache level. Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]
Reserved, RES0.
D1.2.26  DCIDR0, SCS Component Identification Register 0

The DCIDR0 characteristics are:

**Purpose**
Provides CoreSight discovery information for the SCS.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this
register is accessible only to the debugger and RES0 for software. Otherwise the register is
accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if Halting debug is implemented.
This register is RES0 if Halting debug is not implemented.

**Attributes**
32-bit read-only register located at 0xE000EFF0.
Secure software can access the Non-secure view of this register via DCIDR0_NS located at
0xE002EFF0. The location 0xE002EFF0 is RES0 to software executing in Non-secure state and
the debugger.
This register is not banked between Security states.

**Field descriptions**
The DCIDR0 bit assignments are:

```
31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0
  RES0  PRMBL_0
```

**Bits [31:8]**
Reserved, RES0.

**PRMBL_0, bits [7:0]**
CoreSight component identification preamble. See the ARM® CoreSight™ Architecture
Specification.
This field reads as 0x00.
D1.2.27 DCIDR1, SCS Component Identification Register 1

The DCIDR1 characteristics are:

**Purpose**
Provides CoreSight discovery information for the SCS.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if Halting debug is implemented.
This register is RES0 if Halting debug is not implemented.

**Attributes**
32-bit read-only register located at 0xE000EFF4.
Secure software can access the Non-secure view of this register via DCIDR1_NS located at 0xE002EFF4. The location 0xE002EFF4 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The DCIDR1 bit assignments are:

<table>
<thead>
<tr>

D1.2.28  DCIDR2, SCS Component Identification Register 2

The DCIDR2 characteristics are:

**Purpose**  Provides CoreSight discovery information for the SCS.

**Usage constraints**  Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**  Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if Halting debug is implemented.
This register is RES0 if Halting debug is not implemented.

**Attributes**  32-bit read-only register located at 0xE000EFF8.
Secure software can access the Non-secure view of this register via DCIDR2_NS located at 0xE002EFF8. The location 0xE002EFF8 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**

The DCIDR2 bit assignments are:

<table>
<thead>
<tr>

</table>

**Bits [31:8]**

Reserved, RES0.

**PRMBL_2, bits [7:0]**

CoreSight component identification preamble. See the ARM® CoreSight™ Architecture Specification.
This field reads as 0x05.
D1.2.29  DCIDR3, SCS Component Identification Register 3

The DCIDR3 characteristics are:

**Purpose**  Provides CoreSight discovery information for the SCS.

**Usage constraints**  Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**  Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is RES0 if Halting debug is not implemented.

**Attributes**  32-bit read-only register located at 0xE000EFFC.

Secure software can access the Non-secure view of this register via DCIDR3_NS located at 0xE002EFFC. The location 0xE002EFFC is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

**Field descriptions**

The DCIDR3 bit assignments are:

```
   31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0
```

**Bits [31:8]**  Reserved, RES0.

**PRMBL_3, bits [7:0]**  CoreSight component identification preamble. See the ARM® CoreSight™ Architecture Specification.

This field reads as 0xB1.
D1.2.30 DCIMVAC, Data Cache line Invalidate by Address to PoC

The DCIMVAC characteristics are:

**Purpose**
Invalidate data or unified cache line by address to PoC.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit write-only register located at 0xE000EF5C.
Secure software can access the Non-secure view of this register via DCIMVAC_NS located at 0xE002EF5C. The location 0xE002EF5C is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The DCIMVAC bit assignments are:

ADDRESS, bits [31:0]
Address. Writing to this field initiates the maintenance operation for the address written.
D1.2.31 DCISW, Data Cache line Invalidate by Set/Way

The DCISW characteristics are:

**Purpose**
Invalidate data or unified cache line by set/way.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit write-only register located at 0xE000EF60.
Secure software can access the Non-secure view of this register via DCISW_NS located at
0xE002EF60. The location 0xE002EF60 is RES0 to software executing in Non-secure state and
the debugger.
This register is not banked between Security states.

**Field descriptions**
The DCISW bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>4</th>
<th>3</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SetWay</td>
<td>Level</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**SetWay, bits [31:4]**
Cache set/way. Contains two fields: Way, bits[31:32-A], the number of the way to operate on. Set,
bits[B-1:L], the number of the set to operate on. Bits[L-1:4] are RES0. A = \(\log_2(\text{ASSOCIATIVITY})\),
\(L = \log_2(\text{LINELEN})\), \(B = (L + S)\), \(S = \log_2(\text{NSETS})\). ASSOCIATIVITY, LINELEN (line length,
in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache
level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**
Cache level. Cache level to operate on, minus 1. For example, this field is 0 for operations on L1
cache, or 1 for operations on L2 cache.

**Bit [0]**
Reserved, RES0.
D1.2.32  DCRDR, Debug Core Register Data Register

The DCRDR characteristics are:

**Purpose**  
With the DCRSR, provides debug access to the general-purpose registers, special-purpose registers, and the FP Extension registers. If the Main Extension is implemented, it can also be used for message passing between an external debugger and a debug agent running on the PE.

**Usage constraints**  
Privileged access permitted only. Unprivileged accesses generate a BusFault.  
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.  
If the Main Extension is not implemented then this register is accessible only to the debugger and UNKNOWN to software.

**Configurations**  
Present only if Halting debug is implemented.  
This register is RES0 if Halting debug is not implemented.

**Attributes**  
32-bit read/write register located at 0xE000EDF8.  
Secure software can access the Non-secure view of this register via DCRDR_NS located at 0xE002EDF8. The location 0xE002EDF8 is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

**Field descriptions**

The DCRDR bit assignments are:

```
+------------------+
|                  |
| 31               |
|                  |
|                  |
| DBGTMP           |
|                  |
| 0                |
+------------------+
```

**DBGTMP, bits [31:0]**

Data temporary buffer. Provides debug access for reading and writing the general-purpose registers, special-purpose registers, and Floating-point Extension registers.

The value of this register is UNKNOWN if the PE is in Debug state, the debugger has written to DCRSR since entering Debug state and DHCSR.S_REGRDY is set to 0. The value of this register is UNKNOWN if the Main Extension is not implemented and the PE is in Non-debug state.

This field resets to an UNKNOWN value on a Warm reset.
D1.2.33 DCRSR, Debug Core Register Select Register

The DCRSR characteristics are:

**Purpose**
With the DCRDR, provides debug access to the general-purpose registers, special-purpose registers, and the FP extension registers. A write to the DCRSR specifies the register to transfer, whether the transfer is a read or write, and starts the transfer.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE. Writes to this register while the PE is in Non-debug state are ignored. This register is accessible only to the debugger and RES0 to software.

**Configurations**
Present only if Halting debug is implemented. This register is RES0 if Halting debug is not implemented.

**Attributes**
32-bit write-only register located at 0xE000EDF4. This register is not banked between Security states.

**Field descriptions**
The DCRSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-17</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
<tr>
<td>16</td>
<td>REGWnR, bit [16]</td>
<td>0: Read, 1: Write</td>
</tr>
<tr>
<td>15-7</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
<tr>
<td>6-0</td>
<td>REGSEL, bits [6:0]</td>
<td>General-purpose registers R0-R12, Current stack pointer, SP, LR, DebugReturnAddress, xPSR, Current state main stack pointer, SP_main, Current state process stack pointer, SP_process, Current state {CONTROL[7:0],FAULTMASK[7:0],BASEPRI[7:0],PRIMASK[7:0]}</td>
</tr>
</tbody>
</table>
If the Main Extension is not implemented, bits [23:8] of the transfer value are RES0.

0b0011000 Non-secure main stack pointer, MSP_NS.
If the Security Extension is not implemented, this value is reserved.

0b0011001 Non-secure process stack pointer, PSP_NS.
If the Security Extension is not implemented, this value is reserved.

0b0011010 Secure main stack pointer, MSP_S. Accessible only when DHCSR.S_SDE == 1.
If the Security Extension is not implemented, this value is reserved.

0b0011011 Secure process stack pointer, PSP_S. Accessible only when DHCSR.S_SDE == 1.
If the Security Extension is not implemented, this value is reserved.

0b0011100 Secure main stack limit, MSPLIM_S. Accessible only when DHCSR.S_SDE == 1.
If the Security Extension is not implemented, this value is reserved.

0b0011101 Secure process stack limit, PSPLIM_S. Accessible only when DHCSR.S_SDE == 1.
If the Security Extension is not implemented, this value is reserved.

0b0011110 Non-secure main stack limit, MSPLIM_NS.
If the Main Extension is not implemented, this value is reserved.

0b0011111 Non-secure process stack limit, PSPLIM_NS.
If the Main Extension is not implemented, this value is reserved.

0b0100001 FPSCR.
If the Floating-point Extension is not implemented, this value is reserved.

0b0100010 {CONTROL[7:0],FAULTMASK[7:0],BASEPRI[7:0],PRIMASK[7:0]}_S.
If the Main Extension is not implemented, bits [23:8] of the transfer value are RES0. If the Security Extension is not implemented, this value is reserved.

0b0100011 {CONTROL[7:0],FAULTMASK[7:0],BASEPRI[7:0],PRIMASK[7:0]}_NS.
If the Main Extension is not implemented, bits [23:8] of the transfer value are RES0. If the Security Extension is not implemented, this value is reserved.

0b1000000-0b1011111 FP registers, S0-S31.
If the Floating-point Extension is not implemented, these values are reserved.
All other values are reserved.
If the Floating-point and Security Extensions are implemented, then the FPSCR and S0-S31 are not accessible from Non-secure state if DHCSR.S_SDE == 0 and either:
• FPCCR indicates the registers contain values from Secure state.
• NSACR prevents Non-secure access to the registers.
Registers that are not accessible are RAZ/WI.
If this field is written with a reserved value, the PE might behave as if a defined value was written, or ignore the value written, and the value of DCRDR becomes UNKNOWN.
D1.2.34 DDEVARCH, SCS Device Architecture Register

The DDEVARCH characteristics are:

**Purpose**
Provides CoreSight discovery information for the SCS.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if Halting debug is implemented.
This register is RES0 if Halting debug is not implemented.

**Attributes**
32-bit read-only register located at 0xE000EFBC.
Secure software can access the Non-secure view of this register via DDEVARCH_NS located at 0xE002EFBC. The location 0xE002EFBC is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**

The DDEVARCH bit assignments are:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
| ARCHITECT | REVISION | ARCHVER | ARCHPART | PRESENT |
```

**ARCHITECT, bits [31:21]**
Architect. Defines the architect of the component. Bits [31:28] are the JEP106 continuation code (JEP106 bank ID, minus 1) and bits [27:21] are the JEP106 ID code.
The possible values of this field are:
0x23B JEP106 continuation code 0x4, ID code 0x3B. ARM Limited.
Other values are defined by the JEDEC JEP106 standard.
This field reads as 0x23B.

**PRESENT, bit [20]**
DEVARCH Present. Defines that the DEVARCH register is present.
The possible values of this bit are:
1 DEVARCH information present.
This bit reads as one.

**REVISION, bits [19:16]**
Revision. Defines the architecture revision of the component.
The possible values of this field are:
0000 M-profile debug architecture v3.0.
This field reads as 0b0000.

**ARCHVER, bits [15:12]**
Architecture Version. Defines the architecture version of the component.
The possible values of this field are:

0010  M-profile debug architecture v3.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, such that ARCHVER is ARCHID[15:12].
This field reads as 0b0010.

ARCHPART, bits [11:0]
Architecture Part. Defines the architecture of the component.
The possible values of this field are:

0xa04  M-profile debug architecture.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, such that ARCHPART is ARCHID[11:0].
This field reads as 0xa04.
D1.2.35  DDEVTYPE, SCS Device Type Register

The DDEVTYPE characteristics are:

**Purpose**
Provides CoreSight discovery information for the SCS.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if Halting debug is implemented.
This register is RES0 if Halting debug is not implemented.

**Attributes**
32-bit read/write register located at 0xE000EFCC.
Secure software can access the Non-secure view of this register via DDEVTYPE_NS located at 0xE002EFCC. The location 0xE002EFCC is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The DDEVTYPE bit assignments are:

```
  31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8
  7  6  5  4  3  2  1  0
               RES0              SUB    MAJOR
```

**Bits [31:8]**
Reserved, RES0.

**SUB, bits [7:4]**
Sub-type. Component sub-type.
The possible values of this field are:
0x0 Other.
This field reads as 0b0000.

**MAJOR, bits [3:0]**
Major type. CoreSight major type.
The possible values of this field are:
0x0 Miscellaneous.
This field reads as 0b0000.
D1.2.36 DEMCR, Debug Exception and Monitor Control Register

The DEMCR characteristics are:

**Purpose**
Manages vector catch behavior and DebugMonitor handling when debugging.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if Halting debug or the Main Extension is implemented.
This register is RES0 if both Halting debug and Main Extension are not implemented.

**Attributes**
32-bit read/write register located at 0xE000EDFC.
Secure software can access the Non-secure view of this register via DEMCR_NS located at 0xE002EDFC. The location 0xE002EDFC is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Bits [31:25]**
Reserved, RES0.

**TRCENA, bit [24]**
Trace enable. Global enable for all DWT and ITM features.
The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>DWT and ITM features disabled.</td>
</tr>
<tr>
<td>1</td>
<td>DWT and ITM features enabled.</td>
</tr>
</tbody>
</table>

If the DWT and ITM units are not implemented, this bit is RES0. See the descriptions of DWT and ITM for details of which features this bit controls.
Setting this bit to 0 might not stop all events. To ensure that all events are stopped, software must set all DWT and ITM feature enable bits to 0, and that all trace generated by the DWT and ITM has been flushed, before setting this bit to 0.

The effect of this bit on the TPIU, ETM, and other system trace components is IMPLEMENTATION DEFINED.
This bit resets to zero on a Cold reset.

**Bits [23:21]**
Reserved, RES0.
SDME, bit [20]
Secure DebugMonitor enable. Indicates whether the DebugMonitor targets the Secure or the Non-secure state and whether debug events are allowed to be generated by Secure operations.

The possible values of this bit are:
0 Debug event generation by Secure operations prohibited and the DebugMonitor exception targets Non-secure state.
1 Debug event generation by Secure operations allowed and the DebugMonitor exception targets Secure state.

When DebugMonitor is not pending or active, this bit reflects the value of SecureDebugMonitorAllowed(), otherwise, the previous value is retained.
This bit is read-only.
If the Security Extension is not implemented, this bit is RES0.
If the Main Extension is not implemented, this bit is RES0.

MON_REQ, bit [19]
Monitor request. DebugMonitor semaphore bit.
The PE does not use this bit. The monitor software defines the meaning and use of this bit.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

MON_STEP, bit [18]
Monitor step. Enable DebugMonitor stepping.
The possible values of this bit are:
0 Stepping disabled.
1 Stepping enabled.
The effect of changing this bit at an execution priority that is lower than the priority of the DebugMonitor exception is UNPREDICTABLE.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

MON_PEND, bit [17]
Monitor pend. Sets or clears the pending state of the DebugMonitor exception.
The possible values of this bit are:
0 Clear the status of the DebugMonitor exception to not pending.
1 Set the status of the DebugMonitor exception to pending.
When the DebugMonitor exception is pending it becomes active subject to the exception priority rules. The effect of setting this bit to 1 is not affected by the value of the MON_EN bit. This means that software or a debugger can set MON_PEND to 1 and pend a DebugMonitor exception, even when MON_EN is set to 0.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

MON_EN, bit [16]
Monitor enable. Enable the DebugMonitor exception.
The possible values of this bit are:
0 DebugMonitor exception disabled.
1 DebugMonitor exception enabled.
If a debug event halts the PE, the PE ignores the value of this bit.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

**Bits [15:12]**

Reserved, RES0.

**VC_SFERR, bit [11]**

The possible values of this bit are:

0  Halting debug trap on SecureFault disabled.
1  Halting debug trap on SecureFault enabled.

The PE ignores the value of this bit if DHCSR.C_DEBUGEN == 0, HaltingDebugAllowed() == FALSE, or DHCSR.S_SDE == 0.

If the Security Extension is not implemented, this bit is RES0.
If the Main Extension is not implemented, this bit is RES0.
If Halting debug is not implemented, this bit is RES0.

This bit resets to zero on a Cold reset.

**VC_HARDERR, bit [10]**

The possible values of this bit are:

0  Halting debug trap on HardFault disabled.
1  Halting debug trap on HardFault enabled.

The PE ignores the value of this bit if DHCSR.C_DEBUGEN == 0, HaltingDebugAllowed() == FALSE, or the Security Extension is implemented, DHCSR.S_SDE == 0 and the exception targets Secure state.

If Halting debug is not implemented, this bit is RES0.

This bit resets to zero on a Cold reset.

**VC_INTERR, bit [9]**

Vector Catch interrupt errors. Enable Halting debug vector catch for faults during exception entry and return.

The possible values of this bit are:

0  Halting debug trap on faults during exception entry and return disabled.
1  Halting debug trap on faults during exception entry and return enabled.

The PE ignores the value of this bit if DHCSR.C_DEBUGEN == 0, HaltingDebugAllowed() == FALSE, or the Security Extension is implemented, DHCSR.S_SDE == 0 and the exception targets Secure state.

If the Main Extension is not implemented, this bit is RES0.
If Halting debug is not implemented, this bit is RES0.

This bit resets to zero on a Cold reset.

**VC_BUSERR, bit [8]**

The possible values of this bit are:

0  Halting debug trap on BusFault disabled.
1  Halting debug trap on BusFault enabled.

The PE ignores the value of this bit if DHCSR.C_DEBUGEN == 0, HaltingDebugAllowed() == FALSE, or the Security Extension is implemented, DHCSR.S_SDE == 0 and the exception targets Secure state.

If the Main Extension is not implemented, this bit is RES0.
If Halting debug is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

VC_STATERR, bit [7]
Vector Catch state errors. Enable Halting debug trap on a UsageFault exception caused by a state
information error, for example an Undefined Instruction exception.
The possible values of this bit are:
0    Halting debug trap on UsageFault caused by state information error disabled.
1    Halting debug trap on UsageFault caused by state information error enabled.
The PE ignores the value of this bit if DHCSR.C_DEBUGEN == 0, HaltingDebugAllowed() == FALSE, or the Security Extension is implemented, DHCSR.S_SDE == 0 and the exception targets Secure state.
If the Main Extension is not implemented, this bit is RES0.
If Halting debug is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

VC_CHKERR, bit [6]
Vector Catch check errors. Enable Halting debug trap on a UsageFault exception caused by a
checking error, for example an alignment check error.
The possible values of this bit are:
0    Halting debug trap on UsageFault caused by checking error disabled.
1    Halting debug trap on UsageFault caused by checking error enabled.
The PE ignores the value of this bit if DHCSR.C_DEBUGEN == 0, HaltingDebugAllowed() == FALSE, or the Security Extension is implemented, DHCSR.S_SDE == 0 and the exception targets Secure state.
If the Main Extension is not implemented, this bit is RES0.
If Halting debug is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

VC_NOCPERR, bit [5]
Vector Catch NOCP errors. Enable Halting debug trap on a UsageFault caused by an access to a
coprocessor.
The possible values of this bit are:
0    Halting debug trap on UsageFault caused by access to a coprocessor disabled.
1    Halting debug trap on UsageFault caused by access to a coprocessor enabled.
The PE ignores the value of this bit if DHCSR.C_DEBUGEN == 0, HaltingDebugAllowed() == FALSE, or the Security Extension is implemented, DHCSR.S_SDE == 0 and the exception targets Secure state.
If the Main Extension is not implemented, this bit is RES0.
If Halting debug is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

VC_MMERR, bit [4]
Vector Catch MemManage errors. Enable Halting debug trap on a MemManage exception.
The possible values of this bit are:
0    Halting debug trap on MemManage disabled.
1    Halting debug trap on MemManage enabled.
The PE ignores the value of this bit if DHCSR.C_DEBUGEN == 0, HaltingDebugAllowed() == FALSE, or the Security Extension is implemented, DHCSR.S_SDE == 0 and the exception targets Secure state.
If the Main Extension is not implemented, this bit is RES0.
If Halting debug is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

**Bits [3:1]**
Reserved, RES0.

**VC_CORERESET, bit [0]**
Vector Catch core reset. Enable Reset Vector Catch. This causes a warm reset to halt a running system.

The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Halting debug trap on reset disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Halting debug trap on reset enabled.</td>
</tr>
</tbody>
</table>

If DHCSR.C_DEBUGEN == 0 or HaltingDebugAllowed() == FALSE, the PE ignores the value of this bit. Otherwise, when this bit is set to 1 a Warm reset will pend a Vector Catch debug event. The debug event is pended even the PE resets into Secure state and DHCSR.S_SDE == 0.

If Halting debug is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.
D1.2.37 DFSR, Debug Fault Status Register

The DFSR characteristics are:

**Purpose**
Shows which debug event occurred.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if Halting debug or the Main Extension is implemented.
This register is RES0 if both Halting debug and Main Extension are not implemented.

**Attributes**
32-bit read/write-one-to-clear register located at 0xE000ED30.
Secure software can access the Non-secure view of this register via DFSR_NS located at 0xE002ED30. The location 0xE002ED30 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The DFSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:5</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>4</td>
<td>EXTERNAL, bit [4] - External event. Sticky flag indicating whether an External debug request debug event has occurred. The possible values of this bit are: 0 - Debug event has not occurred. 1 - Debug event has occurred. This bit resets to zero on a Cold reset.</td>
</tr>
<tr>
<td>3</td>
<td>Vcatch, bit [3] - Vector Catch event. Sticky flag indicating whether a Vector catch debug event has occurred. The possible values of this bit are: 0 - Debug event has not occurred. 1 - Debug event has occurred. If Halting debug is not implemented, this bit is RES0. This bit resets to zero on a Cold reset.</td>
</tr>
<tr>
<td>2</td>
<td>DWTTRAP, bit [2] - Watchpoint event. Sticky flag indicating whether a Watchpoint debug event has occurred. The possible values of this bit are: 0 - Debug event has not occurred.</td>
</tr>
</tbody>
</table>

![DFSR Diagram](image-url)
1 Debug event has occurred.
If the DWT is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

**BKPT, bit [1]**

Breakpoint event. Sticky flag indicating whether a Breakpoint debug event has occurred.
The possible values of this bit are:
0 Debug event has not occurred.
1 Debug event has occurred.
This bit resets to zero on a Cold reset.

**HALTED, bit [0]**

Halt or step event. Sticky flag indicating that a Halt request debug event or Step debug event has occurred.
The possible values of this bit are:
0 Debug event has not occurred.
1 Debug event has occurred.
This bit resets to zero on a Cold reset.
D1.2.38 DHCSR, Debug Halting Control and Status Register

The DHCSR characteristics are:

**Purpose**
Controls Halting debug.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

It is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software.

**Configurations**
Present only if Halting debug is implemented.
This register is RES0 if Halting debug is not implemented.

**Attributes**
32-bit read/write register located at 0xE000EDF0.
Secure software can access the Non-secure view of this register via DHCSR_NS located at 0xE002EDF0.
The location 0xE002EDF0 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The DHCSR bit assignments are:

On a read:

On a write:

**DBGKEY, bits [31:16], on a write**

Debug key. A debugger must write 0xA05F to this field to enable write access to the remaining bits, otherwise the PE ignores the write access.

The possible values of this field are:

0xA05F  
Writes accompanied by this value update bits[15:0].

Not 0xA05F  
Write ignored.

**Bits [31:27], on a read**

Reserved, RES0.
S_RESTART_ST, bit [26], on a read
Restart sticky status. Indicates the PE has processed a request to clear DHCSR.C_HALT to 0. That is, either a write to DHCSR that clears DHCSR.C_HALT from 1 to 0, or an External Restart Request.

The possible values of this bit are:

0  PE has not left Debug state since the last read of DHCSR.
1  PE has left Debug state since the last read of DHCSR.

If the PE is not halted when C_HALT is cleared to zero, it is UNPREDICTABLE whether this bit is set to 1. If DHCSR.C_DEBUGEN == 0 this bit reads as an UNKNOWN value.

This bit clears to zero when read.

Note
If the request to clear C_HALT is made simultaneously with a request to set C_HALT, for example a restart request and external debug request occur together, then the PE notionally leaves Debug state and immediately halts again and S_RESTART_ST is set to 1.

S_RESET_ST, bit [25], on a read
Reset sticky status. Indicates whether the PE has been reset since the last read of the DHCSR.

The possible values of this bit are:

0  No reset since last DHCSR read.
1  At least one reset since last DHCSR read.

This bit clears to zero when read.

This bit resets to one on a Warm reset.

S_RETIRE_ST, bit [24], on a read
Retire sticky status. Set to 1 every time the PE retires one of more instructions.

The possible values of this bit are:

0  No instruction retired since last DHCSR read.
1  At least one instruction retired since last DHCSR read.

This bit clears to zero when read.

This bit resets to an UNKNOWN value on a Warm reset.

Bits [23:21], on a read
Reserved, RES0.

S_SDE, bit [20], on a read
Secure debug enabled. Indicates whether Secure invasive debug is allowed.

The possible values of this bit are:

0  Secure invasive debug prohibited.
1  Secure invasive debug allowed.

If the PE is in Non-debug state, this bit reflects the value of SecureHaltingDebugAllowed().

If the PE is in Debug state then this bit is 1 if the PE entered Debug state from either Non-secure state with SecureHaltingDebugAllowed() == TRUE or from Secure state, and 0 otherwise. The value of this bit does not change whilst the PE remains in Debug state.

If the Security Extension is not implemented, this bit is RES0.

S_LOCKUP, bit [19], on a read
Lockup status. Indicates whether the PE is in Lockup state.
The possible values of this bit are:
0  Not locked up.
1  Locked up.

This bit can only be read as 1 by a remote debugger, using the DAP. The value of 1 indicates that the PE is running but locked up. The bit clears to 0 when the PE enters Debug state.

**S_SLEEP, bit [18], on a read**

Sleeping status. Indicates whether the PE is sleeping.
The possible values of this bit are:
0  Not sleeping.
1  Sleeping.

The debugger must set the C_HALT bit to 1 to gain control, or wait for an interrupt or other wakeup event to wakeup the system.

**S_HALT, bit [17], on a read**

Halted status. Indicates whether the PE is in Debug state.
The possible values of this bit are:
0  In Non-debug state.
1  In Debug state.

**S_REGRDY, bit [16], on a read**

Register ready status. Handshake flag to transfers through the DCRDR.
The possible values of this bit are:
0  Write to DCRSR performed, but transfer not yet complete.
1  Transfer complete, or no outstanding transfer.

This bit is valid only when the PE is in Debug state, otherwise this bit is UNKNOWN.
This bit resets to an UNKNOWN value on a Warm reset.

**Bits [15:6]**

Reserved, RES0.

**C_SNAPSHOT, bit [5]**

Snap stall control. Allow imprecise entry to Debug state.
The possible values of this bit are:
0  No action.
1  Allow imprecise entry to Debug state, for example by forcing any stalled load or store instruction to be abandoned.

Setting this bit to 1 allows a debugger to request imprecise entry to Debug state. Writing 1 to this bit makes the state of the memory system UNPREDICTABLE. Therefore if a debugger writes 1 to this bit it must reset the system before leaving Debug state.

The effect of setting this bit to 1 is UNPREDICTABLE unless the DHCSR write also sets C_DEBUGEN and C_HALT to 1. This means that if the PE is not already in Debug state, it enters Debug state when the stalled instruction completes.

If the Security Extension is implemented, then writes to this bit are ignored when DHCSR.S_SDE == 0.

If DHCSR.C_DEBUGEN == 0 or HaltingDebugAllowed() == FALSE, the PE ignores this bit and behaves as if it is set to 0.

If the Main Extension is not implemented, this bit is RES0.
--- Note ---

A debugger can write to the DHCSR to clear this bit to 0. However, this does not remove the UNPREDICTABLE state of the memory system caused by setting C_SNAPSTALL to 1. The architecture does not guarantee that setting this bit to 1 will force entry to Debug State. ARM strongly recommends that a value of 1 is never written to C_SNAPSTALL when the PE is in Debug state.

Bit [4]

Reserved, RES0.

C_MASKINTS, bit [3]

Mask interrupts control. When debug is enabled, the debugger can write to this bit to mask PendSV, SysTick and external configurable interrupts.

The possible values of this bit are:

0  Do not mask.
1  Mask PendSV, SysTick and external configurable interrupts.

The effect of any single write to DHCSR that changes the value of this bit is UNPREDICTABLE unless one of:

- Before the write, DHCSR.C_HALT == 1 and the write also writes 1 to DHCSR.C_HALT.
- Before the write, DHCSR.C_DEBUGEN == 0 or HaltingDebugAllowed() == FALSE and the write writes 0 to this bit.

This means that a single write to DHCSR must not clear DHCSR.C_HALT to 0 and change the value of the C_MASKINTS bit.

If the Security Extension is implemented and DHCSR.S_SDE == 0, this bit does not affect interrupts targeting Secure state.

If DHCSR.C_DEBUGEN == 0 or HaltingDebugAllowed() == FALSE, the PE ignores this bit and behaves as if it is set to 0.

If DHCSR.C_DEBUGEN == 0 this bit reads as an UNKNOWN value.

This bit resets to an UNKNOWN value on a Cold reset.

--- Note ---

This bit does not affect NMI.

C_STEP, bit [2]

Step control. Enable single instruction step.

The possible values of this bit are:

0  No effect.
1  Single step enabled.

The PE ignores this bit and behaves as if it set to 0 if any of:

- DHCSR.C_DEBUGEN == 0 or HaltingDebugAllowed() == FALSE.
- The Security Extension is implemented, DHCSR.S_SDE == 0 and the PE is in Secure state.

If DHCSR.C_DEBUGEN == 0 this bit reads as an UNKNOWN value.

This bit resets to an UNKNOWN value on a Cold reset.

C_HALT, bit [1]

Halt control. PE enter Debug state halt request.

The possible values of this bit are:

0  Causes the PE to leave Debug state, if in Debug state.
1  Halt the PE.
The PE sets C_HALT to 1 when a debug event pends an entry to Debug state.
The PE ignores this bit and behaves as if it is set to 0 if any of:
- DHCSR.C_DEBUGEN == 0 or HaltingDebugAllowed() == FALSE.
- The Security Extension is implemented, DHCSR.S_SDE == 0 and the PE is in Secure state.
If DHCSR.C_DEBUGEN == 0 this bit reads as an UNKNOWN value.
This bit resets to zero on a Warm reset.

C_DEBUGEN, bit [0]
Debug enable control. Enable Halting debug.
The possible values of this bit are:
0  Disabled.
1  Enabled.
If a debugger writes to DHCSR to change the value of this bit from 0 to 1, it must also write 0 to the C_MASKINTS bit, otherwise behavior is UNPREDICTABLE.
If this bit is set to 0:
- The PE behaves as if DHCSR.{C_MASKINTS, C_STEP, C_HALT} are all set to 0.
- DHCSR.{S_RESTART_ST, C_MASKINTS, C_STEP, C_HALT} are UNKNOWN on reads of DHCSR.
This bit is read/write to the debugger. Writes from software are ignored.
This bit resets to zero on a Cold reset.
D1.2.39   DLAR, SCS Software Lock Access Register

The DLAR characteristics are:

**Purpose**  
Provides CoreSight Software Lock control for the SCS, see the ARM® CoreSight™ Architecture Specification for details.

**Usage constraints**  
Privileged access permitted only. Unprivileged accesses generate a BusFault.  
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.  
This register is RAZ/WI if accessed via the debugger.

**Configurations**  
Present only if CoreSight identification is implemented.  
This register is RES0 if CoreSight identification is not implemented.  
Present only if the optional Software Lock is implemented.  
This register is RAZ/WI if the Software Lock is not implemented.

**Attributes**  
32-bit write-only register located at 0xE000EFB0.  
Secure software can access the Non-secure view of this register via DLAR_NS located at 0xE002EFB0. The location 0xE002EFB0 is RES0 to software executing in Non-secure state and the debugger.  
This register is not banked between Security states.

**Field descriptions**

The DLAR bit assignments are:

```
+----------------+ 31:0  
|    KEY         |
+----------------+ 0    
```

**KEY, bits [31:0]**

Lock Access control.

Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.
D1.2.40   DLSR, SCS Software Lock Status Register

The DLSR characteristics are:

**Purpose**
Provides CoreSight Software Lock status information for the SCS, see the *ARM® CoreSight™ Architecture Specification* for details.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE. This register is RAZ/WI if accessed via the debugger.

**Configurations**
Present only if CoreSight identification is implemented. This register is RES0 if CoreSight identification is not implemented. Present only if the optional Software Lock is implemented. This register is RAZ/WI if the Software Lock is not implemented.

**Attributes**
32-bit read-only register located at 0xE000EFB4. Secure software can access the Non-secure view of this register via DLSR_NS located at 0xE002EFB4. The location 0xE002EFB4 is RES0 to software executing in Non-secure state and the debugger. This register is not banked between Security states.

**Field descriptions**

The DLSR bit assignments are:

![DLSR Bit Assignments](image)

**Bits [31:3]**
Reserved, RES0.

**nTT, bit [2]**
Not thirty-two bit. See the *ARM® CoreSight™ Architecture Specification*. This bit reads as zero.

**SLK, bit [1]**
Software Lock status. See the *ARM® CoreSight™ Architecture Specification*. The possible values of this bit are:

- **0**: Lock clear. Software writes are permitted to this component's registers.
- **1**: Lock set. Software writes to this component's registers are ignored, and reads have no side-effects.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is RES0. This bit resets to one on a Warm reset.

**SLI, bit [0]**
Software Lock implemented. See the *ARM® CoreSight™ Architecture Specification*. The possible values of this bit are:

- **0**: Software Lock not implemented or debugger access.
- **1**: Software Lock is implemented and software access.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is RAZ.
This bit reads as an IMPLEMENTATION DEFINED value.
D1.2.41  DPIDR0, SCS Peripheral Identification Register 0

The DPIDR0 characteristics are:

**Purpose**
Provides CoreSight discovery information for the SCS.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if Halting debug is implemented.
This register is RES0 if Halting debug is not implemented.

**Attributes**
32-bit read-only register located at 0xE000EFE0.
Secure software can access the Non-secure view of this register via DPIDR0_NS located at 0xE002EFE0. The location 0xE002EFE0 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**

The DPIDR0 bit assignments are:

<table>
<thead>

</tbody>
</table>

**Bits [31:8]**
Reserved, RES0.

**PART_0, bits [7:0]**
Part number bits [7:0]. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.42   DPIDR1, SCS Peripheral Identification Register 1

The DPIDR1 characteristics are:

**Purpose**

Provides CoreSight discovery information for the SCS.

**Usage constraints**

Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**

Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is RES0 if Halting debug is not implemented.

**Attributes**

32-bit read-only register located at 0xE000EFE4.

Secure software can access the Non-secure view of this register via DPIDR1_NS located at 0xE002EFE4. The location 0xE002EFE4 is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

**Field descriptions**

The DPIDR1 bit assignments are:

<table>

</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**DES_0, bits [7:4]**

JEP106 identification code bits [3:0]. See the ARM® CoreSight™ Architecture Specification.

This field reads as an IMPLEMENTATION DEFINED value.

**PART_1, bits [3:0]**

This field reads as an IMPLEMENTATION DEFINED value.
D1.2.43  DPIDR2, SCS Peripheral Identification Register 2

The DPIDR2 characteristics are:

**Purpose**  Provides CoreSight discovery information for the SCS.

**Usage constraints**  Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this
register is accessible only to the debugger and RES0 for software. Otherwise the register is
accessible to the debugger and software.

**Configurations**  Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if Halting debug is implemented.
This register is RES0 if Halting debug is not implemented.

**Attributes**  32-bit read-only register located at 0xE000EFE8.
Secure software can access the Non-secure view of this register via DPIDR2_NS located at
0xE002EFE8. The location 0xE002EFE8 is RES0 to software executing in Non-secure state and
the debugger.
This register is not banked between Security states.

**Field descriptions**

The DPIDR2 bit assignments are:

![Diagram of DPIDR2 bit assignments]

**Bits [31:8]**  Reserved, RES0.

**REVISION, bits [7:4]**  Component revision. See the *ARM® CoreSight™ Architecture Specification.*
This field reads as an IMPLEMENTATION DEFINED value.

**JEDEC, bit [3]**  JEDEC assignee value is used. See the *ARM® CoreSight™ Architecture Specification.*
This bit reads as one.

**DES_1, bits [2:0]**  JEP106 identification code bits [6:4]. See the *ARM® CoreSight™ Architecture Specification.*
This field reads as an IMPLEMENTATION DEFINED value.
D1 Register Specification  
D1.2 Alphabetical list of registers

D1.2.44  DPIDR3, SCS Peripheral Identification Register 3

The DPIDR3 characteristics are:

**Purpose**
Provides CoreSight discovery information for the SCS.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if Halting debug is implemented.
This register is RES0 if Halting debug is not implemented.

**Attributes**
32-bit read-only register located at 0xE000EFEC.
Secure software can access the Non-secure view of this register via DPIDR3_NS located at 0xE002EFEC. The location 0xE002EFEC is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The DPIDR3 bit assignments are:

D1.2.45  DPIDR4, SCS Peripheral Identification Register 4

The DPIDR4 characteristics are:

**Purpose**
Provides CoreSight discovery information for the SCS.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if Halting debug is implemented.
This register is RES0 if Halting debug is not implemented.

**Attributes**
32-bit read-only register located at 0xE000EFD0.
Secure software can access the Non-secure view of this register via DPIDR4_NS located at 0xE002EFD0. The location 0xE002EFD0 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

Field descriptions

The DPIDR5 bit assignments are:

```
+----------------+----------------+
| 31             | 0              |
|                | RES0           |
```

Bits [31:0]  
Reserved, RES0.
D1.2.47 DPIDR6, SCS Peripheral Identification Register 6

The DPIDR6 characteristics are:

**Purpose**
Provides CoreSight discovery information for the SCS.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented. This register is RES0 if CoreSight identification is not implemented. Present only if Halting debug is implemented. This register is RES0 if Halting debug is not implemented.

**Attributes**
32-bit read-only register located at 0xE000EFD8. Secure software can access the Non-secure view of this register via DPIDR6_NS located at 0xE002EFD8. The location 0xE002EFD8 is RES0 to software executing in Non-secure state and the debugger. This register is not banked between Security states.

**Field descriptions**
The DPIDR6 bit assignments are:

```
+------------------+
| 31               |
|                  |
|                  |
| 31:0: RES0       |
|                  |

+------------------+
```

**Bits [31:0]**
Reserved, RES0.
D1.2.48  DPIDR7, SCS Peripheral Identification Register 7

The DPIDR7 characteristics are:

**Purpose**
Provides CoreSight discovery information for the SCS.

**Usage constraints**
- Privileged access permitted only. Unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
- If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
- Present only if CoreSight identification is implemented.
- This register is RES0 if CoreSight identification is not implemented.
- Present only if Halting debug is implemented.
- This register is RES0 if Halting debug is not implemented.

**Attributes**
- 32-bit read-only register located at 0xE000EFDC.
- Secure software can access the Non-secure view of this register via DPIDR7_NS located at 0xE002EFDC. The location 0xE002EFDC is RES0 to software executing in Non-secure state and the debugger.
- This register is not banked between Security states.

**Field descriptions**

The DPIDR7 bit assignments are:

- **Bits [31:0]**
  - Reserved, RES0.
D1.2.49 DSCSR, Debug Security Control and Status Register

The DSCSR characteristics are:

**Purpose**
Provides control and status information for Secure debug.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE. Writes to this register while the PE is in Non-debug state are ignored. This register is accessible only to the debugger and RES0 to software.

**Configurations**
Present only if the Security Extension is implemented. This register is RES0 if the Security Extension is not implemented. Present only if Halting debug is implemented. This register is RES0 if Halting debug is not implemented.

**Attributes**
32-bit read/write register located at 0xE000EE08. This register is not banked between Security states.

**Field descriptions**

The DSCSR bit assignments are:

```
<table>
<thead>
<tr>
<th>31</th>
<th>7</th>
<th>6</th>
<th>15</th>
<th>16</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>CDSKEY</td>
<td>CDS</td>
<td>RES0</td>
<td>SBRSELEN</td>
<td>SBRSEL</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:18]**
Reserved, RES0.

**CDSKEY, bit [17]**
CDS write-enable key. Writes to the CDS bit are ignored unless CDSKEY is concurrently written to zero.

The possible values of this bit are:

- 0: Concurrent write to CDS not ignored.
- 1: Concurrent write to CDS ignored.

**CDS, bit [16]**
Current domain Secure. This field indicates the current Security state of the processor.

The possible values of this bit are:

- 0: PE is in Non-secure state.
- 1: PE is in Secure state.

This bit is only writable if DHCSR.S_SDE is 1, the access to the register originates from the debugger, the PE is halted in Debug state, and CDSKEY is concurrently written to zero.

**Bits [15:2]**
Reserved, RES0.

**SBRSEL, bit [1]**
Secure Banked register select. If SBRSELEN is 1 this bit selects whether the Non-secure or the Secure version of the memory-mapped Banked registers are accessible to the debugger.
The possible values of this bit are:

0  Selects the Non-secure versions.
1  Selects the Secure versions.

This bit behaves as RAZ/WI if DHCSR.S_SDE is 0.
This bit resets to zero on a Cold reset.

**SBRSELEN, bit [0]**

Secure Banked register select enable. Controls whether the SBRSEL field or the current Security state of the processor selects which version of the memory-mapped Banked registers are accessed to the debugger.

The possible values of this bit are:

0  The current Security state of the PE determines which memory-mapped Banked registers are accessed by the debugger.
1  DCSR.SBRSEL selects which memory-mapped Banked registers are accessed by the debugger.

This bit behaves as RAO/WI if DHCSR.S_SDE is 0.
This bit resets to zero on a Cold reset.

--- **Note**

This method of Banked register selection means that the register aliasing is not used for accesses from the debugger. Accesses to the aliased addresses from the debugger have the same behavior as reserved addresses.
D1.2.50 DWT_CIDR0, DWT Component Identification Register 0

The DWT_CIDR0 characteristics are:

**Purpose**
Provides CoreSight discovery information for the DWT.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read-only register located at 0xE0001FF0.
This register is not banked between Security states.

**Field descriptions**
The DWT_CIDR0 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>[31:8]</td>
</tr>
<tr>
<td>PRMBL_0</td>
<td>[7:0]</td>
</tr>
</tbody>
</table>

**Bits [31:8]**
Reserved, RES0.

**PRMBL_0, bits [7:0]**
CoreSight component identification preamble. See the ARM<sup>®</sup> CoreSight™ Architecture Specification.
This field reads as 0x0D.
D1.2.51 DWT_CIDR1, DWT Component Identification Register 1

The DWT_CIDR1 characteristics are:

**Purpose**
Provides CoreSight discovery information for the DWT.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read-only register located at 0xE0001FF4.
This register is not banked between Security states.

**Field descriptions**
The DWT_CIDR1 bit assignments are:

- **Bits [31:8]**
  Reserved, RES0.
- **CLASS, bits [7:4]**
  CoreSight component class. See the ARM® CoreSight™ Architecture Specification.
  This field reads as 0x9.
- **PRMBL_1, bits [3:0]**
  CoreSight component identification preamble. See the ARM® CoreSight™ Architecture Specification.
  This field reads as 0x0.
D1.2.52 DWT_CIDR2, DWT Component Identification Register 2

The DWT_CIDR2 characteristics are:

**Purpose**
Provides CoreSight discovery information for the DWT.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read-only register located at 0xE0001FF8.
This register is not banked between Security states.

**Field descriptions**
The DWT_CIDR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>8-0</td>
<td>PRMBL_2, bits [7:0]</td>
</tr>
</tbody>
</table>

CoreSight component identification preamble. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as 0x05.
D1.2.53  DWT_CIDR3, DWT Component Identification Register 3

The DWT_CIDR3 characteristics are:

**Purpose**
Provides CoreSight discovery information for the DWT.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read-only register located at 0xE0001FFC.
This register is not banked between Security states.

**Field descriptions**
The DWT_CIDR3 bit assignments are:

![DWT_CIDR3 Bit Assignment Diagram](image)

**Bits [31:8]**
Reserved, RES0.

**PRMBL_3, bits [7:0]**
CoreSight component identification preamble. See the ARM® CoreSight™ Architecture Specification.
This field reads as 0xB1.
D1.2.54 DWT_COMP<n>, DWT Comparator Register, n = 0 - 14

The DWT_COMP<n> characteristics are:

**Purpose**
Provides a reference value for use by watchpoint comparator n.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read/write register located at 0xE0001020 + 16n.
This register is not banked between Security states.

**Field descriptions**

The DWT_COMP<n> bit assignments are:

When DWT_FUNCTIONn.MATCH == 0b0001:

\[
\begin{array}{c}
31 \\
- \\
0 \\
\end{array}
\]

**CYCVALUE**, bits [31:0], when DWT_FUNCTIONn.MATCH == 0b0001

Cycle value. Reference value for comparison with cycle count.
This field resets to an UNKNOWN value on a Cold reset.

When DWT_FUNCTIONn.MATCH == 0b001x:

\[
\begin{array}{c}
31 \\
- \\
10 \\
0 \\
\end{array}
\]

**PCVALUE**, bits [31:1], when DWT_FUNCTIONn.MATCH == 0b001x

PC value. Reference value for comparison with program counter.
This field resets to an UNKNOWN value on a Cold reset.

Bit [0], when DWT_FUNCTIONn.MATCH == 0b001x

Reserved, RES0.

When DWT_FUNCTIONn.MATCH == 0bx1xx:

\[
\begin{array}{c}
31 \\
- \\
0 \\
\end{array}
\]

**DVALUE**, bits [31:0], when DWT_FUNCTIONn.MATCH == 0bx1xx

Data address. Reference value for comparison with load or store address.

When DWT_FUNCTIONn.MATCH == 0bx1xx:

\[
\begin{array}{c}
31 \\
- \\
0 \\
\end{array}
\]

**DADDR**, bits [31:0], when DWT_FUNCTIONn.MATCH == 0bx1xx

Data address. Reference value for comparison with load or store address.
For halfword address comparisons, DADDR[0] is RES0. For byte address comparisons, DADDR[1:0] are RES0.

This field resets to an UNKNOWN value on a Cold reset.

**DVALUE, bits [31:0], when DWT_FUNCTIONn.MATCH == 0b10xx**

Data value. Reference value for comparison with load or store data.

For halfword or word comparisons, the data value is in little-endian order. That is, the least significant byte of this register is compared with the byte targeting the lowest address in memory.

For byte or halfword comparisons, if the value of the byte or halfword is not replicated across all byte or halfword lanes, the value used for the comparison is UNKNOWN.

This field resets to an UNKNOWN value on a Cold reset.
D1.2.55  DWT_CPICNT, DWT CPI Count Register

The DWT_CPICNT characteristics are:

**Purpose**
Counts additional cycles required to execute multi-cycle instructions and instruction fetch stalls.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.
Present only if DWT_CTRL.NOPRFCNT == '0'.
This register is RES0 if DWT_CTRL.NOPRFCNT == '1'.

**Attributes**
32-bit read/write register located at 0xE0001008.
This register is not banked between Security states.

**Field descriptions**
The DWT_CPICNT bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:8</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>7:0</td>
<td>CPICNT, base instruction overhead</td>
</tr>
</tbody>
</table>

Counts one on each cycle when all of the following are true:
- DWT_CTRL.CPIEVTENA == 1 and DEMCR.TRCENA == 1.
- No instruction is executed.
- No load-store operation is in progress, see DWT_LSUCNT.
- No exception-entry or exception-exit operation is in progress, see DWT_EXCCNT.
- The PE is not in a power saving mode, see DWT_SLEEPCNT.
- Either SecureNoninvasiveDebugAllowed() == TRUE, or the PE is in Non-secure state and NoninvasiveDebugAllowed() == TRUE.

The definition of "no instruction is executed" is IMPLEMENTATION DEFINED. ARM recommends that this counts each cycle on which no instruction is retired.

Initialized to zero when the counter is disabled and DWT_CTRL.CPIEVTENA is written with 1.
An Event Counter packet is emitted on counter overflow.
This field resets to an UNKNOWN value on a Cold reset.
D1.2.56  DWT_CTRL, DWT Control Register

The DWT_CTRL characteristics are:

**Purpose**
Provides configuration and status information for the DWT unit, and used to control features of the unit.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read/write register located at 0xE0001000.
This register is not banked between Security states.

**Field descriptions**
The DWT_CTRL bit assignments are:

```
| 31  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| NUMCOMP | NOTRCPKT | NOEXTRIG | NOCYCCNT | NOPRFCNT | CYCDISS | CYCEVTENA | FOLDCEVTENA | LSUEVTENA | RES0 | POSTINIT | POSTPRESET | CYCTAP | SYNCTAP | PCSAMPLENA | EXTRCEVTENA | CPIEVTENA | EXCEVTENA | SLEEPEVTENA |
```

**NUMCOMP, bits [31:28]**
Number of comparators. Number of DWT comparators implemented.
A value of zero indicates no comparator support.
This field reads as an IMPLEMENTATION DEFINED value.

**NOTRCPKT, bit [27]**
No trace packets. Indicates whether the implementation does not support trace.
The possible values of this bit are:
0  Trace supported.
1  Trace not supported.
If this bit is RAZ, the NOCYCCNT bit must also RAZ.
If the Main Extension is not implemented, this bit is RES1.
This bit reads as an IMPLEMENTATION DEFINED value.

**NOEXTRIG, bit [26]**
No External Triggers. Shows whether the implementation does not support external triggers.

**NOCYCCNT, bit [25]**
No cycle count. Indicates whether the implementation does not include a cycle counter.
The possible values of this bit are:
0  Cycle counter implemented.
Cycle counter not implemented.
If the Main Extension is not implemented, this bit is RES1.
This bit reads as an IMPLEMENTATION DEFINED value.

NOPRFCNT, bit [24]
No profile counters. Indicates whether the implementation does not include the profiling counters.
The possible values of this bit are:
0  Profiling counters implemented.
1  Profiling counters not implemented.
If the Main Extension is not implemented, this bit is RES1.
This bit reads as an IMPLEMENTATION DEFINED value.

CYCDISS, bit [23]
Cycle counter disabled secure. Controls whether the cycle counter is disabled in Secure state.
The possible values of this bit are:
0  No effect.
1  Disable incrementing of the cycle counter when the PE is in Secure state.
RES0 if the NOCYCCNT bit is RAO.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

CYCEVTENA, bit [22]
Cycle event enable. Enables Event Counter packet generation on POSTCNT underflow.
The possible values of this bit are:
0  No Event Counter packets generated when POSTCNT underflows.
1  If PCSAMPLENA set to 0, an Event Counter packet is generated when POSTCNT
underflows.
RES0 if the NOTRCPKT bit is RAO or the NOCYCCNT bit is RAO.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

FOLDEVTENA, bit [21]
Fold event enable. Enables DWT_FOLDCNT counter.
The possible values of this bit are:
0  DWT_FOLDCNT disabled.
1  DWT_FOLDCNT enabled.
RES0 if the NOPRFCNT bit is RAO. The reset value is 0.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

LSUEVTENA, bit [20]
LSU event enable. Enables DWT_LSUCNT counter.
The possible values of this bit are:
0  DWT_LSUCNT disabled.
1  DWT_LSUCNT enabled.
RES0 if the NOPRFCNT bit is RAO.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.
SLEEPEVTENA, bit [19]
Sleep event enable. Enable DWT_SLEEPCNT counter.
The possible values of this bit are:
0  DWT_SLEEPCNT disabled.
1  DWT_SLEEPCNT enabled.
RES0 if the NOPRFCNT bit is RAO.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

EXCEVTENA, bit [18]
Exception event enable. Enables DWT_EXCCNT counter.
The possible values of this bit are:
0  DWT_EXCCNT disabled.
1  DWT_EXCCNT enabled.
RES0 if the NOPRFCNT bit is RAO.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

CPIEVTENA, bit [17]
CPI event enable. Enables DWT_CPICNT counter.
The possible values of this bit are:
0  DWT_CPICNT disabled.
1  DWT_CPICNT enabled.
RES0 if the NOPRFCNT bit is RAO.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

EXTTRCENA, bit [16]
Exception trace enable. Enables generation of Exception Trace packets.
The possible values of this bit are:
0  Exception Trace packet generation disabled.
1  Exception Trace packet generation enabled.
RES0 if the NOTRCPKT bit is RAO.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.

Bits [15:13]
Reserved, RES0.

PCSAMPLENA, bit [12]
PC sample enable. Enables use of POSTCNT counter as a timer for Periodic PC Sample packet generation.
The possible values of this bit are:
0  Periodic PC Sample packet generation disabled.
1  Periodic PC Sample packet generated on POSTCNT underflow.
RES0 if the NOTRCPKT bit is RAO or the NOCYCCNT bit is RAO.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.
SYNCTAP, bits [11:10]
Synchronization tap. Selects the position of the synchronization packet counter tap on the CYCCNT counter. This determines the Synchronization packet rate.

The possible values of this field are:
- 0b00  Synchronization packet generation disabled.
- 0b01  Synchronization counter tap at CYCCNT[24].
- 0b10  Synchronization counter tap at CYCCNT[26].
- 0b11  Synchronization counter tap at CYCCNT[28].
- RES0 if the NOCYCCNT bit is RAO.

If the Main Extension is not implemented, this field is RES0.
This field resets to an UNKNOWN value on a Cold reset.

CYCTAP, bit [9]
Cycle count tap. Selects the position of the POSTCNT tap on the CYCCNT counter.

The possible values of this bit are:
- 0  POSTCNT tap at CYCCNT[6].
- 1  POSTCNT tap at CYCCNT[10].
- RES0 if the NOCYCCNT bit is RAO.

If the Main Extension is not implemented, this bit is RES0.
This bit resets to an UNKNOWN value on a Cold reset.

POSTINIT, bits [8:5]
POSTCNT initial. Initial value for the POSTCNT counter.
RES0 if the NOCYCCNT bit is RAO.
If the Main Extension is not implemented, this field is RES0.
This field resets to an UNKNOWN value on a Cold reset.

POSTPRESET, bits [4:1]
POSTCNT preset. Reload value for the POSTCNT counter.
RES0 if the NOCYCCNT bit is RAO.
If the Main Extension is not implemented, this field is RES0.
This field resets to an UNKNOWN value on a Cold reset.

CYCCNTENA, bit [0]
CYCCNT enable. Enables CYCCNT.
The possible values of this bit are:
- 0  CYCCNT disabled.
- 1  CYCCNT enabled.
- RES0 if the NOCYCCNT bit is RAO.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Cold reset.
D1.2.57  DWT_CYCCNT, DWT Cycle Count Register

The DWT_CYCCNT characteristics are:

**Purpose**

Shows or sets the value of the processor cycle counter, CYCCNT.

**Usage constraints**

Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**

Present only if the Main Extension is implemented.

This register is RES0 if the Main Extension is not implemented.

Present only if the DWT is implemented.

This register is RES0 if the DWT is not implemented.

Present only if DWT_CTRL.NOCYCCNT == '0'.

This register is RES0 if DWT_CTRL.NOCYCCNT == '1'.

**Attributes**

32-bit read/write register located at 0xE0001004.

This register is not banked between Security states.

**Field descriptions**

The DWT_CYCCNT bit assignments are:

```
  31  |  30  | ...  | 0

  CYCCNT
```

**CYCCNT, bits [31:0]**

Incrementing cycle counter value. Increments one on each processor clock cycle when DWT_CTRL.CYCCNTENA == 1 and DEMCR.TRCENA == 1. On overflow, CYCCNT wraps to zero.

This field resets to an UNKNOWN value on a Cold reset.
D1.2.58  DWT_DEVARCH, DWT Device Architecture Register

The DWT_DEVARCH characteristics are:

**Purpose**
Provides CoreSight discovery information for the DWT.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read-only register located at 0xE0001FBC.
This register is not banked between Security states.

**Field descriptions**

The DWT_DEVARCH bit assignments are:

```
+-----------+-----------+-----------+-----------+-----------+-----------+-----------+
| ARCHITECT | REVISION  | ARCHVER   | ARCHPART  | PRESENT   |
| 31        | 21        | 19        | 16        | 15        | 12        | 11        | 10        | 9         | 8         | 7         | 6         | 5         | 4         | 3         | 2         | 1         |
+-----------+-----------+-----------+-----------+-----------+-----------+-----------+
```

**ARCHITECT, bits [31:21]**

Architect. Defines the architect of the component. Bits [31:28] are the JEP106 continuation code (JEP106 bank ID, minus 1) and bits [27:21] are the JEP106 ID code.
The possible values of this field are:
0x23B  JEP106 continuation code 0x4, ID code 0x3B. ARM Limited.
Other values are defined by the JEDEC JEP106 standard.
This field reads as 0x23B.

**PRESENT, bit [20]**

DEVARCH Present. Defines that the DEVARCH register is present.
The possible values of this bit are:
1  DEVARCH information present.
This bit reads as one.

**REVISION, bits [19:16]**

Revision. Defines the architecture revision of the component.
The possible values of this field are:
0000  DWT architecture v2.0.
This field reads as 0b0000.

**ARCHVER, bits [15:12]**

Architecture Version. Defines the architecture version of the component.
The possible values of this field are:
0001  DWT architecture v2.
ARCHVER and ARCHPART are also defined as a single field, ARCHID, such that ARCHVER is ARCHID[15:12].
This field reads as $0b0001$.

ARCHPART, bits [11:0]
Architecture Part. Defines the architecture of the component.
The possible values of this field are:
$0xA02$      DWT architecture.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, such that ARCHPART is ARCHID[11:0].
This field reads as $0xA02$. 
D1.2.59 DWT_DEVTYPE, DWT Device Type Register

The DWT_DEVTYPE characteristics are:

**Purpose**
Provides CoreSight discovery information for the DWT.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read/write register located at 0xE0001FCC.
This register is not banked between Security states.

**Field descriptions**
The DWT_DEVTYPE bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| RES0 | SUB | MAJOR |

**Bits [31:8]**
Reserved, RES0.

**SUB, bits [7:4]**
Sub-type. Component sub-type.
The possible values of this field are:
0x0 Other.
This field reads as 0b0000.

**MAJOR, bits [3:0]**
Major type. Component major type.
The possible values of this field are:
0x0 Miscellaneous.
This field reads as 0b0000.
D1.2.60  **DWT_EXCCNT, DWT Exception Overhead Count Register**

The DWT_EXCCNT characteristics are:

**Purpose**  
Counts the total cycles spent in exception processing.

**Usage constraints**  
Privileged access permitted only. Unprivileged accesses generate a BusFault.  
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**  
Present only if the Main Extension is implemented.  
This register is RES0 if the Main Extension is not implemented.  
Present only if the DWT is implemented.  
This register is RES0 if the DWT is not implemented.  
Present only if DWT_CTRL.NOPRFCNT == '0'.  
This register is RES0 if DWT_CTRL.NOPRFCNT == '1'.

**Attributes**  
32-bit read/write register located at 0xE000100C.  
This register is not banked between Security states.

**Field descriptions**

The DWT_EXCCNT bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | RES0  | EXCCNT |

**Bits [31:8]**  
Reserved, RES0.

**EXCCNT, bits [7:0]**  
The exception overhead counter.
Counts one on each cycle when all of the following are true:

- DWT_CTRL.EXCEVTENA == 1 and DEMCR.TRCENA == 1.
- No instruction is executed, see DWT_CPICNT.
- An exception-entry or exception-exit related operation is in progress.
- Either SecureNoninvasiveDebugAllowed() == TRUE, or NS-Req for the operation is set to Non-secure and NoninvasiveDebugAllowed() == TRUE.

Exception-entry or exception-exit related operations include the stacking of registers on exception entry, lazy state preservation, unstacking of registers on exception exit, and preemption.

Initialized to zero when the counter is disabled and DWT_CTRL.EXCEVTENA is written with 1. An Event Counter packet is emitted on counter overflow.

This field resets to an UNKNOWN value on a Cold reset.
D1.2.61 DWT_FOLDCNT, DWT Folded Instruction Count Register

The DWT_FOLDCNT characteristics are:

**Purpose**
Increments on the additional cycles required to execute all load or store instructions.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.
Present only if DWT_CTRL.NOPRFCNT == '0'.
This register is RES0 if DWT_CTRL.NOPRFCNT == '1'.

**Attributes**
32-bit read/write register located at 0xE0001018.
This register is not banked between Security states.

**Field descriptions**

The DWT_FOLDCNT bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>8:0</td>
<td>FOLDCNT</td>
</tr>
</tbody>
</table>

Counts on each cycle when all of the following are true:

- DWT_CTRL.FOLDEVTENA == 1 and DEMCR.TRCENA == 1.
- At least two instructions are executed, see DWT_CPICNT.
- Either SecureNoninvasiveDebugAllowed() == TRUE, or the PE is in Non-secure state and NoninvasiveDebugAllowed() == TRUE.

The counter is incremented by the number of instructions executed, minus one.

Initialized to zero when the counter is disabled and DWT_CTRL.FOLDEVTENA is written with 1.
An event is emitted on counter overflow.
This field resets to an UNKNOWN value on a Cold reset.
D1.2.62  DWT_FUNCTION\(n\), DWT Comparator Function Register, \(n = 0 - 14\)

The DWT_FUNCTION\(n\) characteristics are:

**Purpose**
Controls the operation of watchpoint comparator \(n\).

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read/write register located at \(0xE0001028 + 16n\).
This register is not banked between Security states.

**Field descriptions**

The DWT_FUNCTION\(n\) bit assignments are:

```
+----------+----------+----------+----------+----------+----------+
| 31       | 27-26    | 25-24    | 12-11    | 10-9     | 6-5-4-3  |
| MATCH    | DATASIZE | ACTION   |           | RES0     | RES0     |
+----------+----------+----------+----------+----------+----------+
```

**ID, bits [31:27]**
Identify capability. Identifies the capabilities for MATCH for comparator \(n\).

The possible values of this field are:

- **0b00000**  Reserved.
- **0b01000**  Data Address, and Data Address With Value.
- **0b01001**  Cycle Counter, Data Address, and Data Address With Value.
- **0b01010**  Instruction Address, Data Address, and Data Address With Value.
- **0b01011**  Cycle Counter, Instruction Address, Data Address and Data Address With Value.
- **0b11000**  Data Address, Data Address Limit, and Data Address With Value.
- **0b11010**  Instruction Address, Instruction Address Limit, Data Address, Data Address Limit, and Data Address With Value.
- **0b11100**  Data Address, Data Address Limit, Data Value, Linked Data Value, and Data Address With Value.
- **0b11110**  Instruction Address, Instruction Address Limit, Data Address, Data Address Limit, Data Value, Linked Data Value, and Data Address With Value.

All other values are reserved.

Comparator 0 never supports linking. If more than one comparator is implemented, then at least one comparator must support linking. ARM recommends that odd-numbered comparators support linking.

Cycle Counter matching is only supported if the Main Extension is implemented and DWT_CTRL.NOCYCCNT == 0, meaning the cycle counter is implemented. Comparator 0 must support Cycle Counter matching if the cycle counter is implemented.

Data Address With Value is supported for the first four comparators only, and only if the Main Extension and ITM are implemented, and DWT_CTRL.NOTRCPKT == 0. Data Value and Linked Data Value are only supported if the Main Extension is implemented.

This field is read-only.
This field reads as an IMPLEMENTATION DEFINED value.

**Bits [26:25]**

Reserved, RES0.

**MATCHED, bit [24]**

Comparator matched. Set to 1 when the comparator matches.

The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No match</td>
</tr>
<tr>
<td>1</td>
<td>Match. The comparator has matched since the last read of this register.</td>
</tr>
</tbody>
</table>

For an Instruction Address Limit or Data Address Limit comparator, this bit is UNKNOWN on reads.

This bit is read-only.

This bit clears to zero when read.

This bit resets to an UNKNOWN value on a Cold reset.

**Bits [23:12]**

Reserved, RES0.

**DATAVSIZE, bits [11:10]**

Data value size. Defines the size of the object being watched for by Data Value and Data Address comparators.

The possible values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>1 byte</td>
</tr>
<tr>
<td>0b01</td>
<td>2 bytes</td>
</tr>
<tr>
<td>0b10</td>
<td>4 bytes</td>
</tr>
</tbody>
</table>

All other values are reserved.

For an Instruction Address or Instruction Address Limit comparator, DATAVSIZE must be 0b01 (2 bytes). If this comparator is part of an data address range pair, DATAVSIZE must be 0b00 (1 byte).

For a Data Address comparator, DWT_COMPn must be aligned to the size specified by DATAVSIZE. For a Data Value or Linked Data Value comparator:

- For halfword comparisons, DWT_COMPn [31:16] must be equal to DWT_COMPn[15:0].
- For byte comparisons, DWT_COMPn [31:24], DWT_COMPn [23:16], and DWT_COMPn [15:18] must be equal to DWT_COMPn [7:0].

This field resets to an UNKNOWN value on a Cold reset.

**Bits [9:6]**

Reserved, RES0.

**ACTION, bits [5:4]**

Action on match. Defines the action on a match. This field is ignored and the comparator generates no actions if it is disabled by MATCH.

The possible values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b00</td>
<td>Trigger only</td>
</tr>
<tr>
<td>0b01</td>
<td>Generate debug event.</td>
</tr>
<tr>
<td>0b10</td>
<td>For a Cycle Counter, Instruction Address, Data Address, Data Value or Linked Data Value comparator, generate a Data Trace Match packet. For a Data Address With Value comparator, generate a Data Trace Data Value packet.</td>
</tr>
<tr>
<td>0b11</td>
<td>For a Data Address Limit comparator, generate a Data Trace Data Address packet. For a Cycle Counter, Instruction Address Limit, or Data Address comparator, generate a Data Trace PC Value packet.</td>
</tr>
</tbody>
</table>
For a Data Address With Value comparator, generate both a Data Trace PC Value packet and a Data Trace Data Value packet.

If the Main Extension is not implemented, the values 0b10 and 0b11 are reserved.

This field resets to an UNKNOWN value on a Cold reset.

MATCH, bits [3:0]

Match type. Controls the type of match generated by this comparator.

The possible values of this field are:

- 0b0000  Disabled. Never generates a match.
- 0b0001  Cycle Counter. Matches if DWT_CYCCNT equals the comparator value. The comparator is checked each time DWT_CYCCNT is written to, directly or indirectly. Only supported if the Main Extension is implemented, DWT_FUNCTION<n>.ID<0> == 1 and DWT_CTRL.NOCSYCCNT == 0.
- 0b0010  Instruction Address. If not linked to, an instruction matches if the address of the first byte of the instruction matches the comparator address. Only supported if DWT_FUNCTION<n>.ID<1> == 1.
- 0b0011  Instruction Address Limit. An instruction matches if the address of the first byte of the instruction lies between the lower comparator address (specified by comparator <n-1>) and the limit comparator address (specified by this comparator, <n>). Both addresses are inclusive to the range. Comparator <n-1> must be programmed for Instruction Address (0b0010) or Disabled (0b0000), and the lower address must be strictly less-than the limit comparator address, otherwise it is UNPREDICTABLE whether or not any comparator generates matches. Only supported if DWT_FUNCTION<n>.ID<4> == 1 and DWT_FUNCTION<n>.ID<1> == 1.
- 0b0100  Data Address. If not linked to by a Data Address Limit comparator, an access matches if any accessed byte lies between the comparator address and a limit defined by the DATASIZE field. Supported for all comparators.
- 0b0101  Data Address, writes. As 0b0100, except that only write accesses generate a match.
- 0b0110  Data Address, reads. As 0b0100, except that only read accesses generate a match.
- 0b0111  Data Address Limit. An access matches if any byte made by the access lies between the lower address (specified by comparator <n-1>) and the limit address (specified by this comparator, <n>). Both addresses are inclusive to the range. Comparator <n-1> must be programmed for Data Address (0b01xx, not 0b0111), Data Address With Data Value (0b11xx, not 0b1111), or Disabled (0b0000), and the lower address must be strictly less-than the limit comparator address, otherwise it is UNPREDICTABLE whether or not any comparator generates matches. DWT_FUNCTION<n-1>.MATCH[1:0] determines the matching access types. Only supported if DWT_FUNCTION<n>.ID<4> == 1.
- 0b1000  Data Value. An access matches if the value accessed matches the comparator value. Only supported if the Main Extension is implemented and DWT_FUNCTION<n>.ID<2> == 1.
- 0b1001  Data Value, writes. As 0b1000, except that only write accesses generate a match.
- 0b1010  Data Value, reads. As 0b1000, except that only read accesses generate a match.
- 0b1011  Linked Data Value. An access matches if the value accessed matches the comparator value (specified by comparator <n>) and the linked data address (specified by comparator <n-1>) for the same access matches. Comparator <n-1> must be programmed for Data Address (0b01xx, not 0b0111), or Data Address With Value (0b11xx, not 0b1111), or Disabled (0b0000), and DATASIZE for the two comparators must be the same, otherwise it is UNPREDICTABLE whether or not any comparator generates matches. DWT_FUNCTION<n-1>.MATCH[1:0] determines the matching access types.
Only supported if the Main Extension is implemented and  
DWT_FUNCTION<n>.ID<4> == 1 and DWT_FUNCTION<n>.ID<2> == 1.

0b1100  Data Address With Value. As 0b01xx, except that the data value is traced.  
Supported for the first four comparators only, and only if DWT_CTRL.NOTRCPKT == 0 and ITM is also implemented.

0b1101  Data Address With Value, writes. As 0b1100, except that only write accesses generate a match.

0b1110  Data Address With Value, reads. As 0b1100, except that only read accesses generate a match.

Any value not supported by the comparator is reserved. For a pair of linked comparators, <n> and  
<n-1>, DWT_FUNCTION<n-1>.MATCH[1:0] determines the matching access types. See MATCH table for further details.

This field resets to zero on a Cold reset.
D1.2.63  DWT_LAR, DWT Software Lock Access Register

The DWT_LAR characteristics are:

**Purpose**

Provides CoreSight Software Lock control for the DWT, see the *ARM® CoreSight™ Architecture Specification* for details.

**Usage constraints**

Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

This register is RAZ/WI if accessed via the debugger.

**Configurations**

Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is RES0 if the DWT is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

**Attributes**

32-bit write-only register located at 0xE0001FB0.

This register is not banked between Security states.

**Field descriptions**

The DWT_LAR bit assignments are:

![DWT_LAR Bit Assignment Diagram]

**KEY, bits [31:0]**

Lock Access control.

Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.
DWT_LSR, DWT Software Lock Status Register

The DWT_LSR characteristics are:

**Purpose**
Provides CoreSight Software Lock status information for the DWT, see the ARM® CoreSight™ Architecture Specification for details.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE. This register is RAZ/WI if accessed via the debugger.

**Configurations**
Present only if CoreSight identification is implemented. This register is RES0 if CoreSight identification is not implemented. Present only if the DWT is implemented. This register is RES0 if the DWT is not implemented. Present only if the optional Software Lock is implemented. This register is RAZ/WI if the Software Lock is not implemented.

**Attributes**
32-bit read-only register located at 0xE0001FB4. This register is not banked between Security states.

**Field descriptions**
The DWT_LSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-3</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>1</td>
<td>SLK, bit [1] Software Lock status. See the ARM® CoreSight™ Architecture Specification. The possible values of this bit are: 0 Lock clear. Software writes are permitted to this component's registers. 1 Lock set. Software writes to this component's registers are ignored, and reads have no side effects. For a debugger read of this register, or when the Software Lock is not implemented, this bit is RES0. This bit resets to one on a Cold reset.</td>
</tr>
<tr>
<td>0</td>
<td>SLI, bit [0] Software Lock implemented. See the ARM® CoreSight™ Architecture Specification. The possible values of this bit are: 0 Software Lock not implemented or debugger access. 1 Software Lock is implemented and software access. For a debugger read of this register, or when the Software Lock is not implemented, this bit is RAZ.</td>
</tr>
</tbody>
</table>
This bit reads as an IMPLEMENTATION DEFINED value.
D1.2.65 DWT_LSUCNT, DWT LSU Count Register

The DWT_LSUCNT characteristics are:

**Purpose**
Increments on the additional cycles required to execute all load or store instructions.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.
Present only if DWT_CTRL.NOPRFCNT == '0'.
This register is RES0 if DWT_CTRL.NOPRFCNT == '1'.

**Attributes**
32-bit read/write register located at 0xE0001014.
This register is not banked between Security states.

**Field descriptions**
The DWT_LSUCNT bit assignments are:

```
+--------+--------+--------+--------+
|  31    |  30    |   8    |   0    |
|  RES0  |  LSUCNT|
+--------+--------+--------+--------+
```

**Bits [31:8]**
Reserved, RES0.

**LSUCNT, bits [7:0]**
Load-store overhead counter.
Counts one on each cycle when all of the following are true:
- DWT_CTRL.LSUEVTENA == 1 and DEMCR.TRCENA == 1.
- No instruction is executed, see DWT_CPICNT.
- No exception-entry or exception-exit operation is in progress, see DWT_EXCCNT.
- A load-store operation is in progress.
- Either SecureNoninvasiveDebugAllowed() == TRUE, or NS-Req for the operation is set to Non-secure and NoninvasiveDebugAllowed() == TRUE.

Initialized to zero when the counter is disabled and DWT_CTRL.LSUEVTENA is written with 1. An Event Counter packet is emitted on counter overflow.
This field resets to an UNKNOWN value on a Cold reset.
D1.2.66  DWT_PCSR, DWT Program Counter Sample Register

The DWT_PCSR characteristics are:

**Purpose**
Samples the current value of the program counter.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read-only register located at 0xE000101C.
This register is not banked between Security states.

**Field descriptions**

The DWT_PCSR bit assignments are:

```
+-----------------+-----------------+
| 31              | 0               |
| EIASAMPLE       | EIASAMPLE       |
+-----------------+-----------------+
```

**EIASAMPLE, bits [31:0]**

Executed instruction address sample. Recently executed instruction address sample value.
The possible values of this field are:

0xFFFFFFFF

One of the following is true:

- The PE is halted in Debug state.
- The Security Extension is implemented, the sampled instruction was executed in Secure state, and SecureNoninvasiveDebugAllowed() == FALSE.
- NoninvasiveDebugAllowed() == FALSE.
- DEMCR.TRCENA == 0.
- The address of a recently-executed instruction is not available.

**Not 0xFFFFFFFF**

Instruction address of a recently executed instruction. Bit [0] of the sample instruction address is 0.
The conditions when the address of a recently-executed instruction is not available are IMPLEMENTATION DEFINED.
D1.2.67  DWT_PIDR0, DWT Peripheral Identification Register 0

The DWT_PIDR0 characteristics are:

**Purpose**

Provides CoreSight discovery information for the DWT.

**Usage constraints**

Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**

Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is RES0 if the DWT is not implemented.

**Attributes**

32-bit read-only register located at 0xE0001FE0.

This register is not banked between Security states.

**Field descriptions**

The DWT_PIDR0 bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**Bits [31:8]**

Reserved, RES0.

**PART_0, bits [7:0]**

Part number bits [7:0]. See the ARM® CoreSight™ Architecture Specification.

This field reads as an IMPLEMENTATION DEFINED value.
D1.2.68  **DWT_PIDR1, DWT Peripheral Identification Register 1**

The DWT_PIDR1 characteristics are:

**Purpose**
Provides CoreSight discovery information for the DWT.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read-only register located at 0xE0001FE4.
This register is not banked between Security states.

**Field descriptions**
The DWT_PIDR1 bit assignments are:

<table>
<thead>

D1.2.69  DWT_PIDR2, DWT Peripheral Identification Register 2

The DWT_PIDR2 characteristics are:

**Purpose**
Provides CoreSight discovery information for the DWT.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented. This register is RES0 if CoreSight identification is not implemented.

Present only if the DWT is implemented. This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read-only register located at 0xE0001FE8. This register is not banked between Security states.

D1.2.70  DWT_PIDR3, DWT Peripheral Identification Register 3

The DWT_PIDR3 characteristics are:

**Purpose**  Provides CoreSight discovery information for the DWT.

**Usage constraints**  Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**  Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**  32-bit read-only register located at 0xE0001FEC.
This register is not banked between Security states.

**Bits [31:8]**

Reserved, RES0.

**REVAND, bits [7:4]**

RevAnd. See the *ARM® CoreSight™ Architecture Specification*.  
This field reads as an IMPLEMENTATION DEFINED value.

**CMOD, bits [3:0]**

Customer Modified. See the *ARM® CoreSight™ Architecture Specification*.  
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.71  **DWT_PIDR4, DWT Peripheral Identification Register 4**

The DWT_PIDR4 characteristics are:

**Purpose**
Provides CoreSight discovery information for the DWT.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read-only register located at 0xE0001FD0.
This register is not banked between Security states.

**Field descriptions**
The DWT_PIDR4 bit assignments are:

```
+--------+--------+    +--------+--------+
| RES0   | SIZE   |    | DES_2  |
+--------+--------+    +--------+--------+
| 31     | 30     |    | 29     |
| [31:8] | [7:4]  |    | [3:0]  |
```

**Bits [31:8]**
Reserved, RES0.

**SIZE, bits [7:4]**
4KB count. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as zero.

**DES_2, bits [3:0]**
JEP106 continuation code. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.72  DWT_PIDR5, DWT Peripheral Identification Register 5

The DWT_PIDR5 characteristics are:

**Purpose**
Provided CoreSight discovery information for the DWT.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
Present only if the DWT is implemented.

This register is of RES0 if CoreSight identification is not implemented.
This register is of RES0 if the DWT is not implemented.

**Attributes**
32-bit read-only register located at 0xE0001FD4.
This register is not banked between Security states.

**Field descriptions**
The DWT_PIDR5 bit assignments are:

```
+-------------------+-------------------+
|       Bits [31:0]  |
+-------------------+-------------------+
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
+-------------------+-------------------+
|                 RES0 |                 RES0 |
```

**Bits [31:0]**
Reserved, RES0.
D1.2.73 DWT_PIDR6, DWT Peripheral Identification Register 6

The DWT_PIDR6 characteristics are:

**Purpose** Provides CoreSight discovery information for the DWT.

**Usage constraints** Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this
register is accessible only to the debugger and RES0 for software. Otherwise the register is
accessible to the debugger and software.

**Configurations** Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes** 32-bit read-only register located at 0xE0001FD8.
This register is not banked between Security states.

**Field descriptions**
The DWT_PIDR6 bit assignments are:

```
+----------------------------------+
|   31                        | 0   |
|--------------------------------|
|   RES0                     |     |
```

**Bits [31:0]**
Reserved, RES0.
D1.2.74  DWT_PIDR7, DWT Peripheral Identification Register 7

The DWT_PIDR7 characteristics are:

**Purpose**
Provides CoreSight discovery information for the DWT.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.

**Attributes**
32-bit read-only register located at 0xE0001FDC.
This register is not banked between Security states.

**Field descriptions**
The DWT_PIDR7 bit assignments are:

```
+------------------+
| Bits [31:0]      |
| Reserved, RES0   |
```

32-bit read-only register located at 0xE0001FDC.
D1.2.75  DWT_SLEEPCNT, DWT Sleep Count Register

The DWT_SLEEPCNT characteristics are:

**Purpose**
Counts the total number of cycles that the processor is sleeping.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.
Present only if the DWT is implemented.
This register is RES0 if the DWT is not implemented.
Present only if DWT_CTRL.NOPRFCNT == '0'.
This register is RES0 if DWT_CTRL.NOPRFCNT == '1'.

**Attributes**
32-bit read/write register located at 0xE0001010.
This register is not banked between Security states.

**Field descriptions**
The DWT_SLEEPCNT bit assignments are:

```
+---+---+---+---+---+---+---+---+
|   |   |   |   |   |   |   | SLEEPCNT |
+---+---+---+---+---+---+---+---+
```

**Bits [31:8]**
Reserved, RES0.

**SLEEPCNT, bits [7:0]**

Sleep counter.
Counts one on each cycle when all of the following are true:

- DWT_CTRL.SLEEPEVTEA == 1 and DEMCR.TRCENA == 1.
- No instruction is executed, see DWT_CPICNT.
- No load-store operation is in progress, see DWT_LSUCNT.
- No exception-entry or exception-exit operation is in progress, see DWT_EXCCNT.
- The PE is in a power saving mode.
- Either SecureNoninvasiveDebugAllowed() == TRUE, or the PE is in Non-secure state and NoninvasiveDebugAllowed() == TRUE.

Power saving modes include WFI, WFE, and Sleep-on-exit.
All power saving features are IMPLEMENTATION DEFINED and therefore when this counter counts is IMPLEMENTATION DEFINED. In particular, it is IMPLEMENTATION DEFINED whether the counter increments if the PE is in a power saving mode and SCR.SLEEPDEEP is set.
Initialized to zero when the counter is disabled and DWT_CTRL.SLEEPEVTEA is written with 1. An Event Counter packet is emitted on counter overflow.
This field resets to an UNKNOWN value on a Cold reset.

**Note**

ARM recommends that this counter counts all cycles when the PE is sleeping and SCR.SLEEPDEEP is clear, regardless of whether a WFI or WFE instruction, or Sleep-on-exit, caused the entry to the power saving mode.
D1.2.76   EPSR, Execution Program Status Register

The EPSR characteristics are:

**Purpose**
Holds Execution state bits.

**Usage constraints**
Privileged access only. Unprivileged access is RAZ/WI.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write special-purpose register.
This register is not banked between Security states.

**Field descriptions**

The EPSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit位置</th>
<th>功能</th>
<th>描述</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
<tr>
<td>27-23</td>
<td>IT/ICI</td>
<td>T32 state bit. Determines the current instruction set state. The possible values of this bit are: 0: Execution of any instruction generates an INVSTATE UsageFault. 1: Instructions decoded as T32 instructions. This bit resets to an UNKNOWN value on a Warm reset.</td>
</tr>
<tr>
<td>16-10</td>
<td>IT/ICI</td>
<td>If the Main Extension is not implemented, this field is RES0. This field resets to zero on a Warm reset.</td>
</tr>
<tr>
<td>9-0</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:27]**
Reserved, RES0.

**T, bit [24]**
T32 state bit. Determines the current instruction set state. The possible values of this bit are: 0: Execution of any instruction generates an INVSTATE UsageFault. 1: Instructions decoded as T32 instructions. This bit resets to an UNKNOWN value on a Warm reset.

**Bits [23:16]**
Reserved, RES0.

**IT/ICI, bits [15:10, 26:25]**
If-then and interrupt continuation. Depending on value, this field encodes either the current condition and position in an IT block sequence, or information on the outstanding register list for an interrupted exception-continuable multi-cycle load or store instruction.
The field IT[7:0] is equivalent to EPSR[15:10,26:25]. The field ICI[7:0] is equivalent to EPSR[26:25,15:10]. If the Main Extension is not implemented, this field is RES0. This field resets to zero on a Warm reset.

**Bits [9:0]**
Reserved, RES0.
D1.2.77   EXC_RETURN, Exception Return Payload

The EXC_RETURN characteristics are:

**Purpose**
Value provided in LR on entry to an exception, and used with a BX or load to PC to perform an exception return.

**Usage constraints**
None.

**Configurations**
All.

**Attributes**
32-bit payload.

**Field descriptions**

The EXC_RETURN bit assignments are:

```
31  24  23  17  6  5  4  3  2  1  0
PREFIX RES1 S DCRS FType SPSEL Mode
```

**PREFIX, bits [31:24]**
Prefix. Indicates that this is an EXC_RETURN value.

This field reads as 0b11111111.

**Bits [23:7]**
Reserved, RES1.

**S, bit [6]**
Secure or Non-secure stack. Indicates whether a Secure or Non-secure stack is used to restore stack frame on exception return.

The possible values of this bit are:

- 0: Non-secure stack used.
- 1: Secure stack used.

**DCRS, bit [5]**
Default callee register stacking. Indicates whether the default stacking rules apply, or whether the callee registers are already on the stack.

The possible values of this bit are:

- 0: Stacking of the callee saved registers skipped.
- 1: Default rules for stacking the callee registers followed.

**FType, bit [4]**
Stack frame type. Indicates whether the stack frame is a standard integer only stack frame or an extended floating-point stack frame.

The possible values of this bit are:

- 0: Extended stack frame.
- 1: Standard stack frame.

If the Floating-point Extension is not implemented, this bit is RES1.

**Mode, bit [3]**
Mode. Indicates the Mode that was stacked from.
The possible values of this bit are:

0  Handler mode.
1  Thread mode.

SPSEL, bit [2]

Stack pointer selection. Indicates which stack pointer the exception frame resides on.
The possible values of this bit are:

0  Main stack pointer.
1  Process stack pointer.

Bit [1]

Reserved, RES0.

ES, bit [0]

Exception Secure. The security domain the exception was taken to.
The possible values of this bit are:

0  Non-secure.
1  Secure.
D1.2.78 FAULTMASK, Fault Mask Register

The FAULTMASK characteristics are:

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Provides access to the PE FAULTMASK register.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage constraints</td>
<td>Privileged access only. Unprivileged access is RAZ/WI.</td>
</tr>
<tr>
<td>Configurations</td>
<td>Present only if the Main Extension is implemented.</td>
</tr>
<tr>
<td></td>
<td>This register is RES0 if the Main Extension is not implemented.</td>
</tr>
<tr>
<td>Attributes</td>
<td>32-bit read/write special-purpose register.</td>
</tr>
<tr>
<td></td>
<td>This register is banked between Security states.</td>
</tr>
</tbody>
</table>

Field descriptions

The FAULTMASK bit assignments are:

```
+-------------------+-------------------+-------------------+-------------------+
|       |       |       |       |       |       |       |       |       |
| 31    | 30    | ...  | 1      | 0      | FM    |       |       |       |
+-------------------+-------------------+-------------------+-------------------+
```

Bits [31:1]

Reserved, RES0.

FM, bit [0]

Fault mask enable. The Secure and Non-secure FAULTMASK registers individually boost the current execution priority based on the settings of AIRCR.PRIS and AIRCR.BFHFNMINS. If AIRCR.BFHFNMINS is zero, AIRCR.PRIS is zero, and FAULTMASK_NS.FM is one, the execution priority is boosted to 0. If AIRCR.BFHFNMINS is zero, AIRCR.PRIS is one, and FAULTMASK_NS.FM is one, the execution priority is boosted to 0x80. If AIRCR.BFHFNMINS is zero and FAULTMASK_S is one, the execution priority is boosted to -1. If AIRCR.BFHFNMINS is one and FAULTMASK_NS is one, the execution priority is boosted to -1. If AIRCR.BFHFNMINS is one and FAULTMASK_S is one, the execution priority is boosted to -3.

The possible values of this bit are:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No effect.</td>
</tr>
<tr>
<td>1</td>
<td>Boost priority.</td>
</tr>
</tbody>
</table>

On an exception return from a raw execution priority greater or equal to zero, the FM bit corresponding to EXC_RETURN.ES is cleared.

This bit resets to zero on a Warm reset.
D1.2.79   FNC_RETURN, Function Return Payload

The FNC_RETURN characteristics are:

**Purpose**  Value provided in LR on entry to Non-secure state from a Secure BLXNS.

**Usage constraints**  None.

**Configurations**  All.

**Attributes**  32-bit payload.

**Field descriptions**

The FNC_RETURN bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24-23</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREFIX</td>
<td></td>
<td>ONES</td>
<td></td>
</tr>
</tbody>
</table>

**PREFIX, bits [31:24]**  
This field reads as \( \text{0b11111110} \).

**ONES, bits [23:1]**  
This field reads as \( \text{0b11111111111111111111111} \).

**S, bit [0]**  
Secure. Indicates whether the function call was from the Non-secure or Secure state. Because FNC_RETURN is only used when calling from the Secure state, this bit is always set to 1. However, some function chaining cases can result in an SG instruction clearing this bit, so the architecture ignores the state of this bit when processing a branch to FNC_RETURN.

The possible values of this bit are:

0  From Secure state.

1  From Non-secure state.
D1.2.80 FPCAR, Floating-Point Context Address Register

The FPCAR characteristics are:

**Purpose**
Holds the location of the unpopulated floating-point register space allocated on an exception stack frame.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Floating-point Extension is implemented. This register is RES0 if the Floating-point Extension is not implemented.

**Attributes**
32-bit read/write register located at 0xE000EF38. Secure software can access the Non-secure view of this register via FPCAR_NS located at 0xE002EF38. The location 0xE002EF38 is RES0 to software executing in Non-secure state and the debugger. This register is banked between Security states.

**Field descriptions**
The FPCAR bit assignments are:

ADDRESS, bits [31:3]
Address. The location of the unpopulated floating-point register space allocated on an exception stack frame.
This field resets to an UNKNOWN value on a Warm reset.

Bits [2:0]
Reserved, RES0.
D1.2.81 FPCCR, Floating-Point Context Control Register

The FPCCR characteristics are:

**Purpose**
Holds control data for the Floating-point extension.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Floating-point Extension is implemented.
This register is RES0 if the Floating-point Extension is not implemented.

**Attributes**
32-bit read/write register located at 0xE000EF34.
Secure software can access the Non-secure view of this register via FPCCR_NS located at 0xE002EF34. The location 0xE002EF34 is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states on a bit by bit basis.

**Field descriptions**

The FPCCR bit assignments are:

![](image)

**ASPEN, bit [31]**
Automatic state preservation enable. When this bit is set to 1, execution of a floating-point instruction sets the CONTROL.FPCA bit to 1.
This bit is banked between Security states.
The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Executing a floating-point instruction has no effect on CONTROL.FPCA.</td>
</tr>
<tr>
<td>1</td>
<td>Executing a floating-point instruction sets CONTROL.FPCA to 1.</td>
</tr>
</tbody>
</table>

This bit resets to one on a Warm reset.

---

**Note**
Setting this bit to 1 means the hardware automatically preserves floating-point context on exception entry and restores it on exception return.

**LSPEN, bit [30]**
Lazy state preservation enable. Enables lazy context save of floating-point state.
This bit is not banked between Security states.
The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disable automatic lazy context save.</td>
</tr>
<tr>
<td>1</td>
<td>Enable automatic lazy context save.</td>
</tr>
</tbody>
</table>

Writes to this bit from Non-Secure state are ignored if LSPENS is set to one.
This bit resets to one on a Warm reset.
LSPENS, bit [29]
Lazy state preservation enable Secure only. This bit controls whether the LSPEN bit is writeable from the Non-secure state.
This bit is not banked between Security states.
The possible values of this bit are:
0 LSPEN is readable and writeable from both Security states.
1 LSPEN is readable from both Security states, but writes to LSPEN are ignored from the Non-secure state.
This bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

CLRONRET, bit [28]
Clear on return. Clear floating-point caller saved registers on exception return.
This bit is not banked between Security states.
The possible values of this bit are:
0 Disabled.
1 Enabled.
When set to 1 the caller saved floating-point registers S0 to S15, and FPSCR are cleared on exception return (including tail chaining) if CONTROL.FPCA is set to 1 and FPCCR_S.LSPACT is set to 0.
This bit resets to zero on a Warm reset.

CLRONRETS, bit [27]
Clear on return Secure only. This bit controls whether the CLRONRET bit is writeable from the Non-secure state.
This bit is not banked between Security states.
The possible values of this bit are:
0 The CLRONRET field is accessibly from both Security states.
1 The Non-secure view of the CLRONRET field is read only.
This bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

TS, bit [26]
Treat as Secure. Treat floating-point registers as Secure enable.
This bit is not banked between Security states.
The possible values of this bit are:
0 Disabled.
1 Enabled.
When set to 0 the floating-point registers are treated as Non-secure even when the PE is in the Secure state and, therefore, the callee saved registers are never pushed to the stack. If the floating-point registers never contain data that needs to be protected, clearing this flag can reduce interrupt latency. This field behaves as RAZ/WI from the Non-secure state.
This bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

Bits [25:11]
Reserved, RES0.
UFRDY, bit [10]

UsageFault ready. Indicates whether the software executing when the PE allocated the floating-point stack frame was able to set the UsageFault exception to pending.

This bit is banked between Security states.

The possible values of this bit are:

0  Not able to set the UsageFault exception to pending.
1  Able to set the UsageFault exception to pending.

This bit resets to an UNKNOWN value on a Warm reset.

SPLIMVIOL, bit [9]

Stack pointer limit violation. This bit is banked between the Security states and indicates whether the floating-point context violates the stack pointer limit that was active when lazy state preservation was activated. SPLIMVIOL modifies the lazy floating-point state preservation behavior.

This bit is banked between Security states.

The possible values of this bit are:

0  The existing behavior is retained.
1  The memory accesses associated with the floating-point state preservation are not performed. However if the floating-point state is secure and FPCCR.TS is set to 1 the registers are still zeroed and the floating-point state is lost.

This bit resets to an UNKNOWN value on a Warm reset.

MONRDY, bit [8]

DebugMonitor ready. Indicates whether the software executing when the PE allocated the floating-point stack frame was able to set the DebugMonitor exception to pending.

This bit is not banked between Security states.

The possible values of this bit are:

0  Not able to set the DebugMonitor exception to pending.
1  Able to set the DebugMonitor exception to pending.

If DEMCR.SDME is one this bit is RAZ/WI from Non-secure state

This bit resets to an UNKNOWN value on a Warm reset.

SFRDY, bit [7]

SecureFault ready. Indicates whether the software executing when the PE allocated the floating-point stack frame was able to set the SecureFault exception to pending. This bit is only present in the Secure version of the register, and behaves as RAZ/WI when accessed from the Non-secure state.

This bit is not banked between Security states.

This bit is RAZ/WI from Non-secure state.

This bit resets to an UNKNOWN value on a Warm reset.

BFRDY, bit [6]

BusFault ready. Indicates whether the software executing when the PE allocated the floating-point stack frame was able to set the BusFault exception to pending.

This bit is not banked between Security states.

The possible values of this bit are:

0  Not able to set the BusFault exception to pending.
1  Able to set the BusFault exception to pending.

If AIRCR.BFHFNMIN is zero this bit is RAZ/WI from Non-secure state.

This bit resets to an UNKNOWN value on a Warm reset.
MMRDY, bit [5]
MemManage ready. Indicates whether the software executing when the PE allocated the floating-point stack frame was able to set the MemManage exception to pending.

This bit is banked between Security states.
The possible values of this bit are:
0 Not able to set the MemManage exception to pending.
1 Able to set the MemManage exception to pending.

This bit resets to an UNKNOWN value on a Warm reset.

HFRDY, bit [4]
HardFault ready. Indicates whether the software executing when the PE allocated the floating-point stack frame was able to set the HardFault exception to pending.

This bit is not banked between Security states.
The possible values of this bit are:
0 Not able to set the HardFault exception to pending.
1 Able to set the HardFault exception to pending.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.
This bit resets to an UNKNOWN value on a Warm reset.

THREAD, bit [3]
Thread mode. Indicates the PE mode when it allocated the floating-point stack frame.

This bit is banked between Security states.
The possible values of this bit are:
0 Handler mode.
1 Thread mode.

This bit is for fault handler information only and does not interact with the exception model.
This bit resets to an UNKNOWN value on a Warm reset.

S, bit [2]
Security. Security status of the floating-point context. This bit is only present in the Secure version of the register, and behaves as RAZ/WI when accessed from the Non-secure state. This bit is updated whenever lazy state preservation is activated, or when a floating-point instruction is executed.

This bit is not banked between Security states.
The possible values of this bit are:
0 Indicates the floating-point context belongs to the Non-secure state.
1 Indicates the floating-point context belongs to the Secure state.

This bit is RAZ/WI from Non-secure state.
This bit resets to one on a Warm reset.

USER, bit [1]
User privilege. Indicates the privilege level of the software executing when the PE allocated the floating-point stack frame.

This bit is banked between Security states.
The possible values of this bit are:
0 Privileged.
1 Unprivileged.

This bit resets to an UNKNOWN value on a Warm reset.
LSPACT, bit [0]

Lazy state preservation active. Indicates whether lazy preservation of the floating-point state is active.

This bit is banked between Security states.

The possible values of this bit are:

0 Lazy state preservation is not active.
1 Lazy state preservation is active.

This bit resets to zero on a Warm reset.
D1.2.82  FPDSCR, Floating-Point Default Status Control Register

The FPDSCR characteristics are:

**Purpose**
Holds the default values for the floating-point status control data that the PE assigns to the FPSCR when it creates a new floating-point context.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Floating-point Extension is implemented.
This register is RES0 if the Floating-point Extension is not implemented.

**Attributes**
32-bit read/write register located at 0xE000EF3C.
Secure software can access the Non-secure view of this register via FPDSCR_NS located at 0xE002EF3C. The location 0xE002EF3C is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.

**Field descriptions**
The FPDSCR bit assignments are:

```
0 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
RES0 FZ RES0 RMode DN AHP
```

**Bits [31:27]**
Reserved, RES0.

**AHP, bit [26]**
Alternative half-precision. Default value for FPSCR.AHP.
This bit resets to zero on a Warm reset.

**DN, bit [25]**
Default NaN. Default value for FPSCR.DN.
This bit resets to zero on a Warm reset.

**FZ, bit [24]**
Flush-to-zero. Default value for FPSCR.FZ.
This bit resets to zero on a Warm reset.

**RMode, bits [23:22]**
Rounding mode. Default value for FPSCR.RMode.
This field resets to zero on a Warm reset.

**Bits [21:0]**
Reserved, RES0.
D1.2.83 FPSCR, Floating-point Status and Control Register

The FPSCR characteristics are:

**Purpose**
Provides control of the floating-point system.

**Usage constraints**
Privileged access only. Unprivileged access is RAZ/WI.

**Configurations**
Present only if the Floating-point Extension is implemented.
This register is RES0 if the Floating-point Extension is not implemented.

**Attributes**
32-bit read/write special-purpose register.
This register is not banked between Security states.

**Preface**
Writes to the FPSCR can have side-effects on various aspects of processor operation. All of these side-effects are synchronous to the FPSCR write. This means that they are guaranteed not to be visible to earlier instructions in the execution stream, and they are guaranteed to be visible to later instructions in the execution stream.

**Field descriptions**

The FPSCR bit assignments are:

```
 N, bit [31]  Negative condition flag. When updated by a VCMP instruction, this bit indicates whether the result was less than.

The possible values of this bit are:
0       Compare result was not less than.
1       Compare result was less than.
See VCMP for details.
This bit resets to an UNKNOWN value on a Warm reset.

Z, bit [30]  Zero condition flag. When updated by a VCMP instruction, this bit indicates whether the result was equal.

The possible values of this bit are:
0       Compare result was not equal.
1       Compare result was equal.
See VCMP for details.
This bit resets to an UNKNOWN value on a Warm reset.

C, bit [29]  Carry condition flag. When updated by a VCMP instruction, this bit indicates whether the result was not less than.

The possible values of this bit are:
0       Compare result was less than.
```
Compare result was not less than.
See VCMP for details.
This bit resets to an UNKNOWN value on a Warm reset.

V, bit [28]
Overflow condition flag. When updated by a VCMP instruction, this bit indicates whether the result was unordered.
The possible values of this bit are:
0 Compare result was not unordered.
1 Compare result was unordered.
See VCMP for details.
This bit resets to an UNKNOWN value on a Warm reset.

Bit [27]
Reserved, RES0.

AHP, bit [26]
Alternative half-precision control bit. This bit controls how the PE interprets 16-bit floating-point values.
The possible values of this bit are:
0 IEEE half-precision format selected.
1 Alternative half-precision format selected.
This bit resets to an UNKNOWN value on a Warm reset.

DN, bit [25]
Default NaN mode control bit. This bit determines whether floating-point operations propagate NaNs or use the Default NaN.
The possible values of this bit are:
0 NaN operands propagate through to the output of a floating-point operation.
1 Any operation involving one of more NaNs returns the Default NaN.
This bit resets to an UNKNOWN value on a Warm reset.

FZ, bit [24]
Flush-to-zero mode control. This bit determines whether denormal floating-point values are treated as though zero.
The possible values of this bit are:
0 Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE754 standard.
1 Flush-to-zero mode enabled.
This bit resets to an UNKNOWN value on a Warm reset.

RMode, bits [23:22]
Rounding mode control field. This field determines what rounding mode is applied to floating-point operations.
The possible values of this field are:
0b00 Round to Nearest (RN) mode.
0b01 Round towards Plus Infinity (RP) mode.
0b10 Round towards Minus Infinity (RM) mode.
0b11 Round towards Zero (RZ) mode.
This field resets to an UNKNOWN value on a Warm reset.
Bits [21:8]

Reserved, RES0.

IDC, bit [7]
Input Denormal cumulative exception bit. This sticky flag records whether a floating-point input
denormal exception has been detected since last cleared.
The possible values of this bit are:
0 Input Denormal exception has not occurred since 0 was last written to this bit.
1 Input Denormal exception has occurred since 0 was last written to this bit.
This bit resets to an UNKNOWN value on a Warm reset.

Bits [6:5]
Reserved, RES0.

IXC, bit [4]
Inexact cumulative exception bit. This sticky flag records whether a floating-point inexact
exception has been detected since last cleared.
The possible values of this bit are:
0 Inexact exception has not occurred since 0 was last written to this bit.
1 Inexact exception has occurred since 0 was last written to this bit.
This bit resets to an UNKNOWN value on a Warm reset.

UFC, bit [3]
Underflow cumulative exception bit. This sticky flag records whether a floating-point Underflow
exception has been detected since last cleared.
The possible values of this bit are:
0 Underflow exception has not occurred since 0 was last written to this bit.
1 Underflow exception has occurred since 0 was last written to this bit.

OFC, bit [2]
Overflow cumulative exception bit. This sticky flag records whether a floating-point overflow
exception has been detected since last cleared.
The possible values of this bit are:
0 Overflow exception has not occurred since 0 was last written to this bit.
1 Overflow exception has occurred since 0 was last written to this bit.
This bit resets to an UNKNOWN value on a Warm reset.

DZC, bit [1]
Divide by Zero cumulative exception bit. This sticky flag records whether a floating-point divide
by zero exception has been detected since last cleared.
The possible values of this bit are:
0 Division by Zero exception has not occurred since 0 was last written to this bit.
1 Division by Zero exception has occurred since 0 was last written to this bit.
This bit resets to an UNKNOWN value on a Warm reset.

IOC, bit [0]
Invalid Operation cumulative exception bit. This sticky flag records whether a floating-point invalid
operation exception has been detected since last cleared.
The possible values of this bit are:
0 Invalid Operation exception has not occurred since 0 was last written to this bit.
Invalid Operation exception has occurred since 0 was last written to this bit.
This bit resets to an UNKNOWN value on a Warm reset.
D1.2.84  FP_CIDR0, FP Component Identification Register 0

The FP_CIDR0 characteristics are:

**Purpose**
Provides CoreSight discovery information for the FP.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this
register is accessible only to the debugger and RES0 for software. Otherwise the register is
accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

**Attributes**
32-bit read-only register located at 0xE0002FF0.
This register is not banked between Security states.

**Field descriptions**
The FP_CIDR0 bit assignments are:

```
+--------+--------+
| 31     | 0       |
+--------+--------+
| RES0   | PRMBL_0 |
```

**Bits [31:8]**
Reserved, RES0.

**PRMBL_0, bits [7:0]**
CoreSight component identification preamble. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as 0x0D.
D1.2.85   FP_CIDR1, FP Component Identification Register 1

The FP_CIDR1 characteristics are:

**Purpose**
Provides CoreSight discovery information for the FP.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

**Attributes**
32-bit read-only register located at 0xE0002FF4.
This register is not banked between Security states.

**Field descriptions**
The FP_CIDR1 bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

**CLASS, bits [7:4]**
CoreSight component class. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as 0x9.

**PRMBL_1, bits [3:0]**
CoreSight component identification preamble. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as 0x0.
D1.2.86   FP_CIDR2, FP Component Identification Register 2

The FP_CIDR2 characteristics are:

**Purpose**  Provides CoreSight discovery information for the FP.

**Usage constraints**  Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**  Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is RES0 if the FPB is not implemented.

**Attributes**  32-bit read-only register located at 0xE0002FF8.

This register is not banked between Security states.

**Field descriptions**

The FP_CIDR2 bit assignments are:

```
  +---+---+---+---+---+---+---+
  |   |   |   |   |   |   |   |
  +---+---+---+---+---+---+---+
     31          8           0
     RES0        PRMBL_2
```

**Bits [31:8]**  Reserved, RES0.

**PRMBL_2, bits [7:0]**

CoreSight component identification preamble. See the *ARM® CoreSight™ Architecture Specification*.

This field reads as 0x05.
**D1.2.87   FP_CIDR3, FP Component Identification Register 3**

The FP_CIDR3 characteristics are:

**Purpose**
Provides CoreSight discovery information for the FP.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this
register is accessible only to the debugger and RES0 for software. Otherwise the register is
accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

CoreSight component identification preamble. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as 0xB1.
D1.2.88 FP_COMP<n>, Flash Patch Comparator Register, n = 0 - 141

The FP_COMP<n> characteristics are:

**Purpose**
Holds an address for comparison. The effect of the match depends on the configuration of the FPB and whether the comparator is an instruction address comparator or a literal address comparator.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

**Attributes**
32-bit read/write register located at 0xE0002008 + 4n.
This register is not banked between Security states.

**Field descriptions**
The FP_COMP<n> bit assignments are:

When BE==0:

```
 31 30 29 28  2 1 0
 FE RES0 FPADDR 0 BE
```

When BE==1:

```
 31  2 1 0
 BPADDR BE
```

**BPADDR, bits [31:1], when BE==1**
Breakpoint address. Specifies bits[31:1] of the breakpoint instruction address.

**FE, bit [31], when BE==0**
Flash Patch enable. Specifies if Flash Patch enabled.
The possible values of this bit are:
0    Flash Patch disabled.
1    Flash Patch enabled.

**Bits [30:29], when BE==0**
Reserved, RES0.

**FPADDR, bits [28:2], when BE==0**

**Bit [1], when BE==0**
Reserved, RES0.

**BE, bit [0]**
Breakpoint enable. Selects between flashpatch and breakpoint functionality.
The possible values of this bit are:
0    Breakpoint disabled, flashpatch mode selected.
Breakpoint enabled, flashpatch mode de-selected.

The comparator can be completely disabled by writing the entire register to zero.

This bit resets to zero on a Cold reset.
D1.2.89  FP_CTRL, Flash Patch Control Register

The FP_CTRL characteristics are:

**Purpose**
Provides FPB implementation information, and the global enable for the FPB unit.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

**Attributes**
32-bit read/write register located at 0xE0002000.
This register is not banked between Security states.

**Field descriptions**

The FP_CTRL bit assignments are:

### REV, bits [31:28]
Revision. Flash Patch and Breakpoint Unit architecture revision.
The possible values of this field are:
0b0001  Flash Patch Breakpoint version 2 implemented.
All other values are reserved.
This field is read-only.
This field reads as 0b0001.

### Bits [27:15]
Reserved, RES0.

### NUM_CODE, bits [14:12,7:4]
Number of implemented code comparators. Indicates the number of implemented instruction address comparators. Zero indicates no Instruction Address comparators are implemented. The Instruction Address comparators are numbered from 0 to NUM_CODE - 1.
This field is read-only.
This field reads as an IMPLEMENTATION DEFINED value.

### NUM_LIT, bits [11:8]
Number of literal comparators. Indicates the number of implemented literal address comparators. The Literal Address comparators are numbered from NUM_CODE to NUM_CODE + NUM_LIT - 1.
If the Flash Patch remap function is not supported, this field is RES0.
This field is read-only.
This field reads as an IMPLEMENTATION DEFINED value.
Bits [3:2]
Reserved, RES0.

KEY, bit [1]
FP_CTRL write-enable key. Writes to the FP_CTRL are ignored unless KEY is concurrently written to one.
The possible values of this bit are:
0 Concurrent write to FP_CTRL ignored.
1 Concurrent write to FP_CTRL permitted.
This bit reads-as-zero.

ENABLE, bit [0]
Flashpatch global enable. Enables the FPB.
The possible values of this bit are:
0 All FPB functionality disabled.
1 FPB enabled.
This bit resets to zero on a Cold reset.
D1.2.90 FP_DEVARCH, FPB Device Architecture Register

The FP_DEVARCH characteristics are:

**Purpose**
Provides CoreSight discovery information for the FPB.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

**Attributes**
32-bit read-only register located at 0xE0002FBC.
This register is not banked between Security states.

**Field descriptions**
The FP_DEVARCH bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCHITECT</td>
<td>Architect. Defines the architect of the component.</td>
<td>0x23B JEP106 continuation code 0x4, ID code 0x3B. ARM Limited. Other values are defined by the JEDEC JEP106 standard.</td>

<tr>
<td>ARCHVER</td>
<td>Architecture Version. Defines the architecture version of the component.</td>
<td>0001 FPB architecture v2.</td>
</tr>
</tbody>
</table>
ARCHVER and ARCHPART are also defined as a single field, ARCHID, such that ARCHVER is ARCHID[15:12].
This field reads as 0b0001.

**ARCHPART, bits [11:0]**

Architecture Part. Defines the architecture of the component.
The possible values of this field are:
0xA03  FPB architecture.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, such that ARCHPART is ARCHID[11:0].
This field reads as 0xA03.
D1.2.91 FP_DEVTYPE, FPB Device Type Register

The FP_DEVTYPE characteristics are:

**Purpose**
Provides CoreSight discovery information for the FPB.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

**Attributes**
32-bit read/write register located at 0xE0002FCC.
This register is not banked between Security states.

**Field descriptions**
The FP_DEVTYPE bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | RES0 |
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | SUB |
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | MAJOR |

**Bits [31:8]**
Reserved, RES0.

**SUB, bits [7:4]**
Sub-type. Component sub-type.
The possible values of this field are:
0x0 Other.
This field reads as 0b0000.

**MAJOR, bits [3:0]**
Major type. Component major type.
The possible values of this field are:
0x0 Miscellaneous.
This field reads as 0b0000.
D1.2.92 FP_LAR, FPB Software Lock Access Register

The FP_LAR characteristics are:

**Purpose**
Provides CoreSight Software Lock control for the FPB, see the ARM® CoreSight™ Architecture Specification for details.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
This register is RAZ/WI if accessed via the debugger.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.
Present only if the optional Software Lock is implemented.
This register is RAZ/WI if the Software Lock is not implemented.

**Attributes**
32-bit write-only register located at 0xE0002FB0.
This register is not banked between Security states.

**Field descriptions**
The FP_LAR bit assignments are:

![Field Diagram]

**KEY, bits [31:0]**
Lock Access control.
Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.
Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.
D1.2.93 FP_LSR, FPB Software Lock Status Register

The FP_LSR characteristics are:

**Purpose**
Provides CoreSight Software Lock status information for the FPB, see the ARM®
CoreSight™ Architecture Specification for details.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
This register is RAZ/WI if accessed via the debugger.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.
Present only if the optional Software Lock is implemented.
This register is RAZ/WI if the Software Lock is not implemented.

**Attributes**
32-bit read-only register located at 0xE0002FB4.
This register is not banked between Security states.

**Field descriptions**
The FP_LSR bit assignments are:

```
  31 3 2 1 0
    RES0 nTT SLK SLI
```

**Bits [31:3]**
Reserved, RES0.

**nTT, bit [2]**
Not thirty-two bit. See the ARM® CoreSight™ Architecture Specification.
This bit reads as zero.

**SLK, bit [1]**
Software Lock status. See the ARM® CoreSight™ Architecture Specification.
The possible values of this bit are:

0  Lock clear. Software writes are permitted to this component's registers.
1  Lock set. Software writes to this component's registers are ignored, and reads have no
    side-effects.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is RES0.
This bit resets to one on a Cold reset.

**SLI, bit [0]**
Software Lock implemented. See the ARM® CoreSight™ Architecture Specification.
The possible values of this bit are:

0  Software Lock not implemented or debugger access.
1  Software Lock is implemented and software access.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is RAZ.
This bit reads as an IMPLEMENTATION DEFINED value.
D1.2.94  FP_PIDR0, FP Peripheral Identification Register 0

The FP_PIDR0 characteristics are:

**Purpose**
Provides CoreSight discovery information for the FP.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

**Attributes**
32-bit read-only register located at 0xE0002FE0.
This register is not banked between Security states.

**Field descriptions**
The FP_PIDR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RES0</td>
</tr>
<tr>
<td>30-7</td>
<td>PART_0</td>
</tr>
</tbody>
</table>

**Bits [31:8]**
Reserved, RES0.

**PART_0, bits [7:0]**
Part number bits [7:0]. See the [ARM® CoreSight™ Architecture Specification](#).
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.95  FP_PIDR1, FP Peripheral Identification Register 1

The FP_PIDR1 characteristics are:

**Purpose**
Provides CoreSight discovery information for the FP.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

**Attributes**
32-bit read-only register located at 0xE0002FE4.
This register is not banked between Security states.

### Field descriptions

The FP_PIDR1 bit assignments are:

|   |   |   |   |   |   |   |   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|   |   |   |   |   |   |   |   | RES0 |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

**Bits [31:8]**
Reserved, RES0.

**DES_0, bits [7:4]**
JEP106 identification code bits [3:0]. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as an IMPLEMENTATION DEFINED value.

**PART_1, bits [3:0]**
Part number bits [11:8]. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.96 FP_PIDR2, FP Peripheral Identification Register 2

The FP_PIDR2 characteristics are:

**Purpose**
- Provides CoreSight discovery information for the FP.

**Usage constraints**
- Privileged access permitted only. Unprivileged accesses generate a BusFault.
  - This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
  - If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
- Present only if CoreSight identification is implemented.
  - This register is RES0 if CoreSight identification is not implemented.
  - Present only if the FPB is implemented.
  - This register is RES0 if the FPB is not implemented.

**Attributes**
- 32-bit read-only register located at 0xE0002FE8.
  - This register is not banked between Security states.

**Field descriptions**

The FP_PIDR2 bit assignments are:

```
+---+---+---+---+---+---+---+
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16| 15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0|
| RES0| REVISION| 7| 6| 5| 4| 3| 2| 1| 0|
```

**Bits [31:8]**
- Reserved, RES0.

**REVISION, bits [7:4]**
- Component revision. See the *ARM® CoreSight™ Architecture Specification*.
  - This field reads as an IMPLEMENTATION DEFINED value.

**JEDEC, bit [3]**
- JEDEC assignee value is used. See the *ARM® CoreSight™ Architecture Specification*.
  - This bit reads as one.

**DES_1, bits [2:0]**
- JEP106 identification code bits [6:4]. See the *ARM® CoreSight™ Architecture Specification*.
  - This field reads as an IMPLEMENTATION DEFINED value.
D1.2.97 FP_PIDR3, FP Peripheral Identification Register 3

The FP_PIDR3 characteristics are:

**Purpose**  Provides CoreSight discovery information for the FP.

**Usage constraints**  Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**  Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

**Attributes**  32-bit read-only register located at 0xE0002FEC.
This register is not banked between Security states.

**Field descriptions**

The FP_PIDR3 bit assignments are:

```
+-------+-------+-------+-------+
|       |       |       |       |
| 31    | 30    | 29    | 28    |
| RES0  |       |       |       |
| 8      | 7      | 6      | 5      |
| REVAND |       |       |       |
| 4      | 3      | 2      | 1      |
| CMOD   |       |       |       |
| 0      |       |       |       |
```

**Bits [31:8]**  Reserved, RES0.

**REVAND, bits [7:4]**  RevAnd. See the ARM® CoreSight™ Architecture Specification.
This field reads as an IMPLEMENTATION DEFINED value.

**CMOD, bits [3:0]**  Customer Modified. See the ARM® CoreSight™ Architecture Specification.
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.98   FP_PIDR4, FP Peripheral Identification Register 4

The FP_PIDR4 characteristics are:

**Purpose**
Provides CoreSight discovery information for the FP.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is RES0 if the FPB is not implemented.

**Attributes**
32-bit read-only register located at 0xE0002FD0.

This register is not banked between Security states.

**Field descriptions**

The FP_PIDR4 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:8]</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>[7:4]</td>
<td>SIZE, 4KB count. See the ARM® CoreSight™ Architecture Specification. This field reads as zero.</td>
</tr>
<tr>
<td>[3:0]</td>
<td>DES_2, JEP106 continuation code. See the ARM® CoreSight™ Architecture Specification. This field reads as an IMPLEMENTATION DEFINED value.</td>
</tr>
</tbody>
</table>

---

### Bits [31:8]

Reserved, RES0.

### SIZE, bits [7:4]

4KB count. See the ARM® CoreSight™ Architecture Specification.

This field reads as zero.

### DES_2, bits [3:0]

JEP106 continuation code. See the ARM® CoreSight™ Architecture Specification.

This field reads as an IMPLEMENTATION DEFINED value.
D1.2.99   FP_PIDR5, FP Peripheral Identification Register 5

The FP_PIDR5 characteristics are:

**Purpose**

Provides CoreSight discovery information for the FP.

**Usage constraints**

Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**

Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is RES0 if the FPB is not implemented.

**Attributes**

32-bit read-only register located at 0xE0002FD4.

This register is not banked between Security states.

**Field descriptions**

The FP_PIDR5 bit assignments are:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
   RES0
```

**Bits [31:0]**

Reserved, RES0.
D1.2.100   **FP_PIDR6, FP Peripheral Identification Register 6**

The FP_PIDR6 characteristics are:

**Purpose**
Provides CoreSight discovery information for the FP.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

**Attributes**
32-bit read-only register located at 0xE0002FD8.
This register is not banked between Security states.

**Field descriptions**

The FP_PIDR6 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
</tbody>
</table>

Bits [31:0]
Reserved, RES0.
D1.2.101 FP_PIDR7, FP Peripheral Identification Register 7

The FP_PIDR7 characteristics are:

**Purpose**
Provides CoreSight discovery information for the FP.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

**Attributes**
32-bit read-only register located at 0xE0002FDC.
This register is not banked between Security states.

**Field descriptions**
The FP_PIDR7 bit assignments are:

```
  31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
    RES0
```

**Bits [31:0]**
Reserved, RES0.
D1.2.102   FP_REMAP, Flash Patch Remap Register

The FP_REMAP characteristics are:

**Purpose**
Indicates whether the implementation supports Flash Patch remap and, if it does, holds the target address for remap.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if the FPB is implemented.
This register is RES0 if the FPB is not implemented.

**Attributes**
32-bit read-only register located at 0xE0002004.
This register is not banked between Security states.

**Field descriptions**
The FP_REMAP bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:30</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>29</td>
<td>RMPSPT, bit [29]</td>
</tr>
<tr>
<td></td>
<td>Remap supported. Indicates whether the FPB unit supports the Flash Patch remap function.</td>
</tr>
<tr>
<td></td>
<td>The possible values of this bit are:</td>
</tr>
<tr>
<td>0</td>
<td>Flash Patch remap function is not implemented.</td>
</tr>
<tr>
<td>1</td>
<td>Flash Patch remap function is implemented.</td>
</tr>
</tbody>
</table>

**Note**
The Flash Patch remap function must not be implemented if either the Main Extension is not implemented or the Security Extension is implemented.
This bit reads as an IMPLEMENTATION DEFINED value.

**REMAP, bits [28:5]**
Remap address. Holds the bits[28:5] of the Flash Patch remap address.
This field is RES0 if the FPB is not implemented, or if the Flash Patch remap function is not supported.
This field resets to an UNKNOWN value on a Cold reset.

**Bits [4:0]**
Reserved, RES0.
D1.2.103 HFSR, HardFault Status Register

The HFSR characteristics are:

**Purpose**
Shows the cause of any HardFaults.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read/write-one-to-clear register located at 0xE000ED2C.
Secure software can access the Non-secure view of this register via HFSR_NS located at 0xE002ED2C. The location 0xE002ED2C is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The HFSR bit assignments are:

```
[31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0]
   DEBUGEVT FORCED  RES0  VECTTBL
```

**DEBUGEVT, bit [31]**
Debug event. Indicates when a Debug event has occurred.
The possible values of this bit are:
- 0: No Debug event has occurred.
- 1: Debug event has occurred. The Debug Fault Status Register has been updated.
The PE sets this bit to 1 only when Halting debug is disabled and a Debug event occurs. When AIRC.R.BFHFNMINS is set to zero, the Non-secure view of this bit is RAZ/WI.
This bit resets to zero on a Warm reset.

**FORCED, bit [30]**
Forced. Indicates that a fault with configurable priority has been escalated to a HardFault exception, because it could not be made active, because of priority, or because it was disabled.
The possible values of this bit are:
- 0: No priority escalation has occurred.
- 1: Processor has escalated a configurable-priority exception to HardFault.
When AIRC.R.BFHFNMINS is set to zero, the Non-secure view of this bit is RAZ/WI.
This bit resets to zero on a Warm reset.

**Bits [29:2]**
Reserved, RES0.

**VECTTBL, bit [1]**
Vector table. Indicates when a fault has occurred because of a vector table read error on exception processing.
The possible values of this bit are:
- 0: No vector table read fault has occurred.
Vector table read fault has occurred.
When AIRCR.BFHFNMINS is set to zero, the Non-secure view of this bit is RAZ/WI.
This bit resets to zero on a Warm reset.

Bit [0]
Reserved, RES0.
D1.2.104  ICIALLU, Instruction Cache Invalidate All to PoU

The ICIALLU characteristics are:

**Purpose**

Invalidate all instruction caches to PoU.

**Usage constraints**

Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**

This register is always implemented.

**Attributes**

32-bit write-only register located at 0xE000EF50.

Secure software can access the Non-secure view of this register via ICIALLU_NS located at 0xE002EF50. The location 0xE002EF50 is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

**Field descriptions**

The ICIALLU bit assignments are:

---

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Ignored</td>

</tr>
</tbody>
</table>

**Ignored, bits [31:0]**

The value written to this field is ignored. Ignored.
D1.2.105  ICIMVAU, Instruction Cache line Invalidate by Address to PoU

The ICIMVAU characteristics are:

**Purpose**
Invalidate instruction cache line by address to PoU.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit write-only register located at 0xE000EF58.
Secure software can access the Non-secure view of this register via ICIMVAU_NS located at 0xE002EF58. The location 0xE002EF58 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The ICIMVAU bit assignments are:

ADDRESS, bits [31:0]
Address. Writing to this field initiates the maintenance operation for the address written.
D1.2.106  ICSR, Interrupt Control and State Register

The ICSR characteristics are:

**Purpose**
Controls and provides status information for NMI, PendSV, SysTick and interrupts.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000ED04.
Secure software can access the Non-secure view of this register via ICSR_NS located at 0xE002ED04. The location 0xE002ED04 is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states on a bit by bit basis.

**Field descriptions**
The ICSR bit assignments are:

<table>
<thead>
<tr>

PENDNMISET, bit [31], on a write

Pend NMI set. Allows the NMI exception to be set as pending.
This bit is not banked between Security states.

The possible values of this bit are:
0  No effect.
1  Sets the NMI exception pending.
If both PENDNMISET and PENDNMICLR are written to one simultaneously, the pending state of the NMI exception becomes UNKNOWN.
This bit is write-one-to-set. Writes of zero are ignored.
If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

PENDNMISET, bit [31], on a read

Pend NMI set. Indicates whether the NMI exception is pending.
This bit is not banked between Security states.

The possible values of this bit are:
0  NMI exception not pending.
1  NMI exception pending.
If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

PENDNMICLR, bit [30]

Pend NMI clear. Allows the NMI exception pend state to be cleared.
This bit is not banked between Security states.
The possible values of this bit are:

0  No effect.
1  Clear pending status.

This bit is write-only, and reads-as-zero.
This bit is write-one-to-clear. Writes of zero are ignored.
If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

Bit [29]

Reserved, RES0.

PENDSVSET, bit [28], on a write

Pend PendSV set. Allows the PendSV exception for the selected Security state to be set as pending.
This bit is banked between Security states.
The possible values of this bit are:

0  No effect.
1  Sets the PendSV exception pending.

If both PENDNSVSET and PENDSVCLR are written to one simultaneously, the pending state of
the associated PendSV exception becomes UNKNOWN.
This bit is write-one-to-set. Writes of zero are ignored.

PENDSVSET, bit [28], on a read

Pend PendSV set. Indicates whether the PendSV for the selected Security state exception is pending.
This bit is banked between Security states.
The possible values of this bit are:

0  PendSV exception not pending.
1  PendSV exception pending.

This bit resets to zero on a Warm reset.

PENDSVCLR, bit [27]

Pend PendSV clear. Allows the PendSV exception pend state to be cleared for the selected Security
state.
This bit is banked between Security states.
The possible values of this bit are:

0  No effect.
1  Clear pending status.

This bit is write-only, and reads-as-zero.
This bit is write-one-to-clear. Writes of zero are ignored.

PENDSTSET, bit [26], on a write

Pend SysTick set. Allows the SysTick for the selected Security state exception to be set as pending.
This bit is banked between Security states.
The possible values of this bit are:

0  No effect.
1  Sets the SysTick exception for the selected Security state pending.

PENDSTSET, bit [26], on a read

Pend SysTick set. Indicates whether the SysTick for the selected Security state exception is pending.
This bit is not banked between Security states.
The possible values of this bit are:
0  SysTick exception not pending.
1  SysTick exception pending.

If both PENDSTSET and PENDSTCLR are written to one simultaneously, the pending state of the associated SysTick exception becomes UNKNOWN.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this bit is RES0.

This bit resets to zero on a Warm reset.

**PENDSTCLR, bit [25]**

Pend SysTick clear. Allows the SysTick exception pend state to be cleared for the selected Security state.

This bit is not banked between Security states.

The possible values of this bit are:
0  No effect.
1  Clear pending status.

If a single instance of SYSTICK is implemented and the value of ICSR.STTNS is zero, this bit behaves as RAZ/WI when accessed from Non-secure state.

This bit is write-only, and reads-as-zero.

This bit is write-one-to-clear. Writes of zero are ignored.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this bit is RES0.

**STTNS, bit [24]**

SysTick Targets Non-secure. Controls whether in a single SysTick implementation, the SysTick is Secure or Non-secure.

This bit is not banked between Security states.

The possible values of this bit are:
0  SysTick is Secure.
1  SysTick is Non-secure.

Behaves as RAZ/WI when either no SysTick or both SysTick timers are implemented. In a PE with the Main Extension and Security Extension this bit is RES0. This bit is RAZ/WI when accessed from the Non-secure state.

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**ISRPREEMPT, bit [23]**

Interrupt preempt. Indicates whether a pending exception will be serviced on exit from debug halt state.

This bit is not banked between Security states.

The possible values of this bit are:
0  Will not service.
1  Will service a pending exception.

The value of this bit is UNKNOWN when not in debug state.

This bit is read-only.

If neither Halting debug or the Main Extension are implemented, this bit is RES0.
ISRPENDING, bit [22]
Interrupt pending. Indicates whether an external interrupt, generated by the NVIC, is pending.
This bit is not banked between Security states.
The possible values of this bit are:
0  No external interrupt pending.
1  External interrupt pending.
This bit is read-only.
If neither Halting debug or the Main Extension are implemented, this bit is RES0.

--- Note ---
The value of DHCSR.C_MASKINTS is ignored.

Bit [21]
Reserved, RES0.

VECTPENDING, bits [20:12]
Vector pending. The exception number of the highest priority pending and enabled interrupt.
This field is not banked between Security states.
The possible values of this field are:
Zero  No pending and enabled exception.
Non zero  Exception number.
This field is read-only.

--- Note ---
If DHCSR.C_MASKINTS is set, the PendSV, SysTick, and configurable external interrupts are masked and will not be shown as pending in VECTPENDING.

RETTOBASE, bit [11]
Return to base. In Handler mode, indicates whether there is more than one active exception.
This bit is not banked between Security states.
The possible values of this bit are:
0  There is more than one active exception.
1  There is only one active exception.
In Thread mode the value of this bit is UNKNOWN.
This bit is read-only.
If the Main Extension is not implemented, this bit is RES0.

Bits [10:9]
Reserved, RES0.

VECTACTIVE, bits [8:0]
Vector active. The exception number of the current executing exception.
This field is not banked between Security states.
The possible values of this field are:
Zero  Thread mode.
Non zero  Exception number.
This value is the same as the IPSR Exception number. When the IPSR value has been sent to 1 because of a function call to Non-secure state, this field is also set to 1.
This field is read-only.
If neither Halting debug or the Main Extension are implemented, this field is RES0.
D1.2.107  ICTR, Interrupt Controller Type Register

The ICTR characteristics are:

**Purpose**
Provides information about the interrupt controller.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read-only register located at 0xE000E004.
Secure software can access the Non-secure view of this register via ICTR_NS located at 0xE002E004. The location 0xE002E004 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The ICTR bit assignments are:

```
  31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0
    RES0
     INTLINESNUM
```

**Bits [31:4]**
Reserved, RES0.

**INTLINESNUM, bits [3:0]**
Interrupt line set number. Indicates the number of the highest implemented register in each of the NVIC control register sets, or in the case of NVIC_IPRn, 4×INTLINESNUM.
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.108   ID_AFR0, Auxiliary Feature Register 0

The ID_AFR0 characteristics are:

**Purpose**
Provides information about the IMPLEMENTATION DEFINED features of the PE.

**Usage constraints**
- Privileged access permitted only. Unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
- Present only if the Main Extension is implemented.
- This register is RES0 if the Main Extension is not implemented.

**Attributes**
- 32-bit read-only register located at 0xE000ED4C.
- Secure software can access the Non-secure view of this register via ID_AFR0_NS located at 0xE002ED4C. The location 0xE002ED4C is RES0 to software executing in Non-secure state and the debugger.
- This register is not banked between Security states.

**Field descriptions**

The ID_AFR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30:16</th>
<th>15:8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>

</tr>
</tbody>
</table>

**Bits [31:16]**
Reserved, RES0.

**IMPDEFm, bits [4m+3:4m], for m = 0 to 3**
- IMPLEMENTATION DEFINED. IMPLEMENTATION DEFINED meaning.
- This field reads as an IMPLEMENTATION DEFINED value.
D1.2.109   ID_DFR0, Debug Feature Register 0

The ID_DFR0 characteristics are:

Purpose       Provides top level information about the debug system.
Usage constraints  Privileged access permitted only. Unprivileged accesses generate a BusFault.
                    This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
Configurations  Present only if the Main Extension is implemented.
                    This register is RES0 if the Main Extension is not implemented.
Attributes      32-bit read-only register located at \texttt{0xE000ED48}.
                    Secure software can access the Non-secure view of this register via ID_DFR0_NS located at \texttt{0xE002ED48}. The location \texttt{0xE002ED48} is RES0 to software executing in Non-secure state and the debugger.
                    This register is not banked between Security states.

Preface

If Halting Debug is not implemented this register reads as \texttt{0x00000000}.
If Halting Debug is implemented this register reads as \texttt{0x00200000}.

Field descriptions

The ID_DFR0 bit assignments are:

\begin{tabular}{|c|c|}
\hline
31 & 24-23 & 20-19 & 18-1 & 0 \\
\hline
RES0 & MProfDbg & RES0 &  \\
\hline
\end{tabular}

Bits [31:24]

Reserved, RES0.

MProfDbg, bits [23:20]

M-profile debug. Indicates the supported M-profile debug architecture.

The possible values of this field are:

\begin{itemize}
  \item \texttt{0b0000}   Halting Debug is not implemented.
  \item \texttt{0b0010}   ARMv8-M Debug architecture.
  \item All other values are reserved.
\end{itemize}

This field reads as an \texttt{IMPLEMENTATION DEFINED} value.

Bits [19:0]

Reserved, RES0.
D1.2.110  ID_ISAR0, Instruction Set Attribute Register 0

The ID_ISAR0 characteristics are:

**Purpose**
Provides information about the instruction set implemented by the PE.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read-only register located at 0xE000ED60.
Secure software can access the Non-secure view of this register via ID_ISAR0_NS located at 0xE002ED60. The location 0xE002ED60 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Preface**
If coprocessors excluding the floating-point Extension are not supported this register reads as 0x01101110.
If coprocessors excluding the floating-point Extension are supported this register reads as 0x01141110.

**Field descriptions**
The ID_ISAR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

**Bits [31:28]**
Reserved, RES0.

**Divide, bits [27:24]**
Divide. Indicates the supported Divide instructions.
The possible values of this field are:
0b0001  Supports SDIV and UDIV instructions.
All other values are reserved.
This field reads as 0b0001.

**Debug, bits [23:20]**
Debug. Indicates the implemented Debug instructions.
The possible values of this field are:
0b0001  Supports BKPT instruction.
All other values are reserved.
This field reads as 0b0001.

**Coproc, bits [19:16]**
Coprocessor. Indicates the supported Coprocessor instructions.
The possible values of this field are:
0b0000  No coprocessor instructions support other than FPU.
0b0100  Coprocessor instructions supported.
All other values are reserved.
This field reads as an IMPLEMENTATION DEFINED value.

CmpBranch, bits [15:12]

Compare and branch. Indicates the supported combined Compare and Branch instructions.
The possible values of this field are:
0b0001 Supports CBNZ and CBZ instructions.
All other values are reserved.
This field reads as 0b0001.

BitField, bits [11:8]

Bit field. Indicates the supported bit field instructions.
The possible values of this field are:
0b0001 BFC, BFI, SBFX, and UBFX supported.
All other values are reserved.
This field reads as 0b0001.

BitCount, bits [7:4]

Bit count. Indicates the supported bit count instructions.
The possible values of this field are:
0b0001 CLZ supported.
All other values are reserved.
This field reads as 0b0001.

Bits [3:0]

Reserved, RES0.
D1.2.111 ID_ISAR1, Instruction Set Attribute Register 1

The ID_ISAR1 characteristics are:

**Purpose**  
Provides information about the instruction set implemented by the PE.

**Usage constraints**  
Privileged access permitted only. Unprivileged accesses generate a BusFault.  
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**  
Present only if the Main Extension is implemented.  
This register is RES0 if the Main Extension is not implemented.

**Attributes**  
32-bit read-only register located at 0xE000ED64.  
Secure software can access the Non-secure view of this register via ID_ISAR1_NS located at 0xE002ED64. The location 0xE002ED64 is RES0 to software executing in Non-secure state and the debugger.  
This register is not banked between Security states.

**Preface**

If the DSP Extension is not implemented, this register reads as 0x02211000.  
If the DSP Extension is implemented, this register reads as 0x02212000.

**Field descriptions**

The ID_ISAR1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>

<td>Immediate</td>
<td>ADDW, MOVW, MOVT, and SUBW supported.</td>
</tr>
<tr>
<td>19:16</td>
<td>IfThen</td>
<td>IT instruction supported.</td>
</tr>
</tbody>
</table>

**Bits [31:28]**

Reserved, RES0.

**Interwork, bits [27:24]**

Interworking. Indicates the implemented Interworking instructions.  
The possible values of this field are:  
0b0010 BLX, BX, and loads to PC interwork.  
All other values are reserved.  
This field reads as 0b0010.

**Immediate, bits [23:20]**

Immediate. Indicates the implemented for data-processing instructions with long immediates.  
The possible values of this field are:  
0b0010 ADDW, MOVW, MOVT, and SUBW supported.  
All other values are reserved.  
This field reads as 0b0010.

**IfThen, bits [19:16]**

If-Then. Indicates the implemented If-Then instructions.  
The possible values of this field are:  
0b0001 IT instruction supported.  
All other values are reserved.  
This field reads as 0b0001.
Extend, bits [15:12]

Extend. Indicates the implemented Extend instructions.

The possible values of this field are:

- 0b0001: SXTB, SXTH, UXTB, and UXTH.
- 0b0010: Adds SXTB16, SXTAB, SXTAB16, SXTAH, UXTB16, UXTAB, UXTAB16, and UXTAH, DSP Extension only.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

Bits [11:0]

Reserved, RES0.
### D1.2.112 ID_ISAR2, Instruction Set Attribute Register 2

The ID_ISAR2 characteristics are:

**Purpose**
Provides information about the instruction set implemented by the PE.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read-only register located at 0xE000ED68.

Secure software can access the Non-secure view of this register via ID_ISAR2_NS located at 0xE002ED68. The location 0xE002ED68 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Preface**
With bits [11:8] masked, if the DSP Extension is not implemented, this register reads as 0x20112032.

With bits[11:8] masked, if the DSP Extension is implemented, this register reads as 0x20232032.

The value of bits [11:8] is determined by whether the PE implements restartable or continuable multi-access instructions.

**Field descriptions**
The ID_ISAR2 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reversal, bits [31:28]</td>
<td>31-28</td>

<td>3-0</td>
<td></td>
</tr>
</tbody>
</table>
The possible values of this field are:
0b0001  SMULL and SMLAL.
0b0011  Adds all saturating and DSP signed multiplies, DSP Extension only.
All other values are reserved.
This field reads as an IMPLEMENTATION DEFINED value.

Mult, bits [15:12]
Multipies. Indicates the implemented additional Multiply instructions.
The possible values of this field are:
0b0010  MUL, MLA, and MLS.
All other values are reserved.
This field reads as 0b0010.

MultiAccessInt, bits [11:8]
Multi-access instructions. Indicates the support for interruptible multi-access instructions.
The possible values of this field are:
0b0000  No support. LDM and STM instructions are not interruptible.
0b0001  LDM and STM instructions are restartable.
0b0010  LDM and STM instructions are continuable.
All other values are reserved.
This field reads as an IMPLEMENTATION DEFINED value.

MemHint, bits [7:4]
Memory hints. Indicates the implemented Memory Hint instructions.
The possible values of this field are:
0b0011  PLI and PLD instructions implemented.
All other values are reserved.
This field reads as 0b0011.

LoadStore, bits [3:0]
Load/store. Indicates the implemented additional load/store instructions.
The possible values of this field are:
0b0010  Supports load-acquire, store-release, and exclusive load and store instructions.
All other values are reserved.
This field reads as 0b0010.
D1.2.113   ID_ISAR3, Instruction Set Attribute Register 3

The ID_ISAR3 characteristics are:

**Purpose**
Provides information about the instruction set implemented by the PE.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read-only register located at 0xE000ED6C.
Secure software can access the Non-secure view of this register via ID_ISAR3_NS located at 0xE002ED6C. The location 0xE002ED6C is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Preface**
If the DSP Extension is not implemented, this register reads as 0x01111110.
If the DSP Extension is implemented, this register reads as 0x01111131.

**Field descriptions**
The ID_ISAR3 bit assignments are:

<table>
<thead>

<td>Saturate</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:28]**
Reserved, RES0.

**TrueNOP, bits [27:24]**
True no-operation. Indicates the implemented true NOP instructions.
The possible values of this field are:
0b0001   NOP instruction and compatible hints implemented.
All other values are reserved.
This field reads as 0b0001.

**T32Copy, bits [23:20]**
T32 copy. Indicates the support for T32 non flag-setting MOV instructions.
The possible values of this field are:
0b0001   Encoding T1 of MOV (register) supports copying low register to low register.
All other values are reserved.
This field reads as 0b0001.

**TabBranch, bits [19:16]**
Table branch. Indicates the implemented Table Branch instructions.
The possible values of this field are:
0b0001   TBB and TBH implemented.
All other values are reserved.
This field reads as 0b0001.
SynchPrim, bits [15:12]

Synchronization primitives. Used in conjunction with ID_ISAR4.SynchPrim_frac to indicate the implemented Synchronization Primitive instructions.

The possible values of this field are:

0b0001 LDREX, STREX, LDREXB, STREXB, LDREXH, STREXH, and CLREX implemented.

All other values are reserved.

This field reads as 0b0001.

SVC, bits [11:8]

Supervisor call. Indicates the implemented SVC instructions.

The possible values of this field are:

0b0001 SVC instruction implemented.

All other values are reserved.

This field reads as 0b0001.

SIMD, bits [7:4]

Single-instruction, multiple-data. Indicates the implemented SIMD instructions.

The possible values of this field are:

0b0001 SSAT, USAT, and Q-bit implemented.
0b0011 Adds all packed arithmetic and GE-bits, DSP Extension only.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

Saturate, bits [3:0]

Saturate. Indicates the implemented saturating instructions.

The possible values of this field are:

0b0000 None implemented.
0b0001 QADD, QDADD, QDSUB, QSUB, and Q-bit implemented, DSP Extension only.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.
**D1.2.114   ID_ISAR4, Instruction Set Attribute Register 4**

The ID_ISAR4 characteristics are:

**Purpose**
Provides information about the instruction set implemented by the PE.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented. This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read-only register located at 0xE000ED70. Secure software can access the Non-secure view of this register via ID_ISAR4_NS located at 0xE002ED70. The location 0xE002ED70 is RES0 to software executing in Non-secure state and the debugger. This register is not banked between Security states.

**Preface**
This register reads as 0x01310131.

**Field descriptions**

The ID_ISAR4 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

**Bits [31:28]**
Reserved, RES0.

**PSR_M, bits [27:24]**
Program status registers M. Indicates the implemented M profile instructions to modify the PSRs. The possible values of this field are:

- 0b0001  M profile forms of CPS, MRS, and MSR implemented.
- All other values are reserved.

This field reads as 0b0001.

**SyncPrim_frac, bits [23:20]**
Synchronization primitives fractional. Used in conjunction with ID_ISAR3.SynchPrim to indicate the implemented Synchronization Primitive instructions. The possible values of this field are:

- 0b0011  LDREX, STREX, CLREX, LDREXB, LDREXH, STREXB, and STREXH implemented.
- All other values are reserved.

This field reads as 0b0011.

**Barrier, bits [19:16]**
Barrier. Indicates the implemented Barrier instructions. The possible values of this field are:

- 0b0001  DMB, DSB, and ISB barrier instructions implemented.
All other values are reserved. This field reads as `0b0001`.

**Bits [15:12]**

Reserved, `RES0`.

**Writeback, bits [11:8]**

Writeback. Indicates the support for writeback addressing modes.
The possible values of this field are:
- `0b0001` All writeback addressing modes supported.
- All other values are reserved.
  This field reads as `0b0001`.

**WithShifts, bits [7:4]**

With shifts. Indicates the support for writeback addressing modes.
The possible values of this field are:
- `0b0011` Support for constant shifts on load/store and other instructions.
- All other values are reserved.
  This field reads as `0b0011`.

**Unpriv, bits [3:0]**

Unprivileged. Indicates the implemented unprivileged instructions.
The possible values of this field are:
- `0b0010` LDRBT, LDRHT, LDRSBT, LDRSHT, LDRT, STRBT, STRHT, and STRT implemented.
- All other values are reserved.
  This field reads as `0b0010`. 
D1.2.115   ID_ISAR5, Instruction Set Attribute Register 5

The ID_ISAR5 characteristics are:

Purpose       Provides information about the instruction set implemented by the PE.

Usage constraints
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

Configurations
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

Attributes
32-bit read-only register located at 0xE000ED74.
Secure software can access the Non-secure view of this register via ID_ISAR5_NS located at 0xE002ED74. The location 0xE002ED74 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

Field descriptions
The ID_ISAR5 bit assignments are:

```
031 31  0
RES0
```

Bits [31:0]
Reserved, RES0.
D1.2.116   ID_MMFR0, Memory Model Feature Register 0

The ID_MMFR0 characteristics are:

**Purpose**
Provides information about the implemented memory model and memory management support.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read-only register located at 0xE000ED50.
Secure software can access the Non-secure view of this register via ID_MMFR0_NS located at 0xE002ED50. The location 0xE002ED50 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The ID_MMFR0 bit assignments are:

</tr>
</tbody>
</table>

**Bits [31:24]**
Reserved, RES0.

**AuxReg, bits [23:20]**
Auxiliary Registers. Indicates support for Auxiliary Control Registers.
The possible values of this field are:
- 0b0000: No Auxiliary Control Registers.
- 0b0001: Auxiliary Control Registers supported.
All other values are reserved.
This field reads as an IMPLEMENTATION DEFINED value.

**TCM, bits [19:16]**
Tightly coupled memories. Indicates support for tightly coupled memories (TCMs).
The possible values of this field are:
- 0b0000: None supported.
- 0b0001: TCMs supported with IMPLEMENTATION DEFINED control.
All other values are reserved.
This field reads as an IMPLEMENTATION DEFINED value.

**ShareLvl, bits [15:12]**
Shareability Levels. Indicates the number of shareability levels implemented.
The possible values of this field are:
- 0b0000: One level of shareability implemented.
- 0b0001: Two levels of shareability implemented.
All other values are reserved.
This field reads as an IMPLEMENTATION DEFINED value.
OuterShr, bits [11:8]
Outermost Shareability. Indicates the outermost shareability domain implemented.
The possible values of this field are:
0b0000 Implemented as Non-cacheable.
0b0001 Implemented with hardware coherency support.
0b1111 Shareability ignored.
All other values are reserved.
This field reads as an IMPLEMENTATION DEFINED value.

PMSA, bits [7:4]
Protected memory system architecture. Indicates support for the protected memory system architecture (PMSA).
The possible values of this field are:
0b0100 Supports PMSAv8.
All other values are reserved.
This field reads as 0b0100.

Bits [3:0]
Reserved, RES0.
D1.2.117   ID_MMFR1, Memory Model Feature Register 1

The ID_MMFR1 characteristics are:

**Purpose**
Provides information about the implemented memory model and memory management support.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read-only register located at 0xE000ED54.
Secure software can access the Non-secure view of this register via ID_MMFR1_NS located at 0xE002ED54. The location 0xE002ED54 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**

The ID_MMFR1 bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

**Bits [31:0]**
Reserved, RES0.
D1.2.118  ID_MMFR2, Memory Model Feature Register 2

The ID_MMFR2 characteristics are:

**Purpose**
Provides information about the implemented memory model and memory management support.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read-only register located at 0xE000ED58.
Secure software can access the Non-secure view of this register via ID_MMFR2_NS located at 0xE002ED58. The location 0xE002ED58 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The ID_MMFR2 bit assignments are:

<p>| | | | | |</p>
<table>

**Bits [31:28]**
Reserved, RES0.

**WFIStall, bits [27:24]**
WFI stall. Indicates the support for Wait For Interrupt (WFI) stalling.
The possible values of this field are:
0b0000  WFI never stalls.
0b0001  WFI has the ability to stall.
All other values are reserved.
This field reads as an IMPLEMENTATION DEFINED value.

**Bits [23:0]**
Reserved, RES0.
D1.2.119   ID_MMFR3, Memory Model Feature Register 3

The ID_MMFR3 characteristics are:

**Purpose**

Provides information about the implemented memory model and memory management support.

**Usage constraints**

Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**

Present only if the Main Extension is implemented.

This register is RES0 if the Main Extension is not implemented.

**Attributes**

32-bit read-only register located at 0xE000ED5C.

Secure software can access the Non-secure view of this register via ID_MMFR3_NS located at 0xE002ED5C. The location 0xE002ED5C is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

**Field descriptions**

The ID_MMFR3 bit assignments are:

![Field layout diagram]

**Bits [31:12]**

Reserved, RES0.

**BPMaint, bits [11:8]**

Branch predictor maintenance. Indicates the supported branch predictor maintenance.

The possible values of this field are:

- 0b0000: None supported.
- 0b0001: Support for invalidate all of branch predictors.
- All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

**CMaintSW, bits [7:4]**

Cache maintenance set/way. Indicates the supported cache maintenance operations by set/way.

The possible values of this field are:

- 0b0000: None supported.
- 0b0001: Maintenance by set/way operations supported.
- All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

**CMaintVA, bits [3:0]**

Cache maintenance by address. Indicates the supported cache maintenance operations by address.

The possible values of this field are:

- 0b0000: None supported.
- 0b0001: Maintenance by address and instruction cache invalidate all supported.
- All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.
D1.2.120 ID_PFR0, Processor Feature Register 0

The ID_PFR0 characteristics are:

**Purpose**
Gives top-level information about the instruction set supported by the PE.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read-only register located at \(0xE000ED40\).
Secure software can access the Non-secure view of this register via ID_PFR0_NS located at \(0xE002ED40\). The location \(0xE002ED40\) is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Preface**
This register reads as \(0x00000030\).

**Field descriptions**
The ID_PFR0 bit assignments are:

| RES0 | MProgMod | Security | RES0 |

Bits [31:12]

Reserved, RES0.

MProgMod, bits [11:8]

M programmers' model. Identifies support for the M-Profile programmers' model support.

The possible values of this field are:

0b0010 Two-stack programmers’ model.

All other values are reserved.

This field reads as 0b0010.

Security, bits [7:4]

Security. Identifies whether the Security Extension is implemented.

The possible values of this field are:

0b0000 Security Extension not implemented.
0b0001 Security Extension implemented.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

Bits [3:0]

Reserved, RES0.
D1.2.122  IPSR, Interrupt Program Status Register

The IPSR characteristics are:

**Purpose**  Provides privileged access to the current exception number field.

**Usage constraints**  Privileged access only. Unprivileged access is RAZ/WI.

**Configurations**  This register is always implemented.

**Attributes**  32-bit read/write special-purpose register.
This register is not banked between Security states.

### Field descriptions

The IPSR bit assignments are:

```
+-------------------+-------------------+-------------------+-------------------+
| 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Exception|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
```

**Bits [31:9]**

Reserved, RES0.

**Exception, bits [8:0]**

- **Exception number.** Holds the exception number of the currently-executing exception, or zero for Thread mode.
- The possible values of this field are:
  - **Zero**  PE in Thread mode.
  - **Non zero**  PE in Handler mode in given exception number. On a function call from Secure state the value is set to 1 to ensure that the Non-secure state cannot determine which exception handler is executing.

This field resets to zero on a Warm reset.
D1.2.123 ITM_CIDR0, ITM Component Identification Register 0

The ITM_CIDR0 characteristics are:

**Purpose**
Provides CoreSight discovery information for the ITM.

**Usage constraints**
If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.
If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the ITM is implemented.
This register is RES0 if the ITM is not implemented.
If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
32-bit read-only register located at 0xE0000FF0.
This register is not banked between Security states.

**Field descriptions**
The ITM_CIDR0 bit assignments are:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**PRMBL_0, bits [7:0]**
CoreSight component identification preamble. See the ARM® CoreSight™ Architecture Specification.
This field reads as 0x0D.
D1.2.124 ITM_CIDR1, ITM Component Identification Register 1

The ITM_CIDR1 characteristics are:

**Purpose**
Provides CoreSight discovery information for the ITM.

**Usage constraints**
If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.
If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the ITM is implemented.
This register is RES0 if the ITM is not implemented.
If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
32-bit read-only register located at 0xE0000FF4.
This register is not banked between Security states.

D1.2.125 ITM_CIDR2, ITM Component Identification Register 2

The ITM_CIDR2 characteristics are:

**Purpose**
Provides CoreSight discovery information for the ITM.

**Usage constraints**
- If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.
- If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
- Present only if CoreSight identification is implemented.
- Present only if the ITM is implemented.
- If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
- 32-bit read-only register located at 0xE0000FF8.
- This register is not banked between Security states.

**Field descriptions**
The ITM_CIDR2 bit assignments are:

Reserved, RES0.

CoreSight component identification preamble. See the ARM® CoreSight™ Architecture Specification.

This field reads as 0x05.
D1.2.126 ITM_CIDR3, ITM Component Identification Register 3

The ITM_CIDR3 characteristics are:

**Purpose**

Provides CoreSight discovery information for the ITM.

**Usage constraints**

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**

Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is RES0 if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**

32-bit read-only register located at 0xE0000FFC.

This register is not banked between Security states.

**Field descriptions**

The ITM_CIDR3 bit assignments are:

This field reads as 0xB1.
D1.2.127  ITM_DEVARCH, ITM Device Architecture Register

The ITM_DEVARCH characteristics are:

**Purpose**
Provides CoreSight discovery information for the ITM.

**Usage constraints**
- If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.
- If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
- Present only if the Main Extension is implemented.
- This register is RES0 if the Main Extension is not implemented.
- Present only if CoreSight identification is implemented.
- This register is RES0 if CoreSight identification is not implemented.
- Present only if the ITM is implemented.
- This register is RES0 if the ITM is not implemented.
- If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
- 32-bit read-only register located at 0xE0000FBC.
- This register is not banked between Security states.

**Field descriptions**

<tr>
<td>ARCHITECT</td>
<td>REVISION</td>
<td>ARCHVER</td>
<td>ARCHPART</td>
<td>PRESENT</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ARCHITECT, bits [31:21]**
Architect. Defines the architect of the component. Bits [31:28] are the JEP106 continuation code (JEP106 bank ID, minus 1) and bits [27:21] are the JEP106 ID code.

The possible values of this field are:
- 0x23B  JEP106 continuation code 0x4, ID code 0x3B. ARM Limited.
- Other values are defined by the JEDEC JEP106 standard.

This field reads as 0x23B.

**PRESENT, bit [20]**
DEVARCH Present. Defines that the DEVARCH register is present.

The possible values of this bit are:
- 1  DEVARCH information present.

This bit reads as one.

**REVISION, bits [19:16]**
Revision. Defines the architecture revision of the component.

The possible values of this field are:
- 0000  ITM architecture v2.0.

This field reads as 0b0000.

**ARCHIVER, bits [15:12]**
Architecture Version. Defines the architecture version of the component.
The possible values of this field are:

0001  ITM architecture v2.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, such that ARCHVER is ARCHID[15:12].

This field reads as 0b0001.

ARCHPART, bits [11:0]

Architecture Part. Defines the architecture of the component.

The possible values of this field are:

0xA01  ITM architecture.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, such that ARCHPART is ARCHID[11:0].

This field reads as 0xA01.
D1.2.128  ITM_DEVTYPE, ITM Device Type Register

The ITM_DEVTYPE characteristics are:

**Purpose**
Provides CoreSight discovery information for the ITM.

**Usage constraints**
If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is RES0 if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
32-bit read/write register located at 0xE0000FCC.
This register is not banked between Security states.

**Field descriptions**
The ITM_DEVTYPE bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-8</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>7-4</td>
<td>Sub-type. Component sub-type.</td>
</tr>
<tr>
<td>3-0</td>
<td>Major type. Component major type.</td>
</tr>
</tbody>
</table>

**Bits [31:8]**
Reserved, RES0.

**SUB, bits [7:4]**
Sub-type. Component sub-type.
The possible values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0</td>
<td>Other. Only permitted if the MAJOR field reads as 0x0.</td>
</tr>
<tr>
<td>0x4</td>
<td>Associated with a Bus, stimulus derived from bus activity. Only permitted if the MAJOR field reads as 0x3.</td>
</tr>
</tbody>
</table>

This field reads as an IMPLEMENTATION DEFINED value.

**MAJOR, bits [3:0]**
Major type. Component major type.
The possible values of this field are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0</td>
<td>Miscellaneous.</td>
</tr>
<tr>
<td>0x3</td>
<td>Trace Source.</td>
</tr>
</tbody>
</table>

This field reads as an IMPLEMENTATION DEFINED value.
D1.2.129 ITM_LAR, ITM Software Lock Access Register

The ITM_LAR characteristics are:

**Purpose**
Provides CoreSight Software Lock control for the ITM, see the *ARM® CoreSight™ Architecture Specification* for details.

**Usage constraints**
- If the Main Extension is implemented, both privileged and unprivileged accesses are permitted, but unprivileged writes are ignored.
- If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
- This register is RAZ/WI if accessed via the debugger.

**Configurations**
- Present only if CoreSight identification is implemented.
- This register is RES0 if CoreSight identification is not implemented.
- Present only if the ITM is implemented.
- This register is RES0 if the ITM is not implemented.
- If the Main Extension is not implemented then the ITM is not implemented.
- Present only if the optional Software Lock is implemented.
- This register is RAZ/WI if the Software Lock is not implemented.

**Attributes**
- 32-bit write-only register located at 0xE0000FB0.
- This register is not banked between Security states.

**Field descriptions**

The ITM_LAR bit assignments are:

![Key Bit Assignment Diagram]  

**KEY, bits [31:0]**
Lock Access control.

Writing the key value \(0xC5ACCE55\) to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.
D1.2.130   ITM_LSR, ITM Software Lock Status Register

The ITM_LSR characteristics are:

**Purpose**
Provides CoreSight Software Lock status information for the ITM, see the ARM® CoreSight™ Architecture Specification for details.

**Usage constraints**
If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.
If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
This register is RAZ/WI if accessed via the debugger.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the ITM is implemented.
This register is RES0 if the ITM is not implemented.
If the Main Extension is not implemented then the ITM is not implemented.
Present only if the optional Software Lock is implemented.
This register is RAZ/WI if the Software Lock is not implemented.

**Attributes**
32-bit read-only register located at 0xE0000FB4.
This register is not banked between Security states.

**Field descriptions**

The ITM_LSR bit assignments are:

![Bit assignments diagram]

**Bits [31:3]**
Reserved, RES0.

**nTT, bit [2]**
Not thirty-two bit. See the ARM® CoreSight™ Architecture Specification.
This bit reads as zero.

**SLK, bit [1]**
Software Lock status. See the ARM® CoreSight™ Architecture Specification.
The possible values of this bit are:
- **0**: Lock clear. Software writes are permitted to this component's registers.
- **1**: Lock set. Software writes to this component's registers are ignored, and reads have no side-effects.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is RES0.
This bit resets to one on a Warm reset.

**SLI, bit [0]**
Software Lock implemented. See the ARM® CoreSight™ Architecture Specification.
The possible values of this bit are:
- **0**: Software Lock not implemented or debugger access.
1 Software Lock is implemented and software access.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is RAZ.

This bit reads as an IMPLEMENTATION DEFINED value.
D1.2.131   **ITM_PIDR0, ITM Peripheral Identification Register 0**

The ITM_PIDR0 characteristics are:

**Purpose**    Provides CoreSight discovery information for the ITM.

**Usage constraints**
- If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.
- If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
- Present only if CoreSight identification is implemented.
- This register is RES0 if CoreSight identification is not implemented.
- Present only if the ITM is implemented.
- This register is RES0 if the ITM is not implemented.
- If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
- 32-bit read-only register located at 0xE0000FE0.
- This register is not banked between Security states.

**Field descriptions**

The ITM_PIDR0 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td></td>
<td></td>
<td>PART_0</td>
</tr>
</tbody>
</table>

**Bits [31:8]**

Reserved, RES0.

**PART_0, bits [7:0]**

Part number bits [7:0]. See the *ARM® CoreSight™ Architecture Specification*.

This field reads as an IMPLEMENTATION DEFINED value.
D1.2.132   ITM_PIDR1, ITM Peripheral Identification Register 1

The ITM_PIDR1 characteristics are:

**Purpose**  Provides CoreSight discovery information for the ITM.

**Usage constraints**  If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**  Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is RES0 if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**  32-bit read-only register located at 0xE0000FE4.

This register is not banked between Security states.

**Field descriptions**

The ITM_PIDR1 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>RES0</td>
</tr>
<tr>
<td>1:7</td>
<td>RESERVED</td>
</tr>
<tr>
<td>8:15</td>
<td>DES_0</td>
</tr>
<tr>
<td>16:31</td>
<td>PART_1</td>
</tr>
</tbody>
</table>

**Bits [31:8]**  Reserved, RES0.

**DES_0, bits [7:4]**  JEP106 identification code bits [3:0]. See the ARM® CoreSight™ Architecture Specification.

This field reads as an IMPLEMENTATION DEFINED value.

**PART_1, bits [3:0]**  Part number bits [11:8]. See the ARM® CoreSight™ Architecture Specification.

This field reads as an IMPLEMENTATION DEFINED value.
D1.2.133 ITM_PIDR2, ITM Peripheral Identification Register 2

The ITM_PIDR2 characteristics are:

**Purpose**
Provides CoreSight discovery information for the ITM.

**Usage constraints**
If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is RES0 if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
32-bit read-only register located at 0xE0000FE8.

This register is not banked between Security states.

**Field descriptions**

The ITM_PIDR2 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>8-7</td>
<td>REVISION</td>
</tr>
<tr>
<td>0-3</td>
<td>DES_1</td>
</tr>
<tr>
<td>3</td>
<td>JEDEC</td>
</tr>
</tbody>
</table>

**Bits [31:8]**
Reserved, RES0.

**REVISION, bits [7:4]**
Component revision. See the *ARM® CoreSight™ Architecture Specification*.

This field reads as an IMPLEMENTATION DEFINED value.

**JEDEC, bit [3]**
JEDEC assignee value is used. See the *ARM® CoreSight™ Architecture Specification*.

This bit reads as one.

**DES_1, bits [2:0]**
JEP106 identification code bits [6:4]. See the *ARM® CoreSight™ Architecture Specification*.

This field reads as an IMPLEMENTATION DEFINED value.
D1.2.134 ITM_PIDR3, ITM Peripheral Identification Register 3

The ITM_PIDR3 characteristics are:

**Purpose**
Provides CoreSight discovery information for the ITM.

**Usage constraints**
- If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.
- If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
- Present only if CoreSight identification is implemented.
- Present only if the ITM is implemented.
- This register is RES0 if the ITM is not implemented.
- If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
- 32-bit read-only register located at 0xE0000FEC.
- This register is not banked between Security states.

**Field descriptions**

The ITM_PIDR3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>8</td>
<td>REV AND</td>
</tr>
<tr>
<td>7-4</td>
<td>Customer Modified, CMOD</td>
</tr>
</tbody>
</table>

**Bits [31:8]**
- Reserved, RES0.

**REVAND, bits [7:4]**
- RevAnd. See the *ARM® CoreSight™ Architecture Specification*.
- This field reads as an IMPLEMENTATION DEFINED value.

**CMOD, bits [3:0]**
- Customer Modified. See the *ARM® CoreSight™ Architecture Specification*.
- This field reads as an IMPLEMENTATION DEFINED value.
D1.2.135 ITM_PIDR4, ITM Peripheral Identification Register 4

The ITM_PIDR4 characteristics are:

**Purpose**
Provides CoreSight discovery information for the ITM.

**Usage constraints**
- If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.
- If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
- Present only if CoreSight identification is implemented.
- This register is RES0 if CoreSight identification is not implemented.
- Present only if the ITM is implemented.
- This register is RES0 if the ITM is not implemented.
- If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
- 32-bit read-only register located at 0xE0000FD0.
- This register is not banked between Security states.

**Field descriptions**

The ITM_PIDR4 bit assignments are:

```
+------------------+-+------------------+-+------------------+
| 31               | 8 | 7                | 4 | 3                | 0 |
+------------------+-+------------------+-+------------------+
| RES0             | SIZE          | DES_2             |
```

**Bits [31:8]**
- Reserved, RES0.

**SIZE, bits [7:4]**
- 4KB count. See the *ARM® CoreSight™ Architecture Specification*.
- This field reads as zero.

**DES_2, bits [3:0]**
- JEP106 continuation code. See the *ARM® CoreSight™ Architecture Specification*.
- This field reads as an IMPLEMENTATION DEFINED value.
D1.2.136 ITM_PIDR5, ITM Peripheral Identification Register 5

The ITM_PIDR5 characteristics are:

**Purpose**
Provides CoreSight discovery information for the ITM.

**Usage constraints**
- If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.
- If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
- Present only if CoreSight identification is implemented.
- This register is RES0 if CoreSight identification is not implemented.
- Present only if the ITM is implemented.
- This register is RES0 if the ITM is not implemented.
- If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
- 32-bit read-only register located at 0xE0000FD4.
- This register is not banked between Security states.

**Field descriptions**
The ITM_PIDR5 bit assignments are:

![Field description diagram]

**Bits [31:0]**
- Reserved, RES0.
D1.2.137  ITM_PIDR6, ITM Peripheral Identification Register 6

The ITM_PIDR6 characteristics are:

**Purpose**
- Provides CoreSight discovery information for the ITM.

**Usage constraints**
- If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.
- If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
- Present only if CoreSight identification is implemented.
- This register is **RES0** if CoreSight identification is not implemented.
- Present only if the ITM is implemented.
- This register is **RES0** if the ITM is not implemented.
- If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
- 32-bit read-only register located at 0xE0000FD8.
- This register is not banked between Security states.

**Field descriptions**

The ITM_PIDR6 bit assignments are:

![Bit assignments](image)

**Bits [31:0]**
- Reserved, RES0.
### D1.2.138 ITM_PIDR7, ITM Peripheral Identification Register 7

The ITM_PIDR7 characteristics are:

**Purpose**
Provides CoreSight discovery information for the ITM.

**Usage constraints**
- If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.
- If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
- Present only if CoreSight identification is implemented.
- This register is RES0 if CoreSight identification is not implemented.
- Present only if the ITM is implemented.
- This register is RES0 if the ITM is not implemented.
- If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
- 32-bit read-only register located at 0xE0000FDC.
- This register is not banked between Security states.

**Field descriptions**

The ITM_PIDR7 bit assignments are:

![BIT ASSIGNMEMNT](image)

**Bits [31:0]**

Reserved, RES0.
D1.2.139  ITM_STIM<n>, ITM Stimulus Port Register, n = 0 - 255

The ITM_STIM<n> characteristics are:

**Purpose**
Provides the interface for generating Instrumentation packets.

**Usage constraints**
If the Main Extension is implemented, both privileged and unprivileged accesses are permitted, but unprivileged writes are ignored if ITM_TPR.PRIVMASK[<n>/8] is set to one.
If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
All writes are ignored if ITM_TCR.ITMENA == 0 or ITM_TER{<n DIV 32}.STIMENA[<n MOD 32] == 0.
This register is word, halfword, and byte accessible.
Accesses that are not word aligned are UNPREDICTABLE.

**Configurations**
Present only if the ITM is implemented.
This register is RES0 if the ITM is not implemented.
If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
32-bit read/write register located at 0xE0000000 + 4n.
This register is not banked between Security states.

**Field descriptions**
The ITM_STIM<n> bit assignments are:

On a read:

```
31 | 2 1 0
---|---|---
RES0 | DISABLED | FIFOREADY
```

On a write:

```
31 | 0
---|---
STIMULUS
```

**STIMULUS, bits [31:0], on a write**
Stimulus data. Data to write to the stimulus port output buffer, for forwarding as an Instrumentation packet. The size of write access determines the type of Instrumentation packet generated.

**Bits [31:2], on a read**
Reserved, RES0.

**DISABLED, bit [1], on a read**
Disabled. Indicates whether the Stimulus Port is enabled or disabled.
The possible values of this bit are:
0  Stimulus Port and ITM are enabled.
1  Stimulus Port or ITM is disabled.

**FIFOREADY, bit [0], on a read**
FIFO ready. Indicates whether the Stimulus Port can accept data.
The possible values of this bit are:
0  Stimulus Port cannot accept data.
1  Stimulus Port can accept at least one word.
D1.2.140  ITM_TCR, ITM Trace Control Register

The ITM_TCR characteristics are:

**Purpose**
Configures and controls transfers through the ITM interface.

**Usage constraints**
If the Main Extension is implemented, both privileged and unprivileged accesses are permitted, but unprivileged writes are ignored.
If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the ITM is implemented.
This register is RES0 if the ITM is not implemented.
If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
32-bit read/write register located at 0xE0000E80.
This register is not banked between Security states.

**Field descriptions**
The ITM_TCR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-24</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>23</td>
<td>BUSY, bit [23] ITM busy. Indicates whether the ITM is currently processing events.</td>
</tr>
<tr>
<td>16-15</td>
<td>TraceBusID</td>
</tr>
<tr>
<td>12-11</td>
<td>RES0</td>
</tr>
<tr>
<td>8-7</td>
<td>RES0</td>
</tr>
<tr>
<td>6</td>
<td>RES0</td>
</tr>
<tr>
<td>5</td>
<td>RES0</td>
</tr>
<tr>
<td>4</td>
<td>RES0</td>
</tr>
<tr>
<td>3</td>
<td>RES0</td>
</tr>
<tr>
<td>2</td>
<td>RES0</td>
</tr>
<tr>
<td>1</td>
<td>RES0</td>
</tr>
<tr>
<td>0</td>
<td>RES0</td>
</tr>
</tbody>
</table>

**Bits [31:24]**
Reserved, RES0.

**BUSY, bit [23]**
ITM busy. Indicates whether the ITM is currently processing events.
The possible values of this bit are:
0 ITM is not processing any events.
1 Events present and being drained.
Events means the ITM is generating or processing any of:
• Packets generated by the ITM from writes to Stimulus Ports.
• Other packets generated by the ITM itself.
• Packets generated by the DWT.
This bit is read-only.

**TraceBusID, bits [22:16]**
Trace bus identity. Identifier for multi-source trace stream formatting. If multi-source trace is in use, the debugger must write a unique non-zero trace ID value to this field.
The possible values of this field are:
0x0 Multi-source trace not in use.
0x01-0x6F Unique trace ID value to be used for ITM trace packets.
All other values are reserved. If the ITM is the only trace source in the system, this field might be RAZ.
This field resets to an UNKNOWN value on a Cold reset.
Bits [15:12]
Reserved, RES0.

GTSFREQ, bits [11:10]
Global timestamp frequency. Defines how often the ITM generates a global timestamp, based on the
global timestamp clock frequency, or disables generation of global timestamps.
The possible values of this field are:
00 Disable generation of Global Timestamp packets.
01 Generate timestamp request whenever the ITM detects a change in global timestamp
counter bits [47:7]. This is approximately every 128 cycles.
10 Generate timestamp request whenever the ITM detects a change in global timestamp
counter bits [47:13]. This is approximately every 8192 cycles.
11 Generate a timestamp after every packet, if the output FIFO is empty.
If the implementation does not support global timestamping then these bits are reserved, RAZ/WI.
This field resets to zero on a Cold reset.

TSPrescale, bits [9:8]
Timestamp prescale. Local timestamp prescaler, used with the trace packet reference clock.
The possible values of this field are:
00 No prescaling.
01 Divide by 4.
10 Divide by 16.
11 Divide by 64.
If the processor does not implement the timestamp prescaler then these bits are reserved, RAZ/WI.
This field resets to zero on a Cold reset.

Bits [7:6]
Reserved, RES0.

STALLENA, bit [5]
Stall enable. Stall the PE to guarantee delivery of Data Trace packets.
The possible values of this bit are:
0 Drop Hardware Source packets and generate an Overflow packet if the ITM output is
stalled.
1 Stall the PE to guarantee delivery of Data Trace packets.
If stalling is not implemented, this bit is RAZ/WI.

SWOENA, bit [4]
SWO enable. Enables asynchronous clocking of the timestamp counter.
The possible values of this bit are:
0 Timestamp counter uses the processor system clock.
1 Timestamp counter uses asynchronous clock from the TPIU interface. The timestamp
counter is held in reset while the output line is idle.
Which clocking modes are implemented is IMPLEMENTATION DEFINED. If the implementation does
not support both modes this bit is either RAZ or RAO, to indicate the implemented mode.
This bit resets to an UNKNOWN value on a Cold reset.

TXENA, bit [3]
Transmit enable. Enables forwarding of hardware event packet from the DWT unit to the ITM for
output to the TPIU.
The possible values of this bit are:
0 Disabled.
1 Enabled.

It is IMPLEMENTATION DEFINED whether the DWT discards packets that it cannot forward to the ITM.

This bit resets to zero on a Cold reset.

--- Note ---
If a debugger changes this bit from 0 to 1, the DWT might forward a hardware event packet that it has previously generated.

SYNCENA, bit [2]
Synchronization enable. Enables Synchronization packet transmission for a synchronous TPIU.
The possible values of this bit are:
0 Disabled.
1 Enabled.
This bit resets to zero on a Cold reset.

--- Note ---
If a debugger sets this bit to 1 it must also configure DWT_CTRL.SYNCTAP for the correct synchronization speed.

TSENA, bit [1]
Timestamp enable. Enables Local timestamp generation.
The possible values of this bit are:
0 Disabled.
1 Enabled.
This bit resets to zero on a Cold reset.

ITMENA, bit [0]
ITM enable. Enables the ITM.
The possible values of this bit are:
0 Disabled.
1 Enabled.
This is the master enable for the ITM unit. A debugger must set this bit to 1 to permit writes to all Stimulus Port registers.
This bit resets to zero on a Cold reset.
D1.2.141 ITM_TER<n>, ITM Trace Enable Register, n = 0 - 7

The ITM_TER<n> characteristics are:

**Purpose**
Provide an individual enable bit for each ITM_STIM register.

**Usage constraints**
- If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.
- If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the ITM is implemented.

**Attributes**
- 32-bit read/write register located at 0xE0000E00 + 4n.
- This register is not banked between Security states.

**Field descriptions**
The ITM_TER<n> bit assignments are:

![Field diagram]

**STIMENA, bits [31:0]**
Stimulus enable. For STIMENA[m] in ITM_TERn, controls whether ITM_STIM(32n + m) is enabled.

The possible values of each bit are:
- 0: Stimulus port (32n + m) disabled.
- 1: Stimulus port (32n + m) enabled.

Bits corresponding to unimplemented stimulus ports are RAZ/WI. Unprivileged writes to ITM_TERn do not update STIMENA[m] if ITM_TPR.PRIVMASK[(32n+m) DIV 8] is set to 1.

This field resets to zero on a Cold reset.
D1.2.142  ITM_TPR, ITM Trace Privilege Register

The ITM_TPR characteristics are:

**Purpose**
Controls which stimulus ports can be accessed by unprivileged code.

**Usage constraints**
- If the Main Extension is implemented, both privileged and unprivileged accesses are permitted, but unprivileged writes are ignored.
- If the Main Extension is not implemented, unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
- Present only if the ITM is implemented.
- This register is RES0 if the ITM is not implemented.
- If the Main Extension is not implemented then the ITM is not implemented.

**Attributes**
- 32-bit read/write register located at 0xE0000E40.
- This register is not banked between Security states.

**Field descriptions**
The ITM_TPR bit assignments are:

```
+------------------+----------+
| 31               | PRIVMASK |
+------------------+----------+
```

**PRIVMASK, bits [31:0]**
Privilege mask. For PRIVMASK[m], defines the access permissions of ITM_STIM Stimulus Ports 8m to 8m+7 inclusive.

The possible values of each bit are:

<table>
<thead>
<tr>
<th>Bit value</th>
<th>Access permission</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Unprivileged access permitted.</td>
</tr>
<tr>
<td>1</td>
<td>Privileged access only.</td>
</tr>
</tbody>
</table>

Bits corresponding to unimplemented stimulus ports are RAZ/WI.
This field resets to zero on a Cold reset.
D1.2.143   LR, Link Register

The LR characteristics are:

Purpose          Exception and procedure call link register.
Usage constraints Both privileged and unprivileged access permitted.
Configurations   This register is always implemented.
Attributes       32-bit read/write special-purpose register.
                 This register is not banked between Security states.

Field descriptions

The LR bit assignments are:

```
+----------------+------------------+
|   VALUE        |                  |
| 31:0            |                  |
+----------------+------------------+
```

**VALUE, bits [31:0]**

Link register. 32-bit link register updated to hold a return address, FNC_RETURN or
EXC_RETURN on a function call or exception entry. LR can be used as a general-purpose register.
This field resets to an UNKNOWN value on Warm reset when the Main Extension is not implemented.
This field resets to 0xFFFFFFFF on a Warm reset if the Main Extension is implemented.
D1.2.144  MAIR_ATTR, Memory Attribute Indirection Register Attributes

The MAIR_ATTR characteristics are:

**Purpose**
Defines the memory attribute encoding for use in the MPU_MAIR0 and MPU_MAIR1.

**Usage constraints**
None.

**Configurations**
All.

**Attributes**
8-bit payload.

**Field descriptions**

The MAIR_ATTR bit assignments are:

When $\text{Outer} \neq '0000'$:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits [1:0]</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

When $\text{Outer} = '0000'$:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inner [3:0]</td>
<td>Inner attributes. Specifies the Inner memory attributes.</td>
</tr>
<tr>
<td>Device</td>
<td>Device attributes. Specifies the memory attributes for Device.</td>
</tr>
</tbody>
</table>

Outer, bits [7:4]

Outer attributes. Specifies the Outer memory attributes.

The possible values of this field are:
- 0b0000  Device memory.
- 0b00RW  Normal memory, Outer Write-Through transient (RW!='00').
- 0b0100  Normal memory, Outer Non-cacheable.
- 0b01RW  Normal memory, Outer Write-Back Transient (RW!='00').
- 0b10RW  Normal memory, Outer Write-Through Non-transient.
- 0b11RW  Normal memory, Outer Write-Back Non-transient.

R and W specify the outer read and write allocation policy: 0 = do not allocate, 1 = allocate.

Device, bits [3:2], when $\text{Outer} = '0000'$

Device attributes. Specifies the memory attributes for Device.

The possible values of this field are:
- 0b00  Device-nGnRnE.
- 0b01  Device-nGnRE.
- 0b10  Device-nGRE.
- 0b11  Device-GRE.

Bits [1:0], when $\text{Outer} = '0000'$

Reserved, RES0.

Inner, bits [3:0], when $\text{Outer} \neq '0000'$

Inner attributes. Specifies the Inner memory attributes.

The possible values of this field are:
- 0b0000  UNPREDICTABLE.
0b00RW  Normal memory, Inner Write-Through Transient (RW!='00').
0b0100  Normal memory, Inner Non-cacheable.
0b01RW  Normal memory, Inner Write-Back Transient (RW!='00').
0b10RW  Normal memory, Inner Write-Through Non-transient.
0b11RW  Normal memory, Inner Write-Back Non-transient.

R and W specify the inner read and write allocation policy: 0 = do not allocate, 1 = allocate.
D1.2.145   MMFAR, MemManage Fault Address Register

The MMFAR characteristics are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Purpose</strong></td>
<td>Shows the address of the memory location that caused an MPU fault.</td>
</tr>
<tr>
<td><strong>Usage constraints</strong></td>
<td>Privileged access permitted only. Unprivileged accesses generate a BusFault.</td>
</tr>
<tr>
<td><strong>Configurations</strong></td>
<td>Present only if the Main Extension is implemented.</td>
</tr>
<tr>
<td></td>
<td>This register is RES0 if the Main Extension is not implemented.</td>
</tr>
<tr>
<td><strong>Attributes</strong></td>
<td>32-bit read/write register located at 0xE000ED34.</td>
</tr>
<tr>
<td></td>
<td>Secure software can access the Non-secure view of this register via MMFAR_NS located at 0xE002ED34. The location 0xE002ED34 is RES0 to software executing in Non-secure state and the debugger.</td>
</tr>
<tr>
<td></td>
<td>This register is banked between Security states.</td>
</tr>
</tbody>
</table>

Field descriptions

The MMFAR bit assignments are:

```
+-----------------+------------------+
|    31            |      0           |
| ADDRESS          |                  |
```

ADDRESS, bits [31:0]

Data address for a MemManage fault. This register is updated with the address of a location that produced a MemManage fault. The MMFSR shows the cause of the fault, and whether this field is valid. This field is valid only when MMFSR.MMARVALID is set, otherwise it is UNKNOWN.

In implementations without unique BFAR and MMFAR registers, the value of this register is UNKNOWN if BFSR.BFARVALID is set.

This field resets to an UNKNOWN value on a Warm reset.
D1.2.146 MMFSR, MemManage Fault Status Register

The MMFSR characteristics are:

**Purpose**
Shows the status of MPU faults.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
- If the Main Extension is implemented, this register is word, halfword, and byte accessible.
- If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
- 8-bit read/write-one-to-clear register located at 0xE000ED28.
- Secure software can access the Non-secure view of this register via MMFSR_NS located at 0xE002ED28. The location 0xE002ED28 is RES0 to software executing in Non-secure state and the debugger.
- This register is banked between Security states.
- This register is part of CFSR.

**Field descriptions**
The MMFSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The possible values of this bit are:</td>
</tr>
<tr>
<td>0</td>
<td>MMFAR content not valid.</td>
</tr>
<tr>
<td>1</td>
<td>MMFAR content valid.</td>
</tr>
<tr>
<td></td>
<td>This bit resets to zero on a Warm reset.</td>
</tr>
<tr>
<td>6</td>
<td><strong>Reserved, RES0.</strong></td>
</tr>
<tr>
<td></td>
<td>The possible values of this bit are:</td>
</tr>
<tr>
<td>0</td>
<td>No MemManage occurred.</td>
</tr>
<tr>
<td>1</td>
<td>MemManage occurred.</td>
</tr>
<tr>
<td></td>
<td>This bit resets to zero on a Warm reset.</td>
</tr>
<tr>
<td></td>
<td>The possible values of this bit are:</td>
</tr>
<tr>
<td>0</td>
<td>No derived MemManage occurred.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
1 Derived MemManage occurred during exception entry.
This bit resets to zero on a Warm reset.

**MUNSTKERR, bit [3]**
MemManage unstacking error flag. Records whether a derived MemManage fault occurred during exception return unstacking.
The possible values of this bit are:
0 No derived MemManage fault occurred.
1 Derived MemManage fault occurred during exception return.
This bit resets to zero on a Warm reset.

**Bit [2]**
Reserved, RES0.

**DACCVIOL, bit [1]**
Data access violation flag. Records whether a data access violation has occurred.
The possible values of this bit are:
0 No MemManage fault on data access has occurred.
1 MemManage fault on data access has occurred.
A DACCVIOL will be accompanied by an MMFAR update.
This bit resets to zero on a Warm reset.

**IACCVIOL, bit [0]**
Instruction access violation. Records whether an instruction related memory access violation has occurred.
The possible values of this bit are:
0 No MemManage fault on instruction access has occurred.
1 MemManage fault on instruction access has occurred.
An IACCVIOL is only recorded if a faulted instruction is executed.
This bit resets to zero on a Warm reset.
D1.2.147 MPU_CTRL, MPU Control Register

The MPU_CTRL characteristics are:

**Purpose**
Enables the MPU and, when the MPU is enabled, controls whether the default memory map is enabled as a background region for privileged accesses, and whether the MPU is enabled for HardFaults, NMIs, and exception handlers when FAULTMASK is set to 1.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000ED94.
Secure software can access the Non-secure view of this register via MPU_CTRL_NS located at 0xE002ED94. The location 0xE002ED94 is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.

**Field descriptions**
The MPU_CTRL bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:3</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>32</td>
<td>PRIVDEFENA</td>
</tr>
<tr>
<td>31</td>
<td>HFNMIENA</td>
</tr>
<tr>
<td>30</td>
<td>ENABLE</td>
</tr>
</tbody>
</table>

**Bits [31:3]**
Reserved, RES0.

**PRIVDEFENA, bit [2]**
Privileged default enable. Controls whether the default memory map is enabled for privileged software.
The possible values of this bit are:
0 Use of default memory map disabled.
1 Use of default memory map enabled for privilege code.
When the ENABLE bit is set to 0, the PE ignores the PRIVDEFENA bit. If no regions are enabled and the PRIVDEFENA and ENABLE bits are set to 1, only privileged code can execute from the system address map. If no MPU regions are implemented this bit is RES0.
This bit resets to zero on a Warm reset.

**HFNMIENA, bit [1]**
HardFault, NMI enable. Controls whether handlers executing with priority less than 0 access memory with the MPU enabled or disabled. This applies to HardFaults, NMIs, and exception handlers when FAULTMASK is set to 1.
The possible values of this bit are:
0 MPU disabled for these handlers.
1 MPU enabled for these handlers.
If HFNMIENA is set to 1 when ENABLE is set to 0, behavior is UNPREDICTABLE. If no MPU regions are implemented this bit is RES0.
This bit resets to zero on a Warm reset.
ENABLE, bit [0]

Enable. Enables the MPU.

The possible values of this bit are:

0  The MPU is disabled.
1  The MPU is enabled.

Disabling the MPU, by setting the ENABLE bit to 0, means that privileged and unprivileged accesses use the default memory map. If no MPU regions are implemented this bit is RES0. This bit resets to zero on a Warm reset.
D1.2.148  MPU_MAIR0, MPU Memory Attribute Indirection Register 0

The MPU_MAIR0 characteristics are:

**Purpose**
Along with MPU_MAIR1, provides the memory attribute encodings corresponding to the AttrIndx values.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000EDC0.

Secure software can access the Non-secure view of this register via MPU_MAIR0_NS located at 0xE002EDC0. The location 0xE002EDC0 is RES0 to software executing in Non-secure state and the debugger.

This register is banked between Security states.

**Preface**
This register is RES0 if no MPU regions are implemented in the corresponding Security state.

**Field descriptions**
The MPU_MAIR0 bit assignments are:

```
  31  24  23  16  15  8  7  0
  ────┬───┬───┬───┬───┐
  │ Attr3 │ Attr2 │ Attr1 │ Attr0 │
  └──────┴──────┴──────┴──────┘
```

**Attrm**, bits [8m+7:8m], for m = 0 to 3
Attribute m. Memory attribute encoding for MPU regions with an AttrIndx of m.
The possible values of this field are:
- **All**
  See MAIR_ATTR for encoding.
This field resets to an UNKNOWN value on a Warm reset.
D1.2.149 MPU_MAIR1, MPU Memory Attribute Indirection Register 1

The MPU_MAIR1 characteristics are:

**Purpose**
Along with MPU_MAIR0, provides the memory attribute encodings corresponding to the AttrIndx values.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000EDC4.
Secure software can access the Non-secure view of this register via MPU_MAIR1_NS located at 0xE002EDC4. The location 0xE002EDC4 is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.

**Preface**
This register is RES0 if no MPU regions are implemented in the corresponding Security state.

**Field descriptions**
The MPU_MAIR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24-23</th>
<th>16-15</th>
<th>8-7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Atr7</td>
<td>Atr6</td>
<td>Atr5</td>
<td>Atr4</td>
<td></td>
</tr>
</tbody>
</table>

**Attrm, bits [8(m-4)+7:8(m-4)], for m = 4 to 7**
Attribute m. Memory attribute encoding for MPU regions with an AttrIndx of m.
The possible values of this field are:

- **All**
  
  See MAIR_ATTR for encoding.

  This field resets to an UNKNOWN value on a Warm reset.
D1.2.150 MPU_RBAR, MPU Region Base Address Register

The MPU_RBAR characteristics are:

**Purpose**
Provides indirect read and write access to the base address of the currently selected MPU region for the selected Security state.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000ED9C.

Secure software can access the Non-secure view of this register via MPU_RBAR_NS located at 0xE002ED9C. The location 0xE002ED9C is RES0 to software executing in Non-secure state and the debugger.

This register is banked between Security states.

**Preface**
This register provides access to the configuration of the MPU region selected by MPU_RNR_REGION for the appropriate Security state. The field descriptions apply to the currently selected region.

**Field descriptions**
The MPU_RBAR bit assignments are:

![Bit assignments diagram](image)

**BASE, bits [31:5]**
Base address. Contains bits [31:5] of the lower inclusive limit of the selected MPU memory region. This value is zero extended to provide the base address to be checked against.

This field resets to an UNKNOWN value on a Warm reset.

**SH, bits [4:3]**
Shareability. Defines the Shareability domain of this region for Normal memory.

The possible values of this field are:
- **0b00**: Non-shareable.
- **0b10**: Outer Shareable.
- **0b11**: Inner Shareable.

All other values are reserved.

For any type of Device memory, the value of this field is ignored.

This field resets to an UNKNOWN value on a Warm reset.

**AP[2:1], bits [2:1]**
Access permissions. Defines the access permissions for this region.

The possible values of this field are:
- **0b00**: Read/write by privileged code only.
- **0b01**: Read/write by any privilege level.
- **0b10**: Read-only by privileged code only.
- **0b11**: Read-only by any privilege level.
This field resets to an UNKNOWN value on a Warm reset.

**XN, bit [0]**

Execute Never. Defines whether code can be executed from this region.

The possible values of this bit are:

0  Execution only permitted if read permitted.
1  Execution not permitted.

This bit resets to an UNKNOWN value on a Warm reset.
D1.2.151 MPU_RBAR_A<n>, MPU Region Base Address Register Alias, n = 1 - 3

The MPU_RBAR_A<n> characteristics are:

**Purpose**
Provides indirect read and write access to the base address of the MPU region selected by MPU_RNR[7:2]:\(n[1:0]\) for the selected Security state.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read/write register located at \(0xE000EDA4 + 8(n-1)\).
Secure software can access the Non-secure view of this register via MPU_RBAR_A<n>_NS located at \(0xE002EDA4 + 8(n-1)\). The location \(0xE002EDA4 + 8(n-1)\) is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.

**Preface**
This register is an alias of the MPU_RBAR register and provides access to the configuration of the MPU region selected by MPU_RNR.REGION had REGION[1:0] been set to \(n[1:0]\).

**Field descriptions**
The MPU_RBAR_A<n> bit assignments are:

**BASE, bits [31:5]**
Base address. Contains bits [31:5] of the lower inclusive limit of the selected MPU memory region.
This value is zero extended to provide the base address to be checked against.
This field resets to an UNKNOWN value on a Warm reset.

**SH, bits [4:3]**
Shareability. Defines the Shareability domain of this region for Normal memory.
The possible values of this field are:
- \(0b00\): Non-shareable.
- \(0b10\): Outer Shareable.
- \(0b11\): Inner Shareable.
All other values are reserved.
For any type of Device memory, the value of this field is ignored.
This field resets to an UNKNOWN value on a Warm reset.

**AP[2:1], bits [2:1]**
Access permissions. Defines the access permissions for this region.
The possible values of this field are:
- \(0b00\): Read/write by privileged code only.
- \(0b01\): Read/write by any privilege level.
- \(0b10\): Read-only by privileged code only.
0b11 Read-only by any privilege level.
This field resets to an UNKNOWN value on a Warm reset.

XN, bit [0]
Execute Never. Defines whether code can be executed from this region.
The possible values of this bit are:
0 Execution only permitted if read permitted.
1 Execution not permitted.
This bit resets to an UNKNOWN value on a Warm reset.
D1.2.152 MPU_RLAR, MPU Region Limit Address Register

The MPU_RLAR characteristics are:

**Purpose**  
Provides indirect read and write access to the limit address of the currently selected MPU region for the selected Security state.

**Usage constraints**  
Privileged access permitted only. Unprivileged accesses generate a BusFault.  
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**  
This register is always implemented.

**Attributes**  
32-bit read/write register located at 0xE000EDA0.  
Secure software can access the Non-secure view of this register via MPU_RLAR_NS located at 0xE002EDA0. The location 0xE002EDA0 is RES0 to software executing in Non-secure state and the debugger.  
This register is banked between Security states.

**Preface**  
This register provides access to the configuration of the MPU region selected by MPU_RNR.REGION for the appropriate Security state. The field descriptions apply to the currently selected region.

**Field descriptions**  
The MPU_RLAR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31:5 | LIMIT, bits 31:5  
Limit address. Contains bits [31:5] of the upper inclusive limit of the selected MPU memory region.  
This value is postfixed with 0x1F to provide the limit address to be checked against.  
This field resets to an UNKNOWN value on a Warm reset. |
| 4 | Bit [4]  
Reserved, RES0. |
| 3:1 | AttrIndx, bits 3:1  
Attribute index. Associates a set of attributes in the MPU_MAIR0 and MPU_MAIR1 fields.  
This field resets to an UNKNOWN value on a Warm reset. |
| 0 | EN, bit [0]  
Enable. Region enable.  
The possible values of this bit are:  
0 Region disabled.  
1 Region enabled.  
This bit resets to zero on a Warm reset. |
D1.2.153 MPU_RLAR_A<n>, MPU Region Limit Address Register Alias, n = 1 - 3

The MPU_RLAR_A<n> characteristics are:

**Purpose**
Provides indirect read and write access to the limit address of the currently selected MPU region selected by MPU_RNR[7:2]:n[1:0]) for the selected Security state.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read/write register located at 0xE000EDA8 + 8(n-1).
Secure software can access the Non-secure view of this register via MPU_RLAR_A<n>_NS located at 0xE002EDA8 + 8(n-1). The location 0xE002EDA8 + 8(n-1) is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.

**Preface**
This register is an alias of the MPU_RLAR register and provides access to the configuration of the MPU region selected by MPU_RNR.REGION had REGION[1:0] been set to n[1:0].

**Field descriptions**
The MPU_RLAR_A<n> bit assignments are:

![Bit assignment diagram]

**LIMIT, bits [31:5]**
Limit address. Contains bits [31:5] of the upper inclusive limit of the selected MPU memory region. This value is postfixed with 0x1F to provide the limit address to be checked against.

This field resets to an UNKNOWN value on a Warm reset.

**Bit [4]**
Reserved, RES0.

**AttrIndx, bits [3:1]**
Attribute index. Associates a set of attributes in the MPU_MAIR0 and MPU_MAIR1 fields.
This field resets to an UNKNOWN value on a Warm reset.

**EN, bit [0]**
Enable. Region enable.
The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Region disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Region enabled.</td>
</tr>
</tbody>
</table>

This bit resets to zero on a Warm reset.
D1.2.154 MPU_RNR, MPU Region Number Register

The MPU_RNR characteristics are:

**Purpose**
Selects the region currently accessed by MPU_RBAR and MPU_RLAR.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000ED98.
Secure software can access the Non-secure view of this register via MPU_RNR_NS located at 0xE002ED98. The location 0xE002ED98 is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.

**Field descriptions**
The MPU_RNR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
</tr>
<tr>
<td>8-7</td>
<td>REGION</td>
</tr>
</tbody>
</table>

**Bits [31:8]**
Reserved, RES0.

**REGION, bits [7:0]**
Region number. Indicates the memory region accessed by MPU_RBAR and MPU_RLAR.
If no MPU regions are implemented, this field is RES0. Writing a value corresponding to an unimplemented region is CONSTRAINED UNPREDICTABLE.
The field resets to a UNKNOWN value on a Warm reset.
D1.2.155 MPU_TYPE, MPU Type Register

The MPU_TYPE characteristics are:

**Purpose**
The MPU Type Register indicates how many regions the MPU for the selected Security state supports.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read-only register located at 0xE000ED90.
Secure software can access the Non-secure view of this register via MPU_TYPE_NS located at 0xE002ED90. The location 0xE002ED90 is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.

**Field descriptions**
The MPU_TYPE bit assignments are:

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Bit Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-16</td>
<td>RESERVED</td>
<td>RES0</td>
</tr>
<tr>
<td>15-8</td>
<td>DREGION</td>
<td>Data regions. Number of regions supported by the MPU.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If this field reads-as-zero, the PE does not implement an MPU for the selected Security state.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This field reads as an IMPLEMENTATION DEFINED value.</td>
</tr>
<tr>
<td>7-1</td>
<td>RESERVED</td>
<td>RES0</td>
</tr>
<tr>
<td>0</td>
<td>SEPARATE</td>
<td>Separate. Indicates support for separate instructions and data address regions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ARMv8-M only supports unified MPU regions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This bit reads as zero.</td>
</tr>
</tbody>
</table>

Bits [31:16]Reserved, RES0.

DREGION, bits [15:8]
Data regions. Number of regions supported by the MPU.
If this field reads-as-zero, the PE does not implement an MPU for the selected Security state.
This field reads as an IMPLEMENTATION DEFINED value.

Bits [7:1]Reserved, RES0.

SEPARATE, bit [0]
Separate. Indicates support for separate instructions and data address regions.
ARMv8-M only supports unified MPU regions.
This bit reads as zero.
D1.2.156 MSPLIM, Main Stack Pointer Limit Register

The MSPLIM characteristics are:

**Purpose**

Holds the lower limit of the Main stack pointer.

**Usage constraints**

Privileged access only. Unprivileged access is RAZ/WI.

**Configurations**

This register is always implemented.

**Attributes**

32-bit read/write special-purpose register.

This register is banked between Security states.

**Field descriptions**

The MSPLIM bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| LIMIT |

**LIMIT, bits [31:3]**

Stack limit. Bits [31:3] of the Main stack pointer limit address 'FTSSS.

Many instructions and exception entry will generate an exception if the appropriate stack pointer would be updated to a value lower than this limit. If the Main Extension is not implemented, the Non-secure MSPLIM is RAZ/WI.

This field resets to zero on a Warm reset.

**Bits [2:0]**

Reserved, RES0.
D1.2.157  MVFR0, Media and VFP Feature Register 0

The MVFR0 characteristics are:

**Purpose**
Describes the features provided by the Floating-point Extension.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Floating-point Extension is implemented.
This register is RES0 if the Floating-point Extension is not implemented.

**Attributes**
32-bit read-only register located at 0xE000EF40.
Secure software can access the Non-secure view of this register via MVFR0_NS located at 0xE002EF40. The location 0xE002EF40 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Preface**
When floating-point is not implemented this register reads as 0x00000000.
Where single-precision only floating-point is supported this register reads as 0x10110021.
Where single and double-precision floating-point are supported this register reads as 0x10110221.

**Field descriptions**

The MVFR0 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 28 27</td>
<td>24 23 20 19</td>
</tr>
<tr>
<td>FPRound</td>
<td>RES0</td>
</tr>
</tbody>
</table>

**FPRound, bits [31:28]**
Floating-point rounding modes. Indicates the rounding modes supported by the FP Extension.
The possible values of this field are:
0b0001  All rounding modes supported.
All other values are reserved.
This field reads as 0b0001.

**Bits [27:24]**
Reserved, RES0.

**FPSqrt, bits [23:20]**
Floating-point square root. Indicates the support for FP square root operations.
The possible values of this field are:
0b0001  Supported.
All other values are reserved.
This field reads as 0b0001.

**FPDivide, bits [19:16]**
Floating-point divide. Indicates the support for FP divide operations.
The possible values of this field are:
0b0001  Supported.
All other values are reserved.
This field reads as \(0b0001\).

Bits [15:12]
Reserved, RES0.

FPDP, bits [11:8]
Floating-point double-precision. Indicates support for FP double-precision operations.
The possible values of this field are:
\(0b0000\) Not supported.
\(0b0010\) Supported.
All other values are reserved.
This field reads as an IMPLEMENTATION DEFINED value.

FPSP, bits [7:4]
Floating-point single-precision. Indicates support for FP single-precision operations.
The possible values of this field are:
\(0b0010\) Supported.
All other values are reserved.
This field reads as \(0b0010\).

SIMDReg, bits [3:0]
SIMD registers. Indicates size of FP register file.
The possible values of this field are:
\(0b0001\) 16 × 64-bit registers.
All other values are reserved.
This field reads as \(0b0001\).
D1.2.158 MVFR1, Media and VFP Feature Register 1

The MVFR1 characteristics are:

**Purpose**
Describes the features provided by the Floating-point Extension.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Floating-point Extension is implemented.

This register is RES0 if the Floating-point Extension is not implemented.

**Attributes**
32-bit read-only register located at 0xE000EF44.

Secure software can access the Non-secure view of this register via MVFR1_NS located at 0xE002EF44. The location 0xE002EF44 is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

**Preface**
When floating-point is not implemented this register reads as 0x00000000.

Where single-precision only floating-point is supported this register reads as 0x11000011.

Where single and double-precision floating-point are supported this register reads as 0x12000011.

**Field descriptions**
The MVFR1 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>28-27</th>
<th>24-23</th>
<th>8-7</th>
<th>4-3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>FMAC</td>
<td>FPHP</td>
<td>RES0</td>
<td>FPDaN</td>
<td>FFDZ</td>
<td></td>
</tr>
</tbody>
</table>

**FMAC, bits [31:28]**
Fused multiply accumulate. Indicates whether the FP Extension implements the fused multiply accumulate instructions.

The possible values of this field are:

0b0001 Implemented.

All other values are reserved.

This field reads as 0b0001.

**FPHP, bits [27:24]**
Floating-point half-precision. Indicates whether the FP Extension implements half-precision FP conversion instructions.

The possible values of this field are:

0b0001 Half-precision to single-precision implemented.

0b0010 Half-precision to single and double-precision implemented.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

**Bits [23:8]**
Reserved, RES0.
FPDNaN, bits [7:4]

Floating-point default NaN. Indicates whether the FP hardware implementation supports NaN propagation.

The possible values of this field are:

0b0001  Propagation of NaN values supported.

All other values are reserved.

This field reads as 0b0001.

FPFlZ, bits [3:0]

Floating-point flush-to-zero. Indicates whether subnormals are always flushed-to-zero.

The possible values of this field are:

0b0001  Full denormalized numbers arithmetic supported.

All other values are reserved.

This field reads as 0b0001.
D1.2.159 MVFR2, Media and VFP Feature Register 2

The MVFR2 characteristics are:

**Purpose**
Describes the features provided by the Floating-point Extension.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Floating-point Extension is implemented.
This register is RES0 if the Floating-point Extension is not implemented.

**Attributes**
32-bit read-only register located at 0xE000EF48.
Secure software can access the Non-secure view of this register via MVFR2_NS located at 0xE002EF48. The location 0xE002EF48 is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Preface**
When floating-point is not implemented this register reads as 0x00000000.
When floating-point is implemented this register reads as 0x00000040.

**Field descriptions**
The MVFR2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>

<td></td>
<td></td>
<td></td>
<td></td>
<td>FPMisc</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>RES0</td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**
Reserved, RES0.

**FPMisc, bits [7:4]**
Floating-point miscellaneous. Indicates support for miscellaneous FP features.
The possible values of this field are:
0b0100 Selection, directed conversion to integer, VMINNM and VMAXNM supported.
All other values are reserved.
This field reads as 0b0100.

**Bits [3:0]**
Reserved, RES0.
D1.2.160 NSACR, Non-secure Access Control Register

The NSACR characteristics are:

**Purpose**
Defines the Non-secure access permissions for both the FP Extension and coprocessors CP0 to CP7.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented. This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read/write register located at 0xE000ED8C. This register is RAZ/WI when accessed as Non-secure. This register is not banked between Security states.

**Field descriptions**
The NSACR bit assignments are:

```
   31 12 11  10  9  8  7  6  5  4  3  2  1  0
RES0 RES0 CP11 CP10 CP7 CP6 CP5 CP4 CP3 CP2 CP1 CP0
```

**Bits [31:12]**
Reserved, RES0.

**CP11, bit [11]**
CP11 access. Enables Non-secure access to the Floating-point Extension. Programming with a different value than that used for CP10 is UNPREDICTABLE. If the Floating-point Extension is not implemented, this bit is RAZ/WI. This bit resets to an UNKNOWN value on a Warm reset.

**CP10, bit [10]**
CP10 access. Enables Non-secure access to the Floating-point Extension. The possible values of this bit are:

- 0 Non-secure accesses to the Floating-point Extension generate a NOCP UsageFault.
- 1 Non-secure access to the Floating-point Extension permitted.

If the Floating-point Extension is not implemented, this bit is RAZ/WI. This bit resets to an UNKNOWN value on a Warm reset.

**Bits [9:8]**
Reserved, RES0.

**CPm, bit [m], for m = 0 to 7**
CPm access. Enables Non-secure access to coprocessor CPm. The possible values of this field are:

- 0 Non-secure accesses to this coprocessor generate a NOCP UsageFault.
- 1 Non-secure access to this coprocessor permitted.
A CP\(m\) bit is RAZ/WI if CP\(m\) is:
- Not implemented.
- Not enabled for the security state in which the PE is executing.
This field resets to an UNKNOWN value on a Warm reset.
D1.2.161  NVIC_IABR<n>, Interrupt Active Bit Register, n = 0 - 15

The NVIC_IABR<n> characteristics are:

**Purpose**
For each group of 32 interrupts, shows the active state of each interrupt.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read-only register located at 0xE000E300 + 4n.
Secure software can access the Non-secure view of this register via NVIC_IABR<n>_NS located at 0xE002E300 + 4n. The location 0xE002E300 + 4n is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The NVIC_IABR<n> bit assignments are:

![ACTIVE bit assignment diagram]

**ACTIVE, bits [31:0]**
Active state. For ACTIVE[m] in NVIC_IABRn, indicates the active state for interrupt 32n+m.
The possible values of each bit are:

- **0**: Interrupt not active.
- **1**: Interrupt is active.

Bits corresponding to unimplemented interrupts are RES0. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.
This field resets to zero on a Warm reset.
D1.2.162 NVIC_ICER<n>, Interrupt Clear Enable Register, n = 0 - 15

The NVIC_ICER<n> characteristics are:

**Purpose**
Clears or reads the enabled state of each group of 32 interrupts.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write-one-to-clear register located at 0xE000E180 + 4n.
Secure software can access the Non-secure view of this register via NVIC_ICER<n>_NS located at 0xE002E180 + 4n. The location 0xE002E180 + 4n is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The NVIC_ICER<n> bit assignments are:

```
<table>

</tr>
</tbody>
</table>
```

**CLRENA, bits [31:0], on a write**
Clear enable. For CLRENA[m] in NVIC_ICER<n>, allows interrupt 32n + m to be disabled.
The possible values of each bit are:

0  No effect.
1  Disable interrupt 32n + m.

Bits corresponding to unimplemented interrupts are RES0. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

**CLRENA, bits [31:0], on a read**
Clear enable. For CLRENA[m] in NVIC_ICER<n>, indicates whether interrupt 32n + m is enabled.
The possible values of each bit are:

0  Interrupt 32n + m disabled.
1  Interrupt 32n + m enabled.

Bits corresponding to unimplemented interrupts are RES0. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.
This field resets to zero on a Warm reset.
D1.2.163 NVIC_ICPR<n>, Interrupt Clear Pending Register, n = 0 - 15

The NVIC_ICPR<n> characteristics are:

**Purpose**
Clears or reads the pending state of each group of 32 interrupts.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write-one-to-clear register located at 0xE000E280 + 4n.
Secure software can access the Non-secure view of this register via NVIC_ICPR<n>_NS located at 0xE002E280 + 4n. The location 0xE002E280 + 4n is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The NVIC_ICPR<n> bit assignments are:

![CLRPEND bit assignments]

**CLRPEND, bits [31:0], on a write**
Clear pending. For CLRPEND[m] in NVIC_ICPR<n>, allows interrupt 32n + m to be unpended.
The possible values of each bit are:

<table>
<thead>
<tr>
<th>0</th>
<th>No effect.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Clear pending state of interrupt 32n + m.</td>
</tr>
</tbody>
</table>

Bits corresponding to unimplemented interrupts are RES0. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

**CLRPEND, bits [31:0], on a read**
Clear pending. For CLRPEND[m] in NVIC_ICPR<n>, indicates whether interrupt 32n + m is pending.
The possible values of each bit are:

<table>
<thead>
<tr>
<th>0</th>
<th>Interrupt 32n + m is not pending.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Interrupt 32n + m is pending.</td>
</tr>
</tbody>
</table>

Bits corresponding to unimplemented interrupts are RES0. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.
D1.2.164 NVIC_IPR<n>, Interrupt Priority Register, n = 0 - 123

The NVIC_IPR<n> characteristics are:

**Purpose**
Sets or reads interrupt priorities.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
If the Main Extension is implemented, this register is word, halfword, and byte accessible.
If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at $0xE000E400 + 4n$.
Secure software can access the Non-secure view of this register via NVIC_IPR<n>_NS located at $0xE002E400 + 4n$. The location $0xE002E400 + 4n$ is RES0 to software executing in Non-secure state and the debugger.
This register is not banked between Security states.

**Field descriptions**
The NVIC_IPR<n> bit assignments are:

```
+---+---+---+---+---+---+---+---+
|   |PRI_N2|PRI_N1|PRI_N0|PRI_N3|   |
+---+---+---+---+---+---+---+---+
```

PRI_Nm, bits [8m+7:8m], for m = 0 to 3
Priority 'N'+m. For register NVIC_IPRn, this field indicates and allows modification of the priority of interrupt number 4n+m, or is RES0 if the PE does not implement this interrupt.
If the PE implements less than 8 bits of priority, then the least significant bits of this field are RES0.
If interrupt number 4n+3 targets Secure state, this field is RAZ/WI from Non-secure.
This field resets to zero on a Warm reset.
D1.2.165 NVIC_ISER<n>, Interrupt Set Enable Register, n = 0 - 15

The NVIC_ISER<n> characteristics are:

**Purpose**  
Enables or reads the enabled state of each group of 32 interrupts.

**Usage constraints**  
Privileged access permitted only. Unprivileged accesses generate a BusFault.  
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**  
This register is always implemented.

**Attributes**  
32-bit read/write-one-to-set register located at 0xE000E100 + 4n.  
Secure software can access the Non-secure view of this register via NVIC_ISER<n>_NS located at 0xE002E100 + 4n. The location 0xE002E100 + 4n is RES0 to software executing in Non-secure state and the debugger.  
This register is not banked between Security states.

**Field descriptions**

The NVIC_ISER<n> bit assignments are:

```
+-------------------+---
|                   | 31| 0 |
+-------------------+---
| SETENA            |   |
+-------------------+---
```

**SETENA, bits [31:0], on a write**  
Set enable. For SETENA[m] in NVIC_ISERn, allows interrupt 32n + m to be set enabled.  
The possible values of each bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No effect.</td>
</tr>
<tr>
<td>1</td>
<td>Enable interrupt 32n + m.</td>
</tr>
</tbody>
</table>

Bits corresponding to unimplemented interrupts are RES0. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.  
This field resets to zero on a Warm reset.

**SETENA, bits [31:0], on a read**  
Set enable. For SETENA[m] in NVIC_ISERn, indicates whether interrupt 32n + m is enabled.  
The possible values of each bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interrupt 32n + m disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Interrupt 32n + m enabled.</td>
</tr>
</tbody>
</table>

Bits corresponding to unimplemented interrupts are RES0. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.  
This field resets to zero on a Warm reset.
D1.2.166   NVIC_ISPR<n>, Interrupt Set Pending Register, n = 0 - 15

The NVIC_ISPR<n> characteristics are:

**Purpose**
Enables or reads the pending state of each group of 32 interrupts.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write-one-to-set register located at 0xE000E200 + 4n.

Secure software can access the Non-secure view of this register via NVIC_ISPR<n>_NS located at 0xE002E200 + 4n. The location 0xE002E200 + 4n is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

**Field descriptions**

The NVIC_ISPR<n> bit assignments are:

</tbody>
</table>

This field resets to zero on a Warm reset.

SETPEND, bits [31:0], on a write
Set pending. For SETPEND[m] in NVIC_ISPRn, allows interrupt 32n + m to be set pending.
The possible values of each bit are:
0 No effect.
1 Pend interrupt 32n + m.

Bits corresponding to unimplemented interrupts are RES0. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

This field is write-one-to-set. Writes of zero are ignored.

This field resets to zero on a Warm reset.

SETPEND, bits [31:0], on a read
Set pending. For SETPEND[m] in NVIC_ISPRn, indicates whether interrupt 32n + m is pending.
The possible values of each bit are:
0 Interrupt 32n + m is not pending.
1 Interrupt 32n + m pending.

Bits corresponding to unimplemented interrupts are RES0. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

This field resets to zero on a Warm reset.
D1.2.167  NVIC_ITNS<n>, Interrupt Target Non-secure Register, n = 0 - 15

The NVIC_ITNS<n> characteristics are:

**Purpose**
For each group of 32 interrupts, determines whether each interrupt targets Non-secure or Secure state.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000E380 + 4n.
This register is RAZ/WI when accessed as Non-secure.
This register is not banked between Security states.

**Field descriptions**

The NVIC_ITNS<n> bit assignments are:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
```

**ITNS, bits [31:0]**

Interrupt Targets Non-secure. For ITNS[m] in NVIC_ITNSn, this field indicates and allows modification of the target Security state for interrupt 32n+m.

The possible values of each bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interrupt targets Secure state.</td>
</tr>
<tr>
<td>1</td>
<td>Interrupt targets Non-secure state.</td>
</tr>
</tbody>
</table>

Bits corresponding to unimplemented interrupts are RES0. It is IMPLEMENTATION DEFINED whether individual bits are WI and have an IMPLEMENTATION DEFINED constant value. Where an interrupt is configured to target Secure state, accesses to the associated fields in Non-secure versions of the NVIC_IABR, NVIC_ICER, NVIC_ISER, NVIC_ICPR, NVIC_IPR and NVIC_ISPR are RAZ/WI. This field resets to zero on a Warm reset.
D1.2.168  PC, Program Counter

The PC characteristics are:

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Holds the current program counter value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage constraints</td>
<td>Both privileged and unprivileged access permitted.</td>
</tr>
<tr>
<td>Configurations</td>
<td>This register is always implemented.</td>
</tr>
<tr>
<td>Attributes</td>
<td>32-bit read/write special-purpose register.</td>
</tr>
<tr>
<td></td>
<td>This register is not banked between Security states.</td>
</tr>
</tbody>
</table>

Field descriptions

The PC bit assignments are:

```
VALUE, bits [31:0]
```

Program counter. Holds the address of the current instruction plus four.
Software can refer to PC as R15.
This field resets to an UNKNOWN value on a Warm reset.
D1.2.169   PRIMASK, Exception Mask Register

The PRIMASK characteristics are:

**Purpose**  Provides access to the PE PRIMASK register.

**Usage constraints**  Privileged access only. Unprivileged access is RAZ/WI.

**Configurations**  This register is always implemented.

**Attributes**  32-bit read/write special-purpose register.

This register is banked between Security states.

**Field descriptions**

The PRIMASK bit assignments are:

![PRIMASK bit assignments](image)

**Bits [31:1]**

Reserved, RES0.

**PM, bit [0]**

Exception mask register. Setting the Secure PRIMASK to one raises the execution priority to 0. Setting the Non-secure PRIMASK to one raises the execution priority to 0 if AIRCR.PRIS is clear, or 0x80 if AIRCR.PRIS is set.

The possible values of this bit are:

- **0**  No effect on execution priority.
- **1**  Boosts execution priority to either 0 or 0x80.

This bit resets to zero on a Warm reset.
D1.2.170  PSPLIM, Process Stack Pointer Limit Register

The PSPLIM characteristics are:

**Purpose**
Holds the lower limit for the Process stack pointer.

**Usage constraints**
Privileged access only. Unprivileged access is RAZ/WI.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write special-purpose register.
This register is banked between Security states.

**Field descriptions**

The PSPLIM bit assignments are:

```
+---+---+---+---+---+---+
|   |   |   |   | LIMIT |   |
+---+---+---+---+---+---+
```

LIMIT, bits [31:3]
Many instructions and exception entry will generate an exception if the appropriate stack pointer would be updated to a value lower than this limit. If the Main Extension is not implemented, the Non-secure PSPLIM is RAZ/WI.
This field resets to zero on a Warm reset.

Bits [2:0]
Reserved, RES0.
D1.2.171   **R<n>, General-Purpose Register, n = 0 - 12**

The R<n> characteristics are:

**Purpose** General-purpose register.

**Usage constraints** Both privileged and unprivileged accesses are permitted.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations** This register is always implemented.

**Attributes** 32-bit read/write register.

This register is not banked between Security states.

**Field descriptions**

The R<n> bit assignments are:

```
+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+
| 31              | 30              | 29              | 28              | 27              | 0               |
| VALUE           |                  |                  |                  |                  |                  |
```

**VALUE, bits [31:0]**

General purpose register value. ARMv8-M implemented thirteen general-purpose 32-bit registers, R0 to R12.

This field resets to an UNKNOWN value on a Warm reset.
D1.2.172 RETPSR, Combined Exception Return Program Status Registers

The RETPSR characteristics are:

**Purpose**
Value pushed to the stack on exception entry. On exception return this is used to restore the flags and other architectural state. This payload is also used for FNC RETURN stacking, however in this case only some of the fields are used. See FunctionReturn() for details.

**Usage constraints**
None.

**Configurations**
All.

**Attributes**
32-bit payload.

**Field descriptions**

The RETPSR bit assignments are:

When \( \{\text{RETPSR}[26:25], \text{RETPSR}[11:10]\} \neq 0 \):

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 15 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| N  | Z  | C  | V  | Q  | IT | T  | RES0 | GE | IT | SFPA | RES0 | GE | IT | SPREALIGN | Exception |

When \( \{\text{RETPSR}[26:25], \text{RETPSR}[11:10]\} = 0 \):

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 15 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| N  | Z  | C  | V  | Q  | ICI | T  | RES0 | GE | ICI | SFPA | RES0 | GE | ICI | SPREALIGN | Exception |

**N**, bit [31]
Negative flag. Value corresponding to APSR.N.

**Z**, bit [30]
Zero flag. Value corresponding to APSR.Z.

**C**, bit [29]
Carry flag. Value corresponding to APSR.C.

**V**, bit [28]
Overflow flag. Value corresponding to APSR.V.

**Q**, bit [27]
Saturate flag. Value corresponding to APSR.Q.

**T**, bit [24]
T32 state. Value corresponding to EPSR.T.

**Bits [23:21]**
Reserved, RES0.

**SFPA**, bit [20]
Secure floating-point active. Value corresponding to CONTROL.SFPA.

**GE**, bits [19:16]
Greater-than or equal flag. Value corresponding to APSR.GE.
IT, bits [15:10,26:25], when \{RETPSR[26:25], RETPSR[11:10]\} != 0
If-then flags. Value corresponding to EPSR.IT.

ICI, bits [26:25,15:10], when \{RETPSR[26:25], RETPSR[11:10]\} == 0
Interrupt continuation flags. Value corresponding to EPSR.ICI.

SPREALIGN, bit [9]
Stack-pointer re-align. Indicates whether the SP was re-aligned to an 8-byte alignment on exception entry.
The possible values of this bit are:
0 The stack pointer was 8-byte aligned before exception entry began, no special handling is required on exception return.
1 The stack pointer was only 4-byte aligned before exception entry. The exception entry realigned SP to 8-byte alignment by increasing the stack frame size by 4-bytes.

Exception, bits [8:0]
Exception number. Value corresponding to IPSR.Exception.
D1.2.173 SAU_CTRL, SAU Control Register

The SAU_CTRL characteristics are:

**Purpose**
Allows enabling of the Security Attribution Unit.

**Usage constraints**
- Privileged access permitted only. Unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
- 32-bit read/write register located at 0xE000EDD0.
- This register is RAZ/WI when accessed as Non-secure.
- This register is not banked between Security states.

**Preface**
It is IMPLEMENTATION DEFINED whether this register:

- Resets to 0x0 - in this case SAU_REGIONn registers are UNKNOWN at reset.
- Resets to an IMPLEMENTATION DEFINED value.

**Field descriptions**

The SAU_CTRL bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>

<td>Enable. Enables the SAU. The possible values of this bit are: 0: The SAU is disabled. 1: The SAU is enabled. If this register resets to 1, the SAU region registers also reset to an IMPLEMENTATION DEFINED value. This bit resets to an IMPLEMENTATION DEFINED value on a Warm reset.</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>
D1.2.174   **SAU_RBAR, SAU Region Base Address Register**

The SAU_RBAR characteristics are:

**Purpose**
Provides indirect read and write access to the base address of the currently selected SAU region.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000EDDC.
This register is RAZ/WI when accessed as Non-secure.
This register is not banked between Security states.

**Field descriptions**
The SAU_RBAR bit assignments are:

```
+----------+----------+----------+----------+----------+
| 31       | 30       | 29       | 28       | 27       |
| BADDR    | 26       | 25       | 24       | 23       |
| 22       | 21       | 20       | 19       | 18       |
| 17       | 16       | 15       | 14       | 13       |
| 12       | 11       | 10       | 9        | 8        |
| 7        | 6        | 5        | 4        | 3        |
| RES0     | RES0     | RES0     | RES0     | RES0     |
```

**BADDR, bits [31:5]**
Base address. Holds bits [31:5] of the base address for the selected SAU region.
Bits [4:0] of the base address are defined as 0x00.
This field resets to an IMPLEMENTATION DEFINED value on a Warm reset.

**Bits [4:0]**
Reserved, RES0.
D1.2.175   SAU_RLAR, SAU Region Limit Address Register

The SAU_RLAR characteristics are:

**Purpose**  Provides indirect read and write access to the limit address of the currently selected SAU region.

**Usage constraints**  Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**  This register is always implemented.

**Attributes**  32-bit read/write register located at 0xE000EDE0. This register is RAZ/WI when accessed as Non-secure. This register is not banked between Security states.

**Field descriptions**  
The SAU_RLAR bit assignments are:

```
+----------------+-------------------+
| 31             |      24           |
|                 |                  |
| LADDR, bits [31:5] | Bits [4:0]       |
| 31             |      24           |
|                 |                  |
| NSC, bit [1]   |                  |
| 0x0            |                  |
| 531            |                  |
+----------------+-------------------+
```

**LADDR, bits [31:5]**
Limit address. Holds bits [31:5] of the limit address for the selected SAU region. Bits [4:0] of the limit address are defined as 0x1F. This field resets to an IMPLEMENTATION DEFINED value on a Warm reset.

**Bits [4:2]**
Reserved, RES0.

**NSC, bit [1]**
Non-secure callable. Controls whether Non-secure state is permitted to execute an SG instruction from this region. The possible values of this bit are:
0   Region is not Non-secure callable.
1   Region is Non-secure callable.
This bit resets to an IMPLEMENTATION DEFINED value on a Warm reset.

**ENABLE, bit [0]**
Enable. SAU region enable. The possible values of this bit are:
0   SAU region is disabled.
1   SAU region is enabled.
This bit resets to an IMPLEMENTATION DEFINED value on a Warm reset.
D1.2.176 SAU_RNR, SAU Region Number Register

The SAU_RNR characteristics are:

**Purpose**
Selects the region currently accessed by SAU_RBAR and SAU_RLAR.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000EDD8.
This register is RAZ/WI when accessed as Non-secure.
This register is not banked between Security states.

**Field descriptions**

The SAU_RNR bit assignments are:

![SAU_RNR Bit Assignments](image)

- **Bits [31:8]**
  Reserved, RES0.

- **REGION, bits [7:0]**
  Region number. Indicates the SAU region accessed by SAU_RBAR and SAU_RLAR.
  If no SAU regions are implemented, this field is RES0. Writing a value corresponding to an unimplemented region is CONSTRAINED UNPREDICTABLE.
  This field resets to an UNKNOWN value on a Warm reset.
D1.2.177  SAU_TYPE, SAU Type Register

The SAU_TYPE characteristics are:

**Purpose**
Indicates the number of regions implemented by the Security Attribution Unit.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read-only register located at 0xE000EDD4.

This register is RAZ/WI when accessed as Non-secure.

This register is not banked between Security states.

**Field descriptions**

The SAU_TYPE bit assignments are:

![Bit assignments diagram]

**Bits [31:8]**
Reserved, RES0.

**SREGION, bits [7:0]**
SAU regions. The number of implemented SAU regions.
If this field is RAZ, the SAU behaves as follows:

- SAU_CTRL.ENABLE behaves as RAZ/WI.
- It is IMPLEMENTATION DEFINED whether SAU_CTRL.ALLNS behaves as RAO/WI and all attribution is performed by the IDAU.
- SAU_RNR, SAU_RBAR, and SAU_RLAR behave as RAZ/WI.

This field reads as an IMPLEMENTATION DEFINED value.
D1.2.178   SCR, System Control Register

The SCR characteristics are:

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Sets or returns system control data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage constraints</td>
<td>Privileged access permitted only. Unprivileged accesses generate a BusFault.</td>
</tr>
<tr>
<td>This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.</td>
<td></td>
</tr>
<tr>
<td>Configurations</td>
<td>This register is always implemented.</td>
</tr>
<tr>
<td>Attributes</td>
<td>32-bit read/write register located at 0xE000ED10.</td>
</tr>
<tr>
<td>Secure software can access the Non-secure view of this register via SCR_NS located at 0xE002ED10. The location 0xE002ED10 is RES0 to software executing in Non-secure state and the debugger.</td>
<td></td>
</tr>
<tr>
<td>This register is banked between Security states on a bit by bit basis.</td>
<td></td>
</tr>
</tbody>
</table>

Field descriptions

The SCR bit assignments are:

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
RES0 SEVONPEND SLEEPDEEPS SLEEPONEXIT SLEEPDEEP

Bits [31:5]

Reserved, RES0.

SEVONPEND, bit [4]

Send event on pend. Determines whether an interrupt assigned to the same Security state as the SEVONPEND bit transitioning from inactive state to pending state generates a wakeup event.

This bit is banked between Security states.

The possible values of this bit are:

0 Transitions from inactive to pending are not wakeup events.
1 Transitions from inactive to pending are wakeup events.

This bit resets to zero on a Warm reset.

SLEEPDEEPS, bit [3]

Sleep deep secure. This field controls whether the SLEEPDEEP bit is only accessible from the Secure state.

This bit is not banked between Security states.

The possible values of this bit are:

0 The SLEEPDEEP bit accessible from both Security states.
1 The SLEEPDEEP bit behaves as RAZ/WI when accessed from the Non-secure state.

This bit in only accessible from the Secure state, and behaves as RAZ/WI when accessed from the Non-secure state. If a PE does not implement the deep sleep state this bit behaves as RAZ/WI from both Security states.

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

SLEEPDEEP, bit [2]

Sleep deep. Provides a qualifying hint indicating that waking from sleep might take longer. An implementation can use this bit to select between two alternative sleep states.
This bit is not banked between Security states.
The possible values of this bit are:

0  Selected sleep state is not deep sleep.
1  Selected sleep state is deep sleep.

Details of the implemented sleep states, if any, and details of the use of this bit, are
IMPLEMENTATION DEFINED. If the PE does not implement a deep sleep state then this bit can be
RAZ/WI.

This bit resets to zero on a Warm reset.

**SLEEPONEXIT, bit [1]**

Sleep on exit. Determines whether, on an exit from an ISR that returns to the base level of execution
priority, the PE enters a sleep state.

This bit is banked between Security states.
The possible values of this bit are:

0  Enter sleep state disabled.
1  Enter sleep state permitted.

The Secure version of this field is used if the Background state being returned to is the Secure state,
otherwise the Non-secure version is used.

This bit resets to zero on a Warm reset.

**Bit [0]**

Reserved, RES0.
D1.2.179  SFAR, Secure Fault Address Register

The SFAR characteristics are:

**Purpose**  Shows the address of the memory location that caused a Security violation.

**Usage constraints**  Privileged access permitted only. Unprivileged accesses generate a BusFault.
                         This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**  Present only if the Main Extension is implemented.
                     This register is RES0 if the Main Extension is not implemented.

**Attributes**  32-bit read/write register located at 0xE000EDE8.
                 This register is RAZ/WI when accessed as Non-secure.
                 This register is not banked between Security states.

**Field descriptions**

The SFAR bit assignments are:

```
+-----------------+------------------+
|                 | ADDRESS          |
+-----------------+------------------+
| 31              | 0                |
```

**ADDRESS, bits [31:0]**

Address. The address of an access that caused a attribution unit violation. This field is only valid when SFSR.SFARVALID is set. This allows the actual flip flops associated with this register to be shared with other fault address registers. If an implementation chooses to share the storage in this way, care must be taken to not leak Secure address information to the Non-secure state. One way of achieving this is to share the SFAR register with the MMFAR_S register, which is not accessible to the Non-secure state.

This field resets to an UNKNOWN value on a Warm reset.
D1.2.180 SFSR, Secure Fault Status Register

The SFSR characteristics are:

**Purpose**
Provides information about any security related faults.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read/write-one-to-clear register located at 0xE000EDE4.
This register is RAZ/WI when accessed as Non-secure.
This register is not banked between Security states.

**Field descriptions**

The SFSR bit assignments are:

**Bits [31:8]**
Reserved, RES0.

**LSERR, bit [7]**
Lazy state error flag. Sticky flag indicating that an error occurred during lazy state activation or deactivation.

The possible values of this bit are:
- 0: Error has not occurred.
- 1: Error has occurred.

This bit resets to zero on a Warm reset.

**SFARVALID, bit [6]**
Secure fault address valid. This bit is set when the SFAR register contains a valid value. As with similar fields, such as BFSR.BFARVALID and MMFSR.MMARVALID, this bit can be cleared by other exceptions, such as BusFault.

The possible values of this bit are:
- 0: SFAR content not valid.
- 1: SFAR content valid.

This bit resets to zero on a Warm reset.

**LSPERR, bit [5]**
Lazy state preservation error flag. Stick flag indicating that an SAU or IDAU violation occurred during the lazy preservation of floating-point state.

The possible values of this bit are:
- 0: Error has not occurred.
- 1: Error has occurred.

This bit resets to zero on a Warm reset.
INVTRAN, bit [4]
Invalid transition flag. Sticky flag indicating that an exception was raised due to a branch that was not flagged as being domain crossing causing a transition from Secure to Non-secure memory.

The possible values of this bit are:
0 Error has not occurred.
1 Error has occurred.
This bit resets to zero on a Warm reset.

AUVIOL, bit [3]
Attribution unit violation flag.
Sticky flag indicating that an attempt was made to access parts of the address space that are marked as Secure with NS-Req for the transaction set to Non-secure.

This bit is not set if the violation occurred during:
• Lazy state preservation, see LSPERR.
• Vector fetches.

The possible values of this bit are:
0 Error has not occurred.
1 Error has occurred.
This bit resets to zero on a Warm reset.

INVER, bit [2]
Invalid exception return flag. This can be caused by EXC_RETURN.DCRS being set to 0 when returning from an exception in the Non-secure state, or by EXC_RETURN.ES being set to 1 when returning from an exception in the Non-secure state.

The possible values of this bit are:
0 Error has not occurred.
1 Error has occurred.
This bit resets to zero on a Warm reset.

INVIS, bit [1]
Invalid integrity signature flag. This bit is set if the integrity signature in an exception stack frame is found to be invalid during the unstacking operation.

The possible values of this bit are:
0 Error has not occurred.
1 Error has occurred.
This bit resets to zero on a Warm reset.

INVEP, bit [0]
Invalid entry point. This bit is set if a function call from the Non-secure state or exception targets a non-SG instruction in the Secure state. This bit is also set if the target address is a SG instruction, but there is no matching SAU/IDAU region with the NSC flag set.

The possible values of this bit are:
0 Error has not occurred.
1 Error has occurred.
This bit resets to zero on a Warm reset.
D1.2.181   SHCSR, System Handler Control and State Register

The SHCSR characteristics are:

**Purpose**
Provides access to the active and pending status of system exceptions.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000ED24.
Secure software can access the Non-secure view of this register via SHCSR_NS located at 0xE002ED24. The location 0xE002ED24 is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states on a bit by bit basis.

**Preface**
Exception processing automatically updates the SHCSR fields. However, software can write to the register to add or remove the pending or active state of an exception. When updating the SHCSR, ARM recommends using a read-modify-write sequence, to avoid unintended effects on the state of the exception handlers.

Removing the active state of an exception can change the current execution priority, and affect the exception return consistency checks. If software removes the active state, causing a change in current execution priority, this can defeat the architectural behavior that prevents an exception from preempting its own handler.

Pending state bits are set to one when an exception occurs and are cleared to zero when the exception becomes active.
Active state bits are set to one when the associated exception becomes active.

**Field descriptions**
The SHCSR bit assignments are:

![SHCSR Bit Assignments Diagram]

**Bits [31:22]**
Reserved, RES0.

**HARDFAULTPENDED, bit [21]**
HardFault exception pended state. This bit indicates and allows modification of the pending state of the HardFault exception corresponding to the selected Security state.
This bit is banked between Security states.
The possible values of this bit are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>HardFault exception not pending for the selected Security state.</td>
</tr>
<tr>
<td>1</td>
<td>HardFault exception pending for the selected Security state.</td>
</tr>
</tbody>
</table>
This bit resets to zero on a Warm reset.

--- Note ---

The Non-secure HardFault exception will not preempt if AIRCR.BFHFNMINS is set to zero.

**SECUREFAULTPENDED, bit [20]**

SecureFault exception pended state. This bit indicates and allows modification of the pending state of the SecureFault exception.

This bit is not banked between Security states.

The possible values of this bit are:

0  SecureFault exception not pending.
1  SecureFault exception pending.

This bit is RAZ/WI from Non-secure state.

If the Main Extension is not implemented, this bit is RES0.

This bit resets to zero on a Warm reset.

**SECUREFAULTENA, bit [19]**

SecureFault exception enable. The value of this bit defines whether the SecureFault exception is enabled.

This bit is not banked between Security states.

The possible values of this bit are:

0  SecureFault exception disabled.
1  SecureFault exception enabled.

When disabled, exceptions that target SecureFault escalate to Secure state HardFault.

This bit is RAZ/WI from Non-secure state.

If the Main Extension is not implemented, this bit is RES0.

This bit resets to zero on a Warm reset.

**USGFAULTENA, bit [18]**

UsageFault exception enable. The value of this bit defines whether the UsageFault exception is enabled for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

0  UsageFault exception disabled for the selected Security state.
1  UsageFault exception enabled for the selected Security state.

When the UsageFault exception is disabled, exceptions targeting UsageFault escalate to HardFault.

If the Main Extension is not implemented, this bit is RES0.

This bit resets to zero on a Warm reset.

**BUSFAULTENA, bit [17]**

BusFault exception enable. The value of this bit defines whether the BusFault exception is enabled.

This bit is not banked between Security states.

The possible values of this bit are:

0  BusFault exception disabled.
1  BusFault exception enabled.

The BusFault exception is not banked between Security states. When the BusFault exception is disabled, exceptions targeting BusFault escalate to HardFault.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

**MEMFAULTENA, bit [16]**
MemManage exception enable. The value of this bit defines whether the MemManage exception is enabled for the selected Security state.
This bit is banked between Security states.
The possible values of this bit are:
0 MemManage exception disabled for the selected Security state.
1 MemManage exception enabled for the selected Security state.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

--- Note ---
When the MemManage exception is disabled, exceptions targeting MemManage escalate to HardFault.

**SVCALLPENDED, bit [15]**
SVCall exception pended state. This bit indicates and allows modification of the pending state of the SVCall exception for the selected Security state.
This bit is banked between Security states.
The possible values of this bit are:
0 SVCall exception not pending for the selected Security state.
1 SVCall exception pending for the selected Security state.
This bit resets to zero on a Warm reset.

**BUSFAULTPENDED, bit [14]**
BusFault exception pended state. This bit indicates and allows modification of the pending state of the BusFault exception.
This bit is not banked between Security states.
The possible values of this bit are:
0 BusFault exception not pending.
1 BusFault exception pending.
The BusFault exception is not banked between Security states.
If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

**MEMFAULTPENDED, bit [13]**
MemManage exception pended state. This bit indicates and allows modification of the pending state of the MemManage exception for the selected Security state.
This bit is banked between Security states.
The possible values of this bit are:
0 MemManage exception not pending for the selected Security state.
1 MemManage exception pending for the selected Security state.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.
USGFAULTPENDED, bit [12]

UsageFault exception pended state. The UsageFault exception is banked between Security states, this bit indicates and allows modification of the pending state of the UsageFault exception for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

0  UsageFault exception not pending for the selected Security state.
1  UsageFault exception pending for the selected Security state.

If the Main Extension is not implemented, this bit is RES0.

This bit resets to zero on a Warm reset.

SYSTICKACT, bit [11]

SysTick exception active state. This bit indicates and allows modification of the active state of the SysTick exception for the selected Security state.

If two SysTick timers are implemented this bit is banked between Security states.

If less than two SysTick timers are implemented this bit is not banked between Security states.

The possible values of this bit are:

0  SysTick exception not active for the selected Security state.
1  SysTick exception active for the selected Security state.

If two timers are implemented, then SYSTICKACT is banked between Security states. If one timer is implemented this bit corresponds to the Secure state if AIRCR.STTNS is zero, or the Non-secure state if AIRCR.STTNS is one.

This bit resets to zero on a Warm reset.

PENDSVACT, bit [10]

PendSV exception active state. This bit indicates and allows modification of the active state of the PendSV exception for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

0  PendSV exception not active for the selected Security state.
1  PendSV exception active for the selected Security state.

This bit resets to zero on a Warm reset.

Bit [9]

Reserved, RES0.

MONITORACT, bit [8]

DebugMonitor exception active state. This bit indicates and allows modification of the active state of the DebugMonitor exception.

This bit is not banked between Security states.

The possible values of this bit are:

0  DebugMonitor exception not active.
1  DebugMonitor exception active.

If DEMCR.SDME is one this bit is RAZ/WI from Non-secure state

If the Main Extension is not implemented, this bit is RES0.

This bit resets to zero on a Warm reset.

SVCALLACT, bit [7]

SVCall exception active state. This bit indicates and allows modification of the active state of the SVCall exception for the selected Security state.
This bit is banked between Security states.
The possible values of this bit are:
0  SVCall exception not active for the selected Security state.
1  SVCall exception active for the selected Security state.
This bit resets to zero on a Warm reset.

Bit [6]
Reserved, RES0.

NMIACT, bit [5]
NMI exception active state. This bit indicates and allows modification of the active state of the NMI exception.
This bit is not banked between Security states.
The possible values of this bit are:
0  NMI exception not active.
1  NMI exception active.
The NMI exception is not banked between Security states. When AIRCR.BFHFNMINS is zero, the Non-secure view of this bit is RAZ/WI. This field ignores writes if either the value being written is one, AIRCR.BFHFNMINS is zero, the access is from Non-secure state, the access is not via the NS alias, or the access is from a debugger when DHCSR.S_SDE is zero. This bit can only be cleared by access from the Secure state to the NS alias.
This bit resets to zero on a Warm reset.

SECUREFAULTACT, bit [4]
SecureFault exception active state. This bit indicates and allows modification of the active state of the SecureFault exception.
This bit is not banked between Security states.
The possible values of this bit are:
0  SecureFault exception not active.
1  SecureFault exception active.
This bit is RAZ/WI from Non-secure state.
This bit resets to zero on a Warm reset.

USGFAULTACT, bit [3]
UsageFault exception active state for the selected Security state. This bit indicates and allows modification of the active state of the UsageFault exception for the selected Security state.
This bit is banked between Security states.
The possible values of this bit are:
0  UsageFault exception not active for the selected Security state.
1  UsageFault exception active for the selected Security state.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

HARDFAULTACT, bit [2]
HardFault exception active state. Indicates and allows limited modification of the active state of the HardFault exception for the selected Security state.
This bit is banked between Security states.
The possible values of this bit are:
0  HardFault exception not active for the selected Security state.
1  HardFault exception active for the selected Security state.
This field ignores writes if either the value being written is one, the write targets the Secure HardFault active bit, the access is from Non-secure state, or the access is from a debugger when DHCSR.S_SDE is zero.
This bit resets to zero on a Warm reset.

**BUSFAULTACT, bit [1]**

BusFault exception active state. This bit indicates and allows modification of the active state of the BusFault exception.
This bit is not banked between Security states.
The possible values of this bit are:
0       BusFault exception not active.
1       BusFault exception active.
The BusFault exception is not banked between Security states.
If AICR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.

**MEMFAULTACT, bit [0]**

MemManage exception active state for the selected Security state. This bit indicates and allows modification of the active state of the MemManage exception for the selected Security state.
This bit is banked between Security states.
The possible values of this bit are:
0       MemManage exception not active for the selected Security state.
1       MemManage exception active for the selected Security state.
If the Main Extension is not implemented, this bit is RES0.
This bit resets to zero on a Warm reset.
**D1.2.182   SHPR1, System Handler Priority Register 1**

The SHPR1 characteristics are:

**Purpose**
Sets or returns priority for system handlers 4 - 7.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
If the Main Extension is implemented, this register is word, halfword, and byte accessible.
If the Main Extension is not implemented, this register is word accessible only, halfword
and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
32-bit read/write register located at 0xE000ED18.
Secure software can access the Non-secure view of this register via SHPR1_NS located at
0xE002ED18. The location 0xE002ED18 is RES0 to software executing in Non-secure state and
the debugger.
This register is banked between Security states on a bit by bit basis.

**Field descriptions**
The SHPR1 bit assignments are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRI_7</td>
<td>Priority 7. Priority of system handler 7, SecureFault. This field is not banked between Security states. If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are RES0. This field is RAZ/WI from Non-secure state. This field resets to zero on a Warm reset.</td>
</tr>
<tr>
<td>PRI_6</td>
<td>Priority 6. Priority of system handler 6, UsageFault. This field is banked between Security states. If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are RES0. This field resets to zero on a Warm reset.</td>
</tr>
<tr>
<td>PRI_5</td>
<td>Priority 5. Priority of system handler 5, BusFault. This field is not banked between Security states. If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are RES0. If AIRCR.BFHFNMINS is zero this field is RAZ/WI from Non-secure state. This field resets to zero on a Warm reset.</td>
</tr>
<tr>
<td>PRI_4</td>
<td>Priority 4. Priority of system handler 4, MemManage. This field is banked between Security states. If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are RES0. This field resets to zero on a Warm reset.</td>
</tr>
</tbody>
</table>
D1.2.183 SHPR2, System Handler Priority Register 2

The SHPR2 characteristics are:

**Purpose**
Sets or returns priority for system handlers 8 - 11.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
If the Main Extension is implemented, this register is word, halfword, and byte accessible.
If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0x000ED1C.
Secure software can access the Non-secure view of this register via SHPR2_NS located at 0x000ED1C. The location 0x000ED1C is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.

**Field descriptions**
The SHPR2 bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24-23</th>
<th>16-15</th>
<th>8-7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRI_11</td>
<td>PRI_10</td>
<td>PRI_9</td>
<td>PRI_8</td>
<td></td>
</tr>
</tbody>
</table>

**PRI_11, bits [31:24]**
Priority 11. Priority of system handler 11, SVCall.
This field is banked between Security states.
If the PE implements less than 8 bits of priority, then the least significant bits of this field are RES0.
This field resets to zero on a Warm reset.

**PRI_10, bits [23:16]**
Reserved, RES0.

**PRI_9, bits [15:8]**
Reserved, RES0.

**PRI_8, bits [7:0]**
Reserved, RES0.
D1.2.184 SHPR3, System Handler Priority Register 3

The SHPR3 characteristics are:

**Purpose**
Sets or returns priority for system handlers 12 - 15.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.  
If the Main Extension is implemented, this register is word, halfword, and byte accessible.  
If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000ED20.  
Secure software can access the Non-secure view of this register via SHPR3_NS located at 0xE002ED20. The location 0xE002ED20 is RES0 to software executing in Non-secure state and the debugger.  
This register is banked between Security states on a bit by bit basis.

**Field descriptions**
The SHPR3 bit assignments are:

<table>
<thead>
<tr>
<th>Bit assignments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>PRI_15, Priority of system handler 15, SysTick.</td>
</tr>
<tr>
<td>24-23</td>
<td>PRI_14, Priority of system handler 14, PendSV.</td>
</tr>
<tr>
<td>16-15</td>
<td>PRI_13, Reserved, RES0.</td>
</tr>
<tr>
<td>8-7</td>
<td>PRI_12, Priority of system handler 12, DebugMonitor.</td>
</tr>
<tr>
<td>0</td>
<td>Reserved, RES0.</td>
</tr>
</tbody>
</table>

**PRI_15, bits [31:24]**
Priority 15. Priority of system handler 15, SysTick.  
If two SysTick timers are implemented this field is banked between Security states.  
If less than two SysTick timers are implemented this field is not banked between Security states.  
If the PE implements less than 8 bits of priority, then the least significant bits of this field are RES0.  
If one timer is implemented, this field corresponds to the Secure state if AIRCR.STTNS is zero, or the Non-secure state if AIRCR.STTNS is one.  
If only one SysTick timer is implemented and ICSR.STTNS is clear, this field is RAZ/WI from Non-secure state.  
If no SysTick timer is implemented this field is RES0.  
This field resets to zero on a Warm reset.

**PRI_14, bits [23:16]**
Priority 14. Priority of system handler 14, PendSV.  
This field is banked between Security states.  
If the PE implements less than 8 bits of priority, then the least significant bits of this field are RES0.  
This field resets to zero on a Warm reset.

**PRI_13, bits [15:8]**
Reserved, RES0.

**PRI_12, bits [7:0]**
Priority 12. Priority of system handler 12, DebugMonitor.  
This field is not banked between Security states.  
If DEMCR.SDME is 1, this field is RAZ/WI from Non-secure state. If the PE implements less than 8 bits of priority, then the least significant bits of this field are RES0.  
If the Main Extension is not implemented, this field is RES0.
This field resets to zero on a Warm reset.
D1.2.185 SP, Current Stack Pointer Register

The SP characteristics are:

- **Purpose**: Exception and procedure stack pointer register.
- **Usage constraints**: Both privileged and unprivileged access permitted.
- **Configurations**: This register is always implemented.
- **Attributes**: 32-bit read/write special-purpose register.
  This register is not banked between Security states.

**Field descriptions**

The SP bit assignments are:

```
   31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0

   VALUE

  2  1  0

RES0
```

**VALUE, bits [31:2]**

Stack pointer. Holds bits [31:2] of the stack pointer address. The current stack pointer is selected from one of MSP_NS, PSP_NS, MSP_S or PSP_S.

Software can refer to SP as R13.

This field resets to an UNKNOWN value on a Warm reset.

**Bits [1:0]**

Reserved, RES0.
D1.2.186   **SP_NS, Stack Pointer (Non-secure)**

The SP_NS characteristics are:

**Purpose**  Provides access to the current Non-secure stack pointer.

**Usage constraints**  Privileged access only. Unprivileged access is RAZ/WI.

**Configurations**  This register is always implemented.

**Attributes**  32-bit read/write special-purpose register.

This register is not banked between Security states.

**Field descriptions**

The SP_NS bit assignments are:

```
+-------------------+--------+
|  Value, bits [31:2]| VALUE  |
+-------------------+--------+
|                   |  stack pointer. Holds bits[31:2] of the current Non-secure stack pointer address. SP_NS is selected from one of MSP_NS or PSP_NS. Access to SP_NS is provided via MRS and MSR and is subject to stack limit checking. This field resets to an UNKNOWN value on a Warm reset. |
```

231
D1.2.187   STIR, Software Triggered Interrupt Register

The STIR characteristics are:

**Purpose**    Provides a mechanism for software to generate an interrupt.

**Usage constraints**  Unprivileged accesses generate a fault if CCR.USERSETMPEND is zero for the current security state.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**  Present only if the Main Extension is implemented.

This register is RES0 if the Main Extension is not implemented.

**Attributes**  32-bit write-only register located at 0xE000EF00.

Secure software can access the Non-secure view of this register via STIR_NS located at 0xE002EF00. The location 0xE002EF00 is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

**Field descriptions**

The STIR bit assignments are:

```
+---+-+-+-+-+)
| 31| 9 | 8 | 0 |
+---+-+-+-+-+)
     RES0      INTID
```

**Bits [31:9]**  Reserved, RES0.

**INTID, bits [8:0], on a write**

Interrupt ID. Indicates the interrupt to be pended. The value written is (ExceptionNumber - 16).

Writing to this register has the same effect as setting the NVIC_ISPRn bit corresponding to the interrupt to 1. Like NVIC_ISPRn, an attempt to pend an interrupt targeting Secure state from Non-secure is ignored.

**INTID, bits [8:0], on a read**

This field reads as zero.
D1.2.188 SYST_CALIB, SysTick Calibration Value Register

The SYST_CALIB characteristics are:

### Purpose
Reads the SysTick timer calibration value and parameters for the selected Security state.

### Usage constraints
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

### Configurations
Present only if at least one SysTick timer is implemented.

This register is RES0 if no SysTick timer is implemented.

### Attributes
32-bit read-only register located at 0xE000E01C.

Secure software can access the Non-secure view of this register via SYST_CALIB_NS located at 0xE002E01C. The location 0xE002E01C is RES0 to software executing in Non-secure state and the debugger.

This register is banked between Security states.

### Preface
If the Main Extension is implemented then, two SysTick timers are implemented. If the Main Extension is not implemented, then it is IMPLEMENTATION DEFINED whether none, one or two SysTick timers are implemented.

Where two SysTick timers are implemented, this register is banked. Where one SysTick timer is implemented, this register is not banked, and Non-secure accesses behave as RAZ/WI if ICSR.STTNS is clear. If no SysTick timer is implemented, both aliases of this register behave as RES0.

### Field descriptions
The SYST_CALIB bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>NOREF</td>
</tr>
<tr>
<td>30</td>
<td>SKEW</td>
</tr>
<tr>
<td>29</td>
<td>TENMS</td>
</tr>
<tr>
<td>24-21</td>
<td>RES0</td>
</tr>
</tbody>
</table>

#### NOREF, bit [31]
No reference. Indicates whether the IMPLEMENTATION DEFINED reference clock is implemented.

The possible values of this bit are:

0  Reference clock is implemented.
1  Reference clock is not implemented.

When this bit is 1, the CLKSOURCE bit of the SYST_CSR register is forced to 1 and cannot be cleared to 0.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this bit is RES0.

This bit reads as an IMPLEMENTATION DEFINED value.

#### SKEW, bit [30]
Skew. Indicates whether the 10ms calibration value is exact.

The possible values of this bit are:

0  TENMS calibration value is exact.
1  TENMS calibration value is inexact.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.
If no SysTick timer is implemented this bit is RES0.
This bit reads as an IMPLEMENTATION DEFINED value.

**Bits [29:24]**

Reserved, RES0.

**TENMS, bits [23:0]**

Ten milliseconds. Optionally, holds a reload value to be used for 10ms (100Hz) timing, subject to system clock skew errors. If this field is zero, the calibration value is not known.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this field is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this field is RES0.
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.189 SYST_CSR, SysTick Control and Status Register

The SYST_CSR characteristics are:

**Purpose**
Controls the SysTick timer and provides status data for the selected Security state.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if at least one SysTick timer is implemented.
This register is RES0 if no SysTick timer is implemented.

**Attributes**
32-bit read/write register located at 0xE000E010.
Secure software can access the Non-secure view of this register via SYST_CSR_NS located at 0xE002E010. The location 0xE002E010 is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.

**Preface**
If the Main Extension is implemented, then two SysTick timers are implemented. If the Main Extension is not implemented, then it is IMPLEMENTATION DEFINED whether none, one or two SysTick timers are implemented.
Where two SysTick timers are implemented, this register is banked. Where one SysTick timer is implemented, this register is not banked, and Non-secure accesses behave as RAZ/WI if ICSR.STTNS is clear. If no SysTick timer is implemented, both aliases of this register behave as RES0.

**Field descriptions**
The SYST_CSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:17]</td>
<td>RES0</td>
</tr>
<tr>
<td>[16]</td>
<td>COUNTFLAG</td>
</tr>
<tr>
<td>[15:3]</td>
<td>RES0</td>
</tr>
<tr>
<td>[2]</td>
<td>CLKSOURCE</td>
</tr>
<tr>
<td>[1]</td>
<td>ENABLE</td>
</tr>
<tr>
<td>[0]</td>
<td>TICKINT</td>
</tr>
</tbody>
</table>

**Bits [31:17]**
Reserved, RES0.

**COUNTFLAG, bit [16]**
Count flag. Indicates whether the counter has counted to zero since the last read of this register.
The possible values of this bit are:

- **0**: Timer has not counted to 0.
- **1**: Timer has counted to 0.

COUNTFLAG is set to 1 by a count transition from 1 to 0. COUNTFLAG is cleared to 0 if software reads this bit as one, and by any write to the SYST_CVR for the selected Security state. Debugger reads do not clear the COUNTFLAG.

If set this bit clears to zero when read by software. Reads from the debugger do not clear this bit.
If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.
If no SysTick timer is implemented this bit is RES0.
This bit resets to zero on a Warm reset.

**Bits [15:3]**
Reserved, RES0.
CLKSOURCE, bit [2]

Clock source. Indicates the SysTick clock source.

The possible values of this bit are:

0    Uses the IMPLEMENTATION DEFINED external reference clock.
1    Uses the PE clock.

If no external clock is implemented, this bit reads as 1 and ignores writes.
If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.
If no SysTick timer is implemented this bit is RES0.
This bit resets to an IMPLEMENTATION DEFINED value on a Warm reset.

TICKINT, bit [1]

Tick interrupt. Indicates whether counting to 0 causes the status of the SysTick exception to change to pending.

The possible values of this bit are:

0    Count to 0 does not affect the SysTick exception status.
1    Count to 0 changes the SysTick exception status to pending.

Changing the value of the counter to 0 by writing the SysTick does not change the status of the SysTick exception.
If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.
If no SysTick timer is implemented this bit is RES0.
This bit resets to zero on a Warm reset.

ENABLE, bit [0]

SysTick enable. Indicates the enabled status of the SysTick counter.

The possible values of this bit are:

0    Counter is disabled.
1    Counter is enabled.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.
If no SysTick timer is implemented this bit is RES0.
This bit resets to zero on a Warm reset.
D1.2.190 SYST_CVR, SysTick Current Value Register

The SYST_CVR characteristics are:

**Purpose**
- Reads or clears the SysTick timer current counter value for the selected Security state.

**Usage constraints**
- Privileged access permitted only. Unprivileged accesses generate a BusFault.
- This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
- Present only if at least one SysTick timer is implemented.
- This register is RES0 if no SysTick timer is implemented.

**Attributes**
- 32-bit read/write-to-clear register located at 0xE000E018.
- Secure software can access the Non-secure view of this register via SYST_CVR_NS located at 0xE002E018. The location 0xE002E018 is RES0 to software executing in Non-secure state and the debugger.
- This register is banked between Security states.

**Preface**

If the Main Extension is implemented, then two SysTick timers are implemented. If the Main Extension is not implemented, then it is IMPLEMENTATION DEFINED whether none, one or two SysTick timers are implemented. Where two SysTick timers are implemented, this register is banked. Where one SysTick timer is implemented, this register is not banked, and Non-secure accesses behave as RAZ/WI if ICSR.STTNS is clear. If no SysTick timer is implemented, both aliases of this register behave as RES0.

**Field descriptions**

The SYST_CVR bit assignments are:

```
+---------+---------+---------+---------+---------+
| 31      | 24-23   | CURRENT | 0       |
+---------+---------+---------+---------+
| RES0    | CURRENT |         |         |
```

**Bits [31:24]**
- Reserved, RES0.

**CURRENT, bits [23:0], on a read**

Current counter value. Provides the value of the SysTick timer counter for the selected Security state.

It is IMPLEMENTATION DEFINED whether the current counter value decrements if the PE is sleeping and SCR.SLEEPDEEP is set.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this field is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this field is RES0.

This field resets to an UNKNOWN value on a Warm reset.

**CURRENT, bits [23:0], on a write**

Reset counter value. Writing any value clears the SysTick timer counter for the selected Security state to zero.
D1.2.191 SYST_RVR, SysTick Reload Value Register

The SYST_RVR characteristics are:

**Purpose**
Provides access SysTick timer counter reload value for the selected Security state.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if at least one SysTick timer is implemented.
This register is RES0 if no SysTick timer is implemented.

**Attributes**
32-bit read/write register located at 0xE000E014.
Secure software can access the Non-secure view of this register via SYST_RVR_NS located at 0xE002E014. The location 0xE002E014 is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.

**Preface**
If the Main Extension is implemented, then two SysTick timers are implemented. If the Main Extension is not implemented, then it is IMPLEMENTATION DEFINED whether none, one or two SysTick timers are implemented. Where two SysTick timers are implemented, this register is banked. Where one SysTick timer is implemented, this register is not banked, and Non-secure accesses behave as RAZ/WI if ICSR.STTNS is clear. If no SysTick timer is implemented, both aliases of this register behave as RES0.

**Field descriptions**
The SYST_RVR bit assignments are:

```
 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
 RES0 LOAD
```

**Bits [31:24]**
Reserved, RES0.

**RELOAD, bits [23:0]**
Counter reload value. The value to load into the SYST_CVR for the selected Security state when the counter reaches 0.
If only one SysTick timer is implemented and ICSR.STTNS is clear, this field is RAZ/WI from Non-secure state.
If no SysTick timer is implemented this field is RES0.
This field resets to an UNKNOWN value on a Warm reset.
D1.2.192  TPIU_ACPR, TPIU Asynchronous Clock Prescaler Register

The TPIU_ACPR characteristics are:

**Purpose**
Defines a prescaler value for the baud rate of the Serial Wire Output (SWO). Writing to the register automatically updates the prescale counter, immediately affecting the baud rate of the serial data output.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.
If a debugger changes the register value while the TPIU is transmitting data, the effect on the output stream is UNPREDICTABLE and the required recovery process is IMPLEMENTATION DEFINED.

**Configurations**
Present only if the TPIU is implemented and supports SWO. This register is RES0 if the TPIU is not implemented or does not support SWO.

**Attributes**
32-bit read/write register located at 0xE0040010. This register is not banked between Security states.

**Field descriptions**
The TPIU_ACPR bit assignments are:

![Bit assignments](image)

**Bits [31:16]**
Reserved, RES0.

**SWOSCALER, bits [15:0]**
SWO baud rate prescaler. Sets the ratio between an IMPLEMENTATION DEFINED reference clock and the SWO output clock rates. The supported scaler value range is IMPLEMENTATION DEFINED, to a maximum scalar value of 0xFFFF. Unused bits of this field are RAZ/WI.

The possible values of this field are:

\[ n \]
SWO output clock = Asynchronous Reference Clock/(n + 1).

This field resets to zero on a Cold reset.
D1.2.193  TPIU_CIDR0, TPIU Component Identification Register 0

The TPIU_CIDR0 characteristics are:

**Purpose**  Provides CoreSight discovery information for the TPIU.

**Usage constraints**  Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE. If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**  Present only if CoreSight identification is implemented. This register is RES0 if CoreSight identification is not implemented. Present only if the TPIU is implemented. This register is RES0 if the TPIU is not implemented.

**Attributes**  32-bit read-only register located at 0xE0040FF0. This register is not banked between Security states.

**Field descriptions**

The TPIU_CIDR0 bit assignments are:

```
  31   30   29   28   27   26   25   24   23   22   21   20   19   18   17   16   15   14   13   12   11   10   9   8   7   6   5   4   3   2   1   0

   RES0                     PRMBL_0
```

**Bits [31:8]**  Reserved, RES0.

**PRMBL_0, bits [7:0]**  CoreSight component identification preamble. See the *ARM® CoreSight™ Architecture Specification*. This field reads as 0x0D.
D1.2.194 TPIU_CIDR1, TPIU Component Identification Register 1

The TPIU_CIDR1 characteristics are:

**Purpose**
Provides CoreSight discovery information for the TPIU.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read-only register located at 0xE0040FF4.
This register is not banked between Security states.

**Field descriptions**
The TPIU_CIDR1 bit assignments are:

<table>

D1.2.195   TPIU_CIDR2, TPIU Component Identification Register 2

The TPIU_CIDR2 characteristics are:

**Purpose**

Provides CoreSight discovery information for the TPIU.

**Usage constraints**

Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**

Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is RES0 if the TPIU is not implemented.

**Attributes**

32-bit read-only register located at 0xE0040FF8.

This register is not banked between Security states.

**Field descriptions**

The TPIU_CIDR2 bit assignments are:

```
| 31 | 30       | 29       | 28       | 27       | 26       | 25       | 24       | 23       | 22       | 21       | 20       | 19       | 18       | 17       | 16       | 15       | 14       | 13       | 12       | 11       | 10       | 9        | 8        | 7        | 6        | 5        | 4        | 3        | 2        | 1        | 0        |

|     | RES0     |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |
```

**Bits [31:8]**

Reserved, RES0.

**PRMBL_2, bits [7:0]**

CoreSight component identification preamble. See the ARM® CoreSight™ Architecture Specification.

This field reads as 0x05.
D1.2.196 TPIU_CIDR3, TPIU Component Identification Register 3

The TPIU_CIDR3 characteristics are:

**Purpose**
Provides CoreSight discovery information for the TPIU.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read-only register located at 0xE0040FFC.
This register is not banked between Security states.

**Field descriptions**
The TPIU_CIDR3 bit assignments are:

```
+------------------+------------------+
| 31:8             | 8:0              |
| RES0             | PRMBL_3          |
+------------------+------------------+
```

**Bits [31:8]**
Reserved, RES0.

**PRMBL_3, bits [7:0]**
CoreSight component identification preamble. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as 0xB1.
D1.2.197  TPIU_CSPSR, TPIU Current Parallel Port Sizes Register

The TPIU_CSPSR characteristics are:

**Purpose**
Controls the width of the parallel trace port.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read/write register located at 0xE0040004.
This register is not banked between Security states.

**Field descriptions**
The TPIU_CSPSR bit assignments are:

```
+-------------------+-
| 31               0 |
-------------------+
        C_WIDTH
```

**CWIDTH, bits [31:0]**

Current width. C_WIDTH[m] represents a parallel trace port width of (m+1).
The possible values of each bit are:

- 0 Width (N+1) is not the current parallel trace port width.
- 1 Width (N+1) is the current parallel trace port width.

A debugger must set only one bit to 1, and all others must be zero. The effect of writing a value with more than one bit set to 1 is UNPREDICTABLE. The effect of a write to an unsupported bit is UNPREDICTABLE.

This register resets to the value for the smallest supported parallel trace port size.
This field resets to an IMPLEMENTATION DEFINED value on a Cold reset.
D1.2.198 TPIU_DEVTYPE, TPIU Device Type Register

The TPIU_DEVTYPE characteristics are:

**Purpose**
Provides CoreSight discovery information for the TPIU.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE. If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented. This register is RES0 if CoreSight identification is not implemented. Present only if the TPIU is implemented. This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read/write register located at 0xE0040FCC. This register is not banked between Security states.

**Field descriptions**
The TPIU_DEVTYPE bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>...</th>
<th>8</th>
<th>7</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES0</td>
<td>SUB</td>
<td>MAJOR</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits [31:8]**
Reserved, RES0.

**SUB, bits [7:4]**
Sub-type. Component sub-type.
The possible values of this field are:
- 0x0 Other. Only permitted if the MAJOR field reads as 0x0.
- 0x1 Trace port. Only permitted if the MAJOR field reads as 0x1.
This field reads as an IMPLEMENTATION DEFINED value.

**MAJOR, bits [3:0]**
Major type. Component major type.
The possible values of this field are:
- 0x0 Miscellaneous.
- 0x1 Trace sink.
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.199  TPIU_FFCR, TPIU Formatter and Flush Control Register

The TPIU_FFCR characteristics are:

**Purpose**
Controls the TPIU formatter. This register might contain other formatter and flush control fields that are outside the scope of the architecture. Contact ARM for more information.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read/write register located at 0xE0040304.
This register is not banked between Security states.

**Field descriptions**
The TPIU_FFCR bit assignments are:

![Register Diagram]

**Bits [31:15,11,7,3:2]**
Reserved, RES0.

**Bits [14:12]**
Reserved for formatter stop controls.
Reserved, RES0.

**Bits [10:9]**
Reserved for additional trigger mark controls.
Reserved, RES0.

**TrigIn, bit [8]**
Trigger input asserted. Indicate a trigger on the trace port when an IMPLEMENTATION DEFINED TRIGIN signal is asserted.
It is IMPLEMENTATION DEFINED whether this bit is R/W or RAO.
This bit resets to zero on a Cold reset.

**FOnMan, bit [6]**
Flush On Manual. Setting this bit to 1 generates a flush. The TPIU clears the bit to 0 when the flush completes.
This bit resets to zero on a Cold reset.

**Bits [5:4]**
Reserved for additional flush controls.
Reserved, RES0.
EnFmt, bits [1:0]

Formatter control. Selects the output formatting mode.

The possible values of this field are:

- **0b00**  
  Bypass. Disable formatting. Only supported when SWO mode is selected. Only a single trace source is supported in bypass mode:
  - If only a single trace source is connected to this TPIU, it is selected.
  - If multiple sources (including the ITM) are implemented and connected to this TPIU, then all other trace sources, except for the ITM, must be disabled.
  Otherwise, the trace output is UNPREDICTABLE.
  
  All other trace sources are discarded.

- **0b10**  
  Continuous. Enable formatting and embed triggers and null cycles in the formatted output.

All other values are reserved.

If no formatter is implemented, this field is RES0. This field must be set to 0b10 when the parallel trace port is selected, or when using multiple trace sources. Changing the value of this field when TPIU_FFSR.FtStopped is 0 is UNPREDICTABLE.

This field resets to zero on a Cold reset.

--- Note ---

An optional TRACECTL pin might be implemented as part of the parallel trace port that allows Bypass mode when using a parallel trace port and a further mode, EnFmt == 0b01. The CoreSight architecture describes EnFmt[1] as the EnFCont bit and EnFmt[0] as the EnFTC bit.
D1.2.200  TPIU_FFSR, TPIU Formatter and Flush Status Register

The TPIU_FFSR characteristics are:

**Purpose**  Shows the status and capabilities of the TPIU formatter.

**Usage constraints**  Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**  Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**  32-bit read-only register located at 0xE0040300.
This register is not banked between Security states.

**Field descriptions**

The TPIU_FFSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved, RES0</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>FtNonStop, Non-stop formatter</td>
<td>0: Formatter can be stopped. 1: Formatter cannot be stopped. If no formatter is implemented, this bit is RAO.</td>
</tr>
<tr>
<td>2</td>
<td>TCPresent, TRACECTL present</td>
<td>0: No TRACECTL pin available. The data formatter must be used and only in continuous mode. 1: The optional TRACECTL pin is present. If a parallel trace port is not implemented, this bit is RAZ.</td>
</tr>
<tr>
<td>1</td>
<td>FtStopped, Formatter stopped</td>
<td>0: Formatter is enabled. 1: Formatter is stopped.</td>
</tr>
<tr>
<td>0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note**
If a parallel trace port is implemented, ARM recommends the TRACECTL pin is not implemented.

---
The formatter has received a stop request signal and all trace data and post-amble has been output. Any further trace data is ignored.

If no formatter is implemented, or the formatter cannot be stopped, this bit is RAZ.

**FInProg, bit [0]**

Flush in progress. Set to 1 when a flush is initiated and clears to zero when all data received before the flush is acknowledged has been output on the trace port. That is, the trace has been received at the sink, formatted, and output on the trace port.
D1.2.201  TPIU_LAR, TPIU Software Lock Access Register

The TPIU_LAR characteristics are:

**Purpose**
Provides CoreSight Software Lock control for the TPIU, see the *ARM® CoreSight™ Architecture Specification* for details.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

This register is RAZ/WI if accessed via the debugger.

**Configurations**
Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is RES0 if the TPIU is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

**Attributes**
32-bit write-only register located at 0xE0040FB0.

This register is not banked between Security states.

**Field descriptions**
The TPIU_LAR bit assignments are:

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
```

**KEY, bits [31:0]**
Lock Access control.

Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.
D1.2.202 TPIU_LSR, TPIU Software Lock Status Register

The TPIU_LSR characteristics are:

**Purpose**

Provides CoreSight Software Lock status information for the TPIU, see the *ARM® CoreSight™ Architecture Specification* for details.

**Usage constraints**

Privileged access permitted only. Unprivileged accesses generate a BusFault. This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

This register is RAZ/WI if accessed via the debugger.

**Configurations**

Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is RES0 if the TPIU is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

**Attributes**

32-bit read-only register located at 0xE0040FB4.

This register is not banked between Security states.

**Field descriptions**

The TPIU_LSR bit assignments are:

![TPIU_LSR Bit Assignment Diagram]

**Bits [31:3]**

Reserved, RES0.

**nTT, bit [2]**

Not thirty-two bit. See the *ARM® CoreSight™ Architecture Specification*.

This bit reads as zero.

**SLK, bit [1]**

Software Lock status. See the *ARM® CoreSight™ Architecture Specification*.

The possible values of this bit are:

0  Lock clear. Software writes are permitted to this component's registers.

1  Lock set. Software writes to this component's registers are ignored, and reads have no side-effects.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is RES0.

This bit resets to one on a Cold reset.

**SLI, bit [0]**

Software Lock implemented. See the *ARM® CoreSight™ Architecture Specification*.

The possible values of this bit are:

0  Software Lock not implemented or debugger access.
1 Software Lock is implemented and software access.
For a debugger read of this register, or when the Software Lock is not implemented, this bit is RAZ.
This bit reads as an IMPLEMENTATION DEFINED value.
D1.2.203   TPIU_PIDR0, TPIU Peripheral Identification Register 0

The TPIU_PIDR0 characteristics are:

**Purpose**
Provides CoreSight discovery information for the TPIU.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read-only register located at 0xE0040FE0.
This register is not banked between Security states.

**Field descriptions**
The TPIU_PIDR0 bit assignments are:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| RES0 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

**Bits [31:8]**
Reserved, RES0.

**PART_0, bits [7:0]**
Part number bits [7:0]. See the ARM® CoreSight™ Architecture Specification.
This field reads as an IMPLEMENTATION DEFINED value.
### TPIU_PIDR1, TPIU Peripheral Identification Register 1

The TPIU_PIDR1 characteristics are:

**Purpose**
Provides CoreSight discovery information for the TPIU.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read-only register located at 0xE0040FE4.
This register is not banked between Security states.

#### Field descriptions

The TPIU_PIDR1 bit assignments are:

|        | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Reserved | RES0 | DES_0 | PART_1 |

**Bits [31:8]**
Reserved, RES0.

**DES_0, bits [7:4]**
JEP106 identification code bits [3:0]. See the ARM® CoreSight™ Architecture Specification.
This field reads as an IMPLEMENTATION DEFINED value.

**PART_1, bits [3:0]**
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.205 TPIU_PIDR2, TPIU Peripheral Identification Register 2

The TPIU_PIDR2 characteristics are:

**Purpose**
Provides CoreSight discovery information for the TPIU.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read-only register located at 0xE0040FE8.
This register is not banked between Security states.

**Field descriptions**
The TPIU_PIDR2 bit assignments are:

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| RES0 | REVISION | JEDEC | DES_1 |
```

**Bits [31:8]**
Reserved, RES0.

**REVISION, bits [7:4]**
Component revision. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as an IMPLEMENTATION DEFINED value.

**JEDEC, bit [3]**
JEDEC assignee value is used. See the *ARM® CoreSight™ Architecture Specification*.
This bit reads as one.

**DES_1, bits [2:0]**
JEP106 identification code bits [6:4]. See the *ARM® CoreSight™ Architecture Specification*.
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.206   TPIU_PIDR3, TPIU Peripheral Identification Register 3

The TPIU_PIDR3 characteristics are:

**Purpose**   Provides CoreSight discovery information for the TPIU.

**Usage constraints**   Privileged access permitted only. Unprivileged accesses generate a BusFault.
                         This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
                         If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this
                         register is accessible only to the debugger and RES0 for software. Otherwise the register is
                         accessible to the debugger and software.

**Configurations**   Present only if CoreSight identification is implemented.
                      This register is RES0 if CoreSight identification is not implemented.
                      Present only if the TPIU is implemented.
                      This register is RES0 if the TPIU is not implemented.

**Attributes**   32-bit read-only register located at 0xE0040FEC.
                 This register is not banked between Security states.

**Field descriptions**

The TPIU_PIDR3 bit assignments are:

<table>
<thead>

Bits [31:8]   Reserved, RES0.

                     This field reads as an IMPLEMENTATION DEFINED value.

CMOD, bits [3:0]   Customer Modified. See the *ARM® CoreSight™ Architecture Specification*.
                    This field reads as an IMPLEMENTATION DEFINED value.
D1.2.207  TPIU_PIDR4, TPIU Peripheral Identification Register 4

The TPIU_PIDR4 characteristics are:

**Purpose**
Provides CoreSight discovery information for the TPIU.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read-only register located at 0xE0040FD0.
This register is not banked between Security states.

**Field descriptions**
The TPIU_PIDR4 bit assignments are:

<table>
<thead>
<tr>

</tbody>
</table>
D1.2.208 TPIU_PIDR5, TPIU Peripheral Identification Register 5

The TPIU_PIDR5 characteristics are:

**Purpose**
Provides CoreSight discovery information for the TPIU.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read-only register located at 0xE0040FD4.
This register is not banked between Security states.

**Field descriptions**
The TPIU_PIDR5 bit assignments are:

![Bit assignments](image)

**Bits [31:0]**
Reserved, RES0.
D1.2.209   TPIU_PIDR6, TPIU Peripheral Identification Register 6

The TPIU_PIDR6 characteristics are:

**Purpose**
Provides CoreSight discovery information for the TPIU.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read-only register located at 0xE0040FD8.
This register is not banked between Security states.

**Field descriptions**
The TPIU_PIDR6 bit assignments are:

![Bit assignments](image)

**Bits [31:0]**
Reserved, RES0.
D1.2.210   TPIU_PIDR7, TPIU Peripheral Identification Register 7

The **TPIU_PIDR7** characteristics are:

**Purpose**
Provides CoreSight discovery information for the TPIU.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if CoreSight identification is implemented.
This register is RES0 if CoreSight identification is not implemented.
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read-only register located at 0xE0040FDC.
This register is not banked between Security states.

**Field descriptions**
The **TPIU_PIDR7** bit assignments are:

![Bit assignments](image)

**Bits [31:0]**
Reserved, RES0.
D1.2.211 TPIU_PSCR, TPIU Periodic Synchronization Control Register

The TPIU_PSCR characteristics are:

**Purpose**
Defines the reload value for the Periodic Synchronization Counter register. The Periodic Synchronization Counter decrements for each byte that is output by the TPIU. If the formatter is implemented and enabled, the TPIU forces completion of the current frame when the counter reaches zero. It is IMPLEMENTATION DEFINED whether the TPIU forces all trace sources to generate synchronization packets when the counter reaches zero. Bytes generated by the TPIU as part of a Halfword synchronization packet or a Full frame synchronization packet are not counted.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault. 
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present if the TPIU is implemented and DWT_CYCCNT is not implemented.
OPTIONAL if both the TPIU and DWT_CYCCNT are implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read/write register located at 0xE0040308.
This register is not banked between Security states.

**Field descriptions**
The TPIU_PSCR bit assignments are:

```
+----------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+
<table>
<thead>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Bits [31:5]**
Reserved, RES0.

**PSCount, bits [4:0]**
Periodic Synchronization Count. Determines the reload value of the Periodic Synchronization Counter. The reload value takes effect the next time the counter reaches zero. Reads from this register return the reload value programmed into this register.

The possible values of this field are:

- **00000** Synchronization disabled.
- **00111** 128 bytes.
- **01000** 256 bytes.
- **...** ...
- **11111** $2^{31}$ bytes.

All other values are reserved.

The Periodic Synchronization Counter might have a maximum value smaller than $2^{31}$. In this case, if the programmed reload value is greater than the maximum value, then the Periodic Synchronization Counter is reloaded with its maximum value and the TPIU will generate synchronization requests at this interval.

This field resets to $0xA$ on a Cold reset.
Note

In the CoreSight TPIU, TPIU_PSCR specifies the number of frames between synchronizations, each frame being 16 bytes. This definition of TPIU_PSCR specifies a number of bytes and is encoded as a power-of-two rather than a plain binary number.
D1.2.212  TPIU_SPPR, TPIU Selected Pin Protocol Register

The TPIU_SPPR characteristics are:

**Purpose**
Selects the protocol used for trace output.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this
register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

If a debugger changes the register value while the TPIU is transmitting data, the effect on
the output stream is UNPREDICTABLE and the required recovery process is IMPLEMENTATION DEFINED.

**Configurations**
Present only if the TPIU is implemented and supports SWO.

This register is RES0 if the TPIU is not implemented or does not support SWO.

**Attributes**
32-bit read/write register located at 0xE00400F0.

This register is not banked between Security states.

**Field descriptions**

The TPIU_SPPR bit assignments are:

![TPIU_SPPR bit assignment diagram]

Bits [31:2]
Reserved, RES0.

TXMODE, bits [1:0]

Transmit mode. Specifies the protocol for trace output from the TPIU.

The possible values of this field are:

- **00**: Parallel trace port mode. This value is reserved if TPIU_TYPE.PTINVVALID == '1'.
- **01**: Asynchronous SWO, using Manchester encoding. This value is reserved if TPIU_TYPE.MANCVVALID == '0'.
- **10**: Asynchronous SWO, using NRZ encoding. This value is reserved if TPIU_TYPE.NRZVALID == '0'.

All other values are reserved.

The effect of selecting a reserved value, or a mode that the implementation does not support, is UNPREDICTABLE.

This field resets to an IMPLEMENTATION DEFINED value on a Cold reset.
D1.2.213  TPIU_SSPSR, TPIU Supported Parallel Port Sizes Register

The TPIU_SSPSR characteristics are:

**Purpose**
Indicates the supported parallel trace port sizes.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read/write register located at 0xE0040000.
This register is not banked between Security states.

**Field descriptions**
The TPIU_SSPSR bit assignments are:

![Field Diagram](image)

**SWIDTH, bits [31:0]**
Supported width. SWIDTH[m] indicates whether a parallel trace port width of \((m+1)\) is supported.
The possible values of each bit are:
0 Parallel trace port width \((m+1)\) not supported.
1 Parallel trace port width \((m+1)\) supported.
The value of this register is IMPLEMENTATION DEFINED.
This field reads as an IMPLEMENTATION DEFINED value.
D1.2.214 TPIU_TYPE, TPIU Device Identifier Register

The TPIU_TYPE characteristics are:

**Purpose**
Describes the TPIU to a debugger.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.
If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

**Configurations**
Present only if the TPIU is implemented.
This register is RES0 if the TPIU is not implemented.

**Attributes**
32-bit read-only register located at 0xE0040FC8.
This register is not banked between Security states.

**Field descriptions**
The TPIU_TYPE bit assignments are:

```plaintext
  31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0

  RES0 | FIFOSZ | 12 | 11 | 10 | 9 | 8 | 6 | 5 | 4 | 3 | 2 | 1 | 0

  IMPLEMENTATION DEFINED | NRZVALID | MANCVALID | RES0 | IMPLEMENTATION DEFINED
```

**Bits [31:16]**
Reserved, RES0.

**Bits [15:12]**
IMPLEMENTATION DEFINED.

**NRZVALID, bit [11]**
NRZ valid. Indicates support for SWO using UART/NRZ encoding.
The possible values of this bit are:
0 Not supported.
1 Supported.
This bit reads as an IMPLEMENTATION DEFINED value.

**MANCVALID, bit [10]**
Manchester valid. Indicates support for SWO using Manchester encoding.
The possible values of this bit are:
0 Not supported.
1 Supported.
This bit reads as an IMPLEMENTATION DEFINED value.

**PTINVALID, bit [9]**
Parallel Trace Interface invalid. Indicates support for parallel trace port operation.
The possible values of this bit are:
0 Supported.
1 Not supported.
This bit reads as an IMPLEMENTATION DEFINED value.
FIFOSZ, bits [8:6]
FIFO depth. Indicates the minimum implemented size of the TPIU output FIFO for trace data.

The possible values of this field are:

0  IMPLEMENTATION DEFINED FIFO depth.
Other  Minimum FIFO size is $2^{\text{FIFOSZ}}$.

For example, a value of $0b011$ indicates a FIFO size of at least $2^3 = 8$ bytes.
This field reads as an IMPLEMENTATION DEFINED value.

Bits [5:0]
IMPLEMENTATION DEFINED.
D1.2.215 TT_RESP, Test Target Response Payload

The TT_RESP characteristics are:

**Purpose**  Provides the response information from a TT, TTA, TTT, or TTAT instruction.

**Usage constraints**  None.

**Configurations**  All.

**Attributes**  32-bit payload.

**Field descriptions**

The TT_RESP bit assignments are:

```
<p>| | | | | | | | | | | | | |</p>
<table>

<td>R</td>
<td>SREGION</td>
<td></td>
<td>MREGION</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**IREGION, bits [31:24]**
IDAU region number. Indicates the IDAU region number containing the target address.
This field is zero if IRVALID is zero.

**IRVALID, bit [23]**
IREGION valid flag. For a Secure request, indicates the validity of the IREGION field.
The possible values of this bit are:
0  IREGION content not valid.
1  IREGION content valid.
This bit is always zero if the IDAU cannot provide a region number, the address is exempt from security attribution, or if the requesting TT instruction was executed from the Non-secure state.

**S, bit [22]**
Security. For a Secure request, indicates the Security attribute of the target address.
The possible values of this bit are:
0  Target address is Non-secure.
1  Target address is Secure.
This bit is always zero if the requesting TT instruction was executed from the Non-secure state.

**NSRW, bit [21]**
Non-secure read and writeable. Equal to RW AND NOT S. Can be used in combination with the LSLS (immediate) instruction to check both the MPU and SAU/IDAU permissions. This field is only valid if the instruction was executed from Secure state and the RW field is valid.

**NSR, bit [20]**
Non-secure readable. Equal to R AND NOT S. Can be used in combination with the LSLS (immediate) instruction to check both the MPU and SAU/IDAU permissions. This field is only valid if the instruction was executed from Secure state and the R field is valid.

**RW, bit [19]**
Read and writeable.
Set to 1 if the memory location can be read and written according to the permissions of the selected MPU when operating in the current mode. For TTT and TTAT, this field returns the permissions for unprivileged access, regardless of whether the current mode is privileged or unprivileged.
This field is invalid and RAZ if the TT instruction was executed from an unprivileged mode and the A flag was not specified. This field is also RAZ if the address matches multiple MPU regions.

R, bit [18]

Readable.

Read accessibility. Set to 1 if the memory location can be read according to the permissions of the selected MPU when operating in the current mode. For TTT and TTAT, this field returns the permissions for unprivileged access, regardless of whether the current mode is privileged or unprivileged.

This field is invalid and RAZ if the TT instruction was executed from an unprivileged mode and the A flag was not specified. This field is also RAZ if the address matches multiple MPU regions.

SRVALID, bit [17]

SREGION valid flag. For a Secure request indicates validity of the SREGION field.

The possible values of this bit are:

0  SREGION content not valid.
1  SREGION content valid.

This bit is always zero if the requesting TT instruction was executed from the Non-secure state.

The SREGION field will be invalid if any of the following are true:

• SAU_CTRL.ENABLE is set to zero.
• The address specified in the SREGION field does not match any enabled SAU regions.
• The address specified by the SREGION field is exempt from the secure memory attribution.
• The address specified in the SREGION field matches multiple enabled SAU regions.
• The TT instruction was executed from the Non-secure state or the Security extension is not implemented.

MRVALID, bit [16]

MREGION valid flag. Indicates validity of the MREGION field.

The possible values of this bit are:

0  MREGION content not valid.
1  MREGION content valid.

This bit is only valid for TT and TTA instructions, executed in the Secure state or in privileged mode in Non-secure state.

The MREGION field will be invalid if any of the following is true:

• The MPU is not implemented or MPU_CTRL.ENABLE is set to zero.
• The address specified by the MREGION field does not match any enabled MPU regions.
• The address matched multiple MPU regions.
• The TT instruction was executed from an unprivileged mode and the A flag was not specified.
• The address specified in the MREGION field is in the System PPB region of the address space.
• MPU_CTRL.HFNIMENA is set to zero and the requested execution priority is negative for the specified Security state.

SREGION, bits [15:8]

SAU region number. Holds the SAU region that the address maps to.

This field is only valid if the instruction was executed from Secure state. This field is zero if SRVALID is 0.
MREGION, bits [7:0]

MPU region number. Holds the MPU region that the address maps to.

This field is zero if MRVALID is 0.
D1.2.216 UFSR, UsageFault Status Register

The UFSR characteristics are:

**Purpose**
Contains the status for some instruction execution faults, and for data access faults.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.
If the Main Extension is implemented, this register is word, halfword, and byte accessible.
If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are UNPREDICTABLE.

**Configurations**
Present only if the Main Extension is implemented.
This register is RES0 if the Main Extension is not implemented.

**Attributes**
16-bit read/write-one-to-clear register located at 0xE000ED2A.
Secure software can access the Non-secure view of this register via UFSR_NS located at 0xE002ED2A. The location 0xE002ED2A is RES0 to software executing in Non-secure state and the debugger.
This register is banked between Security states.
This register is part of CFSR.

**Field descriptions**
The UFSR bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15:10</td>
<td>Reserved, RES0.</td>
</tr>
<tr>
<td>9</td>

<td>STKOF, Stack overflow flag. Sticky flag indicating whether a stack overflow error has occurred.</td>
</tr>
</tbody>
</table>

**Bits [15:10]**
Reserved, RES0.

**DIVBYZERO, bit [9]**
Divide by zero flag. Sticky flag indicating whether an integer division by zero error has occurred. The possible values of this bit are:
0 Error has not occurred.
1 Error has occurred.
This bit resets to zero on a Warm reset.

**UNALIGNED, bit [8]**
Unaligned access flag. Sticky flag indicating whether an unaligned access error has occurred. The possible values of this bit are:
0 Error has not occurred.
1 Error has occurred.
This bit resets to zero on a Warm reset.

**Bits [7:5]**
Reserved, RES0.

**STKOF, bit [4]**
Stack overflow flag. Sticky flag indicating whether a stack overflow error has occurred.
The possible values of this bit are:
0  Error has not occurred.
1  Error has occurred.
This bit resets to zero on a Warm reset.

NOCP, bit [3]
No coprocessor flag. Sticky flag indicating whether a coprocessor disabled or not present error has occurred.
The possible values of this bit are:
0  Error has not occurred.
1  Error has occurred.
This bit resets to zero on a Warm reset.

INVPC, bit [2]
Invalid PC flag. Sticky flag indicating whether an integrity check error has occurred.
The possible values of this bit are:
0  Error has not occurred.
1  Error has occurred.
This bit resets to zero on a Warm reset.

INVSTATE, bit [1]
Invalid state flag. Sticky flag indicating whether an EPSR.T or EPSR.IT validity error has occurred.
The possible values of this bit are:
0  Error has not occurred.
1  Error has occurred.
This bit resets to zero on a Warm reset.

UNDEFINSTR, bit [0]
Undefined instruction flag. Sticky flag indicating whether an undefined instruction error has occurred.
The possible values of this bit are:
0  Error has not occurred.
1  Error has occurred.
This includes attempting to execute an undefined instruction associated with an enable coprocessor.
This bit resets to zero on a Warm reset.
D1.2.217 VTOR, Vector Table Offset Register

The VTOR characteristics are:

**Purpose**
Holds the vector table address for the selected Security state.

**Usage constraints**
Privileged access permitted only. Unprivileged accesses generate a BusFault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write register located at 0xE000ED08.

Secure software can access the Non-secure view of this register via VTOR_NS located at 0xE002ED08. The location 0xE002ED08 is RES0 to software executing in Non-secure state and the debugger.

This register is banked between Security states.

**Field descriptions**

The VTOR bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>TBLOFF, bits [31:7]</td>
</tr>
<tr>
<td>6</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**TBLOFF, bits [31:7]**
Table offset. Bits [31:7] of the vector table address for the selected Security state.

It is IMPLEMENTATION DEFINED whether any of the TBLOFF bits are WI.

This field resets to an IMPLEMENTATION DEFINED value on a Warm reset.

**Bits [6:0]**
Reserved, RES0.
D1.2.218 XPSR, Combined Program Status Registers

The XPSR characteristics are:

**Purpose**
Provides access to a combination of the APSR, EPSR and IPSR.

**Usage constraints**
Privileged access only. Unprivileged access is RAZ/WI.

**Configurations**
This register is always implemented.

**Attributes**
32-bit read/write special-purpose register.
This register is not banked between Security states.

**Field descriptions**

The XPSR bit assignments are:

When \{XPSR[26:25], XPSR[11:10]\} \(!=\) 0:

<table>
<thead>
<tr>
<th>N</th>
<th>Z</th>
<th>C</th>
<th>V</th>
<th>Q</th>
<th>IT</th>
<th>T</th>
<th>RES0</th>
<th>GE</th>
<th>IT</th>
<th>RES0</th>
<th>Exception</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When \{XPSR[26:25], XPSR[11:10]\} == 0:

<table>
<thead>
<tr>
<th>N</th>
<th>Z</th>
<th>C</th>
<th>V</th>
<th>Q</th>
<th>IT</th>
<th>T</th>
<th>RES0</th>
<th>GE</th>
<th>ICI</th>
<th>RES0</th>
<th>Exception</th>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**N, bit [31]**
Negative flag. Reads or writes the current value of APSR.N.

**Z, bit [30]**
Zero flag. Reads or writes the current value of APSR.Z.

**C, bit [29]**
Carry flag. Reads or writes the current value of APSR.C.

**V, bit [28]**
Overflow flag. Reads or writes the current value of APSR.V.

**Q, bit [27]**
Saturate flag. Reads or writes the current value of APSR.Q.

**T, bit [24]**
T32 state. Reads or writes the current value of EPSR.T.

**Bits [23:20]**
Reserved, RES0.

**GE, bits [19:16]**
Greater-than or equal flag. Reads or writes the current value of APSR.GE.

**IT, bits [15:10,26:25], when \{XPSR[26:25], XPSR[11:10]\} \(!=\) 0**
If-then flags. Reads or writes the current value of EPSR.IT.

**ICI, bits [26:25,15:10], when \{XPSR[26:25], XPSR[11:10]\} == 0**
Interrupt continuation flags. Reads or writes the current value of EPSR.ICI.
Bit [9]

Reserved, RES0.

Exception, bits [8:0]

Exception number. Reads or writes the current value of IPSR.Exception.
Part E

ARMv8-M Pseudocode
Chapter E1
ARM Pseudocode Definition

This chapter provides a definition of the pseudocode that is used in this manual, and defines some built-in functions that are used by pseudocode. It contains the following sections:

• About the ARM pseudocode on page E1-1130.
• Data types on page E1-1131.
• Operators on page E1-1136.
• Statements and control structures on page E1-1142.
• Built-in functions on page E1-1148.
• ARM pseudocode definition index on page E1-1151.

Note

This chapter is not a formal language definition for the pseudocode. It is a guide to help understand the use of ARM pseudocode.
E1.1  About the ARM pseudocode

The ARM pseudocode provides precise descriptions of some areas of the ARM architecture. This includes description of the decoding and operation of all valid instructions.

The following sections describe the ARM pseudocode in detail:

• Data types on page E1-1131.
• Operators on page E1-1136.
• Statements and control structures on page E1-1142.

Built-in functions on page E1-1148 describes some built-in functions that are used by the pseudocode functions that are described elsewhere in this manual. ARM pseudocode definition index on page E1-1151 contains the indexes to the pseudocode.

E1.1.1  General limitations of ARM pseudocode

The pseudocode statements IMPLEMENTATION_DEFINED, SEE, UNDEFINED, and UNPREDICTABLE indicate behavior that differs from that indicated by the pseudocode being executed. If one of them is encountered:

• Earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed.
• No subsequent behavior indicated by the pseudocode occurs.

For more information, see Special statements on page E1-1146.
E1.2 Data types

This section describes:

- General data type rules.
- Bitstrings.
- Integers on page E1-1132.
- Reals on page E1-1132.
- Booleans on page E1-1132.
- Enumerations on page E1-1133.
- Structures on page E1-1133.
- Tuples on page E1-1134.
- Arrays on page E1-1135.

E1.2.1 General data type rules

ARM architecture pseudocode is a strongly typed language. Every literal and variable is of one of the following types:

- Bitstring.
- Integer.
- Boolean.
- Real.
- Enumeration.
- Tuple.
- Struct.
- Array.

The type of a literal is determined by its syntax. A variable can be assigned to without an explicit declaration. The variable implicitly has the type of the assigned value. For example, the following assignments implicitly declare the variables x, y and z to have types integer, bitstring of length 1, and Boolean, respectively.

```c
x = 1;
y = '1';
z = TRUE;
```

Variables can also have their types declared explicitly by preceding the variable name with the name of the type. The following example declares explicitly that a variable named count is an integer.

```c
integer count;
```

This is most often done in function definitions for the arguments and the result of the function.

The remaining subsections describe each data type in more detail.

E1.2.2 Bitstrings

This section describes the bitstring data type.

**Syntax**

```
bits(N) The type name of a bitstring of length N.
bite A synonym of bits(1).
```

**Description**

A bitstring is a finite-length string of 0s and 1s. Each length of bitstring is a different type. The minimum permitted length of a bitstring is 0.
Bitstring constants literals are written as a single quotation mark, followed by the string of 0s and 1s, followed by another single quotation mark. For example, the two constants literals of type bit are '0' and '1'. Spaces can be included in bitstrings for clarity.

The bits in a bitstring are numbered from left to right \( N-1 \) to 0. This numbering is used when accessing the bitstring using bitslices. In conversions to and from integers, bit \( N-1 \) is the MSByte and bit 0 is the LSByte. This order matches the order in which bitstrings derived from encoding diagrams are printed.

Every bitstring value has a left-to-right order, with the bits being numbered in standard little-endian order. That is, the leftmost bit of a bitstring of length \( N \) is bit \( (N-1) \) and its right-most bit is bit 0. This order is used as the most-significant-to-least-significant bit order in conversions to and from integers. For bitstring constants and bitstrings that are derived from encoding diagrams, this order matches the way that they are printed.

Bitstrings are the only concrete data type in pseudocode, corresponding directly to the contents values that are manipulated in registers, memory locations, and instructions. All other data types are abstract.

### E1.2.3 Integers

This section describes the data type for integer numbers.

**Syntax**

```
integer
```

The type name for the integer data type.

**Description**

Pseudocode integers are unbounded in size and can be either positive or negative. That is, they are mathematical integers rather than what computer languages and architectures commonly call integers. Computer integers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as integers.

Integer literals are normally written in decimal form, such as 0, 15, -1234. They can also be written in C-style hexadecimal form, such as 0x55 or 0x80000000. Hexadecimal integer literals are treated as positive unless they have a preceding minus sign. For example, 0x80000000 is the integer +2\(^{31}\). If -2\(^{31}\) needs to be written in hexadecimal, it must be written as -0x80000000.

### E1.2.4 Reals

This section describes the data type for real numbers.

**Syntax**

```
real
```

The type name for the real data type.

**Description**

Pseudocode reals are unbounded in size and precision. That is, they are mathematical real numbers, not computer floating-point numbers. Computer floating-point numbers are represented in pseudocode as bitstrings of the appropriate length, associated with suitable and the pseudocode provides functions to interpret those bitstrings as reals.

Real constants literals are written in decimal form with a decimal point. This means 0 is an integer constant literal, but 0.0 is a real constant literal.

### E1.2.5 Booleans

This section describes the Boolean data type.
### E1 ARM Pseudocode Definition

#### E1.2 Data types

**Syntax**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>The type name for the Boolean data type.</td>
</tr>
<tr>
<td>TRUE, FALSE</td>
<td>The two values a Boolean variable can take.</td>
</tr>
</tbody>
</table>

**Description**

A Boolean is a logical TRUE or FALSE value.

---

**Note**

This is not the same type as bit, which is a bitstring of length 1. A Boolean can only take on one of two values: TRUE or FALSE.

---

#### E1.2.6 Enumerations

This section describes the enumeration data type.

**Syntax and examples**

```plaintext
enumeration Example {Example_One, Example_Two, Example_Three};
```

An example definition for a new enumeration called `Example`, which can take on the values `Example_One`, `Example_Two`, `Example_Three`.

**Description**

An enumeration is a defined set of named values.

An enumeration must contain at least one named value. A named value must not be shared between enumerations.

Enumerations must be defined explicitly, although a variable of an enumeration type can be declared implicitly by assigning one of the named values to it. By convention, each named value starts with the name of the enumeration followed by an underscore. The name of the enumeration is its _type name_, or _type_, and the named values are its _possible values_.

---

#### E1.2.7 Structures

This section describes the structure data type.

**Syntax and examples**

```plaintext
type ShiftSpec is (bits(2) shift, integer amount)
```

An example definition for a new structure called `ShiftSpec` that contains a bitstring member called `shift` and an integer member named `amount`. Structure definitions must not be terminated with a semicolon.

```plaintext
ShiftSpec abc;
```

A declaration of a variable named `abc` of type `ShiftSpec`.

```plaintext
abc.shift
```

Syntax to refer to the individual members within the structure variable.
**Description**

A structure is a compound data type composed of one or more data items. The data items can be of different data types. This can include compound data types. The data items of a structure are called its members and are named.

In the syntax section, the example defines a structure called ShiftSpec with two members. The first is a bitstring of length 2 named shift and the second is an integer named amount. After declaring a variable of that type named abc, the members of this structure are referred to as abc.shift and abc.amount.

Every definition of a structure creates a different type, even if the number and type of their members are identical. For example:

```plaintext
type ShiftSpec1 is (bits(2) shift, integer amount)
type ShiftSpec2 is (bits(2) shift, integer amount)
```

ShiftSpec1 and ShiftSpec2 are two different types despite having identical definitions. This means that the value in a variable of type ShiftSpec1 cannot be assigned to variable of type ShiftSpec2.

**<register_name>_Type and <payload>_Type**

This subsection describes the data structure types for a particular register or payload.

**Example**

```plaintext
RETPSR_Type
The data structure of type RETPSR.
```

**Description**

By convention _Type declares a structure data type for a specific register or payload. See the individual register descriptions for the fields that apply to a particular data structure.

**E1.2.8 Tuples**

This section describes the tuple data type.

**Examples**

```plaintext
(bits(32) shifter_result, bit shifter_carry_out)
An example of the tuple syntax.
```

```plaintext
(shift_t, shift_n) = ('00', 0);
An example of assigning values to a tuple.
```

**Description**

A tuple is an ordered set of data items, separated by commas and enclosed in parentheses. The items can be of different types and a tuple must contain at least one data item.

Tuples are often used as the return type for functions that return multiple results. For example, in the syntax section, the example tuple is the return type of the function Shift_C(), which performs a standard A32/T32 shift or rotation. Its return type is a tuple containing two data items, with the first of type bits(32) and the second of type bit.

Each tuple is a separate compound data type. The compound data type is represented as a comma-separated list of ordered data types between parentheses. This means that the example tuple at the start of this section is of type (bits(32), bit). The general principle that types can be implied by an assignment extends to implying the type of the elements in the tuple. For example, in the syntax section, the example assignment implicitly declares:

- shift_t to be of type bits(2).
- shift_n to be of type integer.
- (shift_t, shift_n) to be a tuple of type (bits(2), integer).
E1.2.9 Arrays

This section describes the array data type.

Syntax

array

The type name for the array data type.

array data_type array_name[A..B];

Declaration of an array of type data_type, which might be compound data type. It is named array_name and is indexed with an integer range from A to B.

Description

An array is an ordered set of fixed size containing items of a single data type. This can include compound data types. Pseudocode arrays are indexed by either enumerations or integer ranges. An integer range is represented by the lower inclusive end of the range, then \( \ldots \), then the upper inclusive end of the range.

For example:

The following example declares an array of 31 bitstrings of length 64, indexed from 0 to 30.

array bits(64) _R[0..30];

Arrays are always explicitly declared, and there is no notation for a constant literal array. Arrays always contain at least one element data item, because:

• Enumerations always contain at least one symbolic constant named value.
• Integer ranges always contain at least one integer.

An array declared with an enumeration type as the index must be accessed using enumeration values of that enumeration type. An array declared with an integer range type as the index must be accessed using integer values from that inclusive range. Accessing such an array with an integer value outside of the range is a coding error.

Arrays do not usually appear directly in pseudocode. The items that syntactically look like arrays in pseudocode are usually array-like functions such as \( R[i] \), \( MemU[address, size] \) or \( Elem[vector, i, size] \). These functions package up and abstract additional operations normally performed on accesses to the underlying arrays, such as register banking, memory protection, endian-dependent byte ordering, exclusive-access housekeeping and Advanced SIMD element processing. See Function and procedure calls on page E1-1142.
E1.3 Operators

This section describes:

- Relational operators.
- Boolean operators.
- Bitstring operators on page E1-1137.
- Arithmetic operators on page E1-1137.
- The assignment operator on page E1-1138.
- Precedence rules on page E1-1140.
- Conditional expressions on page E1-1140.
- Operator polymorphism on page E1-1140.

E1.3.1 Relational operators

The following operations yield results of type boolean.

Equality and non-equality

If two variables \( x \) and \( y \) are of the same type, their values can be tested for equality by using the expression \( x == y \) and for non-equality by using the expression \( x != y \). In both cases, the result is of type boolean.

Both \( x \) and \( y \) must be of type \( \text{bits}(N) \), real, enumeration, boolean, or integer. Named values from an enumeration can only be compared if they are both from the same enumeration. An exception is that a bitstring can be tested for equality with an integer to allow a \( d==15 \) test.

A special form of comparison is defined with a bitstring literal that can contain bit values '0', '1', and 'x'. Any bit with value 'x' is ignored in determining the result of the comparison. For example, if \( \text{opcode} \) is a 4-bit bitstring, the expression \( \text{opcode} == '1x0x' \) matches the values '1000', '1100', '1001', and '1101'. This is known as a bitmask.

Note

This special form is permitted in the implied equality comparisons in the when parts of case ... of ... structures.

Comparisons

If \( x \) and \( y \) are integers or reals, then \( x < y \), \( x <= y \), \( x > y \), and \( x >= y \) are less than, less than or equal, greater than, and greater than or equal comparisons between them, producing Boolean results.

Set membership with \( \text{IN} \)

\(<\text{expression}> \text{IN} \{<\text{set}>\} \) produces TRUE if \(<\text{expression}> \) is a member of \(<\text{set}>\). Otherwise, it is FALSE. \(<\text{set}>\) must be a list of expressions separated by commas.

E1.3.2 Boolean operators

If \( x \) is a Boolean expression, then \( !x \) is its logical inverse.

If \( x \) and \( y \) are Boolean expressions, then \( x && y \) is the result of ANDing them together. As in the C language, if \( x \) is FALSE, the result is determined to be FALSE without evaluating \( y \).

Note

This is known as short circuit evaluation.

If \( x \) and \( y \) are booleans, then \( x || y \) is the result of ORing them together. As in the C language, if \( x \) is TRUE, the result is determined to be TRUE without evaluating \( y \).
**Note**

If \( x \) and \( y \) are booleans or Boolean expressions, then the result of \( x \neq y \) is the same as the result of exclusive-ORing \( x \) and \( y \) together. The operator \( \oplus \) only accepts bitstring arguments.

---

### E1.3 Operators

#### E1.3.3 Bitstring operators

The following operations can be applied only to bitstrings.

**Logical operations on bitstrings**

If \( x \) is a bitstring, \( \overline{x} \) is the bitstring of the same length obtained by logically inverting every bit of \( x \).

If \( x \) and \( y \) are bitstrings of the same length, \( x \land y \), \( x \lor y \), and \( x \oplus y \) are the bitstrings of that same length obtained by logically ANDing, logically ORing, and exclusive-ORing corresponding bits of \( x \) and \( y \) together.

**Bitstring concatenation and slicing**

If \( x \) and \( y \) are bitstrings of lengths \( N \) and \( M \) respectively, then \( x:y \) is the bitstring of length \( N+M \) constructed by concatenating \( x \) and \( y \) in left-to-right order.

The bitstring slicing operator addresses specific bits in a bitstring. This can be used to create a new bitstring from extracted bits or to set the value of specific bits. Its syntax is \( x<integer_list> \), where \( x \) is the integer or bitstring being sliced, and \( integer_list \) is a comma-separated list of integers enclosed in angle brackets. The length of the resulting bitstring is equal to the number of integers in \( integer_list \). In \( x<integer_list> \), each of the integers in \( integer_list \) must be:

- \( \geq 0 \)
- \( < \text{Len}(x) \) if \( x \) is a bitstring.

The definition of \( x<integer_list> \) depends on whether \( integer_list \) contains more than one integer:

- If \( integer_list \) contains more than one integer, \( x<i, j, k, \ldots, n> \) is defined to be the concatenation:
  \[
  x<i> : x<j> : x<k> : \ldots : x<n>.
  \]
- If \( integer_list \) consists of just one integer \( i \), \( x<i> \) is defined to be:
  - \( \text{If } x \text{ is a bitstring, } '0' \text{ if bit } i \text{ of } x \text{ is a zero and } '1' \text{ if bit } i \text{ of } x \text{ is a one.} \)
  - \( \text{If } x \text{ is an integer, and } y \text{ is the unique integer in the range } 0 \text{ to } 2^i - 1 \text{ that is congruent to } x \text{ modulo } 2^i. \text{ Then } x<i> \text{ is } '0' \text{ if } y < 2^i \text{ and } '1' \text{ if } y \geq 2^i. \)

Loosely, this definition treats an integer as equivalent to a sufficiently long two’s complement representation of it as a bitstring.

The notation for a range expression is \( i:j \) with \( i \geq j \) and both end values included. For example, \( \text{instr}<31:28> \) represents \( \text{instr}<31, 30, 29, 28> \).

\( x<integer_list> \) is assignable provided \( x \) is an assignable bitstring and no integer appears more than once in \( integer_list \). In particular, \( x<i> \) is assignable if \( x \) is an assignable bitstring and \( 0 \leq i < \text{Len}(x) \).

Encoding diagrams for registers frequently show named bits or multi-bit fields. For example, the encoding diagram for the APSR shows its bit<31> as \( N \). In such cases, the syntax \( \text{APSR.N} \) is used as a more readable synonym for \( \text{APSR}<31> \) as named bits can be referred to with the same syntax as referring to members of a struct. A comma-separated list of named bits enclosed in angle brackets following the register name allows multiple bits to be addressed simultaneously. For example, \( \text{APSR.<N, C, Q>} \) is synonymous with \( \text{APSR}<31, 29, 27> \).

#### E1.3.4 Arithmetic operators

Most pseudocode arithmetic is performed on integer or real values, with operands obtained by conversions from bitstrings and results converted back to bitstrings. As these data types are the unbounded mathematical types, no issues arise about overflow or similar errors.
Unary plus and minus
If \( x \) is an integer or real, then \( +x \) is \( x \) unchanged, \( -x \) is \( x \) with its sign reversed. Both are of the same type as \( x \).

Addition and subtraction
If \( x \) and \( y \) are integers or reals, \( x + y \) and \( x - y \) are their sum and difference. Both are of type `integer` if \( x \) and \( y \) are both of type `integer`, and `real` otherwise.

There are two cases where the types of \( x \) and \( y \) can be different. A bitstring and an integer can be added together to allow the operation \( PC + 4 \). An integer can be subtracted from a bitstring to allow the operation \( PC - 2 \).

If \( x \) and \( y \) are bitstrings of the same length \( N \), so that \( N = \text{Len}(x) = \text{Len}(y) \), then \( x + y \) and \( x - y \) are the least significant \( N \) bits of the results of converting \( x \) and \( y \) to integers and adding or subtracting them. Signed and unsigned conversions produce the same result:

\[
\begin{align*}
x + y &= (\text{SInt}(x) + \text{SInt}(y))_{N-1:0} \\
&= (\text{UInt}(x) + \text{UInt}(y))_{N-1:0} \\
x - y &= (\text{SInt}(x) - \text{SInt}(y))_{N-1:0} \\
&= (\text{UInt}(x) - \text{UInt}(y))_{N-1:0}
\end{align*}
\]

If \( x \) is a bitstring of length \( N \) and \( y \) is an integer, \( x + y \) and \( x - y \) are the bitstrings of length \( N \) defined by \( x + y = x + y_{N-1:0} \) and \( x - y = x - y_{N-1:0} \). Similarly, if \( x \) is an integer and \( y \) is a bitstring of length \( M \), \( x + y \) and \( x - y \) are the bitstrings of length \( M \) defined by \( x + y = x_{M-1:0} + y \) and \( x - y = x_{M-1:0} - y \).

Multiplication
If \( x \) and \( y \) are integers or reals, then \( x \times y \) is the product of \( x \) and \( y \). It is of type `integer` if \( x \) and \( y \) are both of type `integer`, and `real` otherwise.

Division and modulo
If \( x \) and \( y \) are reals, then \( x/y \) is the result of dividing \( x \) by \( y \), and is always of type `real`.

If \( x \) and \( y \) are integers, then \( x \div y \) and \( x \mod y \) are defined by:

\[
\begin{align*}
x \div y &= \text{RoundDown}(x/y) \\
x \mod y &= x - y \times (x \div y)
\end{align*}
\]

It is a pseudocode error to use any of \( x/y \), \( x \mod y \), or \( x \div y \) in any context where \( y \) can be zero.

Scaling
If \( x \) and \( n \) are of type `integer`, then:

- \( x \ll n = \text{RoundDown}(x \times 2^n) \).
- \( x \gg n = \text{RoundDown}(x \times 2^{\lceil -n \rceil}) \).

Raising to a power
If \( x \) is an integer or a real and \( n \) is an integer then \( x^n \) is the result of raising \( x \) to the power of \( n \), and:

- If \( x \) is of type `integer` then \( x^n \) is of type `integer`.
- If \( x \) is of type `real` then \( x^n \) is of type `real`.

### E1.3.5 The assignment operator

The assignment operator is the `=` character, which assigns the value of the right-hand side to the left-hand side. An assignment statement takes the form:

\[
\text{<assignable_expression>} = \text{<expression>};
\]

This following subsection defines valid expression syntax.
General expression syntax

An expression is one of the following:

- A literal.
- A variable, optionally preceded by a data type name to declare its type.
- The word `UNKNOWN` preceded by a data type name to declare its type.
- The result of applying a language-defined operator to other expressions.
- The result of applying a function to other expressions.

Variable names normally consist of alphanumeric and underscore characters, starting with an alphabetic or underscore character.

Each register defined in an ARM architecture specification defines a correspondingly named pseudocode bitstring variable, and that variable has the stated behavior of the register. For example, if a bit of a register is defined as RAZ/WI, then the corresponding bit of its variable reads as '0' and ignore writes.

An expression like `bits(32) UNKNOWN` indicates that the result of the expression is a value of the given type, but the architecture does not specify what value it is and software must not rely on such values. The value produced must not:

- Return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE and do not return UNKNOWN values,
- Be promoted as providing any useful information to software.

Note

UNKNOWN values are similar to the definition of UNPREDICTABLE, but do not indicate that the entire architectural state becomes unspecified.

Only the following expressions are assignable. This means that these are the only expressions that can be placed on the left-hand side of an assignment.

- Variables.
- The results of applying some operators to other expressions.
  The description of each language-defined operator that can generate an assignable expression specifies the circumstances under which it does so. For example, those circumstances might require that one or more of the expressions the operator operates on is an assignable expression.
- The results of applying array-like functions to other expressions. The description of an array-like function specifies the circumstances under which it can generate an assignable expression.

Note

If the right-hand side in an assignment is a function returning a tuple, an item in the assignment destination can be written as `-` to indicate that the corresponding item of the assigned tuple value is discarded. For example:

```
(shifted, -) = LSL_C(operand, amount);
```

The expression on the right-hand side itself can be a tuple. For example:

```
(x, y) = (function_1(), function_2());
```

Every expression has a data type:

- For a literal, this data type is determined by the syntax of the literal.
- For a variable, there are the following possible sources for the data type
  - An optional preceding data type name.
  - A data type the variable was given earlier in the pseudocode by recursive application of this rule.
A data type the variable is being given by assignment, either by direct assignment to the variable, or by assignment to a list of which the variable is a member. It is a pseudocode error if none of these data type sources exists for a variable, or if more than one of them exists and they do not agree about the type.

- For a language-defined operator, the definition of the operator determines the data type.
- For a function, the definition of the function determines the data type.

### E1.3.6 Precedence rules

The precedence rules for expressions are:

1. Literals, variables and function invocations are evaluated with higher priority than any operators using their results, but see Boolean operators on page E1-1136.

2. Operators on integers follow the normal operator precedence rules of
   - exponentiation before multiply/divide
   - before add/subtract, with sequences of multiply/divides or add/subtracts evaluated left-to-right.

3. Other expressions must be parenthesized to indicate operator precedence if ambiguity is possible, but need not be if all permitted precedence orders under the type rules necessarily lead to the same result. For example, if \( i, j, \) and \( k \) are integer variables, \( i > 0 \land j > 0 \land k > 0 \) is acceptable, but \( i > 0 \land j > 0 \lor k > 0 \) is not.

### E1.3.7 Conditional expressions

If \( x \) and \( y \) are two values of the same type and \( t \) is a value of type boolean, then \( \text{if } t \text{ then } x \text{ else } y \) is an expression of the same type as \( x \) and \( y \) that produces \( x \) if \( t \) is true and \( y \) if \( t \) is false.

### E1.3.8 Operator polymorphism

Operators in pseudocode can be polymorphic, with different functionality when applied to different data types. Each resulting form of an operator has a different prototype definition. For example, the operator \( + \) has forms that act on various combinations of integers, reals and bitstrings.

Table E1-1 summarizes the operand types valid for each unary operator and the result type. Table E1-2 summarizes the operand types valid for each binary operator and the result type.

### Table E1-1 Result and operand types permitted for unary operators

<table>

E1.4  Statements and control structures

This section describes the statements and program structures available in the pseudocode.

E1.4.1  Statements and Indentation

A simple statement is either an assignment, a function call, or a procedure call. Each statement must be terminated with a semicolon.

Indentation normally indicates the structure in compound statements. The statements contained in structures such as if ... then ... else ... or procedure and function definitions are indented more deeply than the statement structure itself. The end of a compound statement structure and their end is indicated by returning to the original indentation level or less.

Indentation is normally done by four spaces for each level. Standard indentation uses four spaces for each level of indent.

E1.4.2  Function and procedure calls

This section describes how functions and procedures are defined and called in the pseudocode.
Procedure and function definitions

A procedure definition has the form:

<procedure name>(<argument prototypes>)
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;

where <argument prototypes> consists of zero or more argument definitions, separated by commas. Each argument definition consists of a type name followed by the name of the argument.

__________ Note __________

This first definition line is not terminated by a semicolon. This distinguishes it from a procedure call.

__________

A function definition is similar, but also declares the return type of the function:

<return type> <function name>(<argument prototypes>)
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;

Array-like functions are similar, but are written with square brackets and have two forms. These two forms exist because reading from and writing to an array element require different functions. They are frequently used in memory operations. An array-like function definition with a return type is equivalent to reading from an array. For example:

<return type> <function name>[<argument prototypes>]
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;

Its related function definition with no return type is equivalent to writing to an array. For example:

<function name>[<argument prototypes>] = <value prototype>
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;

The value prototype determines what data type can be written to the array. The two related functions must share the same name, but the value prototype and return type can be different.

Procedure calls

A procedure call has the form:

<procedure name>(<arguments>);

Return statements

A procedure return has the form:

return;

A function return has the form:

return <expression>;

where <expression> is of the type declared in the function prototype line.
### E1.4.3 Conditional control structures

This section describes how conditional control structures are used in the pseudocode.

#### if ... then ... else ...

In addition to being a ternary operator, a multi-line if ... then ... else ... structure can act as a control structure and has the form:

```plaintext
if <boolean_expression> then
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
elsif <boolean_expression> then
  <statement a>;
  <statement b>;
  ...
  <statement z>;
else
  <statement A>;
  <statement B>;
  ...
  <statement Z>;
```

The block of lines consisting of elsif and its indented statements is optional, and multiple elsif blocks can be used.

The block of lines consisting of else and its indented statements is optional.

Abbreviated one-line forms can be used when the then part, and in the else part if it is present, contain only simple statements such as:

```plaintext
if <boolean_expression> then <statement 1>;
if <boolean_expression> then <statement 1>; else <statement A>;
if <boolean_expression> then <statement 1>; <statement 2>; else <statement A>;
```

**Note**

In these forms, `<statement 1>`, `<statement 2>` and `<statement A>` must be terminated by semicolons. This and the fact that the else part is optional distinguish its use as a control structure from its use as a ternary operator.

#### case ... of ...

A case ... of ... structure has the form:

```plaintext
case <expression> of
  when <literal values1>
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;
  when <literal values2>
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;
  ... more "when" groups if required ...
  otherwise
    <statement A>;
    <statement B>;
    ...
    <statement Z>;
```
In this structure, `<literal values1>` and `<literal values2>` consist of literal values of the same type as `<expression>`, separated by commas. There can be additional `when` groups in the structure. Abbreviated one line forms of `when` and `otherwise` parts can be used when they contain only simple statements.

If `<expression>` has a bitstring type, the literal values can also include bitstring literals containing ‘x’ bits, known as bitmasks. For details see *Equality and non-equality on page E1-1136.*

**E1.4.4 Loop control structures**

This section describes the three loop control structures used in the pseudocode.
repeat … until …

A repeat ... until ... structure has the form:

repeat
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
until <boolean_expression>;

It executes the statement block at least once, and the loop repeats until <boolean expression> evaluates to TRUE. Variables explicitly declared inside the loop body have scope local to that loop and might not be accessed outside the loop body.

while ... do

A while ... do structure has the form:

while <boolean_expression> do
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;

It begins executing the statement block only if the Boolean expression is true. The loop then runs until the expression is false.

for ...

A for ... structure has the form:

for <assignable_expression> = <integer_expr1> to <integer_expr2>
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;

The <assignable_expression> is initialized to <integer_expr1> and compared to <integer_expr2>. If <integer_expr1> is less than <integer_expr2>, the loop body is executed and the <assignable_expression> incremented by one. This repeats until <assignable_expression> is more than or equal to <integer_expr2>. There is an alternate form:

for <assignable_expression> = <integer_expr1> downto <integer_expr2>
  where <integer_expr1> is decremented after the loop body executes and continues until <assignable_expression> is less than or equal than <integer_expr2>.

E1.4.5 Special statements

This section describes statements with particular architecturally-defined behaviors.

UNDEFINED

This subsection describes the statement:

UNDEFINED;

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that the Undefined Instruction exception is taken.
UNPREDICTABLE

This subsection describes the statement:

UNPREDICTABLE;

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is UNPREDICTABLE.

SEE...

This subsection describes the statement:

SEE <reference>;

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that nothing occurs as a result of the current pseudocode because some other piece of pseudocode defines the required behavior. The <reference> indicates where that other pseudocode can be found.

It usually refers to another instruction, but can also refer to another encoding or note of the same instruction.

IMPLEMENTATION_DEFINED

This subsection describes the statement:

IMPLEMENTATION_DEFINED {"<text>"};

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is IMPLEMENTATION DEFINED. An optional <text> field can give more information.

E1.4.6 Comments

The pseudocode supports two styles of comments:

• // starts a comment that is terminated by the end of the line.
• /* starts a comment that is terminated by */. */ statements might not be nested, and the first */ ends the comment.

Note
Comment lines do not require a terminating semicolon.
E1.5 Built-in functions

This section describes:
- Bitstring manipulation functions.
- Arithmetic functions on page E1-1149.

E1.5.1 Bitstring manipulation functions

The following bitstring manipulation functions are defined:

**Bitstring length**

If x is a bitstring:
- The bitstring length function Len(x) returns the length of x as an integer.

**Bitstring concatenation and replication**

If x is a bitstring and n is an integer with \( n \geq 0 \):
- Replicate(x, n) is the bitstring of length \( n \times \text{Len}(x) \) consisting of n copies of x concatenated together.
- Zeros(n) = Replicate('0', n).
- Ones(n) = Replicate('1', n).

**Bitstring count**

If x is a bitstring, BitCount(x) is an integer result equal to the number of bits of x that are ones.
Testing a bitstring for being all zero or all ones

If x is a bitstring:

- $\text{IsZero}(x)$ produces TRUE if all of the bits of $x$ are zeros and FALSE if any of them are ones.
- $\text{IsZeroBit}(x)$ produces '1' if all of the bits of $x$ are zeros and '0' if any of them are ones.

$\text{IsZero}(x)$ and $\text{IsZeroBit}(x)$ work in the corresponding ways. This means:

$$
\text{IsZero}(x) = (\text{BitCount}(x) == 0) \\
\text{IsZeroBit}(x) = \text{if } \text{IsZero}(x) \text{ then } '1' \text{ else } '0' \\
\text{IsOnes}(x) = (\text{BitCount}(x) == \text{Len}(x)) \\
\text{IsOnesBit}(x) = \text{if } \text{IsOnes}(x) \text{ then } '1' \text{ else } '0'
$$

Lowest and highest set bits of a bitstring

If x is a bitstring, and $N = \text{Len}(x)$:

- $\text{LowestSetBit}(x)$ is the minimum bit number of any of the bits of $x$ that are ones. If all of its bits are zeros, $\text{LowestSetBit}(x) = N$.
- $\text{HighestSetBit}(x)$ is the maximum bit number of any of the bits of $x$ that are ones. If all of its bits are zeros, $\text{HighestSetBit}(x) = -1$.
- $\text{CountLeadingZeroBits}(x)$ is the number of zero bits at the left end of $x$, in the range 0 to $N$. This means:
  $$
  \text{CountLeadingZeroBits}(x) = N - 1 - \text{HighestSetBit}(x).
  $$
- $\text{CountLeadingSignBits}(x)$ is the number of copies of the sign bit of $x$ at the left end of $x$, excluding the sign bit itself, and is in the range 0 to $N-1$. This means:
  $$
  \text{CountLeadingSignBits}(x) = \text{CountLeadingZeroBits}(x<N-1:1> \text{ EOR } x<N-2:0>).
  $$

Zero-extension and sign-extension of bitstrings

If $x$ is a bitstring and $i$ is an integer, then $\text{ZeroExtend}(x, i)$ is $x$ extended to a length of $i$ bits, by adding sufficient zero bits to its left. That is, if $i == \text{Len}(x)$, then $\text{ZeroExtend}(x, i) = x$, and if $i > \text{Len}(x)$, then:

$$
\text{ZeroExtend}(x, i) = \text{Replicate}(0, i-\text{Len}(x)) : x
$$

If $x$ is a bitstring and $i$ is an integer, then $\text{SignExtend}(x, i)$ is $x$ extended to a length of $i$ bits, by adding sufficient copies of its leftmost bit to its left. That is, if $i == \text{Len}(x)$, then $\text{SignExtend}(x, i) = x$, and if $i > \text{Len}(x)$, then:

$$
\text{SignExtend}(x, i) = \text{Replicate}(\text{TopBit}(x), i-\text{Len}(x)) : x
$$

It is a pseudocode error to use either $\text{ZeroExtend}(x, i)$ or $\text{SignExtend}(x, i)$ in a context where it is possible that $i < \text{Len}(x)$.

Converting bitstrings to integers

If $x$ is a bitstring, $\text{SInt}()$ is the integer whose two’s complement representation is $x$.

$\text{UInt}()$ is the integer whose unsigned representation is $x$.

$\text{Int}(x, \text{unsigned})$ returns either $\text{SInt}(x)$ or $\text{UInt}(x)$ depending on the value of its second argument.

**E1.5.2 Arithmetic functions**

This section defines built-in arithmetic functions.

**Absolute value**

If $x$ is either of type real or integer, $\text{Abs}(x)$ returns the absolute value of $x$. The result is the same type as $x$. 
Rounding and aligning

If $x$ is a real:

- $\text{RoundDown}(x)$ produces the largest integer $n$ such that $n \leq x$.
- $\text{RoundUp}(x)$ produces the smallest integer $n$ such that $n \geq x$.
- $\text{RoundTowardsZero}(x)$ produces:
  - $\text{RoundDown}(x)$ if $x > 0.0$.
  - 0 if $x == 0.0$.
  - $\text{RoundUp}(x)$ if $x < 0.0$.

If $x$ and $y$ are both of type integer, $\text{Align}(x, y) = y \times (x \text{ DIV } y)$, and is of type integer.

If $x$ is of type bitstring and $y$ is of type integer, $\text{Align}(x, y) = (\text{Align}(\text{UInt}(x), y)) < \text{Len}(x)-1:0>$, and is a bitstring of the same length as $x$.

It is a pseudocode error to use either form of $\text{Align}(x, y)$ in any context where $y$ can be 0. In practice, $\text{Align}(x, y)$ is only used with $y$ a constant power of two, and the bitstring form used with $y = 2^n$ has the effect of producing its argument with its $n$ low-order bits forced to zero.

Maximum and minimum

If $x$ and $y$ are integers or reals, then $\text{Max}(x, y)$ and $\text{Min}(x, y)$ are their maximum and minimum respectively. $x$ and $y$ must both be of type integer or of type real. The function returns a value of the same type as its operands.
E1.6 ARM pseudocode definition index

This section contains the following tables:

- Table E1-3 which contains the pseudocode data types.
- Table E1-4 which contains the pseudocode operators.
- Table E1-5 on page E1-1152 which contains the pseudocode keywords and control structures.
- Table E1-6 on page E1-1153 which contains the statements with special behaviors.

Table E1-3 Index of pseudocode data types

Chapter E2
Pseudocode Specification

This chapter specifies the ARMv8-M pseudocode. It contains the following section:

- *Alphabetical pseudocode List on page E2-1156.*
E2.1 Alphabetical pseudocode List

E2.1.1 ALUWritePC

// ALUWritePC()
// ============

ALUWritePC(bits(32) address)
BranchWritePC(address);

E2.1.2 ASR

// ASR()
// ======

bits(N) ASR(bits(N) x, integer shift)
  assert shift >= 0;
  if shift == 0 then
    result = x;
  else
    (result, -) = ASR_C(x, shift);
  return result;

E2.1.3 ASR_C

// ASR_C()
// ========

(bits(N), bit) ASR_C(bits(N) x, integer shift)
  assert shift > 0;
  extended_x = SignExtend(x, shift+N);
  result = extended_x<shift+N-1:shift>;
  carry_out = extended_x<shift-1>;
  return (result, carry_out);

E2.1.4 AccType

// Memory reference access type
enumeration AccType { AccType_NORMAL,  // Normal loads and stores
  AccType_ORDERED,                   // Load-Acquire and Store-Release
  AccType_STACK,                     // HW generated stacking / unstacking operation
  AccType_LAZYFP,                    // HW generated stacking due to lazy
  AccType_IFETCH,                    // Instruction fetch
  AccType_VECTABLE                   // Vector table fetch
};
E2.1.5 AccessAttributes

// Memory access attributes
type AccessAttributes is (  
  boolean iswrite,  // TRUE for memory stores, FALSE for load accesses  
  boolean ispriv,  // TRUE if the access is privileged, FALSE if unprivileged  
  AccType acctype
)

E2.1.6 ActivateException

// ActivateException()
// ===============
ActivateException(integer exceptionNumber, boolean excIsSecure)
// If the exception is Secure, directly entry the Secure state.
CurrentState = if excIsSecure
  then SecurityState_Secure  
  else SecurityState_NonSecure;
IPSR.Exception = exceptionNumber<8:0>;  // Update IPSR to this exception. This also  
  // causes a transition to privileged handler  
  // mode as IPSR.Exception != 0
if HaveMainExt() then
  // IT/ICI bits cleared
  ITSTATE = Zeros(8);  
// PRIMASK, FAULTMASK, BASEPRI unchanged on exception entry

E2.1.219 ReturnState

// ReturnState()
// =============

(bits(32), ITSTATEType) ReturnState(boolean instExecOk)

// Whether the return address (and associated IT state) point to the current
// instruction or the next instruction only depends on whether the
// instruction executed correctly, and not the type of exception.
//
// For trivial cases this behavior matches the following expectation:-
//  * Faults (eg MemManage, UsageFault, etc) result in the return address
//    pointing to the instruction that caused the fault.
//  * Interrupts and SVC's result in the return address pointing to the next
//    instruction.
//
// However it is important to realise that the behavior can differ from the
// expectation above in complex cases. The following examples illustrate how
// and why the behavior can be different:-
//  1) A MemManage fault occurring at the same time as a higher priority
//     interrupt. The interrupt is taken first due to its priority, but the
//     return address is set to the current instruction because it didn't
//     execute successfully. This ensures the return state is correct for
//     when the pending MemManage fault is taken (which may occur by tail
//     chaining after the interrupt handler returns).
//  2) The architecture states:-
//     "A Fault that is escalated to the priority of a HardFault
//      retains the return address value of the original fault."
//     So a SVC that escalates to a HardFault has the return address of the
//     instruction after SVC (because the SVC succeeded is setting an
//     exception pending).
//  3) The BusFault exception is disabled when a BusFault occurs during
//     lazy FP state preservation. The fault remains pending until a store
//     instruction re-enables the BusFault by writing to the SHCSR
//     register, at which point the exception can be taken. However because
//     the store instruction didn't cause the fault, it just allowed it to
//     be taken the return address points to the instruction after the
//     store.
//
// NOTE: Asynchronous faults (eg async BusFault) deviate from this rule and
// have a return address set to the next instruction. Due to their
// asynchronous nature the address of the actual instruction that
// caused the fault is not known.

// Returns the following values based on the exception cause
// NOTE: ReturnAddress() is always halfword aligned, meaning bit<0> is always zero
// If present the xPSR.IT bits saved to the stack are consistent with
// ReturnAddress()

Part F
Debug Packet Protocols
Chapter F1
ITM and DWT Packet Protocol Specification

This chapter specifies the protocol for packets that send the data generated by the ITM and DWT to an external debugger. It contains the following sections:

• About the ITM and DWT packets on page F1-1304.
• Alphabetical list of DWT and ITM packets on page F1-1307.
F1.1 About the ITM and DWT packets

The following sections give an overview of the ITM and DWT packets and how the TPIU transmits them:
• Uses of ITM and DWT packets
• ITM and DWT protocol packet headers on page F1-1305
• Packet transmission by the trace sink on page F1-1305

Note
This chapter describes packet transmission by a trace sink such as a TPIU. The ITM can send packets to any suitable trace sink. Regardless of the actual trace sink used, the ITM formats the packets as described in this chapter.

F1.1.1 Uses of ITM and DWT packets

The ITM sends a packet to the trace sink when:
• Software writes to a stimulus register. This generates an Instrumentation packet.
• The hardware generates a Protocol packet. Protocol packets include timestamps and synchronization packets.
• It receives a packet from the DWT, for forwarding to the trace sink.

The DWT sends a packet to the ITM for forwarding to the trace sink when:
• A DWT comparator matches and generates one or more Data Trace packets.
• It samples the PC.
• One of the performance profile counters wraps.

This chapter describes the packet protocol used.
F1.1.2 ITM and DWT protocol packet headers

F1.1.3 Packet transmission by the trace sink

The trace sink either:
- Forms the packets into frames, as required by the ARM CoreSight™ Architecture Specification.
- Transmits the packets over a serial port.

For each packet, the trace sink transmits:
- The header byte first, followed by any payload bytes.
- Each byte of the packet least significant bit (LSB) first.

Figures in this chapter show each packet as a sequence of bytes, with the LSB of each byte to the right and the most significant bit (MSB) to the left. Figure F1-1 on page F1-1306 shows this convention, and how it relates to data transmission for a packet with a header byte and two payload bytes.
Figure F1-1 Convention for packet descriptions

In some sections, the figures are split into separate figures for the header byte and payload bytes. For instance, where the number of payload bytes varies according to a field in the header.

The ITM merges the packets from the ITM and DWT with the Local and Global timestamp, Synchronization, and other Protocol packets, and forwards them to the trace sink as a single data stream. The trace sink then merges this data stream with the data from the ETM, if implemented.
F1.2  Alphabetical list of DWT and ITM packets

F1.2.1  Data Trace Data Address packet

The Data Trace Data Address packet characteristics are:

**Purpose**
Indicates a DWT comparator generated a match, and the address that matched. Data Address packets are only generated for Data Address range comparator pairs. The address might be compressed. However, it is not required that Short and Medium packets are generated when the address bits match.

**Attributes**
Multi-part Hardware source packet comprising:
- 8-bit header.
- 8, 16, or 32-bit payload.

### Data Trace Data Address packet header

The Data Trace Data Address packet header bit assignments are:

<table>
<thead>
<tr>
<th>Bit Assignment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7:6, 4:3, 0</td>
<td>Hardware Source packet type.</td>
</tr>
<tr>
<td>5:4</td>
<td>DWT comparator index.</td>
</tr>
<tr>
<td>2</td>
<td>Source.</td>
</tr>
<tr>
<td>1:0</td>
<td>Size.</td>
</tr>
</tbody>
</table>

**ID [4:3, 0], byte 0 bits [7:6,3]**

Hardware Source packet type. Bits [7:3] discriminate between Hardware Source packet types. The possible values of this field are:
- 01xx1  Data Trace Data Address packet.
  This field reads as 0b011.

**CMPN, byte 0 bits [5:4]**

DWT comparator index. Defines which comparator generated a match. Data Trace Data Address packets can be compressed relative to the value in DWT_COMP<CMPN>. The number of traced bits is indicated by the SS field. The remainder of the address bits comes from DWT_COMP<CMPN>. Either comparator in a Data Address range comparator pair can be used.

**SH, byte 0 bit [2]**

Source. The possible values of this bit are:
- 1  Hardware source packet.
  This bit reads as 0b1.

**SS, byte 0 bits [1:0]**

Size. The possible values of this field are:
- 01  Short Data Address packet.
- 10  Medium Data Address packet.
- 11  Long Data Address packet.

The value 0b00 encodes a Protocol packet.
Data Trace Data Address packet payload

When Long Data Address packet, \( SS = \text{0b11} \), the Data Trace Data Address packet payload bit assignments are:

\[
\begin{array}{c|c|c|c|c|c|c|c}
7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
DADDR[7:0] & & & & & & & \\
DADDR[15:8] & & & & & & & \\
DADDR[31:24] & & & & & & & \\
\end{array}
\]

When Medium Data Address packet, \( SS = \text{0b10} \), the Data Trace Data Address packet payload bit assignments are:

\[
\begin{array}{c|c|c|c|c|c|c|c}
7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
DADDR[7:0] & & & & & & & \\
DADDR[15:8] & & & & & & & \\
\end{array}
\]

When Short Data Address packet, \( SS = \text{0b01} \), the Data Trace Data Address packet payload bit assignments are:

\[
\begin{array}{c|c|c|c|c|c|c|c}
7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
DADDR[7:0] & & & & & & & \\
\end{array}
\]

\text{DADDR}[31:0], bytes \(<4:1>\), when Long Data Address packet, \( SS = \text{0b11} \)
\begin{itemize}
\item Data address.
\end{itemize}

\text{DADDR}[15:0], bytes \(<2:1>\), when Medium Data Address packet, \( SS = \text{0b10} \)
\begin{itemize}
\item Data address. \( \text{DADDR}[31:16] = \text{DWT\_COMP<CMPN>[31:16]} \).
\end{itemize}

\text{DADDR}[7:0], byte \(<1>\), when Short Data Address packet, \( SS = \text{0b01} \)
\begin{itemize}
\item Data address. \( \text{DADDR}[31:8] = \text{DWT\_COMP<CMPN>[31:8]} \).
\end{itemize}

F1.2.2 Data Trace Data Value packet

The Data Trace Data Value packet characteristics are:

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Indicates a DWT comparator generated a match, and the value that matched.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attributes</td>
<td>Multi-part Hardware source packet comprising:</td>
</tr>
<tr>
<td></td>
<td>• 8-bit header.</td>
</tr>
<tr>
<td></td>
<td>• 8, 16, or 32-bit payload.</td>
</tr>
</tbody>
</table>

Data Trace Data Value packet header

The Data Trace Data Value packet header bit assignments are:

\[
\begin{array}{c|c|c|c|c|c|c|c}
1 & 0 & CMPN & WnR & 1 & \# \text{0b00} & \\
\end{array}
\]

ID[4:3], byte 0 bits [7:6]

Hardware Source packet type. Bits [7:3] discriminate between Hardware Source packet types. The possible values of this field are:

\text{10xxx}  \begin{itemize}
\item Data Trace Data Value packet.
\end{itemize}

This field reads as \text{0b10}. 
CMPN, byte 0 bits [5:4]  
DWT comparator index. Defines which comparator generated a match.

WnR, byte 0 bit [3]  
Write-not-read. The possible values of this bit are:  
0 Read.  
1 Write.

SH, byte 0 bit [2]  
Source. The possible values of this bit are:  
1 Hardware source packet.  
This bit reads as 0b1.

SS, byte 0 bits [1:0]  
Size. The possible values of this field are:  
01 Byte Data Value packet.  
10 Halfword Data Value packet.  
11 Word Data Value packet.  
The value 0b00 encodes a Protocol packet.

**Data Trace Data Value packet payload**

When Byte Data Value packet, SS == 0b01, the Data Trace Data Value packet payload bit assignments are:

<table>
<thead>
<tr>
<th>Bit 7</th>
<th>Bit 6</th>
<th>Bit 5</th>
<th>Bit 4</th>
<th>Bit 3</th>
<th>Bit 2</th>
<th>Bit 1</th>
<th>Bit 0</th>
<th>Data Value[7:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte 1</td>
<td></td>
<td></td>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

DVALUE[31:0], bytes <4:1>, when Word Data Value packet, SS == 0b11  
Data value.

DVALUE[15:0], byte 1 bits [15:0], when Halfword Data Value packet, SS == 0b10  
Data value.

DVALUE[7:0], byte <1>, when Byte Data Value packet, SS == 0b01  
Data value.
F1.2.3 Data Trace Match packet

The Data Trace Match packet characteristics are:

**Purpose**
Indicates a DWT comparator generated a match.

**Attributes**
16-bit Hardware source packet.

The Data Trace Match packet bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>MATCH</td>
</tr>
<tr>
<td>6</td>
<td>CMPN</td>
</tr>
<tr>
<td>5</td>
<td>ID[4:3]</td>

<tr>
<td>4</td>
<td>ID[0]</td>
</tr>
<tr>
<td>3</td>
<td>SH</td>
</tr>
<tr>
<td>2</td>
<td>SS[1:0]</td>
</tr>
<tr>
<td>1</td>
<td>SS[0]</td>
</tr>
<tr>
<td>0</td>
<td>MATCH</td>
</tr>
</tbody>
</table>

**Byte 1 bits [7:1]**

This field reads as 0b0000000.

**MATCH, byte 1 bit [0]**

Data Trace Match packet. Discriminates between the Data Trace PC Value packet and the Data Trace Match packet. The possible values of this bit are:

- 1  Data Trace Match packet.

This bit reads as 0b1.

**ID[4:3], byte 0 bits [7:6]**

Hardware Source packet type. Bits [7:3] discriminate between Hardware Source packet types. The possible values of this field are:

- 01xx0  Data Trace PC Value packet or Data Trace Match packet.

This field reads as 0b010.

**CMPN, byte 0 bits [5:4]**

DWT comparator index. Defines which comparator generated a match.

**SH, byte 0 bit [2]**

Source. The possible values of this bit are:

- 1  Hardware source packet.

This bit reads as 0b1.

**SS, byte 0 bits [1:0]**

Size. The possible values of this field are:

- 01  Source packet, 1-byte payload, 2-byte packet.

The value 0b00 encodes a Protocol packet. All other values are reserved. This field reads as 0b1.

F1.2.4 Data Trace PC Value packet

The Data Trace PC Value packet characteristics are:

**Purpose**
Indicates a DWT comparator generated a match, and the address of the instruction that matched. The address might be compressed. However, it is not required that Short and Medium packets are generated when the address bits match.
Attributes

Multi-part Hardware source packet comprising:

- 8-bit header.
- 8, 16, or 32-bit payload.

Data Trace PC Value packet header

The Data Trace PC Value packet header bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
<th># 0b00</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>CMPN</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>ID[4:3]</td>
<td></td>
<td>ID[0]</td>
<td>SH</td>
<td>SS</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

ID[4:3,0], byte 0 bits [7:6,3]

Hardware Source packet type. Bits [7:3] discriminate between Hardware Source packet types. The possible values of this field are:

- `01xx0` Data Trace PC Value packet or Data Trace Match packet.
- `Bit [0] of byte 1 discriminates between the Data Trace PC Value packet and the Data Trace Match packet.`

This field reads as `0b010`.

CMPN, byte 0 bits [5:4]

DWT comparator index. Defines which comparator generated a match. Data Trace PC Value packets can be compressed relative to the value in DWT_COMP<CMPN>. The number of traced bits is indicated by the SS field. The remainder of the address bits comes from DWT_COMP<CMPN>. Either comparator in an Instruction Address range comparator pair can be used.

Byte 0 bit [3]

This bit reads as `0b0`.

SH, byte 0 bit [2]

Source. The possible values of this bit are:

- `1` Hardware source packet.

This bit reads as `0b1`.

SS, byte 0 bits [1:0]

Size. The possible values of this field are:

- `01` Short PC Value packet.
- `10` Medium PC Value packet.
- `11` Long PC Value packet.

The value `0b00` encodes a Protocol packet.

Data Trace PC Value packet payload

When Long PC Value packet, SS == `0b11`, the Data Trace PC Value packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
<th>Byte 1</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>PC[7:1]</td>
</tr>
</tbody>
</table>

|   |   |   |   |   | Byte 2 |
|---|---|---|---|---|
|   |   |   | PC[15:8] |

|   |   |   |   | Byte 3 |
|---|---|---|---|
|   |   | PC[23:16] |

|   |   |   |   | Byte 4 |
|---|---|---|---|
|   |   | PC[31:24] |
When Medium PC Value packet, SS == 0b10, the Data Trace PC Value packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>PC[7:1]</td>
<td>0</td>
<td></td>
<td></td>

<td></td>
<td></td>
</tr>
<tr>
<td>PC[15:8]</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When Short PC Value packet, SS == 0b01, the Data Trace PC Value packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>PC[7:1]</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>MATCH</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

PC[31:1], bytes <4:2>, byte 1 bits [7:1], when Long PC Value packet, SS == 0b11
Instruction address.

PC[15:1], byte <2>, byte 1 bits [7:1], when Medium PC Value packet, SS == 0b10
Instruction address. PC[31:16] == DWT_COMP<CMPN>[31:16].

PC[7:1], byte 1 bits [7:1], when Short PC Value packet, SS == 0b01
Instruction address. PC[31:8] == DWT_COMP<CMPN>[31:8].

MATCH, byte 1 bit [0]
Data Trace Match packet. Discriminates between the Data Trace PC Value packet and the Data Trace Match packet. The possible values of this bit are:
0 Data Trace PC Value packet.
This bit reads as 0b0.

**F1.2.5 Event Counter packet**

The Event Counter packet characteristics are:

**Purpose**
Indicates one or more DWT counters wraps through zero.

**Attributes**
16-bit Hardware source packet.

The Event Counter packet bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>SH</td>
<td>SS</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Byte 1 bits [7:6]**
Reserved. This field is RES0.

**Cyc, byte 1 bit [5]**
POSTCNT timer decremented to zero. See DWT_CTRL for more information on the POSTCNT timer.

**Fold, byte 1 bit [4]**
DWT_FOLDCNT counter wrapped from 0xFF to zero.

**LSU, byte 1 bit [3]**
DWT_LSUCNT counter wrapped from 0xFF to zero.
Sleep, byte 1 bit [2]
   DWT_SLEEPCNT counter wrapped from 0xFF to zero.

Exc, byte 1 bit [1]
   DWT_EXCCNT counter wrapped from 0xFF to zero.

CPI, byte 1 bit [0]
   DWT_CPICNT counter wrapped from 0xFF to zero.

ID, byte 0 bits [7:3]
   Hardware Source packet type. Bits [7:3] discriminate between Hardware Source packet types. The possible values of this field are:
   0b00000   Event Counter packet.
   This field reads as 0b00000.

SH, byte 0 bit [2]
   Source. The possible values of this bit are:
   1   Hardware source packet.
   This bit reads as 0b1.

SS, byte 0 bits [1:0]
   Size. The possible values of this field are:
   01   Source packet, 1-byte payload, 2-byte packet.
   The value 0b00 encodes a Protocol packet. All other values are reserved. This field reads as 0b01.

F1.2.6 Exception Trace packet

The Exception Trace packet characteristics are:

Purpose   Indicates the PE has entered, exited or returned to an exception.
Attributes 24-bit Hardware source packet.

The Exception Trace packet bit assignments are:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>7:6</td>
<td>0</td>
</tr>
<tr>
<td>5</td>
<td>0</td>

<td>RES0</td>
</tr>
</tbody>
</table>
```

Byte 2

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>ExceptionNumber[8]</td>
</tr>
</tbody>
</table>
```

Byte 2 bits [7:6,3:1]
   Reserved. This field is RES0.

FN, byte 2 bits [5:4]
   Function. The possible values of this field are:
   0b01   Entered exception indicated by ExceptionNumber.
   0b10   Exited exception indicated by ExceptionNumber.
   0b11   Returned to exception indicated by ExceptionNumber.
   All other values are reserved.
ExceptionNumber, byte 2 bit [0], byte <1>
The exception number.

ID, byte 0 bits [7:3]
Hardware Source packet type. Bits [7:3] discriminate between Hardware Source packet types. The possible values of this field are:
0b00001    Exception Trace packet.
This field reads as 0b0001.

SH, byte 0 bit [2]
Source. The possible values of this bit are:
1    Hardware source packet.
This bit reads as 0b1.

SS, byte 0 bits [1:0]
Size. The possible values of this field are:
10    Source packet, 2-byte payload, 3-byte packet.
The value 0b00 encodes a Protocol packet. All other values are reserved. This field reads as 0b10.

F1.2.7 Extension packet
The Extension packet characteristics are:

Purpose
An Extension packet provides additional information about the identified source. The amount of information required determines the number of payload bytes, 0-4. The architecture only defines one use of the Extension packet, to provide a Stimulus port page number. For this use, SH == 0, and a single byte Extension packet is emitted.

Attributes
8, 16, 24, 32, or 40-bit Protocol packet.

When 1-byte packet, the Extension packet bit assignments are:

```
  7  6  5  4  3  2  1  0
 C EX[2:0] SH 0 0
```

When 2-byte packet, the Extension packet bit assignments are:

```
  7  6  5  4  3  2  1  0
 1 EX[2:0] SH 0 0
```

```
  0 EX[9:3]
 C
```

Byte 0

Byte 1
When 3-byte packet, the Extension packet bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>

EX[23:3], byte 3 bits [6:0], byte 2 bits [6:0], byte 1 bits [6:0], when 4-byte packet

Extension information.
C, byte 2 bit [7]
Continuation bit. The possible values of this bit are:
0       3-byte packet.
1       At least 4-byte packet.

EX[17:3], byte 2 bits [6:0], byte 1 bits [6:0], when 3-byte packet
Extension information.

C, byte 1 bit [7]
Continuation bit. The possible values of this bit are:
0       2-byte packet.
1       At least 3-byte packet.

EX[9:3], byte 1 bits [6:0], when 2-byte packet
Extension information.

C, byte 0 bit [7]
Continuation bit. The possible values of this bit are:
0       1-byte packet.
1       At least 2-byte packet.

EX[2:0], byte 0 bits [6:4]
Extension information.

--- Note ---
If SH == 1, then EX defines PAGE, the Stimulus port page number.

ID[1], byte 0 bit [3]
Protocol packet type. Bits [6:2] discriminate between Protocol packet types. The possible values of this bit are:
xxx1x   Extension packet.
This bit reads as 0b1.

SH, byte 0 bit [2]
Source. The possible values of this bit are:
0       Extension packet for Instrumentation packet.
1       Extension packet for Hardware source packet.

SS, byte 0 bits [1:0]
Packet type. The possible values of this field are:
00       Protocol packet.
Other values encode different sizes of Hardware and Software source packets. This field reads as 0b00.

F1.2.8   Global Timestamp 1 packet

The Global Timestamp 1 packet characteristics are:

Purpose
Contains the least significant bits of the global timestamp value. The ITM might compress this value if it is not generating a full timestamp by omitting significant bits if they are unchanged from the previous timestamp value.
Attributes

Multi-part Protocol packet comprising:

- 8-bit header.
- 8, 16, 24, or 32-bit payload.

Global Timestamp 1 packet header

The Global Timestamp 1 packet header bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

C, byte 0 bit [7]

Continuation bit. This bit reads as 0b1.

ID[4,2:0], byte 0 bits [6,4:2]

Protocol packet type. Bits [6:2] discriminate between Protocol packet types. The possible values of this field are:

- 0101 Global Timestamp packet.

This field reads as 0b0101.

T, byte 0 bit [5]

Global Timestamp packet type. The possible values of this bit are:

- 0 Global Timestamp 1 packet.

This bit reads as 0b0.

SS, byte 0 bits [1:0]

Packet type. The possible values of this field are:

- 00 Protocol packet.

Other values encode different sizes of Hardware and Software source packets. This field reads as 0b00.

Global Timestamp 1 packet payload

When 7-bit timestamp, the Global Timestamp 1 packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>TS[6:0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When 14-bit timestamp, the Global Timestamp 1 packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>TS[6:0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>TS[13:7]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
When 21-bit timestamp, the Global Timestamp 1 packet payload bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Continuation bit</td>
<td>0b0</td>
</tr>
<tr>
<td>1</td>

<td></td>
</tr>
<tr>
<td>2</td>
<td>ClkCh</td>
<td></td>
</tr>
<tr>
<td>3, 4, 5, 6, 7</td>
<td>Global Timestamp</td>
<td></td>
</tr>
</tbody>
</table>

When 26-bit or full timestamp, the Global Timestamp 1 packet payload bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Continuation bit</td>
<td>0b0</td>
</tr>
<tr>
<td>1</td>
<td>Wrap</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>ClkCh</td>
<td></td>
</tr>
<tr>
<td>3, 4, 5, 6, 7</td>
<td>Global Timestamp</td>
<td></td>
</tr>
</tbody>
</table>

**Note**

When the clock change input to the processor is asserted, the ITM must output a full 48-bit or 64-bit global timestamp value.
C, byte 2 bit [7]

Continuation bit. The possible values of this bit are:

0  14-bit timestamp.
1  At least 21-bit timestamp.

TS[13:0], byte 2 bits [6:0], byte 1 bits [6:0], when 14-bit timestamp

C, byte 1 bit [7]

Continuation bit. The possible values of this bit are:

0  7-bit timestamp.
1  At least 14-bit timestamp.

TS[6:0], byte 1 bits [6:0], when 7-bit timestamp

F1.2.9 Global Timestamp 2 packet

The Global Timestamp 2 packet characteristics are:

Purpose Provides the most significant bits of a full 48 or 64-bit timestamp.

Attributes Multi-part Protocol packet comprising:

- 8-bit header.
- 32 or 48-bit payload.

Global Timestamp 2 packet header

The Global Timestamp 2 packet header bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Byte 0

C, byte 0 bit [7]

Continuation bit. This bit reads as 0b1.

ID[4:2:0], byte 0 bits [6:4:2]

Protocol packet type. Bits [6:2] discriminate between Protocol packet types. The possible values of this field are:

0x101  Global Timestamp packet.

This field reads as 0b0101.

T, byte 0 bit [5]

Global Timestamp packet type. The possible values of this bit are:

1  Global Timestamp 2 packet.

This bit reads as 0b1.

SS, byte 0 bits [1:0]

Packet type. The possible values of this field are:

00  Protocol packet.

Other values encode different sizes of Hardware and Software source packets. This field reads as 0b00.
Global Timestamp 2 packet payload

When 48-bit Global Timestamp 2 packet, the Global Timestamp 2 packet payload bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

C, byte 6 bit [7]

Continuation bit. This bit reads as 0b0.

Byte 6 bits [6:3], when 64-bit Global Timestamp 2 packet

Reserved. This field is RES0.

TS[63:26], byte 6 bits [2:0], byte 5 bits [6:0], byte 4 bits [6:0], byte 3 bits [6:0], byte 2 bits [6:0], byte 1 bits [6:0], when 64-bit Global Timestamp 2 packet

Most significant bits of the Global Timestamp.

Byte 5 bit [7], byte 3 bit [7], byte 2 bit [7], byte 1 bit [7]

Continuation bits. This field is RAO.

C, byte 4 bit [7]

Continuation bit. The possible values of this bit are:

0  The packet is 5 bytes long. 48-bit timestamp is implemented.
1  The packet is 7 bytes long. 64-bit timestamp is implemented.

Byte 4 bits [6:1], when 48-bit Global Timestamp 2 packet

Reserved. This field is RES0.

TS[47:26], byte 4 bit [0], byte 3 bits [6:0], byte 2 bits [6:0], byte 1 bits [6:0], when 48-bit Global Timestamp 2 packet

Most significant bits of the Global Timestamp.
F1.2.10 Instrumentation packet

The Instrumentation packet characteristics are:

**Purpose**
A software write to an ITM stimulus port generates an Instrumentation packet.

**Attributes**
Multi-part Software source packet comprising:
- 8-bit header.
- 8, 16, or 32-bit payload.

**Instrumentation packet header**

The Instrumentation packet header bit assignments are:

```
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0</td>
<td># 0b00</td>
<td>SH</td>
<td>SS</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

- **A**, byte 0 bits [7:3]
  - Port number, 0-31.

- **SH**, byte 0 bit [2]
  - Source. The possible values of this bit are:
    - 0 Instrumentation packet (Software source).
    - This bit reads as 0b0.

- **SS**, byte 0 bits [1:0]
  - Size. The possible values of this field are:
    - 01 Byte Instrumentation packet.
    - 10 Halfword Instrumentation packet.
    - 11 Word Instrumentation packet.
  - The value 0b00 encodes a Protocol packet.

**Instrumentation packet payload**

When Byte Instrumentation packet, SS == 0b01, the Instrumentation packet payload bit assignments are:

```
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Payload[7:0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

When Halfword Instrumentation packet, SS == 0b10, the Instrumentation packet payload bit assignments are:

```
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Payload[7:0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>Payload[15:8]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

When Word Instrumentation packet, SS == 0b11, the Instrumentation packet payload bit assignments are:

<table>
<thead>
<tr>
<th>Payload[31:0]</th>
<th>Byte 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Payload[15:8]</td>
<td>Byte 3</td>
</tr>
<tr>
<td>Payload[23:16]</td>
<td>Byte 2</td>
</tr>
<tr>
<td>Payload[7:0]</td>
<td>Byte 1</td>
</tr>
</tbody>
</table>

Payload[31:0], bytes <4:1>, when Word Instrumentation packet, SS == 0b11
Payload value.

Payload[15:0], byte 1 bits [15:0], when Halfword Instrumentation packet, SS == 0b10
Payload value.

Payload[7:0], byte <1>, when Byte Instrumentation packet, SS == 0b1
Payload value.

### F1.2.11 Local Timestamp 1 packet

The Local Timestamp 1 packet characteristics are:

**Purpose**  
A Local Timestamp 1 packet encodes timestamp information, for generic control and synchronization, based on a timestamp counter in the ITM. To reduce the trace bandwidth:

- The local timestamping scheme uses delta timestamps, meaning each local timestamp value gives the interval since the generation of the previous Local timestamp packet.
- The Local timestamp packet length, 1-5 bytes, depends on the required timestamp value.

Whenever the ITM outputs a Local timestamp packet, it clears its timestamp counter to zero. Provides the most significant bits of a full 48 or 64-bit timestamp. If the ITM outputs the Local Timestamp synchronously to the corresponding ITM or DWT data, and the required timestamp value is in the range 1-6, it uses the Local Timestamp 2 packet.

**Attributes**  
Multi-part Protocol packet comprising:

- 8-bit header.
- 8, 16, 24, or 32-bit payload.

**Local Timestamp 1 packet header**

The Local Timestamp 1 packet header bit assignments are:

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>ID[4]</td>
<td>TC</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>SS</td>
</tr>
</tbody>
</table>

**C, byte 0 bit [7]**
Continuation bit. This bit reads as 0b1.

**ID[4:1:0], byte 0 bits [6:3:2]**
Protocol packet type. Bits [6:2] discriminate between Protocol packet types. The possible values of this field are:

- 01x00  Local Timestamp 1 packet.

This field reads as 0b100.
TC, byte 0 bits [5:4]

Indicates the relationship between the generation of the Local timestamp packet and the corresponding ITM or DWT data packet. The possible values of this field are:

00 The local timestamp value is synchronous to the corresponding ITM or DWT data. The value in the TS field is the timestamp counter value when the ITM or DWT packet is generated.

01 The local timestamp value is delayed relative to the ITM or DWT data. The value in the TS field is the timestamp counter value when the Local timestamp packet is generated.

——— Note ————

The local timestamp value corresponding to the previous ITM or DWT packet is UNKNOWN, but must be between the previous and current local timestamp values.

10 Output of the ITM or DWT packet corresponding to this Local timestamp packet is delayed relative to the associated event. The value in the TS field is the timestamp counter value when the ITM or DWT packets is generated.

This encoding indicates that the ITM or DWT packet was delayed relative to other trace output packets.

11 Output of the ITM or DWT packet corresponding to this Local timestamp packet is delayed relative to the associated event, and this Local timestamp packet is delayed relative to the ITM or DWT data. This is a combination of the conditions indicated by values 0b01 and 0b10.

SS, byte 0 bits [1:0]

Packet type. The possible values of this field are:

00 Protocol packet.

Other values encode different sizes of Hardware and Software source packets. This field reads as 0b00.

Local Timestamp 1 packet payload

When 7-bit timestamp, the Local Timestamp 1 packet payload bit assignments are:

```
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>

C, byte 4 bit [7]
Continuation bit. This bit reads as 0b0.

TS[27:0], byte 4 bits [6:0], byte 3 bits [6:0], byte 2 bits [6:0], byte 1 bits [6:0], when 28-bit timestamp
Local Timestamp.

C, byte 3 bit [7]
Continuation bit. The possible values of this bit are:
0 21-bit timestamp.
1 28-bit timestamp.

TS[20:0], byte 3 bits [6:0], byte 2 bits [6:0], byte 1 bits [6:0], when 21-bit timestamp
Local Timestamp. TS[27:21] are zero.

C, byte 2 bit [7]
Continuation bit. The possible values of this bit are:
0 14-bit timestamp.
1 At least 21-bit timestamp.

TS[13:0], byte 2 bits [6:0], byte 1 bits [6:0], when 14-bit timestamp
Local Timestamp. TS[27:14] are zero.

C, byte 1 bit [7]
Continuation bit. The possible values of this bit are:
0 7-bit timestamp.
1 At least 14-bit timestamp.

TS[6:0], byte 1 bits [6:0], when 7-bit timestamp
Local Timestamp. TS[27:7] are zero.

**F1.2.12 Local Timestamp 2 packet**

The Local Timestamp 2 packet characteristics are:

**Purpose**
If the ITM outputs the Local Timestamp synchronously to the corresponding ITM or DWT data, and the required timestamp value is in the range 1-6, it uses the Local Timestamp 2 packet. For more information, see Local Timestamp 1 packet.

**Attributes**
8-bit Protocol packet.
The Local Timestamp 2 packet bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>

<td>TS</td>
<td>ID[1:0]</td>
<td>SS</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

C, byte 0 bit [7]
Continuation bit. This bit reads as 0b0.

TS, byte 0 bits [6:4]
Local timestamp value, in the range 0b001 to 0b110. The value 0b000 encodes a Synchronization packet and the value 0b111 encodes an Overflow packet.

ID[1:0], byte 0 bits [3:2]
Protocol packet type. Bits [6:2] discriminate between Protocol packet types. The possible values of this field are:

00000 Local Timestamp 2 packet.
This field reads as 0b0.

SS, byte 0 bits [1:0]
Packet type. The possible values of this field are:
00 Protocol packet.
Other values encode different sizes of Hardware and Software source packets. This field reads as 0b0.

F1.2.13 Overflow packet

The Overflow packet characteristics are:

**Purpose**
The ITM outputs an Overflow packet if:
- Software writes to a Stimulus Port register when the stimulus port output buffer is full.
- The DWT attempts to generate a Hardware source packet when the DWT output buffer is full.
- The Local timestamp counter overflows.

The Overflow packet comprises a header with no payload.

**Attributes**
8-bit Protocol packet.

The Overflow packet bit assignments are:

<table>
<thead>
<tr>
<th></th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

C, byte 0 bit [7]
Continuation bit. This bit reads as 0b0.

ID, byte 0 bits [6:2]
Protocol packet type. Bits [6:2] discriminate between Protocol packet types. The possible values of this field are:

11100 Overflow packet.
This field reads as 0b11100.
SS, byte 0 bits [1:0]

Packet type. The possible values of this field are:

00  Protocol packet.

Other values encode different sizes of Hardware and Software source packets. This field reads as 0b00.

F1.2.14 Periodic PC Sample packet

The Periodic PC Sample packet characteristics are:

Purpose

The DWT unit generates PC samples at fixed time intervals, with an accuracy of one clock cycle. The POSTCNT counter period determines the PC sampling interval. Software configures the DWT_CTRL.CYCTAP and DWT_CTRL.POSTINIT fields to determine how POSTCNT relates to DWT_CYCCNT. The DWT_CTRL.PCSAMPLENA bit enables PC sampling.

Attributes

Multi-part Hardware source packet comprising:

• 8-bit header.
• 8 or 32-bit payload.

Periodic PC Sample packet header

The Periodic PC Sample packet header bit assignments are:

ID, byte 0 bits [7:3]

Discriminator ID. The possible values of this field are:

0b00010  Periodic PC Sample packet.

This field reads as 0b00010.

SH, byte 0 bit [2]

Source. The possible values of this bit are:

1  Hardware source packet.

This bit reads as 0b1.

SS, byte 0 bits [1:0]

Size. The possible values of this field are:

01  Source packet, 1-byte payload, 2-byte packet.

11  Source packet, 4-byte payload, 5-byte packet.

SS == 0b10 is invalid for a Periodic PC Sample packet.

The value 0b00 encodes a Protocol packet.

This field reads as 0bx1.
Periodic PC Sample packet payload

When Allowed and not sleeping, SS == \texttt{0b11}, the Periodic PC Sample packet payload bit assignments are:

\begin{verbatim}
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte 1</td>
<td>Byte 2</td>
<td>Byte 3</td>
<td>Byte 4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
\end{verbatim}

When Allowed and sleeping, SS == \texttt{0b01}, the Periodic PC Sample packet payload bit assignments are:

\begin{verbatim}
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Byte 1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
\end{verbatim}

When Prohibited, SS == \texttt{0b01}, the Periodic PC Sample packet payload bit assignments are:

\begin{verbatim}
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Byte 1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
\end{verbatim}

PC, bytes <4:1>, when Allowed and not sleeping, SS == \texttt{0b11}

Periodic PC sample value.

Byte <1>, when Allowed and sleeping, SS == \texttt{0b01}

This field reads as \texttt{0b00000000}.

Byte <1>, when Prohibited, SS == \texttt{0b01}

This field reads as \texttt{0b11111111}.

F1.2.15 Synchronization packet

The Synchronization packet characteristics are:

**Purpose**

A Synchronization packet provides a unique pattern in the bit stream. Trace capture hardware can identify this pattern and use it to identify the alignment of packet bytes in the bitstream.

**Attributes**

48-bit Protocol packet.

A Synchronization packet is at least forty-seven 0 bits followed by single 1 bit. This section describes the smallest possible Synchronization packet.

The Synchronization packet bit assignments are:

\begin{verbatim}
<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Byte 0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RAZ</td>
<td>Byte 1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RAZ</td>
<td>Byte 2</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RAZ</td>
<td>Byte 3</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RAZ</td>
<td>Byte 4</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>RAZ</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Byte 5</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
\end{verbatim}

**Byte 5 bit [7]**

Indicates the end of the Synchronization packet. This bit reads as \texttt{0b1}. 
Byte 5 bits [6:0], bytes <4:1>
This field is RAZ.

Byte <0>
This field reads as \texttt{0b00000000}. 
Appendix G1
Architectural Constraints on UNPREDICTABLE behaviors

This chapter specifies the architectural constraints on UNPREDICTABLE behaviors in the ARMv8 architecture. It contains the following sections:

• CONSTRAINED UNPREDICTABLE behaviors on page G1-1332.
G1.1 CONSTRAINED UNPREDICTABLE behaviors

ARMv8 defines architecturally required constraints on many behaviors that are UNPREDICTABLE in ARMv7. The following sections define those constraints:

- **Overview of the constraints on ARMv7 UNPREDICTABLE behaviors** on page G1-1333.
- **Using the Stack Pointer (R13)** on page G1-1333.
- **Using the Program Counter (R15)** on page G1-1333.
- **Loads and Stores to unaligned locations** on page G1-1335.
- **Instructions in IT blocks and EPSR.IT** on page G1-1334.
- **SBZ or SBO fields in instructions** on page G1-1335.
- **Immediate constants in T32 data-processing instructions** on page G1-1335.
- **Caching of control or data values** on page G1-1335.
- **Inadequate context synchronization** on page G1-1336
- **Syndrome register handling for instructions treated as UNDEFINED** on page G1-1336.
- **Multi-access instructions that load the PC from Device memory** on page G1-1336.
- **CONSTRAINED UNPREDICTABLE behavior in specific Instructions** on page G1-1337.
  - BFC, BFI on page G1-1337.
  - CLZ on page G1-1337.
  - CMP (register) on page G1-1338.
  - CPS on page G1-1338.
  - IT on page G1-1338.
  - LDC, LDC2 (literal) on page G1-1338.
  - LDM, LDMA, LDMFD on page G1-1338.
  - LDMDB, LDMEA on page G1-1339.
  - LDR (immediate), LDR (register), LDRB (immediate), LDRB (register), LDRBT, LDRSB (immediate), LDRSB (register), LDRST, LDRSH (register), LDRSHT, LDRT on page G1-1340.
  - LDRD (immediate), LDRD (register), LDRD (literal) on page G1-1340.
  - MRRC on page G1-1340.
  - MSR (register) on page G1-1340.
  - RBIT, REV, REV16, REVSH on page G1-1341.
  - SBFX on page G1-1341.
  - SDIV, UDIV on page G1-1341.
  - SMULL, SMLAL, SMLALTB, SMLATT, SMLALD, SMULSD, UMULL, UMULAL on page G1-1341.
  - STM, STMIA, STMEA on page G1-1341.
  - STMDB, STMFD on page G1-1342.
  - STR (immediate), STR (register), STRB (immediate), STRB (register), STRBT, STRH (immediate), STRH (register), STRHT, STRT on page G1-1343.
  - STRD (immediate), STRD (register) on page G1-1344.
  - STREX, STREXB, STREXD, STREXH, STLEX, STELXB, STELXD, STLEXH on page G1-1344.
  - Load-Exclusive/Store-Exclusive pairs on page G1-1336.
  - Out of range values of the Set/Way/Index fields in cache maintenance instructions on page G1-1337.
- **CONSTRAINED UNPREDICTABLE behavior floating-point instructions** on page G1-1345.
  - VCVT (between floating-point and fixed-point) on page G1-1345.
  - VLDM and VPOP on page G1-1345.
  - VMOV (between two general-purpose registers and two single-precision registers) on page G1-1345.
  - VMOV (between two general-purpose registers and a doubleword floating-point register) on page G1-1346.
  - VSTM and VPUSH on page G1-1346.
- **Reserved values in System and memory-mapped registers** on page G1-1346.
G1.1 Overview of the constraints on ARMv7 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes cases where the architecture has a feature that software must not use. Where previous versions of the architecture define behavior as UNPREDICTABLE, the ARMv8-M architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

--- Note ---

Software that is compatible with the ARMv8-M architecture must not rely on these CONSTRAINED UNPREDICTABLE cases.

G1.2 Using the Stack Pointer (R13)

Bits [1:0] of all stack pointers, including R13, are RAZ/WI. Software must treat bits [1:0] of the stack pointers as RES0.

Where an instruction states that the SP as UNPREDICTABLE and SP is used:

- The value that is read or written from or to the SP is UNKNOWN.
- The instruction is permitted to be treated as UNDEFINED.
- If the SP is being written, it is UNKNOWN whether a stack-limit check is applied.

G1.3 Using the Program Counter (R15)

All use of R15 as a named register specifier for a source register that is described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to be executed as a NOP.
- Read or return an UNKNOWN value for the source register that is specified as R15.

All use of R15 as a named register specifier for a destination register that is described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to be executed as a NOP.
- Ignore the write.
- Branch to an UNKNOWN location.

The choice between these behaviors might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Instructions that are CONSTRAINED UNPREDICTABLE when the base register is R15 and the instruction specifies a base register Write-Back, are treated as having R15 as both a source register and a destination register.

For instructions that have two destination registers, for example LDRD, MRRC (if the Main Extension is implemented), and many of the multiply instructions, if Rt, Rt2, RdLo, or RdHi is R15, then the other destination register of the pair is UNKNOWN, if the CONSTRAINED UNPREDICTABLE behavior for the write to R15 is either to ignore the write or to branch to an UNKNOWN location.

For instructions that affect any or all of APSR.{N, Z, C, V} or APSR.GE when the register specifier is not R15, any flags that are affected by an instruction that is CONSTRAINED UNPREDICTABLE when the register specifier R15 becomes UNKNOWN.

In addition, for MRRC instructions that use R15 as the destination register descriptor (and therefore target APSR.{N, Z, C, V}) where these instructions are described as being CONSTRAINED UNPREDICTABLE the status of the flags becomes UNKNOWN.
G1.1.4 Branching into an IT block

Branching into an IT block, other than by way of exception return or exit from Debug state, leads to CONSTRAINED UNPREDICTABLE behavior. Execution starts from the address that is determined by the branch, but each instruction in the IT block is:

- Executed as if it is not in an IT block, meaning that it is executed unconditionally.
- Executed as if it had passed its Condition code check within an IT block.
- Executed as a NOP. That is, it behaves as if it had failed the condition code check.

For exception returns or Debug state exits that cause EPSR.IT to be set to a reserved value with a nonzero value in EPSR.IT, the EPSR.IT bits are forced to ‘00000000’.

Exception returns or Debug state exits that set EPSR.IT to a non-reserved value can occur when the flow of execution returns to a point:

- Outside an IT block, but with the EPSR.IT bits set to a value other than ‘00000000’.
- Inside an IT block, but with a different value of the EPSR.IT bits than if the IT block had been executed without an exception return or Debug state exit.

In this case the instructions at the target of the exception return or Debug state exit must do one of the following:

- Execute as if they passed the condition code check for the remaining iterations of the EPSR.IT state machine.
- Execute as NOPs. That is, they behave as if they failed the condition code check for the remaining iterations of the EPSR.IT state machine.

G1.1.5 Instructions in IT blocks and EPSR.IT

A number of instructions in the architecture are described as being CONSTRAINED UNPREDICTABLE either:

- Anywhere within an IT block.
- As an instruction within an IT block, other than the last instruction within an IT block.

Unless otherwise stated in this manual, when these instructions are committed for execution, one of the following occurs:

- An UNDEFINED exception is taken.
- The instructions are executed as if they had passed the condition code check.
- The instructions execute as NOPs, as if they had failed the condition code check.

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Many instructions that are CONSTRAINED UNPREDICTABLE in an IT block are branch instructions or other non-sequential instructions that change the PC. Where these instructions are not treated as UNDEFINED within an IT block, the remaining iterations of the EPSR.IT state machine must be treated in one of the following ways:

- EPSR.IT is cleared to 0.
- EPSR.IT advances for either a sequential or a nonsequential change of the PC in the same way as it does for instructions that are not CONSTRAINED UNPREDICTABLE that cause a sequential change of the PC.

Note
This behavior does not apply to an instruction that is the last instruction in an IT block.

The instructions that are addressed by the updated PC must do one of the following:

- Execute as if they had passed the condition code check for the remaining iterations of the EPSR.IT state machine.
- Execute as NOPs. That is, they behave as if they had failed the condition code check for the remaining iterations of the EPSR.IT state machine.

The remaining iterations of the EPSR.IT state machine must behave in one of the following ways:

- The EPSR.IT state machine advances as if it were in an IT block.
- The EPSR.IT bits are ignored.
Appendix G1 Architectural Constraints on UNPREDICTABLE behaviors
G1.1 CONSTRAINED UNPREDICTABLE behaviors

- The EPSR.IT bits are forced to '00000000'.

G1.1.6 Loads and Stores to unaligned locations

Some unaligned loads and stores in the ARMv7 architecture are described as UNPREDICTABLE. These behaviors are defined in the ARMv8-M architecture to do one of the following:
- Take an alignment fault.
- Perform the specified load or store to the unaligned memory location.

G1.1.7 SBZ or SBO fields in instructions

Many of the instructions have (0) or (1) in the instruction decode to indicate should-be-zero, SBZ, or should-be-one, SBO. If the instruction bit pattern of an instruction is executed with these fields not having the should be values, one of the following must occur:
- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the should-be value.
- Any destination registers of the instruction become UNKNOWN.

The exceptions to this rule are:
- LDM, LDMIA, LDMFD on page C2-393.
- LDMDB, LDMEA on page C2-396.
- LDR (immediate) on page C2-398.
- LDRB (literal) on page C2-408.
- LDRD (immediate) on page C2-412.
- LDRH (literal) on page C2-422.
- LDRSB (literal) on page C2-428.
- LDRSH (literal) on page C2-434.
- POP on page C2-505.
- PUSH on page C2-507.
- SDIV on page C2-545.
- STM, STMIA, STMIA on page C2-595.
- STMDB, STMFD on page C2-597.
- UDIV on page C2-657.

G1.1.8 Immediate constants in T32 data-processing instructions

The description of immediate constants in data processing include constant values that were UNPREDICTABLE in ARMv7. Top level T32 instruction set encoding on page C2-264 describes instructions as \{hw1, hw2\}, where hw1 is the left-hand halfword in the 32-bit encoding diagram for the instruction. The UNPREDICTABLE cases are where both:
- hw2 [7:0] == 0b0000000.
- hw1 [10] == 0 and either:
  - hw2 [14:12] == 0b001.
  - hw2 [14:12] == 0b010.
  - hw2 [14:12] == 0b11.

In ARMv8, the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce the value 0b0000000.

G1.1.9 Caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache. The existence of such copies can lead to CONSTRAINED UNPREDICTABLE behavior, if the cache has not been correctly invalidated following a change of the control or data values.
Unless explicitly stated otherwise, the behavior of the PE is consistent with:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

**G1.1.10 Inadequate context synchronization**

The ARM architecture requires that changes to registers in the System Control Block must be synchronized before they take effect. CONSTRAINED UNPREDICTABLE behavior might occur if the synchronization has not been performed.

In these cases, the behavior of the processor is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

**G1.1.11 Syndrome register handling for instructions treated as UNDEFINED**

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, an exception is taken. The exception number that is written to the IPSR is UNKNOWN.

**G1.1.12 Multi-access instructions that load the PC from Device memory**

Multi-access instructions that load the PC from Device memory are UNPREDICTABLE. In the ARMv8-M architecture an implementation must perform one of the following behaviors:

- It loads the PC from the memory location as if the memory location had the Normal Non-cacheable attribute.
- It generates a MPU MemManage fault.

**G1.1.13 Security Attribution Unit and SAU_RNR_REGION**

If the Main Extension and Security Extension are implemented, setting the SAU_RNR_REGION field to a value that does not correspond to an implemented memory region is CONSTRAINED UNPREDICTABLE as follows:

- Any subsequent read of SAU_RNR_REGION returns an UNKNOWN value.
- Any read of a register that is specified in the unimplemented region returns an UNKNOWN value.
- Any write to a register specified in the unimplemented region becomes UNKNOWN.

**G1.1.14 Load-Exclusive/Store-Exclusive pairs**

Load-Exclusive and Store-Exclusive instruction constraints on page B6-166 defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors that are associated with using Load-Exclusive/Store-Exclusive pairs. These cases were UNPREDICTABLE in ARMv7. In summary, these cases are:

- The transaction size of a StoreExcl instruction is different from the transaction size of the preceding LoadExcl instruction in the same thread of execution.
- The memory attributes for a StoreExcl instruction are different from the memory attributes for the preceding LoadExcl instruction in the same thread of execution, because the translation of the accessed address changes between the LoadExcl instruction and the StoreExcl instruction.
In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global exclusive monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in Load-Exclusive and Store-Exclusive instruction constraints on page B6-166 for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

G1.1.15 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions DCCISW, DCCSW, and DCISW, if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

• The instruction generates a BusFault.
• The instruction performs cache maintenance on one of:
  — No cache lines.
  — A single arbitrary cache line.
  — Multiple arbitrary cache lines.

G1.1.16 CONSTRAINED UNPREDICTABLE behavior in specific Instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the instructions that are listed in Alphabetical list of instructions on page C2-312. Where the pseudocode for an instruction describes UNPREDICTABLE behavior the constraints on that behavior are described in this section.

Note

• The pseudocode that is used in this section to describe cases that can result in CONSTRAINED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.
• If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

BFC, BFI

If the most significant bit is less than the least significant bit the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The output value is UNKNOWN.

CLZ

If the T1 encoding is used then hw1 [3:0] must equal hw2 [3:0] as the two source register specifiers must be consistent. If these two registers specifiers are inconsistent, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The register that is specified by hw1[3:0] is used as the source register.
• The register that is specified by hw2[3:0] is used as the source register.
• The value in the destination register is UNKNOWN.
CMP (register)

If the T2 encoding is used with \( n \) less than 8 and \( m \) less than 8 then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:
- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs the comparison between \( Rn \) and \( Rm \).
- The condition flags become UNKNOWN.

CPS

If in the encoding of the instruction \( I \) or \( F == 000 \) then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:
- The instruction is UNDEFINED.
- The instruction is treated as a NOP.

IT

If \( \text{firstcond} == '0b1111' \) (or \( \text{firstcond} == '0b1110' \) \&\& \( \text{BitCount (mask)} != 1 \)) then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:
- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The \( 0b1111 \) condition is treated as being the same as the \( 0b1110 \) condition meaning "always", and the state machine is progressed in the same was as for another \( \text{cond_base} \) value.

LDC, LDC2 (literal)

If \( W == 1 \) or \( P == 0 \) then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:
- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The load instruction is performed without a Write-Back.
- The instruction uses the same addressing mode as described in the equivalent immediate offset instruction.
  - If the instruction results in Write-Back to the PC (R15), then the principles that are expressed in section 1.1.2 apply.

LDM, LDMIA, LDMFD

T1

If the number of registers that are loaded is zero, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:
- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is performed as an LDM with the same addressing mode but targeting an unspecified set of registers (potentially including the PC (R15)). If the instruction specifies a Write-Back, the modification to the base address Write-Back might differ from the number of registers loaded.

T2

If the number of registers that are loaded is one, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:
- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is performed as an LDM with the same addressing mode but targeting an unspecified set of registers (potentially including the PC (R15)).
If hw2 bit [13] is set to one, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode but SP (R13) is UNKNOWN.

If \( P = 1 \) and \( M = 1 \), then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN.

In addition, if an exception occurs during a T2 instruction specifying a Write-Back, the base register address might be corrupted such that the instruction cannot be repeated.

**LDMDB, LDMEA**

If the number of registers that are loaded is zero then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode but SP (R13) is UNKNOWN.

If the instruction specifies a Write-Back, and the register to be written back is also in the list to be loaded, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN.

In addition, if an exception occurs during a LDMB or LDMEA instruction specifying a Write-Back, the base register address might be corrupted such that the instruction cannot be repeated.
LDR (immediate), LDR (register), LDRB (immediate), LDRB (register), LDRBT, LDRSB (immediate), LDRSB (register), LDRST, LDRST (register), LDRSHT, LDRT

If the instruction specifies a Write-Back, and the register to be written back is also in the list to be loaded, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN.

In addition, if an exception occurs during any LDR, LDRB, LDRBT, LDRSB, LDRST, LDRSHT or LDRT instruction specifying Write-Back, the base register address might be corrupted such that the instruction cannot be repeated.

LDRD (immediate), LDRD (register), LDRD (literal)

If the instruction specifies a Write-Back, and the register to be written back is also in the list to be loaded, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN.

In addition, if an exception occurs during a LDRD (immediate, register or literal) instruction specifying Write-Back, the base register address might be corrupted such that the instruction cannot be repeated.

If the instruction specifies the same register for the two registers that are being loaded, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction performs all the loads using the specified addressing mode and the content of the register being loaded takes an UNKNOWN.

MRRC

If the instruction the same register for the two registers that are being transferred into, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The value of the register being transferred into is UNKNOWN.

MSR (register)

If the mask of this instruction is set to 0b00, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.

If the mask of this instruction is set to 0b10, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• Treats the mask as an UNKNOWN value.
Appendix G1 Architectural Constraints on UNPREDICTABLE behaviors

G1.1 CONSTRAINED UNPREDICTABLE behaviors

RBIT, REV, REV16, REVSH

In the encoding of these instructions \( hw1[3:0] \) must equal \( hw2[3:0] \) as the two target registers specifiers must be consistent. If the two register specifiers are not consistent, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The register that is specified at \( hw1[3:0] \) is used as the source register.
- The register that is specified at \( hw2[3:0] \) is used as the source register.
- The value in the destination register is UNKNOWN.

SBFX

If the most significant bit is less than 31 then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The output value in the register is UNKNOWN.

SDIV, UDIV

If \( hw2[15:12] \) \(!=0b1111\) then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs a divide with no side-effects to other registers.
- The instruction performs a divide and the register that is specified by bits \( [15:12] \) becomes UNKNOWN.

SMULL, SMLAL, SMLALTB, SMLATT, SMLALD, SMLSLD, UMULL, UMLAL

If the instruction specifies the same register for the two destination registers, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The values in the target registers are UNKNOWN.

STM, STMIA, STMEA

If the number of registers that are stored is zero then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is performed using the specified addressing mode but the value that is stored for the base register is UNKNOWN.

T2

If the instruction performs a Write-Back, and the base register is in the list of the registers to be written to then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is performed using the specified addressing mode but the value that is stored for the base register is UNKNOWN.
If the number of registers that are specified to be stored is one, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction stores a single register using the specified addressing modes.
- The instruction is performed as an STM with the same addressing mode but targeting an unspecified set of registers (potentially including the PC (R15)).

If hw2 bit [13] is set to one, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction stores a single register using the specified addressing modes.
- The instruction performs all of the stores using the specified addressing mode but the value corresponding to the SP (R13) is UNKNOWN.

If hw2 bit [15] is set to one, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the stores using the specified addressing mode but the value corresponding to the PC (R15) is UNKNOWN.

--- Note ---
This is an exception to the principles set out in Using the Program Counter (R15) on page G1-1333.

---

If the instruction uses the PC (R15) as a base register and specifies Write-Back, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The store instruction is performed without a Write-Back.
- The instruction is performed using the same addressing mode as described in the immediate offset instruction. If the performance of the instruction results in Write-Back to the PC (R15), then the principles described in Using the Program Counter (R15) on page G1-1333 apply.

**STMDB, STMFD**

If the number of registers stored is zero, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction stores a single register using the specified addressing modes.
- The instruction is performed as an STM with the same addressing mode but targeting an unspecified set of registers (potentially including the PC (R15)). If the instruction specifies Write-Back, then the modification to the base address on Write-Back might differ from the number of registers stored.

**T1**

If the instruction performs a Write-Back, and the base register is in the list of registers to be written to then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the stores using the specified addressing mode with the value stored to the base register being UNKNOWN.

If the number of registers stored is one, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction stores a single register using the specified addressing modes.
• The instruction is performed as an STM with the same addressing mode but targeting an unspecified set of registers (potentially including the PC (R15)).

If $hw2$ bit[13] is set to one, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:
• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction performs all the stores using the specified addressing mode but the value corresponding to the SP (R13) is UNKNOWN.

——— Note ————
This is an exception to the principles set out in Using the Stack Pointer (R13) on page G1-1333.

——— Note ————
If $hw2$ bit [15] is set to one, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:
• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction performs all of the stores using the specified addressing mode but the value corresponding to the PC (R15) is UNKNOWN.

——— Note ————
This is an exception to the principles set out in Using the Program Counter (R15) on page G1-1333.

If the instruction uses the PC (R15) as a base register and specifies a Write-Back, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:
• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The store instruction is performed without a Write-Back.
• The instruction uses the same addressing mode as described in the equivalent immediate offset instruction. If this results in a Write-Back to the PC (R15) then the principles described in Using the Program Counter (R15) on page G1-1333 apply.

STR (immediate), STR (register), STRB (immediate), STRB (register), STRBT, STRH (immediate), STRH (register), STRHT, STRT

If the PC (R15) is specified as the transfer register, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:
• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction performs all of the stores using the specified addressing mode but the value corresponding to the PC (R15) is UNKNOWN.

If the instruction performs a Write-Back, and the register stored is the base register, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:
• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The instruction performs all of the stores using the specified addressing mode but the value stored is UNKNOWN.

If the instruction uses the PC (R15) as a base register and specifies Write-Back then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:
• The instruction is UNDEFINED.
• The instruction is treated as a NOP.
• The store instruction is performed without a Write-Back.
• The instruction uses the same addressing mode as described in the equivalent immediate offset instruction. If this results in a Write-Back to the PC (R15) then the principles set out in Using the Program Counter (R15) on page G1-1333 apply.

**STRD (immediate), STRD (register)**

If the PC (R15) is specified as the transfer register, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a \texttt{NOP}.
- The instruction performs all of the stores using the specified addressing mode but the value corresponding to the PC (R15) is UNKNOWN.

If the instruction performs a Write-Back, and the register stored is the base register, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a \texttt{NOP}.
- The instruction performs all of the stores using the specified addressing mode but the value stored is UNKNOWN.

If the instruction uses the PC (R15) as a base register and specifies Write-Back then the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a \texttt{NOP}.
- The store instruction is performed without a Write-Back.
- The instruction uses the same addressing mode as described in the equivalent immediate offset instruction. If this results in a Write-Back to the PC (R15) then the principles set out in Using the Program Counter (R15) on page G1-1333 apply.

**STREX, STREXB, STREXD, STREXH, STLEX, STELXB, STELXD, STLEXH**

If the destination register for the exclusive result (encoded as \texttt{Rd}) is the same register as the transfer register the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a \texttt{NOP}.
- The store instruction is performed but the value is UNKNOWN.

If the destination register for the exclusive result (encoded as \texttt{Rd}) is the same register as the base register the behavior is CONSTRAINED UNPREDICTABLE and one of the following can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a \texttt{NOP}.
- The store instruction is performed, to an UNKNOWN address.
CONSTRAINED UNPREDICTABLE behavior floating-point instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the floating-point instructions listed in *Alphabetical list of instructions* on page C2-312.

---

**Note**

- The pseudocode used in this section to describe cases that can result in CONSTRAINED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.
- If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

**VCVT (between floating-point and fixed-point)**

For a description of this instruction and the encoding, see *VCVT (between floating-point and fixed-point)* on page C2-698.

If the `frac_bits` are more than zero then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The result of the conversion is UNKNOWN.

The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Privilege level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VLDM and VPOP**

For a description of this instruction and the encoding, see *VLDM* on page C2-728 and *VPOP* on page C2-765.

If the number of registers loaded is zero then the behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors can occur:

- The instruction is undefined.
- The instruction is treated as a NOP.
- The instruction is performed as a VLDM/VPOP with the same addressing mode but loads no registers.

If the register list specified describes a register that is greater than the number of implemented registers, or more than 16 registers in the case of Double-precision instructions, or for Double precision instructions with an odd value of `imm8` includes any of the registers D16-D31, then one of the following behaviors can occur:

- The instruction is undefined.
- The instruction is treated as a NOP.

The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Privilege level by instructions that are not CONSTRAINED UNPREDICTABLE.

**VMOV (between two general-purpose registers and two single-precision registers)**

For a description of this instruction and the encoding, see *VMOV (between two general-purpose registers and two single-precision registers)* on page C2-748.

If the destination registers are the same register then the behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The register being transferred becomes UNKNOWN.

The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Privilege level by instructions that are not CONSTRAINED UNPREDICTABLE.
Appendix G1 Architectural Constraints on UNPREDICTABLE behaviors

G1.1 CONSTRAINED UNPREDICTABLE behaviors

If \( m = 31 \) for the VMOV instruction involving two single-precision registers, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- Any or all of the single-precision registers become UNKNOWN for a move to the single-precision registers, and R0 to R12 listed in the instruction become UNKNOWN for a move from the single-precision registers but no other general purpose registers are affected.

**VMOV (between two general-purpose registers and a doubleword floating-point register)**

For a description of this instruction and the encoding, see VMOV (between two general-purpose registers and a doubleword floating-point register) on page C2-746.

If the destination registers are the same register then the behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The register being transferred becomes UNKNOWN.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED.

**VSTM and VPUSH**

For a description of this instruction and the encoding, see VSTM on page C2-786 and VPUSH on page C2-767.

If the number of registers loaded is zero then the behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is performed as an VSTM/VPUSH with the same addressing modes but no registers are stored.

If the register list specified describes a register that is greater than the number of implemented registers, or more than 16 registers in the case of Double-precision instructions, or for Double precision instructions with an odd value of imm8 includes any of the registers D16 -D31, then one of the following behaviors can occur:

- The instruction is undefined.
- The instruction is treated as a NOP.
- The memory locations specified in the instruction and the number of registers that are specified by the instruction (if the register list had not gone out of range) become UNKNOWN. If the instruction specifies Write-Back then that register becomes UNKNOWN. No other memory locations are affected.

The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Privilege level by instructions that are not CONSTRAINED UNPREDICTABLE.

**G1.1.18   Reserved values in System and memory-mapped registers**

Unless otherwise stated, all unallocated or reserved values of fields with allocated values within the memory-mapped registers described in this manual behave in one of the following ways:

- The encoding maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.
- The encoding causes the field to have no functional effect.
Glossary

AAPCS
Procedure Call Standard for the ARM Architecture.

Address dependency
An address dependency exists when the value that is returned by a read computes the address of a subsequent access. An address dependency exists even if the value that is returned by the first read does not change the address of the second read or write.

Addressing mode
Means a method for generating the memory address used by a load/store instruction.

Aligned
A data item stored at an address that is exactly divisible by the highest power of 2 that divides exactly into its size in bytes. Aligned halfwords, words and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.

An aligned access is one where the address of the access is aligned to the size of each element of the access.

APSR
See Application Program Status Register.

Application Program Status Register (APSR)
The register containing those bits that deliver status information about the results of instructions, the N, Z, C, and V bits of the XPSR. In an implementation that includes the DSP extension, the APSR includes the GE bits that provide status information from DSP operations.

See also XPSR, APSR, IPSR, and EPSR on page B3-42.

Architecturally executed
An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired it has been architecturally executed. Any instruction that, in a simple sequential execution of a program, is treated as a NOP because it fails its condition code check, is an architecturally executed instruction.

In a PE that performs speculative execution, an instruction is not architecturally executed if the PE discards the results of a speculative execution.

See also Condition code check, Simple sequential execution.
Architecturally UNKNOWN
An architecturally UNKNOWN value is a value that is not defined by the architecture but must meet the requirements of the definition of UNKNOWN. Implementations can define the value of the field, but are not required to do so.
See also IMPLEMENTATION DEFINED.

Associativity
See Cache associativity.

Atomicity
Describes either single-copy atomicity or multi-copy atomicity. Atomicity on page B5-122 defines these forms of atomicity for the ARM architecture.
See also Multi-copy atomicity, Single-copy atomicity.

Background state
The state of the PE before the last (previous) preemption occurred.

Banked register
A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.

Base register
A register specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the address that is sent to memory.

Base register writeback
Describes writing back a modified value to the base register used in an address calculation.

Behaves as if
Where this manual indicates that a PE behaves as if a certain condition applies, all descriptions of the operation of the PE must be re-evaluated taking account of that condition, together with any other conditions that affect operation.

Big-endian memory
Means that, for example:

- A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the most significant byte in the halfword at that address.
See also Endianness, Little-endian memory.

Blocking
Describes an operation that does not permit following instructions to be executed before the operation completes.
A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.

Branch prediction
Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target.
See also Prefetching.

Breakpoint
A debug event triggered by the execution of a particular instruction, specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.

Byte
An 8-bit data item.

Cache associativity
The number of locations in a cache set to which an address can be assigned. Each location is identified by its way value.

Cache Write-Back granule
The maximum size of the memory that can be overwritten. In some implementations, the CTR identifies the Cache Write-Back Granule.

Cache level
The position of a cache in the cache hierarchy. In the ARM architecture, the lower numbered levels are those closest to the PE. For more information, see Caches on page B5-147.
Cache line
The basic unit of storage in a cache. Its size in words is always a power of two, usually 4 or 8 words. A cache line must be aligned to a suitable memory boundary. A memory cache line is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.

Cache sets
Areas of a cache, divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two.

Cache way
A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to (Associativity-1). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way n consists of the cache line with index n from each cache set.

Callee-saved registers
Are registers that a called procedure must preserve. To preserve a callee-saved register, the called procedure would normally either not use the register at all, or store the register to the stack during procedure entry and re-load it from the stack during procedure exit.

Caller-saved registers
Are registers that a called procedure is not required to preserve. If the calling procedure requires their values to be preserved, it must store and reload them itself.

Coherence order
See Coherent.

Coherent
Data accesses from a set of observers to a byte in memory are coherent if accesses to that byte in memory by the members of that set of observers are consistent with there being a single total order of all writes to that byte in memory by all members of the set of observers. This single total order of all to writes to that memory location is the coherence order for that byte in memory.

Condition code check
The process of determining whether a conditional instruction executes normally or is treated as a NOP. For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally. For a T32 instruction in an IT block, the value of EPSR.IT determines whether the instruction is executed normally.

See also Condition code field, Condition flags, Conditional execution.

Condition code field
A 4-bit field in an instruction that specifies the condition under which the instruction executes.

See also Condition code check.

Condition flags
The N, Z, C, and V bits of APSR, or XPSR. See XPSR, APSR, IPSR, and EPSR on page B3-42 for more information.

See also Condition code check.

Conditional execution
When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a NOP. See Conditional execution on page C1-253.

See also Condition code check.

Configuration
Settings made on reset, or immediately after reset, and normally expected to remain static throughout program execution.

CONSTRAINED UNPREDICTABLE
Where an instruction can result in UNPREDICTABLE behavior, the ARMv8 architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

In body text, the term CONSTRAINED UNPREDICTABLE is shown in SMALL CAPITALS.

See also UNPREDICTABLE.

Context switch
The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.
**Context synchronization event**

A context synchronization event is one of the following:

- Performing an ISB operation. An ISB operation is performed when an ISB instruction is executed and does not fail its condition code check.
- Taking an exception.
- Returning from an exception.
- Exit from Debug state.
- Executing a DCPS instruction.
- Executing a DRPS instruction.

For more information, see *Context Synchronization Event* on page B3-98.

---

**Control dependency**

A control dependency exists when the data value that is returned by a read access determines the condition flags, and the values of the flags determine the address of a subsequent read access. This address determination might be through conditional execution, or through the evaluation of a branch.

**Data Watchpoint and Trace (DWT)**

The Data Watchpoint and Trace unit is a component of ARMv8-M debug that optionally provides a number of trace, sampling, and profiling functions.

**DCB**

*See Debug Control Block (DCB).*

**Debug Control Block (DCB)**

A region in the System Control Space that is assigned to registers that support debug features.

*See also System Control Space (SCS).*

**Debugger**

In most of this manual, *debugger* refers to any agent that is performing debug. However, some parts of the manual require a more rigorous definition, and define debugger locally. See Chapter B11 *Debug*.

**Deprecated**

Something that is present in the ARM architecture for backwards compatibility. Whenever possible software must avoid using deprecated features. Features that are deprecated but are not optional are present in current implementations of the ARM architecture, but might not be present, or might be deprecated and optional, in future versions of the ARM architecture.

*See also OPTIONAL.*

**Digital signal processing (DSP)**

 Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.

**Direct access**

A read or write of a register.

**Domain**

In the ARM architecture, *domain* is used in the following contexts.

- **Shareability domain**
  Defines a set of observers for which the Shareability attributes make the data or unified caches transparent for data accesses.

- **Power domain**
  Defines a block of logic with a single, common, power supply.

**Do-Not-Modify (DNM)**

Means the value must not be altered by software. DNM fields read as *UNKNOWN* values, and must only be written with the value read from the same field on the same PE.

**Double-precision value**

Consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

**Doubleword**

A 64-bit data item. Doublewords are normally at least word-aligned in ARM systems.
Doubleword-aligned
Means that the address is divisible by 8.

DSP
See Digital signal processing (DSP).

DWT
See Data Watchpoint and Trace (DWT).

Embedded Trace Macrocell (ETM)
A component of the ARM CoreSight Debug and Trace solution. An ETM provides non-invasive trace of PE operation.

Endianness
An aspect of the system memory mapping. For more information see Endianness on page B5-119.
See also Big-endian memory and Little-endian memory.

EPSR
See Execution Program Status Register (EPSR).

ETM
See Embedded Trace Macrocell (ETM).

Exception
Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.

Exception vector
A fixed address that contains the address of the first instruction of the corresponding exception handler.

Execution Program Status Register (EPSR)
A register that contains the Execution state bits and is part of the XPSR.
See also XPSR, APSR, IPSR, and EPSR on page B3-42.

Execution stream
The stream of instructions that would have been executed by sequential execution of the program.

Explicit access
A read from memory, or a write to memory, generated by a load or store instruction executed by the PE.

Fault
An exception because of some form of system error.

Flush-to-zero mode
A processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and intermediate results with zeros, without significantly affecting the accuracy of their final results.

General-purpose registers
The registers that the base instructions use for processing:
• The general-purpose registers are R0-R12. R13-R14 are the SP and LR, respectively. For more information, see Registers on page B3-41.

See also High registers, Low registers.

Halfword
A 16-bit data item. Halfwords are normally halfword-aligned in ARM systems.

Halfword-aligned
Means that the address is divisible by 2.

High registers
The general-purpose registers R8-R14. Most 16-bit T32 instructions cannot access the high registers.

Note
In some contexts, high registers refers to R8-R15, meaning R8-R14 and the PC.

See also General-purpose registers, Low registers.

If-Then block (IT block)
An IT block is a block of up to four instructions following an If-Then (IT) instruction. Each instruction in the block is conditional. The conditions for the instructions are either all the same, or some are the inverse of others.

Immediate and offset fields
Are unsigned unless otherwise stated.
Immediate value
A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many T32 instructions can be used with an immediate argument.

IMP
An abbreviation used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.

IMPLEMENTATION DEFINED
Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations.

In body text, the term IMPLEMENTATION DEFINED is shown in SMALL CAPITALS.

Implicit access
An access that is not explicit.

See also Explicit access.

Imprecise exception
An exception that is generated as the result of a system error. An imprecise exception is reported at the time that is asynchronous to the instruction that caused it.

Index register
A register specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.

Indirect access
A read or write of a register that is not a direct access.

For example, an indirect write to a register might occur as the side-effect of executing an instruction that does not perform a direct write to the register, or because of some operation that is performed by an external agent.

See also Direct access.

Inline literals
These are constant addresses and other data items held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.

Instrumentation Trace Macrocell (ITM)
A component of the ARM CoreSight Debug and Trace solution. An ITM provides a memory-mapped register interface that applications can use to write logging or event words to a trace sink.

Interrupt Program Status Register (IPSR)
The register that provides status information on whether an application thread or exception handler is currently executing on the processor. If an exception handler is executing, the register provides information on the exception type. The register is part of the XPSR.

See also XPSR, APSR, IPSR, and EPSR on page B3-42.

Interworking
A method of working that permits branches between software using the A32 and T32 instruction sets in the ARMv8-A architecture. For ARMv8-M, interworking is described in Instruction set, interworking support on page C1-261.

IPSR
See Interrupt Program Status Register (IPSR).

ITM
See Instrumentation Trace Macrocell (ITM).

Level
See Cache level.

Level of Coherence (LoC)
The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency.

See also Cache level, Point of coherency (PoC).

Level of Unification, Inner Shareable (LoUIS)
The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable Shareability domain.

See also Cache level, Point of unification (PoU).
Level of Unification, uniprocessor (LoUU)
For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE.

See also Cache level, Point of unification (PoU).

Line
See Cache line.

Little-endian memory
Means that, for example:

- A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the least significant byte in the halfword at that address.

See also Big-endian memory, Endianness.

Load/Store architecture
An architecture where data-processing operations only operate on register contents, not directly on memory contents.

LoC
See Level of Coherence (LoC).

Lockup
A PE state where the PE stops executing instructions in response to an error for which escalation to an appropriate HardFault handler is not possible because of the current execution priority. For more information, see Lockup on page B3-90.

LoUIS
See Level of Unification, Inner Shareable (LoUIS).

LoUU
See Level of Unification, uniprocessor (LoUU).

Low registers
General-purpose registers R0-R7. Unlike the high registers, all T32 instructions can access the Low registers.

Memory barriers
The term memory barrier is the general term that is applied to an instruction, or sequence of instructions, that forces synchronization events by a PE regarding retiring Load/Store instructions. For more information see Memory barriers on page B5-130.

Memory coherency
The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.

Memory hint
A memory hint instruction provides advance information to memory systems about future memory accesses, without actually loading or storing any data to or from the register file. PLD and PLI are the only memory hint instructions defined in ARMv8-M.

Memory Protection Unit (MPU)
A hardware unit whose registers provide simple control of a limited number of protection regions in memory, for more information, see Chapter B8 The ARMv8-M Protected Memory System Architecture.

MPU
See Memory Protection Unit (MPU).

Multi-copy atomicity
The form of atomicity described in Multi-copy atomicity on page B5-122.

See also Atomicity, Single-copy atomicity.

NaN
Not a Number. A floating-point value that can be used when neither a numeric value nor an infinity is appropriate. A NaN can be a quiet NaN, that propagate through most floating-point operations, or a signaling NaN, that causes an Invalid Operation floating-point exception when used. For more information, see the IEEE Standard for Floating-point Arithmetic.

Non-Return-to-Zero (NRZ)
A physical layer signalling scheme used on asynchronous communication ports
NRZ  See Non-Return-to-Zero (NRZ).

Observer  A master in the system that is capable of observing memory accesses. For more information, see Observability of memory accesses on page B5-125.

Obsolete  Obsolete indicates something that is no longer supported by ARM. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.

Offset addressing  Means that the memory address is formed by adding or subtracting an offset to or from the base register value.

OPTIONAL  When applied to a feature of the architecture, OPTIONAL indicates a feature that is not required in an implementation of the ARM architecture:

- If a feature is OPTIONAL and deprecated, this indicates that the feature is being phased out of the architecture. ARM expects such a features to be included in a new implementation only if there is a known backwards-compatibility reason for the inclusion of the feature. A feature that is OPTIONAL and deprecated might not be present in future versions of the architecture.
- A feature that is OPTIONAL but not deprecated is, typically, a feature added to a version of the ARM architecture after the initial release of that version of the architecture. ARM recommends that such features are included in all new implementations of the architecture.

In body text, these meanings of the term OPTIONAL are shown in SMALL CAPITALS.

Note: Do not confuse these ARM-specific uses of OPTIONAL with other uses of optional, where it has its usual meaning. These include:

- Optional arguments in the syntax of many instructions.
- Behavior determined by an implementation choice.

See also Deprecated.

PE  See Processing element (PE).

Physical address (PA)  An address that identifies a location in the physical memory map.

PoC  See Point of coherency (PoC).

PoU  See Point of unification (PoU).

Point of coherency (PoC)  For a particular MVA, the point at which all agents that can access memory are guaranteed to see the same copy of a memory location.

Point of unification (PoU)  For a particular PE, the point by which the instruction and data caches of that PE are guaranteed to see the same copy of a memory location.

Post-indexed addressing  Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

Prefetching  Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.

In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.

See also Simple sequential execution.
Pre-indexed addressing
Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

Privileged access
Memory systems typically differentiate between privileged and unprivileged accesses, and support more restrictive permissions for unprivileged accesses. Some instructions can be used only by privileged software.

Program Status Registers (XPSR)
XPSR is the term used to describe the combination of the APSR, EPSR and IPSR into a single 32-bit Program Status Register.

See also XPSR, APSR, IPSR, and EPSR on page B3-42.

Processing element (PE)
The abstract machine defined in the ARM architecture, as documented in an ARM Architecture Reference Manual. A PE implementation compliant with the ARM architecture must conform with the behaviors described in the corresponding ARM Architecture Reference Manual.

Protection region
A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

Protection Unit
See Memory Protection Unit (MPU).

Pseudo-instruction
UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, MOV $Rd, $Rm, LSL #<n> is a pseudo-instruction that is expected to disassemble as LSL $Rd, $Rm, #<n>.

See also Chapter C1 Instruction Set Overview.

Quadword
A 128-bit data item. Quadwords are normally at least word-aligned in ARM systems.

Quadword-aligned
Means that the address is divisible by 16.

Quiet NaN
A NaN that propagates unchanged through most floating-point operations.

RAO
See Read-As-One (RAO).

RAZ
See Read-As-Zero (RAZ).

RAO/SBOP
In versions of the ARM architecture before ARMv8, Read-As-One, Should-Be-One-or-Preserved on writes.
In ARMv8, RES1 replaces this description.

See also UNK/SBOP, Read-As-One (RAO), RES1, Should-Be-One-or-Preserved (SBOP).

RAO/WI
Read-As-One, Writes Ignored.
Hardware must implement the field as Read-as-One, and must ignore writes to the field.
Software can rely on the field reading as all 1s, and on writes being ignored.
This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also Read-As-One (RAO).

RAZ/SBZP
In versions of the ARM architecture before ARMv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes.
In ARMv8, RES0 replaces this description.

See also UNK/SBZP, Read-As-Zero (RAZ), RES0, Should-Be-Zero-or-Preserved (SBZP).
**RAZ/WI**  
Read-As-Zero, Writes Ignored.  
Hardware must implement the field as Read-as-Zero, and must ignore writes to the field.  
Software can rely on the field reading as all 0s, and on writes being ignored.  
This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.  
*See also* Read-As-Zero (RAZ).

**Read-allocate cache**  
A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.

**Read-As-One (RAO)**  
Hardware must implement the field as reading as all 1s.  
Software:  
- Can rely on the field reading as all 1s.  
- Must use a SBOP policy to write to the field.  
This description can apply to a single bit that reads as 1, or to a field that reads as all 1s. It applies only to a bit or field that is read-only.  
*See also* RAO/SBOP, RAO/WI, RES1.

**Read-As-Zero (RAZ)**  
Hardware must implement the field as reading as all 0s.  
Software:  
- Can rely on the field reading as all 0s  
- Must use a SBZP policy to write to the field.  
This description can apply to a single bit that reads as 0, or to a field that reads as all 0s. It applies only to a bit or field that is read-only.  
*See also* RAZ/SBZP, RAZ/WI, RES0.

**Read, modify, write**  
In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields updated in that register, and the new value written back.

**Register data dependency**  
A register data dependency exists between a first data value and a second data value when either:  
- The register that holds the first data value is used in the calculation of the second data value, and the calculation between the first data value and the second data value does not consist of either:  
  - A conditional branch whose condition is determined by the first data value.  
  - A conditional selection, move, or computation whose condition is determined by the first data value, where the input data values for the selection, move, or computation do not have a data dependency on the first data value.  
- There is a register data dependency between the first data value and a third data value, and between the third data value and the second data value.

**RES0**  
A reserved bit or field with *Should-Be-Zero-or-Preserved (SBZP)* behavior, or equivalent read-only or write-only behavior. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory.  
Within the architecture, there are some cases where a register bit or field:  
- Is RES0 in some defined architectural context.  
- Has different defined behavior in a different architectural context.
--- Note ---

RES0 is not used in descriptions of instruction encodings.

---

This means the definition of RES0 for fields in read/write registers is:

**If a bit is RES0 in all contexts**

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 0. In this case:
   - Reads of the bit always return 0.
   - Writes to the bit are ignored.
2. The bit can be written. In this case:
   - An indirect write to the register sets the bit to 0.
   - A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.
   - If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
   - A direct write to the bit must update a storage location associated with the bit.
   - The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this manual explicitly defines additional properties for the bit.

Whether RES0 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

**If a bit is RES0 only in some contexts**

For a bit in a read/write register, when the bit is described as RES0:

- An indirect write to the register sets the bit to 0.
- A read of the bit returns the value last successfully written to the bit, by either a direct or an indirect write, regardless of the use of the register when the bit was written.
- If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES0 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES0 indicates that the bit reads as 0, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES0 indicates that software must treat the bit as SBZ.

A bit that is RES0 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 0.
- Must use an SBZP policy to write to the bit.

This RES0 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES0.

In body text, the term RES0 is shown in SMALL CAPITALS.

See also Read-As-Zero (RAZ), RES1, Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.
RES1

A reserved bit or field with Should-Be-One-or-Preserved (SBOP) behavior, or equivalent read-only or write-only behavior. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory.

Within the architecture, there are some cases where a register bit or field:

• Is RES1 in some defined architectural context.
• Has different defined behavior in a different architectural context.

——— Note ————

RES1 is not used in descriptions of instruction encodings.
———

This means the definition of RES1 for fields in read/write registers is:

If a bit is RES1 in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 1. In this case:
   • Reads of the bit always return 1.
   • Writes to the bit are ignored.

2. The bit can be written. In this case:
   • An indirect write to the register sets the bit to 1.
   • A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.
     If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
   • A direct write to the bit must update a storage location associated with the bit.
   • The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this manual explicitly defines additional properties for the bit.

Whether RES1 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

If a bit is RES1 only in some contexts

For a bit in a read/write register, when the bit is described as RES1:

• An indirect write to the register sets the bit to 1.
• A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

——— Note ————

As indicated in this list, this value might be written by an indirect write to the register.
———

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

• A direct write to the bit must update a storage location associated with the bit.
• While the use of the register is such that the bit is described as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

• Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
• The value of the bit can be written, and a read returns the last value written to the bit.
The RES1 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES1 indicates that the bit reads as 1, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES1 indicates that software must treat the bit as SBO.

A bit that is RES1 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 1.
- Must use an SBOP policy to write to the bit.

This RES1 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES1.

In body text, the term RES1 is shown in SMALL CAPITALS.

See also Read-As-One (RAO), RES0, Should-Be-One-or-Preserved (SBOP), UNKNOWN.

**Reserved**

Unless otherwise stated:

- Instructions that are reserved or that access reserved registers have UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
- Bit positions described as reserved are:
  - In an RW or WO register, RES0.
  - In an RO register, UNK.

See also CONSTRAINED UNPREDICTABLE, RES0, RES1, UNDEFINED, UNK, UNPREDICTABLE.

**Return Link**

A value relating to the return address.

**RISC**

Reduced Instruction Set Computer.

**Rounding error**

The value of the rounded result of an arithmetic operation minus the exact result of the operation.

**Rounding mode**

Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format. The rounding modes are defined by the IEEE Standard for Floating-point Arithmetic.

**Saturated arithmetic**

Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in ARM processors, in which overflowing results wrap around from $+2^{31} - 1$ to $-2^{31}$ or vice versa.

**SBO**

See Should-Be-One (SBO).

**SBOP**

See Should-Be-One-or-Preserved (SBOP).

**SBZ**

See Should-Be-Zero (SBZ).

**SBZP**

See Should-Be-Zero-or-Preserved (SBZP).

**Security hole**

A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. The ARM architecture forbids security holes.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Serial Wire Output (SWO)**

An asynchronous TPIU port supporting one or both of the NRZ and Manchester encodings.

**Serial Wire Viewer (SWV)**

The combination of an SWO and at least one of a DWT unit or an ITM, providing data tracing capability.

**Self-modifying code**

Code that writes one or more instructions to memory and then executes them. When using self-modifying code, cache maintenance and barrier instructions must be used to ensure synchronization.

**Set**

See Cache sets.
**Should-Be-One (SBO)**
Hardware must ignore writes to the field.

ARM strongly recommends that software writes the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.

*See also* CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Should-Be-One-or-Preserved (SBOP)**
From the introduction of the ARMv8 architecture, the description *Should-Be-One-or-Preserved (SBOP)* is superseded by *RES1*.

Hardware must ignore writes to the field.

If software has read the field since the PE implementing the field was last reset and initialized, it must preserve the value of the field by writing the value that it previously read from the field. Otherwise, it must write the field as all 1s.

If software writes a value to the field that is not a value previously read for the field and is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

*See also* CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Should-Be-Zero (SBZ)**
Hardware must ignore writes to the field.

ARM strongly recommends that software writes the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.

*See also* CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Should-Be-Zero-or-Preserved (SBZP)**
From the introduction of the ARMv8 architecture, the description *Should-Be-Zero-or-Preserved (SBZP)* is superseded by *RES0*.

Hardware must ignore writes to the field.

If software has read the field since the PE implementing the field was last reset and initialized, it must preserve the value of the field by writing the value that it previously read from the field. Otherwise, it must write the field as all 0s.

If software writes a value to the field that is not a value previously read for the field and is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

*See also* CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

**Signaling NaNs**
Cause an Invalid Operation exception whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

**Signed data types**
Represent an integer in the range $-2^{N-1}$ to $+2^{N-1}-1$, using two's complement format.

**Signed immediate and offset fields**
Are encoded in two's complement notation unless otherwise stated.

**SIMD**
Single-Instruction, Multiple-Data.
Simple sequential execution
The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and ARM does not expect this model to correspond to a realistic implementation of the architecture.

Single-copy atomicity
The form of atomicity described in Single-copy atomicity on page B5-122.
See also Atomicity, Multi-copy atomicity.

Single peripheral
A single peripheral is a region of memory of an IMPLEMENTATION DEFINED size that is defined by the peripheral

Single-precision value
A 32-bit word that is interpreted as a basic single-precision floating-point number according to the IEEE Standard for Floating-point Arithmetic.

Spatial locality
The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

Special-purpose register
One of a specified set of registers for which all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization. For more information see Registers on page B3-41.

Speculative writes
All of the following are speculative writes:

• Writes generated by store instructions that appear in the Execution stream after a branch that is not architecturally resolved.

• Writes generated by store instructions that appear in the Execution stream after an instruction where a synchronous exception condition has not been architecturally resolved.

• Writes generated by conditional store instructions for which the conditions for the instruction have not been architecturally resolved.

• Writes generated by store instructions for which the data being written comes from a register that has not been architecturally committed.

System Control Block (SCB)
An address region in the System Control Space, used for key feature control and configuration associated with the exception model.
See also System Control Space (SCS).

System Control Space (SCS)
A region of the memory map reserved for system control and configuration registers.
See also Debug Control Block (DCB), System Control Space (SCS).

T32 instruction
One or two halfwords that specify an operation to be performed by a PE. T32 instructions must be halfword-aligned. For more information, see Chapter C1 Instruction Set Overview.
T32 instructions were previously called Thumb instructions.

Tail-chaining
An optimization that removes unstacking and stacking operations. For more information see Tail-chaining on page B3-81.

Temporal locality
The observed effect that after a program has accessed a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.

TPIU
See Trace Port Interface Unit (TPIU).
Unaligned
An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.

Trace Port Interface Unit (TPIU)
A component of the ARM CoreSight Debug and Trace solution. A TPIU provides an external interface for one or more trace sources in the processor implementation.

UAL
See Unified Assembler Language.

Unaligned memory accesses
Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

Unallocated
Except where otherwise stated in this manual, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE, or as an unallocated hint instruction.

A bit in a register is unallocated if the architecture does not assign a function to that bit.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE.

UNDEFINED
Indicates an instruction that generates an Undefined Instruction exception.

In body text, the term UNDEFINED is shown in SMALL CAPITALS.

See also Chapter C1 Instruction Set Overview.

Unified Assembler Language
The assembler language introduced with Thumb-2 technology that is used in this manual. See Chapter C1 Instruction Set Overview for details.

Unified cache
Is a cache used for both processing instruction fetches and processing data loads and stores.

Unindexed addressing
Means addressing in which the base register value is used directly as the virtual address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0.

In the M-profile, the LDC, LDC2, STC, and STC2 instructions have an explicit unindexed addressing mode that permits the offset field in the instruction to specify additional coprocessor options.

UNK
An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a multi-bit field. Software must not rely on the field reading as zero.

See also UNKNOWN.

UNK/SBOP
Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also Read-As-One (RAO), Should-Be-One-or-Preserved (SBOP), UNKNOWN.

UNK/SBZP
Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also Read-As-Zero (RAZ), Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.
UNKNOWN
An UNKNOWN value does not contain valid data, and can vary from moment to moment, instruction to instruction, and implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE, are not CONSTRAINED UNPREDICTABLE, and do not return UNKNOWN values.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.

In body text, the term UNKNOWN is shown in SMALL CAPITALS.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNK, UNPREDICTABLE.

UNPREDICTABLE
Means the behavior cannot be relied upon. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.

In body text, the term UNPREDICTABLE is shown in SMALL CAPITALS.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED.

Unsigned data types
Represent a non-negative integer in the range $0$ to $+2^N-1$, using normal binary format.

Watchpoint
A debug event triggered by an access to memory, specified in terms of the address of the location in memory being accessed.

Way
See Cache way.

WI
Writes Ignored. In a register that software can write to, a WI attribute applied to a bit or field indicates that the bit or field ignores the value written by software and retains the value it had before that write.

See also RAO/WI, RAZ/WI, RES0, RES1.

Word
A 32-bit data item. Words are normally word-aligned in ARM systems.

Word-aligned
Means that the address is divisible by 4.

Write-allocate cache
A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.

Write-back cache
A cache in which when a cache hit occurs on a store access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to main memory when the cache line is cleaned or reallocated. Another common term for a write-back cache is a copy-back cache.

Write-through cache
A cache in which when a cache hit occurs on a store access, the data is written both to the cache and to main memory. This is normally done using a write buffer, to avoid slowing down the PE.

Write buffer
A block of high-speed memory that optimizes stores to main memory.

Write-one-to-clear
Writing 1 to the relevant bit clears it to 0. Writing 0 to the bit has no effect.

Write-one-to-set
Writing 1 to the relevant bit sets it to 0. Writing 0 to the bit has no effect.

XPSR
See Program Status Registers (XPSR).
