A64 -- Base Instructions (alphabetic order)

ADC: Add with Carry.

ADCS: Add with Carry, setting flags.

ADD (extended register): Add (extended register).

ADD (immediate): Add (immediate).

ADD (shifted register): Add (shifted register).

ADDG: Add with Tag.

ADDS (extended register): Add (extended register), setting flags.

ADDS (immediate): Add (immediate), setting flags.

ADDS (shifted register): Add (shifted register), setting flags.

ADR: Form PC-relative address.

ADRP: Form PC-relative address to 4KB page.

AND (immediate): Bitwise AND (immediate).

ANDS (immediate): Bitwise AND (immediate), setting flags.

ANDS (shifted register): Bitwise AND (shifted register), setting flags.

ASR (immediate): Arithmetic Shift Right (immediate): an alias of SBFM.

ASR (register): Arithmetic Shift Right (register): an alias of ASRV.

ASRV: Arithmetic Shift Right Variable.

AT: Address Translate: an alias of SYS.

AUTDA, AUTDZA: Authenticate Data address, using key A.

AUTDB, AUTDZB: Authenticate Data address, using key B.

AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA: Authenticate Instruction address, using key A.

AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB: Authenticate Instruction address, using key B.

AXFLAG: Convert floating-point condition flags from Arm to external format.

B: Branch.

B.cond: Branch conditionally.

BFC: Bitfield Clear: an alias of BFM.

BFI: Bitfield Insert: an alias of BFM.

BFM: Bitfield Move.

BFXIL: Bitfield extract and insert at low end: an alias of BFM.

BIC (shifted register): Bitwise Bit Clear (shifted register).

BICS (shifted register): Bitwise Bit Clear (shifted register), setting flags.

BL: Branch with Link.

BLR: Branch with Link to Register.
BLRAA, BLRAAZ, BLRAB, BLRABZ: Branch with Link to Register, with pointer authentication.

BR: Branch to Register.

BRAA, BRAAZ, BRAB, BRABZ: Branch to Register, with pointer authentication.

BRK: Breakpoint instruction.

BTI: Branch Target Identification.

CAS, CASA, CASAL, CASL: Compare and Swap word or doubleword in memory.

CASB, CASAB, CASALB, CASLB: Compare and Swap byte in memory.

CASH, CASAH, CASALH, CASLH: Compare and Swap halfword in memory.

CASP, CASPA, CASPAL, CASPL: Compare and Swap Pair of words or doublewords in memory.

CBNZ: Compare and Branch on Nonzero.

CBZ: Compare and Branch on Zero.

CCMN (immediate): Conditional Compare Negative (immediate).

CCMN (register): Conditional Compare Negative (register).

CCMP (immediate): Conditional Compare (immediate).

CCMP (register): Conditional Compare (register).

CFINV: Invert Carry Flag.

CFP: Control Flow Prediction Restriction by Context: an alias of SYS.

CINC: Conditional Increment: an alias of CSINC.

CINV: Conditional Invert: an alias of CSINV.

CLREX: Clear Exclusive.

CLS: Count Leading Sign bits.

CLZ: Count Leading Zeros.

CMN (immediate): Compare Negative (immediate): an alias of ADDS (immediate).

CMP (immediate): Compare (immediate): an alias of SUBS (immediate).

CMPP: Compare with Tag: an alias of SUBPS.

CNEG: Conditional Negate: an alias of CSNEG.

CPP: Cache Prefetch Prediction Restriction by Context: an alias of SYS.

CRC32CB, CRC32CH, CRC32CW, CRC32CX: CRC32C checksum.

CSDB: Consumption of Speculative Data Barrier.

CSEL: Conditional Select.

CSET: Conditional Set: an alias of CSINC.
CSETM: Conditional Set Mask: an alias of CSINV.
CSINC: Conditional Select Increment.
CSINV: Conditional Select Invert.
CSNEG: Conditional Select Negation.
DC: Data Cache operation: an alias of SYS.
DCPS1: Debug Change PE State to EL1.
DCPS2: Debug Change PE State to EL2.
DCPS3: Debug Change PE State to EL3.
DFB: Data Full Barrier: an alias of DSB.
DGH: Data Gathering Hint.
DMB: Data Memory Barrier.
DRPS: Debug restore process state.
DSB: Data Synchronization Barrier.
DVP: Data Value Prediction Restriction by Context: an alias of SYS.
EON (shifted register): Bitwise Exclusive OR NOT (shifted register).
EOR (immediate): Bitwise Exclusive OR (immediate).
EOR (shifted register): Bitwise Exclusive OR (shifted register).
ERET: Exception Return.
ERETAA, ERETAB: Exception Return, with pointer authentication.
ESB: Error Synchronization Barrier.
EXTR: Extract register.
GMI: Tag Mask Insert.
HINT: Hint instruction.
HLT: Halt instruction.
HVC: Hypervisor Call.
IC: Instruction Cache operation: an alias of SYS.
IRG: Insert Random Tag.
JSB: Instruction Synchronization Barrier.
LDADD, LDADDA, LDADDAL, LDADDL: Atomic add on word or doubleword in memory.
LDADDB, LDADDAB, LDADDALB, LDADDLB: Atomic add on byte in memory.
LDADDH, LDADDAH, LDADDALH, LDADDLH: Atomic add on halfword in memory.
LDAPR: Load-Acquire RCpc Register.
LDAPRB: Load-Acquire RCpc Register Byte.
LDAPRH: Load-Acquire RCpc Register Halfword.
LDAPUR: Load-Acquire RCpc Register (unscaled).
LDAPURB: Load-Acquire RCpc Register Byte (unscaled).
LDAPURH: Load-Acquire RCpc Register Halfword (unscaled).
LDAPURSB: Load-Acquire RCpc Register Signed Byte (unscaled).
LDAPURSH: Load-Acquire RCpc Register Signed Halfword (unscaled).
LDAPURSW: Load-Acquire RCpc Register Signed Word (unscaled).
LDAR: Load-Acquire Register.
LDARB: Load-Acquire Register Byte.
LDARH: Load-Acquire Register Halfword.
LDAXP: Load-Acquire Exclusive Pair of Registers.
LDAXR: Load-Acquire Exclusive Register.
LDAXRB: Load-Acquire Exclusive Register Byte.
LDAXRH: Load-Acquire Exclusive Register Halfword.
LDCLR, LDCLRA, LDCLRAL, LDCLRL: Atomic bit clear on word or doubleword in memory.
LDCLRAB, LDCLRALB, LDCLRLB: Atomic bit clear on byte in memory.
LDCLRH, LDCLRALH, LDCLRLH: Atomic bit clear on halfword in memory.
LDEOR, LDEORA, LDEORAL, LDEORL: Atomic exclusive OR on word or doubleword in memory.
LDEORAB, LDEORALB, LDEORLB: Atomic exclusive OR on byte in memory.
LDEORH, LDEORALH, LDEORLH: Atomic exclusive OR on halfword in memory.
LDG: Load Allocation Tag.
LDGM: Load Tag Multiple.
LDLAR: Load LOAcquire Register.
LDLARB: Load LOAcquire Register Byte.
LDLARH: Load LOAcquire Register Halfword.
LDNP: Load Pair of Registers, with non-temporal hint.
LDP: Load Pair of Registers.
LDPSW: Load Pair of Registers Signed Word.
LDR (immediate): Load Register (immediate).
LDR (literal): Load Register (literal).
LDR (register): Load Register (register).
LDRAA, LDRAB: Load Register, with pointer authentication.
LDRB (immediate): Load Register Byte (immediate).
LDRB (register): Load Register Byte (register).
LDRH (immediate): Load Register Halfword (immediate).
LDRH (register): Load Register Halfword (register).
LDRSB (immediate): Load Register Signed Byte (immediate).
LDRSB (register): Load Register Signed Byte (register).
LDRSH (immediate): Load Register Signed Halfword (immediate).
**LDRSH (register)**: Load Register Signed Halfword (register).

**LDRSW (immediate)**: Load Register Signed Word (immediate).

**LDRSW (literal)**: Load Register Signed Word (literal).

**LDRSW (register)**: Load Register Signed Word (register).

**LDSET, LDSETA, LDSETAL, LDSETL**: Atomic bit set on word or doubleword in memory.

**LDSETB, LDSETAB, LDSETALB, LDSETLB**: Atomic bit set on byte in memory.

**LDSETH, LDSETAH, LDSETALH, LDSETLH**: Atomic bit set on halfword in memory.

**LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL**: Atomic signed maximum on word or doubleword in memory.

**LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB**: Atomic signed maximum on byte in memory.

**LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH**: Atomic signed maximum on halfword in memory.

**LDSMIN, LDSMINA, LDSMINAL, LDSMINI**: Atomic signed minimum on word or doubleword in memory.

**LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB**: Atomic signed minimum on byte in memory.

**LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH**: Atomic signed minimum on halfword in memory.

**LDTR**: Load Register (unprivileged).

**LDTRB**: Load Register Byte (unprivileged).

**LDTRH**: Load Register Halfword (unprivileged).

**LDTRSB**: Load Register Signed Byte (unprivileged).

**LDTRSH**: Load Register Signed Halfword (unprivileged).

**LDTRSW**: Load Register Signed Word (unprivileged).

**LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL**: Atomic unsigned maximum on word or doubleword in memory.

**LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB**: Atomic unsigned maximum on byte in memory.

**LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH**: Atomic unsigned maximum on halfword in memory.

**LDUMIN, LDUMINA, LDUMINAL, LDUMINL**: Atomic unsigned minimum on word or doubleword in memory.

**LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB**: Atomic unsigned minimum on byte in memory.

**LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH**: Atomic unsigned minimum on halfword in memory.

**LDUR**: Load Register (unscaled).

**LDURB**: Load Register Byte (unscaled).

**LDURH**: Load Register Halfword (unscaled).

**LDURSB**: Load Register Signed Byte (unscaled).

**LDURSH**: Load Register Signed Halfword (unscaled).

**LDURSW**: Load Register Signed Word (unscaled).

**LDXP**: Load Exclusive Pair of Registers.

**LDXR**: Load Exclusive Register.

**LDXRB**: Load Exclusive Register Byte.

**LDXRH**: Load Exclusive Register Halfword.

**LSL (immediate)**: Logical Shift Left (immediate): an alias of UBFM.
LSL (register): Logical Shift Left (register): an alias of LSLV.
LSLV: Logical Shift Left Variable.
LSR (immediate): Logical Shift Right (immediate): an alias of UBFM.
LSR (register): Logical Shift Right (register): an alias of LSRV.
LSRV: Logical Shift Right Variable.
MADD: Multiply-Add.
MNEG: Multiply-Negate: an alias of MSUB.
MOV (bitmask immediate): Move (bitmask immediate): an alias of ORR (immediate).
MOV (inverted wide immediate): Move (inverted wide immediate): an alias of MOVN.
MOV (to/from SP): Move between register and stack pointer: an alias of ADD (immediate).
MOV (wide immediate): Move (wide immediate): an alias of MOVZ.
MOVK: Move with keep.
MOVN: Move with NOT.
MOVSZ: Move wide with zero.
MRS: Move System Register.
MSR (immediate): Move immediate value to Special Register.
MSR (register): Move general-purpose register to System Register.
MSUB: Multiply-Subtract.
MUL: Multiply: an alias of MADD.
MVN: Bitwise NOT: an alias of ORN (shifted register).
NEG: Negate, setting flags: an alias of SUBS (shifted register).
NGC: Negate with Carry: an alias of SBC.
NGCS: Negate with Carry, setting flags: an alias of SBCS.
NOP: No Operation.
ORN (shifted register): Bitwise OR NOT (shifted register).
ORR (immediate): Bitwise OR (immediate).
ORR (shifted register): Bitwise OR (shifted register).
PACDA, PACDZA: Pointer Authentication Code for Data address, using key A.
PACDB, PACDZB: Pointer Authentication Code for Data address, using key B.
PACGA: Pointer Authentication Code, using Generic key.
PACIA, PACIA1716, PACIAZ, PACIASP, PACIZA: Pointer Authentication Code for Instruction address, using key A.
PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB: Pointer Authentication Code for Instruction address, using key B.
PRFM (immediate): Prefetch Memory (immediate).
PRFM (literal): Prefetch Memory (literal).
PRFM (register): Prefetch Memory (register).
PRFUM: Prefetch Memory (unscaled offset).
PSB CSYNC: Profiling Synchronization Barrier.
PSSBB: Physical Speculative Store Bypass Barrier.
RBIT: Reverse Bits.
RET: Return from subroutine.
RETA, RETAB: Return from subroutine, with pointer authentication.
REV: Reverse Bytes.
REV16: Reverse bytes in 16-bit halfwords.
REV32: Reverse bytes in 32-bit words.
REV64: Reverse Bytes: an alias of REV.
RMIF: Rotate, Mask Insert Flags.
ROR (immediate): Rotate right (immediate): an alias of EXTR.
ROR (register): Rotate Right (register): an alias of RORV.
RORV: Rotate Right Variable.
SB: Speculation Barrier.
SBC: Subtract with Carry.
SBCS: Subtract with Carry, setting flags.
SBFIZ: Signed Bitfield Insert in Zero: an alias of SBFM.
SBFM: Signed Bitfield Move.
SBFX: Signed Bitfield Extract: an alias of SBFM.
SDIV: Signed Divide.
SETF8, SETF16: Evaluation of 8 or 16 bit flag values.
SEV: Send Event.
SEVL: Send Event Local.
SMADDL: Signed Multiply-Add Long.
SMC: Secure Monitor Call.
SMNEGL: Signed Multiply-Negate Long: an alias of SMSUBL.
SMSUBL: Signed Multiply-Subtract Long.
SMULH: Signed Multiply High.
SMULL: Signed Multiply Long: an alias of SMADDL.
SSBB: Speculative Store Bypass Barrier.
ST2G: Store Allocation Tags.
STADD, STADDL: Atomic add on word or doubleword in memory, without return: an alias of LDADD, LDADDA, LDADDAL, LDADDL.
STADDB, STADDLB: Atomic add on byte in memory, without return: an alias of LDADDB, LDADDAB, LDADDALB, LDADDLB.
STADDH, STADDLH: Atomic add on halfword in memory, without return: an alias of LDADDH, LDADDAH, LDADDAHL, LDADDLH.

STCLR, STCLRL: Atomic bit clear on word or doubleword in memory, without return: an alias of LDCLR, LDCLRA, LDCLRAL, LDCLRL.

STCLRB, STCLRLB: Atomic bit clear on byte in memory, without return: an alias of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB.

STCLRH, STCLRLH: Atomic bit clear on halfword in memory, without return: an alias of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH.

STEOR, STEORL: Atomic exclusive OR on word or doubleword in memory, without return: an alias of LDEOR, LDEORA, LDEORAL, LDEORL.

STEORB, STEORLB: Atomic exclusive OR on byte in memory, without return: an alias of LDEORB, LDEORAB, LDEORALB, LDEORLB.

STEORH, STEORLH: Atomic exclusive OR on halfword in memory, without return: an alias of LDEORH, LDEORAH, LDEORALH, LDEORLH.

STG: Store Allocation Tag.

STGM: Store Tag Multiple.

STGP: Store Allocation Tag and Pair of registers.

STLLR: Store LORelease Register.

STLLRB: Store LORelease Register Byte.

STLLRH: Store LORelease Register Halfword.

STLR: Store-Release Register.

STLRB: Store-Release Register Byte.

STLRH: Store-Release Register Halfword.

STLUR: Store-Release Register (unscaled).

STLURB: Store-Release Register Byte (unscaled).

STLURH: Store-Release Register Halfword (unscaled).

STLXP: Store-Release Exclusive Pair of registers.

STLXR: Store-Release Exclusive Register.

STLXRB: Store-Release Exclusive Register Byte.

STLXRH: Store-Release Exclusive Register Halfword.

STNP: Store Pair of Registers, with non-temporal hint.

STP: Store Pair of Registers.

STR (immediate): Store Register (immediate).

STR (register): Store Register (register).

STRB (immediate): Store Register Byte (immediate).

STRB (register): Store Register Byte (register).

STRH (immediate): Store Register Halfword (immediate).

STRH (register): Store Register Halfword (register).

STSET, STSETL: Atomic bit set on word or doubleword in memory, without return: an alias of LDSET, LDSETA, LDSETAL, LDSETL.
STSETB, STSETLB: Atomic bit set on byte in memory, without return: an alias of LDSETB, LDSETAB, LDSETALB, LDSETLB.

STSETH, STSETLH: Atomic bit set on halfword in memory, without return: an alias of LDSETH, LDSETHA, LDSETHAL, LDSETHL.

STSMAX, STSMAXL: Atomic signed maximum on word or doubleword in memory, without return: an alias of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL.

STSMAXB, STSMAXLB: Atomic signed maximum on byte in memory, without return: an alias of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB.

STSMAXH, STSMAXLH: Atomic signed maximum on halfword in memory, without return: an alias of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH.

STSMIN, STSMINL: Atomic signed minimum on word or doubleword in memory, without return: an alias of LDSMIN, LDSMINA, LDSMINAL, LDSMINL.

STSMINB, STSMINLB: Atomic signed minimum on byte in memory, without return: an alias of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB.

STSMINH, STSMINLH: Atomic signed minimum on halfword in memory, without return: an alias of LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH.

STTR: Store Register (unprivileged).

STTRB: Store Register Byte (unprivileged).

STTRH: Store Register Halfword (unprivileged).

STUMAX, STUMAXL: Atomic unsigned maximum on word or doubleword in memory, without return: an alias of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL.

STUMAXB, STUMAXLB: Atomic unsigned maximum on byte in memory, without return: an alias of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB.

STUMAXH, STUMAXLH: Atomic unsigned maximum on halfword in memory, without return: an alias of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH.

STUMIN, STUMINL: Atomic unsigned minimum on word or doubleword in memory, without return: an alias of LDUMIN, LDUMINA, LDUMINAL, LDUMINL.

STUMINB, STUMINLB: Atomic unsigned minimum on byte in memory, without return: an alias of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB.

STUMINH, STUMINLH: Atomic unsigned minimum on halfword in memory, without return: an alias of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH.

STUR: Store Register (unscaled).

STURB: Store Register Byte (unscaled).

STURH: Store Register Halfword (unscaled).

STXP: Store Exclusive Pair of registers.

STXR: Store Exclusive Register.

STXRB: Store Exclusive Register Byte.

STXRH: Store Exclusive Register Halfword.

STZ2G: Store Allocation Tags, Zeroing.

STZG: Store Allocation Tag, Zeroing.

STZGM: Store Tag and Zero Multiple.

SUB (extended register): Subtract (extended register).

SUB (immediate): Subtract (immediate).
SUB (shifted register): Subtract (shifted register).
SUBG: Subtract with Tag.
SUBP: Subtract Pointer.
SUBPS: Subtract Pointer, setting Flags.
SUBS (extended register): Subtract (extended register), setting flags.
SUBS (immediate): Subtract (immediate), setting flags.
SUBS (shifted register): Subtract (shifted register), setting flags.
SVC: Supervisor Call.
SWP, SWPA, SWPAL, SWPL: Swap word or doubleword in memory.
SWPB, SWPAB, SWPALB, SWPLB: Swap byte in memory.
SWPH, SWPAH, SWPALH, SWPLH: Swap halfword in memory.
SXTB: Signed Extend Byte: an alias of SBFM.
SXTH: Sign Extend Halfword: an alias of SBFM.
SXTW: Sign Extend Word: an alias of SBFM.
SYS: System instruction.
SYSL: System instruction with result.
TBNZ: Test bit and Branch if Nonzero.
TBZ: Test bit and Branch if Zero.
TLBI: TLB Invalidate operation: an alias of SYS.
TSB CSYNC: Trace Synchronization Barrier.
TST (immediate): Test bits (immediate): an alias of ANDS (immediate).
UBFIZ: Unsigned Bitfield Insert in Zero: an alias of UBFM.
UBFM: Unsigned Bitfield Move.
UBFX: Unsigned Bitfield Extract: an alias of UBFM.
UDF: Permanently Undefined.
UDIV: Unsigned Divide.
UMADDL: Unsigned Multiply-Add Long.
UMNEGL: Unsigned Multiply-Negate Long: an alias of UMSUBL.
UMSUBL: Unsigned Multiply-Subtract Long.
UMULH: Unsigned Multiply High.
UMULL: Unsigned Multiply Long: an alias of UMADDL.
UXTB: Unsigned Extend Byte: an alias of UBFM.
UXTH: Unsigned Extend Halfword: an alias of UBFM.
WFE: Wait For Event.
WFI: Wait For Interrupt.
XAFLAG: Convert floating-point condition flags from external format to Arm format.

XPACD, XPACI, XPACLRI: Strip Pointer Authentication Code.

YIELD: YIELD.
ADC

Add with Carry adds two register values and the Carry flag value, and writes the result to the destination register.

| sf | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | Rm | 0 | 0 | 0 | 0 | 0 | 0 | Rn | Rd |

32-bit (sf == 0)

ADC <Wd>, <Wn>, <Wm>

64-bit (sf == 1)

ADC <Xd>, <Xn>, <Xm>

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler Symbols

| <Wd> | Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field. |
| <Wn> | Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field. |
| <Wm> | Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field. |
| <Xd> | Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field. |
| <Xn> | Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field. |
| <Xm> | Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field. |

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
(result, -) = AddWithCarry(operand1, operand2, PSTATE.C);
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADCS

Add with Carry, setting flags, adds two register values and the Carry flag value, and writes the result to the destination register. It updates the condition flags based on the result.

<table>

32-bit (sf == 0)

ADCS <Wd>, <Wn>, <Wm>

64-bit (sf == 1)

ADCS <Xd>, <Xn>, < Xm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcv;
(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);
PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADD (extended register)

Add (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the \(<Rm>\) register can be a byte, halfword, word, or doubleword.

Assembler Symbols

\(<Wd|WSP\rangle\) Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\(<Wn|WSP\rangle\) Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

\(<Wm\rangle\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

\(<Xd|SP\rangle\) Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

\(<Xn|SP\rangle\) Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

\(<R>\) Is a width specifier, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>010</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>

\(<m>\) Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

\(<\text{extend}>\) For the 32-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;\text{extend}&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UXTX</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

ADD (extended register)
For the 64-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
(result, -) = AddWithCarry(operand1, operand2, '0');
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADD (immediate)

Add (immediate) adds a register value and an optionally-shifted immediate value, and writes the result to the destination register.

This instruction is used by the alias MOV (to/from SP).

32-bit (sf == 0)

```
ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

64-bit (sf == 1)

```
ADD <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}
```

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;

```
case sh of
  when '0' imm = ZeroExtend(imm12, datasize);
  when '1' imm = ZeroExtend(imm12:Zeros(12), datasize);
```

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

<table>
<thead>
<tr>
<th>sh</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LSL #0</td>
</tr>
<tr>
<td>1</td>

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
(result, -) = AddWithCarry(operand1, operand2, '0');
X[d] = result;
```

ADD (shifted register)
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADDG

Add with Tag adds an immediate value scaled by the Tag granule to the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

Integer

(ARMv8.5)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

```

Literal

ADR <Xd>, <label>

```
int d = UInt(Rd);
bits(64) imm;
imm = SignExtend(immhi:immlo, 64);
```

Assembler Symbols

- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<label>` is the program label whose address is to be calculated. Its offset from the address of this instruction, in the range +/-1MB, is encoded in "immhi:immlo".

Operation

```
bits(64) base = PC[ ];
Xd[d] = base + imm;
```
ADRP

Form PC-relative address to 4KB page adds an immediate value that is shifted left by 12 bits, to the PC value to form a
PC-relative address, with the bottom 12 bits masked out, and writes the result to the destination register.

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

**Literal**

```
ADRP <Xd>, <label>
```

`integer d = UInt(Rd);`
`bits(64) imm;`
`imm = SignExtend(immhi:immlo:Zeros(12), 64);`

**Assembler Symbols**

- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<label>` Is the program label whose 4KB page address is to be calculated. Its offset from the page address of
  this instruction, in the range +/-4GB, is encoded as "immhi:immlo" times 4096.

**Operation**

```
bits(64) base = PC[];
base<11:0> = Zeros(12);
Xd[d] = base + imm;
```
**AND (immediate)**

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

<table>
<thead>

### 32-bit (sf == 0 && N == 0)

AND <Wd|WSP>, <Wn>, #<imm>

### 64-bit (sf == 1)

AND <Xd|SP>, <Xn>, #<imm>

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;
if sf == '0' && N != '0' then UNDEFINED;
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

**Assembler Symbols**

- **<Wd|WSP>** Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- **<Wn>** Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- **<Xd|SP>** Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- **<Xn>** Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- **<imm>** For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".
  - For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = X[n];

result = operand1 AND imm;
if d == 31 then
  SP[] = result;
else
  X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**AND (shifted register)**

Bitwise AND (shifted register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>
```

- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
- For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
result = operand1 AND operand2;
X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
The values of the data supplied in any of its registers.
The values of the NZCV flags.

The response of this instruction to asynchronous exceptions does not vary based on:
The values of the data supplied in any of its registers.
The values of the NZCV flags.
ANDS (immediate)

Bitwise AND (immediate), setting flags, performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias TST (immediate).

### 32-bit (sf == 0 && N == 0)

ANDS <Wd>, <Wn>, #<imm>

### 64-bit (sf == 1)

ANDS <Xd>, <Xn>, #<imm>

integer d = UInt(Rd);

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This is an alias of ASRV. This means:

- The encodings in this description are named to match the encodings of ASRV.
- The description of ASRV gives the operational pseudocode for this instruction.

32-bit (sf == 0)

ASR <Wd>, <Wn>, <Wm>

is equivalent to

ASRV <Wd>, <Wn>, <Wm>

and is always the preferred disassembly.

64-bit (sf == 1)

ASR <Xd>, <Xn>, <Xm>

is equivalent to

ASRV <Xd>, <Xn>, <Xm>

and is always the preferred disassembly.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of ASRV gives the operational pseudocode for this instruction.

Operational information

`<op1>` is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

`<Cm>` is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

`<op2>` is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

`<Xt>` is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

### Operation

The description of `SYS` gives the operational pseudocode for this instruction.
AUTDA, AUTDZA

Authenticate Data address, using key A. This instruction authenticates a data address, using a modifier and key A. The address is in the general-purpose register that is specified by <Xd>.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDA.
- The value zero, for AUTDZA.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

**Integer (Armv8.3)**

```
AUTDB, AUTDZB

Authenticate Data address, using key B. This instruction authenticates a data address, using a modifier and key B. The address is in the general-purpose register that is specified by \(<Xd>\).

The modifier is:
- In the general-purpose register or stack pointer that is specified by \(<Xn|SP>\) for AUTDB.
- The value zero, for AUTDZB.

If the authentication fails, the upper bits of the address are corrupted and any subsequent use of the address results in a Translation fault.

### Integer (Armv8.3)

```
0 1 1 0 1 0 1 1 0 0 0 0 0 1 0 0 0 | Z 1 1 1 |
    Rn     Rd
```

#### AUTDB (Z == 0)

AUTDB \(<Xd>, <Xn|SP>\)

#### AUTDZB (Z == 1 && Rn == 1111)

AUTDZB \(<Xd>\)

```plaintext
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HavePACExt() then
  UNDEFINED;
if Z == '0' then // AUTDB
  if n == 31 then source_is_sp = TRUE;
else // AUTDZB
  if n != 31 then UNDEFINED;
```

### Assembler Symbols

- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn|SP>\) Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

### Operation

```plaintext
if HavePACExt() then
  if source_is_sp then
    X[d] = AuthDB(X[d], SP[], FALSE);
  else
    X[d] = AuthDB(X[d], X[n], FALSE);
```

AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA

Authenticate Instruction address, using key A. This instruction authenticates an instruction address, using a modifier and key A.

The address is:
- In the general-purpose register that is specified by <Xd> for AUTIA and AUTIZA.
- In X17, for AUTIA1716.
- In X30, for AUTIASP and AUTIAZ.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTIA.
- The value zero, for AUTIZA and AUTIAZ.
- In X16, for AUTIA1716.
- In SP, for AUTIASP.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

It has encodings from 2 classes: Integer and System

**Integer**
**(Armv8.3)**

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
| 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | Z | 1 | 0 | 0 |
```

**AUTIA (Z == 0)**

AUTIA <Xd>, <Xn|SP>

**Operation**

```c
if HavePACExt() then
  if source_is_sp then
    X[d] = AuthIB(X[d], SP[], FALSE);
  else
    X[d] = AuthIB(X[d], X[n], FALSE);

```
AXFLAG

Convert floating-point condition flags from Arm to external format. This instruction converts the state of the PSTATE.{N,Z,C,V} flags from a form representing the result of an Arm floating-point scalar compare instruction to an alternative representation required by some software.

System
(Armv8.5)

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 0 1 0 1 0 0 0 0 0 0 1 0 0 (0) (0) (0) (0) 0 1 0 1 1 1 1 1
```

System

```
AXFLAG
if !HaveFlagFormatExt() then UNDEFINED;
```

Operation

```
bit Z = PSTATE.Z OR PSTATE.V;
bite C = PSTATE.C AND NOT(PSTATE.V);

PSTATE.N = '0';
PSTATE.Z = Z;
PSTATE.C = C;
PSTATE.V = '0';
```

B.cond

Branch conditionally to a label at a PC-relative offset, with a hint that this is not a subroutine call or return.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0  | 1  | 0  | 1  | 0  | 1  | 0  | 0  | imm19 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | cond |

19-bit signed PC-relative branch offset

B.<cond> <label>

bits(64) offset = \texttt{SignExtend}(imm19:'00', 64);

Assembler Symbols

<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

\[
\text{if } \text{ConditionHolds}(\text{cond}) \text{ then }
\text{BranchTo}(\text{PC}[] + \text{offset}, \text{BranchType_DIR});
\]
Branch causes an unconditional branch to a label at a PC-relative offset, with a hint that this is not a subroutine call or return.

32-bit (sf == 0 && N == 0)

BFC `<Wd>`, `#<lsb>`, `#<width>

is equivalent to

BFM `<Wd>`, WZR, #(-<lsb> MOD 32), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

64-bit (sf == 1 && N == 1)

BFC `<Xd>`, `#<lsb>`, `#<width>

is equivalent to

BFM `<Xd>`, XZR, #(-<lsb> MOD 64), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

Assembler Symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<lsb>` For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- `<width>` For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
BFI

Bitfield Insert copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 && N == 0)

BFI <Wd>, <Wn>, #<lsb>, #<width>

is equivalent to

BFM <Wd>, <Wn>, #(<lsb> MOD 32), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

64-bit (sf == 1 && N == 1)

BFI <Xd>, <Xn>, #<lsb>, #<width>

is equivalent to

BFM <Xd>, <Xn>, #(<lsb> MOD 64), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<lsb> For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.

For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.

<width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly.
If \(<\text{imms}\) is greater than or equal to \(<\text{immr}\)\, this copies a bitfield of \((<\text{imms}\> - <\text{immr}\> + 1)\) bits starting from bit position \(<\text{immr}\> in the source register to the least significant bits of the destination register.
If \(<\text{imms}\) is less than \(<\text{immr}\)\, this copies a bitfield of \((<\text{imms}\> + 1)\) bits from the least significant bits of the source register to bit position \((\text{regsize} - <\text{immr}\>)\) of the destination register, where \text{regsize} is the destination register size of 32 or 64 bits.
In both cases the other bits of the destination register remain unchanged.

This instruction is used by the aliases \text{BFC}\, \text{BFI}\, and \text{BFXIL}.

### 32-bit (sf == 0 && N == 0)

\text{BFM} <Wd>, <Wn>, #<immr>, #<imms>

### 64-bit (sf == 1 && N == 1)

\text{BFM} <Xd>, <Xn>, #<immr>, #<imms>

```plaintext
inger = \text{UInt}(<\text{immr}>);
(wmask, tmask) = \text{DecodeBitMasks}(\text{N}, \text{imms}, \text{immr}, \text{FALSE});
```

### Assembler Symbols

- \(\langle\text{Wd}\rangle\): Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(\langle\text{Wn}\rangle\): Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(\langle\text{Xd}\rangle\): Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(\langle\text{Xn}\rangle\): Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(\langle\text{immr}\rangle\): For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field. For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.
- \(\langle\text{imms}\rangle\): For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field. For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

BFXIL

Bitfield Extract and Insert Low copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 && N == 0)

BFXIL <Wd>, <Wn>, #<lsb>, #<width>

is equivalent to

BFM <Wd>, <Wn>, #<lsb>, #{<lsb>+<width>-1}

and is the preferred disassembly when UInt(imms) >= UInt(immr).

64-bit (sf == 1 && N == 1)

BFXIL <Xd>, <Xn>, #<lsb>, #<width>

is equivalent to

BFM <Xd>, <Xn>, #<lsb>, #{<lsb>+<width>-1}

and is the preferred disassembly when UInt(imms) >= UInt(immr).

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<lsb> For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.

<width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**BIC (shifted register)**

Bitwise Bit Clear (shifted register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

<table>
<thead>
<tr>
<th>sf</th>
<th>0</th>
<th>0</th>
<th>0</th>
<th>1</th>
<th>0</th>
<th>1</th>
<th>shift</th>
<th>Rm</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

### 32-bit (sf == 0)

\[
\text{BIC } \langle Wd \rangle, \langle Wn \rangle, \langle Wm \rangle\{, \langle shift \rangle \#<amount>\}
\]

### 64-bit (sf == 1)

\[
\text{BIC } \langle Xd \rangle, \langle Xn \rangle, \langle Xm \rangle\{, \langle shift \rangle \#<amount>\}
\]

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

### Assembler Symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

### Operation

\[
\text{bits(datasize) operand1 = } X[n];
\text{bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount); }
\text{operand2 = NOT(operand2);}
\text{result = operand1 AND operand2;}
\text{X[d] = result;}
\]
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
BICS (shifted register)

Bitwise Bit Clear (shifted register), setting flags, performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

32-bit (sf == 0)

BICS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit (sf == 1)

BICS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>

</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
operand2 = NOT(operand2);
result = operand1 AND operand2;
PSTATE.<N,Z,C,V> = result<datasize-1>:istoBit(result):'00';
X[d] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
BL

Branch with Link branches to a PC-relative offset, setting the register X30 to PC+4. It provides a hint that this is a subroutine call.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 0 0 1 0 1
```

**26-bit signed PC-relative branch offset**

```
BL <label>

bits(64) offset = SignExtend(imm26:'00', 64);
```

**Assembler Symbols**

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as “imm26” times 4.

**Operation**

```
X[30] = PC[] + 4;
BranchTo(PC[] + offset, BranchType_DIRCALL);
```

Internal version only: isa v31.05b, AdvSIMD v29.02, pseudocode v2019-12_rc3_1, sve v2019-12_rc3 ; Build timestamp: 2019-12-13T15:23

BLR

Branch with Link to Register calls a subroutine at an address in a register, setting register X30 to PC+4.

\[
\begin{array}{cccccccccccccccccccccccc}
1 & 1 & 0 & 1 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & Rn & 0 & 0 & 0 & 0 & 0 & Rm \\
\end{array}
\]

Integer

BLR <Xn>

integer n = UInt(Rn);

Assembler Symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

Operation

bits(64) target = X[n];

X[30] = PC[] + 4;

BranchTo(target, BranchType_INDCALL);
BLRAA, BLRAAZ, BLRAB, BLRABZ

Branch with Link to Register, with pointer authentication. This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and calls a subroutine at the authenticated address, setting register X30 to PC+4.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xm|SP> for BLRAA and BLRAB.
- The value zero, for BLRAAZ and BLRABZ.

Key A is used for BLRAA and BLRAAZ, and key B is used for BLRAB and BLRABZ.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

**Integer**

(Armv8.3)

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| 1   | 1  | 0  | 1  | 0  | 1  | 1  | 1  | 1  | 1  | 1  | 0  | 0  | 0  | 0  | 0  | 1  | 1  | 0  | 1  | 1  | 1  | 1  | 1  | 1  | 0  | 0  | 0  | 0  | 0  |
```

**Key A, zero modifier (Z == 0 & M == 0 & Rm == 11111)**

BLRAAZ <Xn>

**Key A, register modifier (Z == 1 & M == 0)**

BLRAA <Xn>, <Xm|SP>

**Key B, zero modifier (Z == 0 & M == 1 & Rm == 11111)**

BLRABZ <Xn>

**Key B, register modifier (Z == 1 & M == 1)**

BLRAB <Xn>, <Xm|SP>

```
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean use_key_a = (M == '0');
boolean source_is_sp = ((Z == '1') & (m == 31));
if !HavePACExt() then
  UNDEFINED;
if Z == '0' & m != 31 then
  UNDEFINED;
```

**Assembler Symbols**

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

<Xm|SP> Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.
Operation

bits(64) target = X[n];
bits(64) modifier = if source_is_sp then SP[] else X[m];

if use_key_a then
target = AuthIA(target, modifier, TRUE);
else
target = AuthIB(target, modifier, TRUE);

X[30] = PC[] + 4;

BranchTo(target, BranchType_INDCALL);
BR

Branch to Register branches unconditionally to an address in a register, with a hint that this is not a subroutine return.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

**BR** <Xn>

integer n = UInt(Rn);

**Assembler Symbols**

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

**Operation**

bits(64) target = X[n];

BranchTo(target, BranchType_INDIR);
BRAA, BRAAZ, BRAB, BRABZ

Branch to Register, with pointer authentication. This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and branches to the authenticated address. The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xm|SP> for BRAA and BRAB.
- The value zero, for BRAAZ and BRABZ.

Key A is used for BRAA and BRAAZ, and key B is used for BRAB and BRABZ.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

BRK #<imm>

  if HaveBTIExt() then
      SetBTypeCompatible(TRUE);
\end{verbatim}

\subsubsection*{Assembler Symbols}

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

\subsubsection*{Operation}

\begin{verbatim}
AArch64.SoftwareBreakpoint(imm16);
\end{verbatim}
**BTI**

Branch Target Identification. A BTI instruction is used to guard against the execution of instructions which are not the intended target of a branch.

Outside of a guarded memory region, a BTI instruction executes as a NOP. Within a guarded memory region while $PSTATE.BTYPE \neq 0b00$, a BTI instruction compatible with the current value of $PSTATE.BTYPE$ will not generate a Branch Target Exception and will allow execution of subsequent instructions within the memory region.

The operand $<targets>$ passed to a BTI instruction determines the values of $PSTATE.BTYPE$ which the BTI instruction is compatible with.

Within a guarded memory region, while $PSTATE.BTYPE \neq 0b00$, all instructions will generate a Branch Target Exception, other than BRK, BTI, HLT, PACIASP, and PACIBSP, which may not. See the individual instructions for details.

**System**

CAS, CASA, CASAL, CASL

Compare and Swap word or doubleword in memory reads a 32-bit word or 64-bit doubleword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- CASA and CASAL load from memory with acquire semantics.
- CASL and CASAL store to memory with release semantics.
- CAS has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*.
For information about memory accesses see *Load/Store addressing modes*.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.
If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, or <Xs>, is restored to the value held in the register before the instruction was executed.

**No offset**  
(Armv8.1)

If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- CASB and CASALB load from memory with acquire semantics.
- CASLB and CASALB store to memory with release semantics.
- CASB has no memory ordering requirements.

For more information about memory ordering semantics see Load-Acquire, Store-Release.
For information about memory accesses see Load/Store addressing modes.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is \(<Ws>\), is restored to the values held in the register before the instruction was executed.

```

op

32-bit (sf == 0)

CCMN <Wn>, #<imm>, #<nzcv>, <cond>

64-bit (sf == 1)

CCMN <Xn>, #<imm>, #<nzcv>, <cond>

integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(4) flags = nzcv;
bits(datasize) imm = ZeroExtend(imm5, datasize);

Assembler Symbols

- `<Wn>`: Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xn>`: Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<imm>`: Is a five bit unsigned (positive) immediate encoded in the "imm5" field.
- `<nzcv>`: Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.
- `<cond>`: Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
bits(datasize) operand1 = X[n];
if ConditionHolds(cond) then
  (-, flags) = AddWithCarry(operand1, imm, '0');
PSTATE.<N,Z,C,V> = flags;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CCMN (register)

Conditional Compare Negative (register) sets the value of the condition flags to the result of the comparison of a register value and the inverse of another register value if the condition is TRUE, and an immediate value otherwise.

System

CFINV

if !HaveFlagManipulateExt() then UNDEFINED;

Operation

PSTATE.C = NOT(PSTATE.C);

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Control Flow Prediction Restriction by Context prevents control flow predictions that predict execution addresses, based on information gathered from earlier execution within a particular execution context, from allowing later speculative execution within that context to be observable through side-channels.

For more information, see **CFP RCTX, Control Flow Prediction Restriction by Context**.

This is an alias of **SYS**. This means:

- The encodings in this description are named to match the encodings of **SYS**.
- The description of **SYS** gives the operational pseudocode for this instruction.

**System**

(Armv8.5)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

**Assembler Symbols**

\(<Xt>\)

Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

**Operation**

The description of **SYS** gives the operational pseudocode for this instruction.
CINC

Conditional Increment returns, in the destination register, the value of the source register incremented by 1 if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSINC. This means:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CINC <Wd>, <Wn>, <cond>

is equivalent to

CSINC <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

64-bit (sf == 1)

CINC <Xd>, <Xn>, <cond>

is equivalent to

CSINC <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
<cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINC gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CINV

Conditional Invert returns, in the destination register, the bitwise inversion of the value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSINV. This means:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode for this instruction.

| op | Rm | cond | o2 | Rn |

32-bit (sf == 0)

CINV <Wd>, <Wn>, <cond>

is equivalent to

CSINV <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

64-bit (sf == 1)

CINV <Xd>, <Xn>, <cond>

is equivalent to

CSINV <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINV gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CLREX

Clear Exclusive clears the local monitor of the executing PE.

```
+-----------+------------+------------------+
| bit 31    | bit 30     | bit 29           |
| 1 1 0 1   | 0 1 0 0    | 0 0 0 1          |

CLS

Count Leading Sign bits counts the number of leading bits of the source register that have the same value as the most significant bit of the register, and writes the result to the destination register. This count does not include the most significant bit of the source register.

32-bit (sf == 0)

CLS <Wd>, <Wn>

64-bit (sf == 1)

CLS <Xd>, <Xn>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

integer result;
bits(datasize) operand1 = X[n];
result = CountLeadingSignBits(operand1);
X[d] = result<datasize-1:0>;

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
Count Leading Zeros counts the number of binary zero bits before the first binary one bit in the value of the source register, and writes the result to the destination register.

32-bit \( sf == 0 \)

```
CLZ <Wd>, <Wn>
```

64-bit \( sf == 1 \)

```
CLZ <Xd>, <Xn>
```

```python
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
```

### Assembler Symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

### Operation

```python
integer result;
bits(datasize) operand1 = X[n];
result = CountLeadingZeroBits(operand1);
X[d] = result<datasize-1:0>;
```

### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CMN (extended register)

Compare Negative (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (extended register). This means:

- The encodings in this description are named to match the encodings of ADDS (extended register).
- The description of ADDS (extended register) gives the operational pseudocode for this instruction.

### 32-bit (sf == 0)

CMN <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

is equivalent to

ADDS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

and is always the preferred disassembly.

### 64-bit (sf == 1)

CMN <Xn|SP>, <R><m>{, <extend> {#<amount>}}

is equivalent to

ADDS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

and is always the preferred disassembly.

### Assembler Symbols

- `<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>` Is a width specifier, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>010</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>

- `<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
- `<extend>` For the 32-bit variant: is the extension to be applied to the second source operand, encoded in "option":
If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UXTX</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

The description of ADDS (extended register) gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CMN (immediate)

Compare Negative (immediate) adds a register value and an optionally-shifted immediate value. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (immediate). This means:

- The encodings in this description are named to match the encodings of ADDS (immediate).
- The description of ADDS (immediate) gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CMN \(<Wn|WSP>, \#<imm>{, <shift>}\)

is equivalent to

ADDS WZR, \(<Wn|WSP>, \#<imm>{, <shift>}\)

and is always the preferred disassembly.

64-bit (sf == 1)

CMN \(<Xn|SP>, \#<imm>{, <shift>}\)

is equivalent to

ADDS XZR, \(<Xn|SP>, \#<imm>{, <shift>}\)

and is always the preferred disassembly.

Assembler Symbols

- \(<Wn|WSP>\) Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- \(<Xn|SP>\) Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- \(<imm>\) Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
- \(<shift>\) Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in "sh":

<table>
<thead>
<tr>
<th>sh</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LSL #0</td>
</tr>
<tr>
<td>1</td>
<td>LSL #12</td>
</tr>
</tbody>
</table>

Operation

The description of ADDS (immediate) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**CMN (shifted register)**

Compare Negative (shifted register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of **ADDS (shifted register)**. This means:

- The encodings in this description are named to match the encodings of **ADDS (shifted register)**.
- The description of **ADDS (shifted register)** gives the operational pseudocode for this instruction.

**32-bit (sf == 0)**

CMN \(<Wn>, <Wm}\{, <shift> \#<amount>\}

is equivalent to

**ADDS WZR, <Wn>, <Wm} {, <shift> \#<amount>\}

and is always the preferred disassembly.

**64-bit (sf == 1)**

CMN \(<Xn>, <Xm}\{, <shift> \#<amount>\}

is equivalent to

**ADDS XZR, <Xn>, <Xm} {, <shift> \#<amount>\}

and is always the preferred disassembly.

**Assembler Symbols**

- \(<Wn>\) is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xn>\) is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<shift>\) is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":
  
<table>
<thead>
<tr>
<th>(\text{shift})</th>
<th>(&lt;\text{shift}&gt;)</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- \(<\text{amount}>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

The description of **ADDS (shifted register)** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
CMP (extended register)

Compare (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (extended register). This means:

- The encodings in this description are named to match the encodings of SUBS (extended register).
- The description of SUBS (extended register) gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CMP <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

is equivalent to

SUBS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

and is always the preferred disassembly.

64-bit (sf == 1)

CMP <Xn|SP>, <R><m>{, <extend> {#<amount>}}

is equivalent to

SUBS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>

<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

The description of SUBS (extended register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CMP (immediate)

Compare (immediate) subtracts an optionally-shifted immediate value from a register value. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (immediate). This means:

- The encodings in this description are named to match the encodings of SUBS (immediate).
- The description of SUBS (immediate) gives the operational pseudocode for this instruction.

| sf | 1 | 1 | 1 | 0 | 0 | 0 | 1 | 0 | sh | imm12 | Rn | 1 | 1 | 1 | 1 | Rd |
|----|----|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|

32-bit (sf == 0)

CMP <Wn|WSP>, #<imm>{, <shift>}

is equivalent to

SUBS WZR, <Wn|WSP>, #<imm> {, <shift>}

and is always the preferred disassembly.

64-bit (sf == 1)

CMP <Xn|SP>, #<imm>{, <shift>}

is equivalent to

SUBS XZR, <Xn|SP>, #<imm> {, <shift>}

and is always the preferred disassembly.

Assembler Symbols

- <Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.
- <Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.
- <imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the “imm12” field.
- <shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

<table>
<thead>
<tr>
<th>sh</th>
<th>&lt;shift&gt;</th>

</tbody>
</table>

Operation

The description of SUBS (immediate) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**CMP (shifted register)**

Compare (shifted register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (shifted register). This means:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

### 32-bit (sf == 0)

\[
\text{CMP} \ <Wn>, \ <Wm>\{, \ <shift> \ #<amount>\}
\]

is equivalent to

\[
\text{SUBS} \ WZR, \ <Wn>, \ <Wm> \{, \ <shift> \ #<amount>\}
\]

and is always the preferred disassembly.

### 64-bit (sf == 1)

\[
\text{CMP} \ <Xn>, \ <Xm>\{, \ <shift> \ #<amount>\}
\]

is equivalent to

\[
\text{SUBS} \ XZR, \ <Xn>, \ <Xm> \{, \ <shift> \ #<amount>\}
\]

and is always the preferred disassembly.

### Assembler Symbols

- `<Wn>`: Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>`: Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xn>`: Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>`: Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>`: Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- `<amount>`: For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

### Operation

The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
CMPP

Compare with Tag subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, updates the condition flags based on the result of the subtraction, and discards the result.

This is an alias of SUBPS. This means:

- The encodings in this description are named to match the encodings of SUBPS.
- The description of SUBPS gives the operational pseudocode for this instruction.

Integer
(Armv8.5)

\[
\begin{array}{cccccccccccccccccccc}
1 & 0 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 0 & \text{Xm} & 0 & 0 & 0 & 0 & 0 & \text{Xn} & 1 & 1 & 1 & 1 & 1 & 1 & \text{Xd}
\end{array}
\]

Assembler Symbols

- \text{CMPP} <Xn|SP>, <Xm|SP>
- \text{SUBPS} XZR, <Xn|SP>, <Xm|SP>

Is equivalent to

and is always the preferred disassembly.

Operation

The description of SUBPS gives the operational pseudocode for this instruction.
CNEG

Conditional Negate returns, in the destination register, the negated value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSNEG. This means:

- The encodings in this description are named to match the encodings of CSNEG.
- The description of CSNEG gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CNEG <Wd>, <Wn>, <cond>

is equivalent to

CSNEG <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

64-bit (sf == 1)

CNEG <Xd>, <Xn>, <cond>

is equivalent to

CSNEG <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSNEG gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CPP

Cache Prefetch Prediction Restriction by Context prevents cache allocation predictions, based on information gathered from earlier execution within a particular execution context, from allowing later speculative execution within that context to be observable through side-channels.

For more information, see CPP RCTX, Cache Prefetch Prediction Restriction by Context.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

System
(Armv8.5)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

System

CPP RCTX, \(<Xt>\)

is equivalent to

SYS #3, C8, C3, #7, \(<Xt>\)

and is always the preferred disassembly.

Assembler Symbols

\(<Xt>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.
**CRC32B, CRC32H, CRC32W, CRC32X**

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

In Armv8-A, this is an **OPTIONAL** instruction, and in Armv8.1 it is mandatory for all implementations to implement it. **ID_AA64ISAR0_EL1**. CRC32 indicates whether this instruction is supported.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

### CRC32X (sf == 1 && sz == 11)

CRC32X <Wd>, <Wn>, <Xm>

if !HaveCRCExt() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sf == '1' && sz != '11' then UNDEFINED;
if sf == '0' && sz == '11' then UNDEFINED;
integer size = 8 << UInt(sz);

**Assembler Symbols**

<Wd> Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.
<Wm> Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.

**Operation**

bits(32) acc = X[n];  // accumulator
bits(size) val = X[m];  // input value
bits(32) poly = 0x04C11DB7<31:0>;

bits(32+size) tempacc = BitReverse(acc):Zeros(size);
bits(size+32) tempval = BitReverse(val):Zeros(32);

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CRC32CB, CRC32CH, CRC32CW, CRC32CX

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x1EDC6F41 is used for the CRC calculation.

In Armv8-A, this is an **OPTIONAL** instruction, and in Armv8.1 it is mandatory for all implementations to implement it.  
**ID_AA64ISAR0_EL1**. CRC32 indicates whether this instruction is supported.

**CRC32CB** (sf == 0 & sz == 00)

CRC32CB <Wd>, <Wn>, <Wm>

**CRC32CH** (sf == 0 & sz == 01)

CRC32CH <Wd>, <Wn>, <Wm>

As the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.

As the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.

As the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.

As the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.

Operation

```
bits(32) acc = X[n];    // accumulator
bits(size) val = X[m];    // input value
bits(32) poly = 0x1EDC6F41<31:0>;

bits(32+size) tempacc = BitReverse(acc) | Zeros(size);
bits(size+32) tempval = BitReverse(val) | Zeros(32);

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Consumption of Speculative Data Barrier is a memory barrier that controls speculative execution and data value prediction. No instruction other than branch instructions appearing in program order after the CSDB can be speculatively executed using the results of any:

- Data value predictions of any instructions.
- PSTATE.{N,Z,C,V} predictions of any instructions other than conditional branch instructions appearing in program order before the CSDB that have not been architecturally resolved.
- Predictions of SVE predication state for any SVE instructions.

For purposes of the definition of CSDB, PSTATE.{N,Z,C,V} is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or PSTATE.{N,Z,C,V} predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

System

CSDB

// Empty.

Operation

ConsumptionOfSpeculativeDataBarrier();
CSEL

Conditional Select returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register.

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

if ConditionHolds(cond) then
    result = operand1;
else
    result = NOT(operand2);
result = result + 1;
X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
• The values of the NZCV flags.

The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
Data Cache operation. For more information, see \texttt{op0==0b01, cache maintenance, TLB maintenance, and address translation instructions}.

This is an alias of \texttt{SYS}. This means:

\begin{itemize}
  \item The encodings in this description are named to match the encodings of \texttt{SYS}.
  \item The description of \texttt{SYS} gives the operational pseudocode for this instruction.
\end{itemize}

\end{tabular}

\texttt{<op1>} Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

\texttt{<Cm>} Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

\texttt{<op2>} Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

\texttt{<Xt>} Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.
\end{verbatim}
Operation

The description of SYS gives the operational pseudocode for this instruction.
DCPS1

Debug Change PE State to EL1, when executed in Debug state:

- If executed at EL0 changes the current Exception level and SP to EL1 using SP_EL1.
- Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS1 instruction is:

- EL1 if the instruction is executed at EL0.
- Otherwise, the Exception level at which the instruction is executed.

When the target Exception level of a DCPS1 instruction is ELx, on executing this instruction:

- \( ELR_{ELx} \) becomes UNKNOWN.
- \( SPSR_{ELx} \) becomes UNKNOWN.
- \( ESR_{ELx} \) becomes UNKNOWN.
- \( DLR_{EL0} \) and \( DSPSR_{EL0} \) become UNKNOWN.
- The endianness is set according to \( SCTLR_{ELx} \) EE.

This instruction is UNDEFINED at EL0 in Non-secure state if EL2 is implemented and \( HCR_{EL2}.TGE == 1 \).

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see DCPS.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 0 1 0 1 0 0 1 0 1 imm16 0 0 0 0 1

System

DCPS1 {#<imm>}

if !Halted() then UNDEFINED;

Assembler Symbols

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

\textbf{DCPSInstruction}(LL);
DCPS2

Debug Change PE State to EL2, when executed in Debug state:
• If executed at EL0 or EL1 changes the current Exception level and SP to EL2 using SP_EL2.
• Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS2 instruction is:
• EL2 if the instruction is executed at an exception level that is not EL3.
• EL3 if the instruction is executed at EL3.

When the target Exception level of a DCPS2 instruction is ELx, on executing this instruction:
• \textit{ELR ELx} becomes \textit{UNKNOWN}.
• \textit{SPSR ELx} becomes \textit{UNKNOWN}.
• \textit{ESR ELx} becomes \textit{UNKNOWN}.
• \textit{DLR EL0} and \textit{DSPSR EL0} become \textit{UNKNOWN}.
• The endianness is set according to \textit{SCTLR ELx} EE.

This instruction is UNDEFINED at the following exception levels:
• All exception levels if EL2 is not implemented.
• At EL0 and EL1 if EL2 is disabled in the current Security state.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see \textit{DCPS}.

### System

DCPS2 \{#<imm>\}

\texttt{if !Halted() then UNDEFINED;}

### Assembler Symbols

\texttt{<imm>} \hspace{1em} Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the “imm16” field.

### Operation

\texttt{DCPSInstruction(LL);}

DCPS3

Debug Change PE State to EL3, when executed in Debug state:
- If executed at EL3 selects SP_EL3.
- Otherwise, changes the current Exception level and SP to EL3 using SP_EL3.

The target exception level of a DCPS3 instruction is EL3.

On executing a DCPS3 instruction:
- $ELR_{EL3}$ becomes UNKNOWN.
- $SPSR_{EL3}$ becomes UNKNOWN.
- $ESR_{EL3}$ becomes UNKNOWN.
- $DLR_{EL0}$ and $DSPSR_{EL0}$ become UNKNOWN.
- The endianness is set according to $SCTRL_{EL3}.EE$.

This instruction is UNDEFINED at all exception levels if either:
- $EDSCR.SDD == 1$.
- EL3 is not implemented.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see DCPS.

Operation

DCPSInstruction(LL);
DFB

Data Full Barrier is a memory barrier that ensures the completion of memory accesses. If executed at EL2, this instruction orders memory accesses irrespective of their Exception level or associated VMID. If executed at EL1 or EL0, this instruction behaves as DSB SY.

This is an alias of DSB. This means:

- The encodings in this description are named to match the encodings of DSB.
- The description of DSB gives the operational pseudocode for this instruction.

System
(v.)

```
1 1 0 1 0 1 0 1 0 0 0 0 1 1 0 0 1 1 1 1 0 0 1 0 0 1 1 1 1 1
```

This instruction is equivalent to

DSB #12

and is always the preferred disassembly.

Operation

The description of DSB gives the operational pseudocode for this instruction.
DGH

DGH is a hint instruction. A DGH instruction is not expected to be performance optimal to merge memory accesses with Normal Non-cacheable or Device-GRE attributes appearing in program order before the hint instruction with any memory accesses appearing after the hint instruction into a single memory transaction on an interconnect.

System
(Armv8.6)

```
31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0
1  1  0  1  0  1  0  0  0  0  1  1  0  0  1  0  0  0  0  0  1  1  0  1  1  1  1  1

Assembler Symbols

<option> Specifies the limitation on the barrier operation. Values are:

SY
Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = 0b1111.

ST
Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1110.

LD
Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1101.

ISH
Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b1011.

ISHST
Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1010.

ISHLD
Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1001.

NSH
Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = 0b0111.

NSHST
Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0110.

NSHLD
Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.
OSH
Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.

OSHST
Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.

OSHLD
Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of CRm, other than the values 0b0000 and 0b0100, that are not listed above are reserved, and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) or see Data Synchronization Barrier (DSB).
The value 0b0000 is used to encode SSBB and the value 0b0100 is used to encode PSSBB.

<imm>
Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the “CRm” field.

Operation

DataSynchronizationBarrier(domain, types);
DVP

Data Value Prediction Restriction by Context prevents data value predictions, based on information gathered from earlier execution within an particular execution context, from allowing later speculative execution within that context to be observable through side-channels.

For more information, see DVP RCTX, Data Value Prediction Restriction by Context.

This is an alias of SYS. This means:

integer shift_amount = UInt(imm6);

Assembler Symbols

- <Wd> is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xd> is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <shift> is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
operand2 = NOT(operand2);
result = operand1 EOR operand2;
X[d] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**EOR (immediate)**

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register.

![Register Layout](image)

**32-bit (sf == 0 && N == 0)**

EOR <Wd|WSP>, <Wn>, #<imm>

**64-bit (sf == 1)**

EOR <Xd|SP>, <Xn>, #<imm>

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;
if sf == '0' && N != '0' then UNDEFINED;
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

**Assembler Symbols**

- `<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<imm>` For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".
  For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = X[n];
result = operand1 EOR imm;
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
EOR (shifted register)

Bitwise Exclusive OR (shifted register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

```

Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
ERET

Exception Return using the ELR and SPSR for the current Exception level. When executed, the PE restores \textit{PSTATE} from the SPSR, and branches to the address held in the ELR. The PE checks the SPSR for the current Exception level for an illegal return event. See \textit{Illegal return events from AArch64 state}.

ERET is \textit{UNDEFINED} at EL0.

\begin{verbatim}
31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0
1  1  0  1  0  1  1  0  1  0  0  1  1  1  1  1  0  0  0  0  0  0  1  1  1  1  1  0  0  0  0  0
\end{verbatim}

ERET
if PSTATE.EL == \texttt{EL0} then UNDEFINED;
\end{verbatim}

Operation

\begin{verbatim}
\texttt{AArch64.CheckForERetTrap}(FALSE, TRUE);
\texttt{bits}(64) target = \texttt{ELR}[];
\texttt{AArch64.ExceptionReturn}(target, \texttt{SPSR}[]);
\end{verbatim}
ERETAA, ERETAB

Exception Return, with pointer authentication. This instruction authenticates the address in ELR, using SP as the modifier and the specified key, the PE restores PSTATE from the SPSR for the current Exception level, and branches to the authenticated address.

Key A is used for ERETAA, and key B is used for ERETAB.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.
The authenticated address is not written back to ELR.
The PE checks the SPSR for the current Exception level for an illegal return event. See Illegal return events from AArch64 state.
ERETAA and ERETAB are UNDEFINED at EL0.

ESB

Error Synchronization Barrier is an error synchronization event that might also update DISR_EL1 and VDISR_EL2. This instruction can be used at all Exception levels and in Debug state. In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. See Error Synchronization Barrier in the Arm(R) Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for Armv8-A architecture profile. If the RAS Extension is not implemented, this instruction executes as a NOP.

HINT

Hint instruction is for the instruction set space that is reserved for architectural hint instructions.
Some encodings described here are not allocated in this revision of the architecture, and behave as NOPs. These encodings might be allocated to other hint functionality in future revisions of the architecture and therefore must not be used by software.

System

HINT #<imm>

SystemHintOp op;

case CRm:op2 of
    when '0000 000' op = SystemHintOp_NOP;
    when '0000 001' op = SystemHintOp_YIELD;
    when '0000 010' op = SystemHintOp_WFE;

                SetBTypeCompatible(BTypeCompatible_BT(op2<2:1>));
            otherwise EndOfInstruction();

Assembler Symbols

<imm> Is a 7-bit unsigned immediate, in the range 0 to 127 encoded in the "CRm:op2" field.
The encodings that are allocated to architectural hint functionality are described in the "Hints" table in the "Index by Encoding".

For allocated encodings of "CRm:op2":

- A disassembler will disassemble the allocated instruction, rather than the HINT instruction.
- An assembler may support assembly of allocated encodings using HINT with the corresponding <imm> value, but it is not required to do so.

**Operation**

HVC

Hypervisor Call causes an exception to EL2. Non-secure software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is UNDEFINED:
- At EL0.
- At EL1 if EL2 is not enabled in the current Security state.
- When $SCR_EL3.HCE$ is set to 0.

On executing an HVC instruction, the PE records the exception as a Hypervisor Call exception in $ESR_ELx$, using the EC value 0x16, and the value of the immediate argument.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 0 1 0 1 0 0 0 1 0 1 0 | imm16 | 0 0 0 1 0
```

System

HVC #<imm>

// Empty.

Assembler Symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
if (!HaveEL(EL2) || PSTATE.EL == EL0 || (PSTATE.EL == EL1 && (!IsSecureEL2Enabled() && IsSecure()))) then UNDEFINED;

hvc_enable = if HaveEL(EL3) then SCR_EL3.HCE else NOT(HCR_EL2.HCD);
if hvc_enable == '0' then UNDEFINED;
else AArch64.CallHypervisor(imm16);
```
IC

Instruction Cache operation. For more information, see op0==0b01, cache maintenance, TLB maintenance, and address translation instructions.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

```

System

IC `<ic_op>{, <Xt>}`

is equivalent to

SYS #<op1>, C7, <Cm>, #<op2>{, <Xt>}

and is the preferred disassembly when SysOp(op1,'0111',CRm,op2) == Sys_IC.

Assembler Symbols

- `<ic_op>`: Is an IC instruction name, as listed for the IC system instruction pages, encoded in "op1:CRm:op2":
  - op1 CRm op2 `<ic_op>`:
    - 000 0001 000: IALLUIS
    - 000 0101 000: IALLU
    - 011 0101 001: IVAU

- `<op1>`: Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

- `<Cm>`: Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

- `<op2>`: Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

- `<Xt>`: Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.
Insert Random Tag inserts a random Logical Address Tag into the address in the first source register, and writes the result to the destination register. Any tags specified in the optional second source register or in GCR_EL1.Exclude are excluded from the selection of the random Logical Address Tag.

**Integer**

(Armv8.5)

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

```

**Assembler Symbols**

- `<Xd|SP>`: Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Xd" field.
- `<Xn|SP>`: Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Xn" field.
- `<Xm>`: Is the 64-bit name of the second general-purpose source register, encoded in the "Xm" field. Defaults to XZR if absent.

**Operation**

```
bits(64) operand = if n == 31 then SP[] else X[n];
bits(64) exclude_reg = X[m];
bits(16) exclude = exclude_reg<15:0> OR GCR_EL1.Exclude;
if AArch64.AllocationTagAccessIsEnabled() then
    if GCR_EL1.RRND == '1' then
        rtag = _ChooseRandomNonExcludedTag(exclude);
    else
        bits(4) start = RGSR_EL1.TAG;
        bits(4) offset = AArch64.RandomTag();
        rtag = AArch64.ChooseNonExcludedTag(start, offset, exclude);
    end
    RGSR_EL1.TAG = rtag;
else
    rtag = '0000';
bits(64) result = AArch64.AddressWithAllocationTag(operand, rtag);
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```
**ISB**

Instruction Synchronization Barrier flushes the pipeline in the PE and is a context synchronization event. For more information, see Instruction Synchronization Barrier (ISB).

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 0 1 0 0 1 0 0 0 0 1 1 0 0 1 1 1 1 1 1
```

**System**

ISB `{<option>|<imm>}`

// No additional decoding required

**Asmblnder Symbols**

`<option>` Specifies an optional limitation on the barrier operation. Values are:

- **SY**
  
  Full system barrier operation, encoded as CRm = 0b1111. Can be omitted.
  
  All other encodings of CRm are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

`<imm>` Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

**Operation**

`InstructionSynchronizationBarrier();`

Internal version only: isa v31.05b, AdvSIMD v29.02, pseudocode v2019-12_rc3_1, sve v2019-12_rc3; Build timestamp: 2019-12-13T15:23

LDADD, LDADDA, LDADDAL, LDADDL

Atomic add on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDADDA and LDADDAL load from memory with acquire semantics.
- LDADDL and LDADDAL store to memory with release semantics.
- LDADD has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Store-Release.* For information about memory accesses see *Load/Store addressing modes.*

This instruction is used by the alias STADD, STADDL.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDAPR

Load-Acquire RCpc Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from the derived address in memory, and writes it to a register.

The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release*, except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see *Load/Store addressing modes*.

### Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDAPRH

Load-Acquire RCpc Register Halfword derives an address from a base register value, loads a halfword from the derived address in memory, zero-extends it and writes it to a register.

The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release*, except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see *Load/Store addressing modes*.

bits(32) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 4, AccType_ORDERED];

X[t] = SignExtend(data, 64);
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDAR**

Load-Acquire Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about memory accesses, see Load/Store addressing modes.

For this instruction, if the destination is WZR/XZR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

32-bit (size == 10)

```assembly
LDAR <Wt>, [<Xn|SP>{,0}]
```

64-bit (size == 11)

```assembly
LDAR <Xt>, [<Xn|SP>{,0}]
```

integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
boolean tag_checked = n != 31;

**Assember Symbols**

- `<Wt>` is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xt>` is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Operation**

```assembly
bits(64) address;
bbs(elsize) data;
constant integer dbytes = elsize DIV 8;
if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];
data = Mem[address, dbytes, AccType_ORDERED];
X[t] = ZeroExtend(data, regsize);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDARB

Load-Acquire Register Byte derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about memory accesses, see Load/Store addressing modes.

For this instruction, if the destination is WZR/XZR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDAXP

Load-Acquire Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and is single-copy atomic for each doubleword at doubleword granularity. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

32-bit (sz == 0)

data = MemAtomic(address, MemAtomicOp_BIC, value, ldacctype, stacctype);

if t != 31 then
    X[t] = ZeroExtend(data, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDEOR, LDEORA, LDEORAL, LDEORL

Atomic exclusive OR on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, performs an exclusive OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDEORA and LDEORAL load from memory with acquire semantics.
- LDEORL and LDEORAL store to memory with release semantics.
- LDEOR has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*. For information about memory accesses see *Load/Store addressing modes*.

This instruction is used by the alias **STEOR, STEORL**.

For information about the constrained unpredictable behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDNP.

Assembler Symbols

- `<Wt1>` Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
- `<Wt2>` Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
- `<Xt1>` Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt2" field.
- `<Xt2>` Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<imm>` For the 32-bit variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as `<imm>/4`. For the 64-bit variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as `<imm>/8`.

Shared Decode

```java
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);
if opc<0> == '1' then UNDEFINED;
integer scale = 2 + UInt(opc<1>);
integer datasize = 8 << scale;
bzts(64) offset = LSL(SignExtend(imm7, 64), scale);
boolean tag_checked = n != 31;
```
Operation

bits(64) address;

```
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDR (immediate)

Load Register (immediate) loads a word or doubleword from memory and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see Load/Store addressing modes. The Unsigned offset variant scales the immediate offset value by the size of the value accessed before adding it to the base register value.

It has encodings from 3 classes: Post-index, Pre-index and Unsigned offset

Post-index

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

- \(<\text{Wt}>\) is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- \(<\text{Xt}>\) is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- \(<\text{Xn}|\text{SP}>\) is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- \(<\text{Wm}>\) when option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- \(<\text{Xm}>\) when option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- \(<\text{extend}>\) is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when \(<\text{amount}>\) is omitted, encoded in "opc":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

- \(<\text{amount}>\) for the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#2</td>
</tr>
</tbody>
</table>

- For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#3</td>
</tr>
</tbody>
</table>
Shared Decode

integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
integer regsize;

regsize = if size == '11' then 64 else 32;
integer datasize = 8 << scale;

Operation

bits(64) offset = ExtendReg(m, extend_type, shift);
if HaveMTEExt() then
    SetTagCheckedInstruction(TRUE);

bits(64) address;
bits(datasize) data;

if n == 31 then

    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, datasize DIV 8, AccType_NORMAL];
X[t] = ZeroExtend(data, regsize);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDRAA, LDRAB

Load Register, with pointer authentication. This instruction authenticates an address from a base register using a modifier of zero and the specified key, adds an immediate offset to the authenticated address, and loads a 64-bit doubleword from memory at this resulting address into a register.

Key A is used for LDRAA, and key B is used for LDRAB.

If the authentication passes, the PE behaves the same as for an LDR instruction. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the base register, unless the pre-indexed variant of the instruction is used. In this case, the address that is written back to the base register does not include the pointer authentication code.

For information about memory accesses, see Load/Store addressing modes.

**LDRSB (immediate)**

Load Register Signed Byte (immediate) loads a byte from memory, sign-extends it to either 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see *Load/Store addressing modes*.

It has encodings from 3 classes: **Post-index**, **Pre-index** and **Unsigned offset**.

**Post-index**

```
|   0   | 1   | 1   | 1   | 0   | 0   | 0   | 1   | x   | 0   | imm9 | 0   | 1   | Rn   | Rt   |
+-------+-----+-----+-----+-----+-----+-----+-----+-----+-----+------|-----|-----|------|------|
| size  | opc |     |     |     |     |     |     |     |     |      |     |     |      |      |
```

**32-bit (opc == 11)**

LDRSB <Wt>, [<Xn|SP>], #<simm>

**64-bit (opc == 10)**

LDRSB <Xt>, [<Xn|SP>], #<simm>

boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);

**Pre-index**

```
|   0   | 1   | 1   | 1   | 0   | 0   | 0   | 1   | x   | 0   | imm9 | 1   | 1   | Rn   | Rt   |
+-------+-----+-----+-----+-----+-----+-----+-----+-----+-----+------|-----|-----|------|------|
| size  | opc |     |     |     |     |     |     |     |     |      |     |     |      |      |
```

**32-bit (opc == 11)**

LDRSB <Wt>, [<Xn|SP>], #<simm>!

**64-bit (opc == 10)**

LDRSB <Xt>, [<Xn|SP>], #<simm>!

boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);

**Unsigned offset**

```
|   0   | 1   | 1   | 1   | 0   | 0   | 1   | 1   | x   | 0   | imm12 |     |     | Rn   | Rt   |
+-------+-----+-----+-----+-----+-----+-----+-----+-----+-----+--------|-----|-----|------|------|
| size  | opc |     |     |     |     |     |     |     |     |        |     |     |      |      |
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it, and writes it to a register. For information about memory accesses, see Load/Store addressing modes.

### 32-bit with extended register offset (opc == 11 && option != 011)

LDRSB `<Wt>`, `[<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]

### 32-bit with shifted register offset (opc == 11 && option == 011)

LDRSB `<Wt>`, `[<Xn|SP>, <Xm>{, LSL <amount>}]

### 64-bit with extended register offset (opc == 10 && option != 011)

LDRSB `<Xt>`, `[<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]

### 64-bit with shifted register offset (opc == 10 && option == 011)

LDRSB `<Xt>`, `[<Xn|SP>, <Xm>{, LSL <amount>}]

```asm
if option<1> == '0' then UNDEFINED;    // sub-word index
``` 

ExtendType extend_type = DecodeRegExtend(option);

### Assembler Symbols

- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<Wm>` When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<Xm>` When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<extend>` Is the index extend specifier, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

- `<amount>` Is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDRSW (immediate)

Load Register Signed Word (immediate) loads a word from memory, sign-extends it to 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index, Pre-index and Unsigned offset.

Post-index

```
1 0 1 1 0 0 0 1 0 0 | imm9 | 0 1 | Rn | Rt

size               opc
```

LDRSW <Xt>, [<Xn|SP>], #<simm>

boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);

Pre-index

```
1 0 1 1 0 0 0 1 0 0 | imm9 | 1 1 | Rn | Rt

size               opc
```

LDRSW <Xt>, [<Xn|SP>, #<simm>]

boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);

Unsigned offset

```
1 0 1 1 0 0 0 1 1 0 | imm12 | Rn | Rt

size               opc
```

LDRSW <Xt>, [<Xn|SP>{, #<pimm}>]

boolean wback = FALSE;
boolean postindex = FALSE;
bits(64) offset = LSL(ZeroExtend(imm12, 64), 2);

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRSW (immediate).

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
Is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4.

**Shared Decode**

```pseudocode
integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = wback || n != 31;
```

**Operation**

```pseudocode
if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

bits(64) address;
bits(32) data;

boolean wb_unknown = FALSE;

if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of

        SP[] = address;
    else
        X[n] = address;
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
Load Register Signed Word (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses, see Load/Store addressing modes.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 0  | 1  | 0  | 1  | 0  | 0  | imm19 | | R   |
| opc|

**Literal**

LDRSW `<Xt>`, `<label>`

```plaintext
integer t = UInt(Rt);
bits(64) offset;
offset = SignExtend(imm19:'00', 64);
```

**Assembler Symbols**

- `<Xt>`: Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
- `<label>`: Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

**Operation**

```plaintext
bits(64) address = PC[] + offset;
bits(32) data;
if HaveMTEExt() then
    SetTagCheckedInstruction(FALSE);
data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDRSW (register)

Load Register Signed Word (register) calculates an address from a base register value and an offset register value, loads a word from memory, sign-extends it to form a 64-bit value, and writes it to a register. The offset register value can be shifted left by 0 or 2 bits. For information about memory accesses, see Load/Store addressing modes.

</tbody>
</table>

64-bit

LDRSW <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]

if option<1> == '0' then UNDEFINED; // sub-word index

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#2</td>
</tr>
</tbody>
</table>

Shared Decode

integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
Operation

bits(64) offset = ExtendReg(m, extend_type, shift);
if HaveMTEExt() then
  SetTagCheckedInstruction(TRUE);

bits(64) address;
bits(32) data;

if n == 31 then
  CheckSPAlignment();
  address = SP[];
else
  address = X[n];
address = address + offset;

data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDSET, LDSETA, LDSETAL, LDSETL**

Atomic bit set on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDSETA and LDSETAL load from memory with acquire semantics.
- LDSETL and LDSETAL store to memory with release semantics.
- LDSET has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*. For information about memory accesses see *Load/Store addressing modes*.

This instruction is used by the alias **STSET, STSETL**.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDSMIN, LDSMINA, LDSMINAL, LDSMINL**

Atomic signed minimum on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDSMINA and LDSMINAL load from memory with acquire semantics.
- LDSMINL and LDSMINAL store to memory with release semantics.
- LDSMIN has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*. For information about memory accesses see *Load/Store addressing modes*.

This instruction is used by the alias **STSMIN, STSMINL**.

```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDTRSH

Load Register Signed Halfword (unprivileged) loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes.

\textbf{Operational information}

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDTRSW

Load Register Signed Word (unprivileged) loads a word from memory, sign-extends it to 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.<E2H, TGE> is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes.

Unscaled offset

LDTRSW <Xt>, [<Xn|SP>{, #<simm>}

bits(64) offset = SignExtend(imm9, 64);

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && (!EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11');
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '11';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
    acctype = AccType_UNPRIV;
else
    acctype = AccType_NORMAL;

boolean tag_checked = n != 31;

Operation

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

bits(64) address;
bits(32) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 4, acctype];
X[t] = SignExtend(data, 64);
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL**

Atomic unsigned maximum on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDUMAXA and LDUMAXAL load from memory with acquire semantics.
- LDUMAXL and LDUMAXAL store to memory with release semantics.
- LDUMAX has no memory ordering requirements.

For more information about memory ordering semantics see [Load-Acquire, Store-Release](#).
For information about memory accesses see [Load/Store addressing modes](#).

This instruction is used by the alias **STUMAX, STUMAXL**.

if t != 31 then
  X[t] = ZeroExtend(data, regsize);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB**

Atomic unsigned minimum on byte in memory atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, **LDUMINAB** and **LDUMINALB** load from memory with acquire semantics.
- **LDUMINLB** and **LDUMINALB** store to memory with release semantics.
- **LDUMINB** has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*. For information about memory accesses see *Load/Store addressing modes*.

This instruction is used by the alias **STUMINB, STUMINLB**.

LDXP

Load Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit
doublewords from memory, and writes them to two registers. A 32-bit pair requires the address to be doubleword
aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned
and is single-copy atomic for each doubleword at doubleword granularity. The PE marks the physical address being
accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See
Synchronization and semaphores. For information about memory accesses see Load/Store addressing modes.

32-bit (sz == 0)

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDXRB

Load Exclusive Register Byte derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*. For information about memory accesses see *Load/Store addressing modes*.

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |

```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LSL (register)**

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This is an alias of **LSLV**. This means:

- The encodings in this description are named to match the encodings of **LSLV**.
- The description of **LSLV** gives the operational pseudocode for this instruction.

| sf | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|    | 0  | 0  | 1  | 1  | 0  | 1  | 0  | 1  | 0  | 1  | 0  | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

**32-bit (sf == 0)**

```
LSL <Wd>, <Wn>, <Wm>
```

is equivalent to

```
LSLV <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

**64-bit (sf == 1)**

```
LSL <Xd>, <Xn>, <Xm>
```

is equivalent to

```
LSLV <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wd>` is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

**Operation**

The description of **LSLV** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
LSL (immediate)

Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| sf  | 1  | 0  | 1  | 0  | 1  | 0  | 1  | 0  | N  | immr | != | x11111 | Rn   | Rd   |

**32-bit (sf == 0 && N == 0 && imms != 011111)**

LSL `<Wd>, <Wn>, #<shift>`

is equivalent to

UBFM `<Wd>, <Wn>, #(-<shift> MOD 32), #(31-<shift>)`

and is the preferred disassembly when `imms + 1 == immr`.

**64-bit (sf == 1 && N == 1 && imms != 111111)**

LSL `<Xd>, <Xn>, #<shift>`

is equivalent to

UBFM `<Xd>, <Xn>, #(-<shift> MOD 64), #(63-<shift>)`

and is the preferred disassembly when `imms + 1 == immr`.

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<shift>` For the 32-bit variant: is the shift amount, in the range 0 to 31.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63.

**Operation**

The description of UBFM gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Logical Shift Left Variable shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This instruction is used by the alias LSL (register).

32-bit (sf == 0)

```
LSLV <Wd>, <Wn>, <Wm>
```

64-bit (sf == 1)

```
LSLV <Xd>, <Xn>, <Xm>
```

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

Assembler Symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

```plaintext
bits(datasize) result;
bits(datasize) operand2 = X[m];
result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
LSR (register)

Logical Shift Right (register) shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This is an alias of LSRV. This means:

- The encodings in this description are named to match the encodings of LSRV.
- The description of LSRV gives the operational pseudocode for this instruction.

32-bit (sf == 0)

LSR <Wd>, <Wn>, <Wm>

is equivalent to

LSRV <Wd>, <Wn>, <Wm>

and is always the preferred disassembly.

64-bit (sf == 1)

LSR <Xd>, <Xn>, <Xm>

is equivalent to

LSRV <Xd>, <Xn>, <Xm>

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of LSRV gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Logical Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

MNEG

Multiply-Negate multiplies two register values, negates the product, and writes the result to the destination register.

This is an alias of MSUB. This means:

- The encodings in this description are named to match the encodings of MSUB.
- The description of MSUB gives the operational pseudocode for this instruction.

### 32-bit (sf == 0)

MNEG <Wd>, <Wn>, <Wm>

is equivalent to

MSUB <Wd>, <Wn>, <Wm>, WZR

and is always the preferred disassembly.

### 64-bit (sf == 1)

MNEG <Xd>, <Xn>, <Xm>

is equivalent to

MSUB <Xd>, <Xn>, <Xm>, XZR

and is always the preferred disassembly.

### Assembler Symbols

- **<Wd>** Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Wn>** Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- **<Wm>** Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- **<Xd>** Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Xn>** Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- **<Xm>** Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

### Operation

The description of MSUB gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**MOV (to/from SP)**

Move between register and stack pointer: Rd = Rn.

This is an alias of **ADD (immediate)**. This means:

- The encodings in this description are named to match the encodings of **ADD (immediate)**.
- The description of **ADD (immediate)** gives the operational pseudocode for this instruction.

32-bit (sf == 0)

MOV <Wd|WSP>, <Wn|WSP>

is equivalent to

ADD <Wd|WSP>, <Wn|WSP>, #0

and is the preferred disassembly when (Rd == '11111' || Rn == '11111').

64-bit (sf == 1)

MOV <Xd|SP>, <Xn|SP>

is equivalent to

ADD <Xd|SP>, <Xn|SP>, #0

and is the preferred disassembly when (Rd == '11111' || Rn == '11111').

**Assembler Symbols**

- `<Wd|WSP>` is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Wn|WSP>` is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Xd|SP>` is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xn|SP>` is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

**Operation**

The description of **ADD (immediate)** gives the operational pseudocode for this instruction.
MOV (inverted wide immediate)

Move (inverted wide immediate) moves an inverted 16-bit immediate value to a register.

This is an alias of MOVN. This means:

- The encodings in this description are named to match the encodings of MOVN.
- The description of MOVN gives the operational pseudocode for this instruction.

```
   sf   0  0  1  0  0  1  0  1  hw   imm16   Rd
  opc
```

32-bit (sf == 0 & hw == 0x)

MOV <Wd>, #<imm>

is equivalent to

MOVN <Wd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when ! (IsZero(imm16) && hw != '00') && ! IsOnes(imm16).

64-bit (sf == 1)

MOV <Xd>, #<imm>

is equivalent to

MOVN <Xd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when ! (IsZero(imm16) && hw != '00').

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <imm> For the 32-bit variant: is a 32-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw", but excluding 0xffff0000 and 0x0000ffff
  For the 64-bit variant: is a 64-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw".
- <shift> For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.
  For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

The description of MOVN gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (wide immediate)

Move (wide immediate) moves a 16-bit immediate value to a register.

This is an alias of MOVZ. This means:

- The encodings in this description are named to match the encodings of MOVZ.
- The description of MOVZ gives the operational pseudocode for this instruction.

32-bit (sf == 0 && hw == 0x)

MOV <Wd>, #<imm>

is equivalent to

MOVZ <Wd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when ! (IsZero(imm16) && hw != '00').

64-bit (sf == 1)

MOV <Xd>, #<imm>

is equivalent to

MOVZ <Xd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when ! (IsZero(imm16) && hw != '00').

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<imm> For the 32-bit variant: is a 32-bit immediate which can be encoded in "imm16:hw".

For the 64-bit variant: is a 64-bit immediate which can be encoded in "imm16:hw".

<shift> For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.

For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

The description of MOVZ gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (bitmask immediate)

Move (bitmask immediate) writes a bitmask immediate value to a register.

This is an alias of ORR (immediate). This means:

- The encodings in this description are named to match the encodings of ORR (immediate).
- The description of ORR (immediate) gives the operational pseudocode for this instruction.

32-bit (sf == 0 & N == 0)

MOV <Wd|WSP>, #<imm>

is equivalent to

ORR <Wd|WSP>, WZR, #<imm>

and is the preferred disassembly when !MoveWidePreferred(sf, N, imms, immr).

64-bit (sf == 1)

MOV <Xd|SP>, #<imm>

is equivalent to

ORR <Xd|SP>, XZR, #<imm>

and is the preferred disassembly when !MoveWidePreferred(sf, N, imms, immr).

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<imm> For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

Operation

The description of ORR (immediate) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (register)

Move (register) copies the value in a source register to the destination register.

This is an alias of **ORR (shifted register)**. This means:

- The encodings in this description are named to match the encodings of **ORR (shifted register)**.
- The description of **ORR (shifted register)** gives the operational pseudocode for this instruction.

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|------------------------|------------------------|------------------------|------------------------|
| sf | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | Rm | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | Rd |
| opc | shift | N | imm6 | Rn |

**32-bit (sf == 0)**

MOV <Wd>, <Wm>

is equivalent to

ORR <Wd>, WZR, <Wm>

and is always the preferred disassembly.

**64-bit (sf == 1)**

MOV <Xd>, < Xm>

is equivalent to

ORR <Xd>, XZR, <Xm>

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

**Operation**

The description of **ORR (shifted register)** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOVK

Move wide with keep moves an optionally-shifted 16-bit immediate value into a register, keeping other bits unchanged.

\[
\begin{array}{ccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccc
**MOVN**

Move wide with NOT moves the inverse of an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (inverted wide immediate).

<table>
<thead>
<tr>
<th>sf</th>
<th>0 0 1 0 0 1 0 1</th>
<th>hw</th>
<th>imm16</th>
<th>Rd</th>
</tr>

#### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MRS

Move System Register allows the PE to read an AArch64 System register into a general-purpose register.

```
1 1 0 1 0 1 0 0 1 1 | 1 | op0 | op1 | CRn | CRm | op2 | Rt
L
```

System

MRS <Xt>, (<systemreg>|<op0>|<op1>|<Cn>|<Cm>|<op2>)

```
AArch64.CheckSystemAccess('1':o0, op1, CRn, CRm, op2, Rt, L);
```

integer t = UInt(Rt);

integer sys_op0 = 2 + UInt(o0);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.

<systemreg> Is a System register name, encoded in the "o0:op1:CRn:CRm:op2".
The System register names are defined in 'AArch64 System Registers' in the System Register XML.

<op0> Is an unsigned immediate, encoded in "o0":

<table>
<thead>
<tr>
<th>o0</th>
<th>&lt;op0&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

Operation

```
X[t] = AArch64.SysRegRead(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2);
```

MSR (immediate)

Move immediate value to Special Register moves an immediate value to selected bits of the PSTATE. For more information, see Process state, PSTATE.

The bits that can be written by this instruction are:

- PSTATE.D, PSTATE.A, PSTATE.I, PSTATE.F, and PSTATE.SP.
- If ARMv8.0-SSBS is implemented, PSTATE.SSBS.
- If ARMv8.1-PAN is implemented, PSTATE.PAN.
- If ARMv8.2-UAO is implemented, PSTATE-UAO.
- If ARMv8.4-DIT is implemented, PSTATE.DIT.
- If ARMv8.5-MemTag is implemented, PSTATE.TCO.

MSR (register)

Move general-purpose register to System Register allows the PE to write an AArch64 System register from a general-purpose register.

```
  31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
  ___________ ___________ ___________ ___________ ___________ ___________ ___________
  | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 | 0 | op1 | CRn | CRm | op2 | Rt |
  | L |
```

System

MSR (<systemreg>|<op0>|<op1>|<Cn>|<Cm>|<op2>), <Xt>

\[\text{AArch64.CheckSystemAccess('1':o0, op1, CRn, CRm, op2, Rt, L);}\]

```
  integer t = UInt(Rt);

  integer sys_op0 = 2 + UInt(o0);
  integer sys_op1 = UInt(op1);
  integer sys_op2 = UInt(op2);
  integer sys_crn = UInt(CRn);
  integer sys_crm = UInt(CRm);
```

Assembler Symbols

<systemreg> Is a System register name, encoded in the "o0:op1:CRn:CRm:op2".

The System register names are defined in 'AArch64 System Registers' in the System Register XML.

<op0> Is an unsigned immediate, encoded in "o0":

```
  o0  <op0>
    0  2
    1  3
```

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

\[\text{AArch64.SysRegWrite(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, Xt[t]);}\]
MSUB

Multiply-Subtract multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register.

This instruction is used by the alias MNEG.

<table>
<thead>
<tr>

Operation

bits(destsize) operand1 = X[n];
bits(destsize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;
result = UInt(operand3) - (UInt(operand1) * UInt(operand2));
X[d] = result<destsize-1:0>;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MUL

Multiply: \( Rd = Rn \times Rm \).

This is an alias of MADD. This means:

- The encodings in this description are named to match the encodings of MADD.
- The description of MADD gives the operational pseudocode for this instruction.

<table>

32-bit (sf == 0)

MUL \(<Wd>, <Wn>, <Wm>\)

is equivalent to

MADD \(<Wd>, <Wn>, <Wm>, WZR\)

and is always the preferred disassembly.

64-bit (sf == 1)

MUL \(<Xd>, <Xn>, <Xm>\)

is equivalent to

MADD \(<Xd>, <Xn>, <Xm>, XZR\)

and is always the preferred disassembly.

Assembler Symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of MADD gives the operational pseudocode for this instruction.
MVN

Bitwise NOT writes the bitwise inverse of a register value to the destination register.

This is an alias of ORN (shifted register). This means:

- The encodings in this description are named to match the encodings of ORN (shifted register).
- The description of ORN (shifted register) gives the operational pseudocode for this instruction.

32-bit (sf == 0)

MVN <Wd>, <Wm>{, <shift> #<amount>}

is equivalent to

ORN <Wd>, WZR, <Wm>{, <shift> #<amount>}

and is always the preferred disassembly.

64-bit (sf == 1)

MVN <Xd>, <Xm>{, <shift> #<amount>}

is equivalent to

ORN <Xd>, XZR, <Xm>{, <shift> #<amount>}

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.
<Wm> Is the 32-bit name of the general-purpose source register, encoded in the “Rm” field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.
<Xm> Is the 64-bit name of the general-purpose source register, encoded in the “Rm” field.
<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

Operation

The description of ORN (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
- The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
NEG (shifted register)

Negate (shifted register) negates an optionally-shifted register value, and writes the result to the destination register.

This is an alias of SUB (shifted register). This means:

- The encodings in this description are named to match the encodings of SUB (shifted register).
- The description of SUB (shifted register) gives the operational pseudocode for this instruction.

32-bit (sf == 0)

NEG \(<Wd>, <Wm>{, <shift> #<amount>}\)

is equivalent to

SUB \(<Wd>, WZR, <Wm>{, <shift> #<amount>}\)

and is always the preferred disassembly.

64-bit (sf == 1)

NEG \(<Xd>, <Xm>{, <shift> #<amount>}\)

is equivalent to

SUB \(<Xd>, XZR, <Xm>{, <shift> #<amount>}\)

and is always the preferred disassembly.

Assembler Symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.
- \(<Wm>\) Is the 32-bit name of the general-purpose source register, encoded in the “Rm” field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.
- \(<Xm>\) Is the 64-bit name of the general-purpose source register, encoded in the “Rm” field.
- \(<shift>\) Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- \(<amount>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

Operation

The description of SUB (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
○ The values of the data supplied in any of its registers.
○ The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  ○ The values of the data supplied in any of its registers.
  ○ The values of the NZCV flags.
NEGS

Negate, setting flags, negates an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This is an alias of SUBS (shifted register). This means:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

### 32-bit (sf == 0)

NEGS <Wd>, <Wm>{, <shift> #<amount>}

is equivalent to

SUBS <Wd>, WZR, <Wm> {, <shift> #<amount>}

and is always the preferred disassembly.

### 64-bit (sf == 1)

NEGS <Xd>, <Xm>{, <shift> #<amount>}

is equivalent to

SUBS <Xd>, XZR, <Xm> {, <shift> #<amount>}

and is always the preferred disassembly.

#### Assembler Symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xm> Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SBCS gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
NOP

No Operation does nothing, other than advance the value of the program counter by 4. This instruction can be used for instruction alignment purposes.

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

System

// Empty.

Operation

// do nothing

Operational information

If PSTATE.DIT is 1:
  • The execution time of this instruction is independent of:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
  • The response of this instruction to asynchronous exceptions does not vary based on:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
ORN (shifted register)

Bitwise OR NOT (shifted register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias **MVN**.

32-bit (sf == 0)

ORN <Wd>, <Wn>, <Wm> {, <shift> #<amount>}

64-bit (sf == 1)

ORN <Xd>, <Xn>, <Xm> {, <shift> #<amount>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>

bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
result = operand1 OR operand2;
X[d] = result;

Operational information

If PSTATE.DIT is 1:
  • The execution time of this instruction is independent of:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
  • The response of this instruction to asynchronous exceptions does not vary based on:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
PACDA, PACDZA

Pointer Authentication Code for Data address, using key A. This instruction computes and inserts a pointer authentication code for a data address, using a modifier and key A. The address is in the general-purpose register that is specified by <Xd>.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDA.
- The value zero, for PACDZA.

Integer
(Armv8.3)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

if source_is_sp then
    X[d] = AddPACDA(X[d], SP[1]);
else
    X[d] = AddPACDA(X[d], X[n]);
**PACDB, PACDZB**

Pointer Authentication Code for Data address, using key B. This instruction computes and inserts a pointer authentication code for a data address, using a modifier and key B.

The address is in the general-purpose register that is specified by <Xd>.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDB.
- The value zero, for PACDZB.

**Integer**  
(Armv8.3)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

    if n == 31 then source_is_sp = TRUE;
else // PACDZB
    if n != 31 then UNDEFINED;

**Assembler Symbols**

<Xd>  
Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP>  
Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

**Operation**

if source_is_sp then
    X[d] = AddPACDB(X[d], SP[]);
else
    X[d] = AddPACDB(X[d], X[n]);
PACGA

Pointer Authentication Code, using Generic key. This instruction computes the pointer authentication code for an address in the first source register, using a modifier in the second source register, and the Generic key. The computed pointer authentication code is returned in the upper 32 bits of the destination register.

Integer
(ARMv8.3)

\[
\begin{array}{cccccccccccccccccccc}
\hline
1 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 0 & R_m & 0 & 0 & 1 & 1 & 0 & 0 & R_n & R_d
\end{array}
\]

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm|SP> Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Rm" field.

Operation

if source_is_sp then
    X[d] = AddPACGA(X[n], SP());
else
    X[d] = AddPACGA(X[n], X[m]);
PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA

Pointer Authentication Code for Instruction address, using key A. This instruction computes and inserts a pointer authentication code for an instruction address, using a modifier and key A.

The address is:
- In the general-purpose register that is specified by \texttt{<Xd>} for PACIA and PACIZA.
- In X17, for PACIA1716.
- In X30, for PACIASP and PACIAZ.

The modifier is:
- In the general-purpose register or stack pointer that is specified by \texttt{<Xn|SP>} for PACIA.
- The value zero, for PACIZA and PACIAZ.
- In X16, for PACIA1716.
- In SP, for PACIASP.

It has encodings from 2 classes: \texttt{Integer} and \texttt{System}

PRFM (immediate)

Prefetch Memory (immediate) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory.
For information about memory accesses, see Load/Store addressing modes.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

| 1 | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | imm12 | Rn | Rt |

Unsigned offset

PRFM (<prfop>|#<imm5>), {<Xn|SP>{, #<pimm>}}

bits(64) offset = LSL(ZeroExtend(imm12, 64), 3);

Assembler Symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.
<type> is one of:
PLD Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
PLI Preload instructions, encoded in the "Rt<4:3>" field as 0b01.
PST Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.
<target> is one of:
L1 Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
L2 Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
L3 Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.
<policy> is one of:
KEEP Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
STRM Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory.
For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field.
This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<pimm> Is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

Shared Decode

integer n = UInt(Rn);
integer t = UInt(Rt);
if HaveMTEExt() then
  SetTagCheckedInstruction(FALSE);

bits(64) address;
if n == 31 then
  address = SP[ ];
else
  address = X[n];

address = address + offset;
Prefetch(address, t<4:0>);
Prefetch Memory (literal) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory.

For information about memory accesses, see Load/Store addressing modes.

   1 1 1 1 1 0 0 0 1 0 1  Rm  option  S 1 0  Rn  Rt
```

Integer

```prfm (<prfop>|#<imm5>), [<Xn|SP>, (<Wm>|<Xm}){, <extend> {<amount>}}]

if option<1> == '0' then UNDEFINED;    // sub-word index
ExtendType extend type = DecodeRegExtend(option);
integer shift = if S == '1' then 3 else 0;
```

Assembler Symbols

- `<prfop>` Is the prefetch operation, defined as `<type><target><policy>`. `<type>` is one of:
  - **PLD** Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
  - **PLI** Preload instructions, encoded in the "Rt<4:3>" field as 0b01.
  - **PST** Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.

- `<target>` is one of:
  - **L1** Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
  - **L2** Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
  - **L3** Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

- `<policy>` is one of:
  - **KEEP** Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
  - **STRM** Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory. For other encodings of the "Rt" field, use `<imm5>`.

- `<imm5>` Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using `<prfop>`.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<Wm>` When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<Xm>` When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#3</td>
</tr>
</tbody>
</table>

Shared Decode

Prefetch Memory (unscaled offset) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFUM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory. For information about memory accesses, see Load/Store addressing modes.

### Assembler Symbols

- `<prfop>` is the prefetch operation, defined as `<type><target><policy>`. `<type>` is one of:
  - `PLD`: Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
  - `PLI`: Preload instructions, encoded in the "Rt<4:3>" field as 0b01.
  - `PST`: Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.
- `<target>` is one of:
  - `L1`: Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
  - `L2`: Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
  - `L3`: Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.
- `<policy>` is one of:
  - `KEEP`: Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
  - `STRM`: Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory. For other encodings of the "Rt" field, use `<imm5>`.

- `<imm5>` is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using `<prfop>`.

- `<Xn|SP>` is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

- `<simm>` is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

### Shared Decode

```plaintext
integer n = UInt(Rn);

Profiling Synchronization Barrier. This instruction is a barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. A following DSB instruction completes when the writes to the profiling buffer have completed.

If the Statistical Profiling Extension is not implemented, this instruction executes as a NOP.

System

```
Physical Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same physical address.

The semantics of the Physical Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the PSSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the PSSBB.

- When a load to a location appears in program order before the PSSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order after the PSSBB.

```

32-bit (sf == 0)

RBIT <Wd>, <Wn>

64-bit (sf == 1)

RBIT <Xd>, <Xn>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

bits(datasize) operand = X[n];
bits(datasize) result;
for i = 0 to datasize-1
  result<datasize-1-i> = operand<i>;
X[d] = result;

Operational information

If PSTATE.DIT is 1:
  • The execution time of this instruction is independent of:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
  • The response of this instruction to asynchronous exceptions does not vary based on:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
RET

Return from subroutine branches unconditionally to an address in a register, with a hint that this is a subroutine return.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Integer

RET \{<Xn>\}

integer n = UInt(Rn);

Assembler Symbols

\(<Xn>\) Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field. Defaults to X30 if absent.

Operation

\[
\text{bits(64)} \ target = X[n];
\]

\text{BranchTo}(target, \text{BranchType\_RET});

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**RETAA, RETAB**

Return from subroutine, with pointer authentication. This instruction authenticates the address that is held in LR, using SP as the modifier and the specified key, branches to the authenticated address, with a hint that this instruction is a subroutine return.

Key A is used for RETAA, and key B is used for RETAB.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to LR.

**Integer**

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
REV64

Reverse Bytes reverses the byte order in a 64-bit general-purpose register. When assembling for Armv8.2, an assembler must support this pseudo-instruction. It is **optional** whether an assembler supports this pseudo-instruction when assembling for an architecture earlier than Armv8.2.

This is a pseudo-instruction of **REV**. This means:

- The encodings in this description are named to match the encodings of **REV**.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of **REV** gives the operational pseudocode for this instruction.

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1  | 0  | 1  | 0  | 1  | 0  | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 1  | Rn |   | Rd |   | sf |   | opc |
```

64-bit

**REV64**  

**<Xd>, <Xn>**

is equivalent to

**REV**  

**<Xd>, <Xn>**

**Assembler Symbols**

- **<Xd>** Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Xn>** Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

**Operation**

The description of **REV** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
RMIF

Performs a rotation right of a value held in a general purpose register by an immediate value, and then inserts a selection of the bottom four bits of the result of the rotation into the PSTATE flags, under the control of a second immediate mask.

Integer
(Armv8.4)

</tbody>
</table>

RMIF <Xn>, #<shift>, #<mask>

if !HaveFlagManipulateExt() then UNDEFINED;
integer lsb = UInt(imm6);
integer n = UInt(Rn);  

Assembler Symbols

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<shift> Is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
<mask> Is the flag bit mask, an immediate in the range 0 to 15, which selects the bits that are inserted into the NZCV condition flags, encoded in the "mask" field.

Operation

bits(4) tmp;
bits(64) tmpreg = X[n];
tmp = (tmpreg:tmpreg)<lsb+3:lsb>;
if mask<3> == '1' then PSTATE.N = tmp<3>;
if mask<2> == '1' then PSTATE.Z = tmp<2>;
if mask<1> == '1' then PSTATE.C = tmp<1>;
if mask<0> == '1' then PSTATE.V = tmp<0>;

Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
ROR (immediate)

Rotate right (immediate) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This is an alias of EXTR. This means:

- The encodings in this description are named to match the encodings of EXTR.
- The description of EXTR gives the operational pseudocode for this instruction.

<table>
<thead>
<tr>
<th>sf</th>
<th>0</th>

<th>0</th>
<th>1</th>
<th>1</th>
<th>1</th>
<th>N</th>
<th>0</th>
<th>Rm</th>
<th>imms</th>
<th>Rn</th>
<th>Rd</th>
</tr>
</thead>
</table>

### 32-bit (sf == 0 && N == 0 && imms == 0xxxxx)

ROR <Wd>, <Ws>, #<shift>

is equivalent to

EXTR <Wd>, <Ws>, <Ws>, #<shift>

and is the preferred disassembly when Rn == Rm.

### 64-bit (sf == 1 && N == 1)

ROR <Xd>, <Xs>, #<shift>

is equivalent to

EXTR <Xd>, <Xs>, <Xs>, #<shift>

and is the preferred disassembly when Rn == Rm.

### Assembler Symbols

- `<Wd>` is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Ws>` is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xs>` is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- `<shift>` For the 32-bit variant: is the amount by which to rotate, in the range 0 to 31, encoded in the "imms" field.
  - For the 64-bit variant: is the amount by which to rotate, in the range 0 to 63, encoded in the "imms" field.

### Operation

The description of EXTR gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This is an alias of RORV. This means:

- The encodings in this description are named to match the encodings of RORV.
- The description of RORV gives the operational pseudocode for this instruction.

op2

ROR <Xd>, <Xn>, <Xm>

is equivalent to

RORV <Xd>, <Xn>, <Xm>

and is always the preferred disassembly.

### Assembler Symbols

- `<Wd>` is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

### Operation

The description of RORV gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
RORV

Rotate Right Variable provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ROR (register).

| sf | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 1 | 1 | Rm | 0 | 0 | 1 | 0 | 1 | 1 | Rn | Rd |
|----|---|---|---|---|---|---|---|---|---|----|---|---|---|---|---|---|---|---|---|
| op2 |

32-bit (sf == 0)

RORV <Wd>, <Wn>, <Wm>

64-bit (sf == 1)

RORV <Xd>, <Xn>, <Xm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

bits(datasize) result;
bits(datasize) operand2 = X[m];
result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Speculation Barrier is a barrier that controls speculation. The semantics of the Speculation Barrier are that the execution, until the barrier completes, of any instruction that appears later in the program order than the barrier:

- Cannot be performed speculatively to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception.

In particular, any instruction that appears later in the program order than the barrier cannot cause a speculative allocation into any caching structure where the allocation of that entry could be indicative of any data value present in memory or in the registers.

The SB instruction:

- Cannot be speculatively executed as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception. The potentially exception generating instruction can complete once it is known not to be speculative, and all data values generated by instructions appearing in program order before the SB instruction have their predicted values confirmed.

When the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after an uncompleted SB instruction, the SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched.

System

SB

if !HaveSBExt() then UNDEFINED;

Operation

SpeculationBarrier();
SBC

Subtract with Carry subtracts a register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

This instruction is used by the alias **NGC**.

  ◦ The values of the NZCV flags.
SBFIZ

Signed Bitfield Insert in Zeros copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, setting the destination bits below the bitfield to zero, and the bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 & N == 0)

```
SBFIZ <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when UInt(imms) < UInt(immr).

64-bit (sf == 1 & N == 1)

```
SBFIZ <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when UInt(imms) < UInt(immr).

Assembler Symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SBFM

Signed Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly. If \(<\text{imms}>\) is greater than or equal to \(<\text{immr}>\), this copies a bitfield of \((<\text{imms}>-<\text{immr}>+1)\) bits starting from bit position \(<\text{immr}>\) in the source register to the least significant bits of the destination register. If \(<\text{imms}>\) is less than \(<\text{immr}>\), this copies a bitfield of \((<\text{imms}>+1)\) bits from the least significant bits of the source register to bit position \((\text{regsize}-<\text{immr}>)\) of the destination register, where \(\text{regsize}\) is the destination register size of 32 or 64 bits.

In both cases the destination bits below the bitfield are set to zero, and the bits above the bitfield are set to a copy of the most significant bit of the bitfield.

This instruction is used by the aliases \texttt{ASR (immediate)}, \texttt{SBFIZ}, \texttt{SBFX}, \texttt{SXTB}, \texttt{SXTH}, and \texttt{SXTW}.

SBFX

Signed Bitfield Extract copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 && N == 0)

SBFX <Wd>, <Wn>, #<lsb>, #<width>

is equivalent to

SBFM <Wd>, <Wn>, #<lsb>, #{<lsb>+<width>-1}

and is the preferred disassembly when BFXPreferred(sf, opc<1>, imms, immr).

64-bit (sf == 1 && N == 1)

SBFX <Xd>, <Xn>, #<lsb>, #<width>

is equivalent to

SBFM <Xd>, <Xn>, #<lsb>, #{<lsb>+<width>-1}

and is the preferred disassembly when BFXPreferred(sf, opc<1>, imms, immr).

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<lsb> For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.

<width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SDIV

Signed Divide divides a signed integer register value by another signed integer register value, and writes the result to the destination register. The condition flags are not affected.

32-bit (sf == 0)

SDIV <Wd>, <Wn>, <Wm>

64-bit (sf == 1)

SDIV <Xd>, <Xn>, < Xm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

SMC

Secure Monitor Call causes an exception to EL3.
SMC is available only for software executing at EL1 or higher. It is UNDEFINED in EL0.
If the values of HCR_EL2.TSC and SCR_EL3.SMD are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception, recording it in ESR_ELx, using the EC value 0x17, that is taken to EL3.
If the value of HCR_EL2.TSC is 1 and EL2 is enabled in the current Security state, execution of an SMC instruction at EL1 generates an exception that is taken to EL2, regardless of the value of SCR_EL3.SMD. For more information, see Traps to EL2 of Non-secure EL1 execution of SMC instructions.
If the value of HCR_EL2.TSC is 0 and the value of SCR_EL3.SMD is 1, the SMC instruction is UNDEFINED.

SMNEGL

Signed Multiply-Negate Long multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This is an alias of SMSUBL. This means:

- The encodings in this description are named to match the encodings of SMSUBL.
- The description of SMSUBL gives the operational pseudocode for this instruction.

### 64-bit

**SMNEGL** `<Xd>, <Wn>, <Wm>`

is equivalent to

**SMSUBL** `<Xd>, <Wn>, <Wm>, XZR`

and is always the preferred disassembly.

**Assembler Symbols**

- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

**Operation**

The description of SMSUBL gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SMSUBL

Signed Multiply-Subtract Long multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMNEGL.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

64-bit

SMULL <Xd>, <Wn>, <Wm>

is equivalent to

SMADDL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of SMADDL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the SSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the SSBB.
- When a load to a location appears in program order before the SSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order after the SSBB.

```
31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0
1  1  0  1  0  1  0  0  0  0  0  0  1  1  0  0  1  1  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0

CRm  opc
```

**System**

SSBB

// No additional decoding required

**Operation**

```c
SpeculativeStoreBypassBarrierToVA();
```
ST2G

Store Allocation Tags stores an Allocation Tag to two Tag granules of memory. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

It has encodings from 3 classes: Post-index, Pre-index and Signed offset

Post-index
(Armv8.5)

ST2G <Xt|SP>, [<Xn|SP>], #<simm>

integer n = UInt(Xn);
integer t = UInt(Xt);
bits(64) offset = LSL(SignExtend(imm9, 64), LOG2_TAG_GRANULE);
boolean writeback = TRUE;
boolean postindex = TRUE;

Pre-index
(Armv8.5)

ST2G <Xt|SP>, [<Xn|SP>], #<simm>!

integer n = UInt(Xn);
integer t = UInt(Xt);
bits(64) offset = LSL(SignExtend(imm9, 64), LOG2_TAG_GRANULE);
boolean writeback = TRUE;
boolean postindex = FALSE;

Signed offset
(Armv8.5)

ST2G <Xt|SP>, [<Xn|SP>{, #<simm>}]

integer n = UInt(Xn);
integer t =UInt(Xt);
bits(64) offset = LSL(SignExtend(imm9, 64), LOG2_TAG_GRANULE);
boolean writeback = FALSE;
boolean postindex = FALSE;

Assembler Symbols

<Xt|SP> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Xt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Xn" field.
<simm> Is the optional signed immediate offset, a multiple of 16 in the range -4096 to 4080, defaulting to 0 and encoded in the "imm9" field.

**Operation**

\[
\text{bits}(64) \text{ address;}
\text{bits}(64) \text{ data} = \text{if } t == 31 \text{ then } SP[] \text{ else } X[t];
\text{bits}(4) \text{ tag} = \text{AArch64.AllocationTagFromAddress}(data);
\text{SetTagCheckedInstruction}(FALSE);
\]

if \( n == 31 \) then
\[
\text{CheckSPAlignment}();
\text{address} = SP[];
\]
else
\[
\text{address} = X[n];
\]
if !postindex then
\[
\text{address} = \text{address} + \text{offset};
\]
\[
\text{AArch64.MemTag}[\text{address, AccType_NORMAL}] = \text{tag};
\text{AArch64.MemTag}[\text{address+TAG_GRANULE, AccType_NORMAL}] = \text{tag};
\]
if writeback then
\[
\text{if postindex then }
\text{address} = \text{address} + \text{offset};
\]
\[
\text{if } n == 31 \text{ then }
SP[] = \text{address};
\text{else }
X[n] = \text{address};
\]
STADD, STADDL

Atomic add on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory.

- STADD has no memory ordering semantics.
- STADDL stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDADD, LDADDA, LDADDAL, LDADDL. This means:

- The encodings in this description are named to match the encodings of LDADD, LDADDA, LDADDAL, LDADDL.
- The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational pseudocode for this instruction.

Integer

**32-bit LDADD alias (size == 10 & R == 0)**

STADD <Ws>, [<Xn|SP>]

is equivalent to

LDADD <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

**32-bit LDADDL alias (size == 10 & R == 1)**

STADDL <Ws>, [<Xn|SP>]

is equivalent to

LDADDL <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

**64-bit LDADD alias (size == 11 & R == 0)**

STADD <Xs>, [<Xn|SP>]

is equivalent to

LDADD <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

**64-bit LDADDL alias (size == 11 & R == 1)**

STADDL <Xs>, [<Xn|SP>]

is equivalent to

LDADDL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.
Assembler Symbols

<w> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<x> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<n|sp> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STADDB, STADDLB

Atomic add on byte in memory, without return, atomically loads an 8-bit byte from memory, adds the value held in a register to it, and stores the result back to memory.

- STADDB has no memory ordering semantics.
- STADDLB stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDADDB, LDADDAB, LDADDALB, LDADDLB. This means:

- The encodings in this description are named to match the encodings of LDADDB, LDADDAB, LDADDALB, LDADDLB.
- The description of LDADDB, LDADDAB, LDADDALB, LDADDLB gives the operational pseudocode for this instruction.

No memory ordering (R == 0)

STADDB <Ws>, [<Xn|SP>]

is equivalent to

LDADDB <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Release (R == 1)

STADDLB <Ws>, [<Xn|SP>]

is equivalent to

LDADDLB <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDADDB, LDADDAB, LDADDALB, LDADDLB gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STADDH, STADDLH

Atomic add on halfword in memory, without return, atomically loads a 16-bit halfword from memory, adds the value held in a register to it, and stores the result back to memory.

- STADDH has no memory ordering semantics.
- STADDLH stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about memory accesses see *Load/Store addressing modes*.

This is an alias of LDADDH, LDADDAH, LDADDALH, LDADDLH. This means:

- The encodings in this description are named to match the encodings of LDADDH, LDADDAH, LDADDALH, LDADDLH.
- The description of LDADDH, LDADDAH, LDADDALH, LDADDLH gives the operational pseudocode for this instruction.

No memory ordering (R == 0)

STCLRB <Ws>, [<Xn|SP>]

is equivalent to

LDCLRB <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Release (R == 1)

STCLRLB <Ws>, [<Xn|SP>]

is equivalent to

LDCLRLB <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STCLRH, STCLRLH

Atomic bit clear on halfword in memory, without return, atomically loads a 16-bit halfword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

- STCLRH has no memory ordering semantics.
- STCLRLH stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH. This means:

- The encodings in this description are named to match the encodings of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH.
- The description of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH gives the operational pseudocode for this instruction.

STLXP

Store-Release Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords to a memory location if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and, if the Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

32-bit (sz == 0)

STLXP <Ws>, <Wt1>, <Wt2>, [<Xn|SP>{,#0}]

64-bit (sz == 1)

STLXP <Ws>, <Xt1>, <Xt2>, [<Xn|SP>{,#0}]

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);  // ignored by load/store single register
integer s = UInt(Rs);    // ignored by all loads and store-release
integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;

For information about the CONstrained UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STLXP.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
0 If the operation updates memory.
1 If the operation fails to update memory.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:
• Memory is not updated.
• <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:
• If AArch64ExclusiveMonitorsPass() returns TRUE, the exception is generated.
• Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.
If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation**

```plaintext
bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

    X[s] = ZeroExtend(status, 32);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STLXR

Store-Release Exclusive Register stores a 32-bit word or a 64-bit doubleword to memory if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

32-bit (size == 10)

STLXR <Ws>, <Wt>, [<Xn|SP>{,#0}]

64-bit (size == 11)

STLXR <Ws>, <Xt>, [<Xn|SP>{,#0}]

integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);    // ignored by all loads and store-release

integer elsize = 8 << UInt(size);
boolean tag_checked = n != 31;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STLXR.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
0 If the operation updates memory.
1 If the operation fails to update memory.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:
• Memory is not updated.
• <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:
• If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
• Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
Operation

bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, dbytes) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, dbytes, AccTypeORDEREDATOMIC] = data;
    status = ExclusiveMonitorsStatus();
    X[s] = ZeroExtend(status, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STLXRB

Store-Release Exclusive Register Byte stores a byte from a 32-bit register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

No offset

STLXRB <Ws>, <Wt>, [<Xn|SP>{,#0}]

integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);  // ignored by all loads and store-release
boolean tag_checked = n != 31;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STLXRB.

Assembler Symbols

<Ws>  Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0  If the operation updates memory.

1  If the operation fails to update memory.

<Wt>  Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP>  Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

• Memory is not updated.
• <Ws> is not updated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
Operation

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STLXRH

Store-Release Exclusive Register Halfword stores a halfword from a 32-bit register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

No offset

STLXRH <Ws>, <Wt>, [<Xn|SP>]{,#0}

integer n = UInt(Rn);  
integer t = UInt(Rt);  
integer s = UInt(Rs);    // ignored by all loads and store-release

boolean tag_checked = n != 31;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STLXRH.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0   If the operation updates memory.

1   If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment
If a synchronous Data Abort exception is generated by the execution of this instruction:
• Memory is not updated.
• <Ws> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:
• If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
• Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
Operation

bits(64) address;
bits(16) data;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

#### Shared Decode

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```
Operation

bits(64) offset = \textit{ExtendReg}(m, extend\_type, shift);
if \textit{HaveMTEExt}() then
  \textit{SetTagCheckedInstruction}(TRUE);

bits(64) address;
bits(16) data;

if n == 31 then
  \textit{CheckSPAlignment}();
  address = \textit{SP}[];
else
  address = \textit{X}[n];

address = address + offset;

data = \textit{X}[t];
\textit{Mem}[address, 2, \textit{AccType\_NORMAL}] = data;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STSET, STSETL

Atomic bit set on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- STSET has no memory ordering semantics.
- STSETL stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDSET, LDSETA, LDSETAL, LDSETL. This means:

- The encodings in this description are named to match the encodings of LDSET, LDSETA, LDSETAL, LDSETL.
- The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode for this instruction.

32-bit LDSET alias (size == 10 && R == 0)

STSET <Ws>, [<Xn|SP>]

is equivalent to

LDSET <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

32-bit LDSETL alias (size == 10 && R == 1)

STSETL <Ws>, [<Xn|SP>]

is equivalent to

LDSETL <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

64-bit LDSET alias (size == 11 && R == 0)

STSET <Xs>, [<Xn|SP>]

is equivalent to

LDSET <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

64-bit LDSETL alias (size == 11 && R == 1)

STSETL <Xs>, [<Xn|SP>]

is equivalent to

LDSETL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.
Assembler Symbols

<<Ws>> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<<Xs>> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<<Xn|SP>> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STSETB, STSETLB

Atomic bit set on byte in memory, without return, atomically loads an 8-bit byte from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- STSETB has no memory ordering semantics.
- STSETLB stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDSETB, LDSETAB, LDSETALB, LDSETLB. This means:

- The encodings in this description are named to match the encodings of LDSETB, LDSETAB, LDSETALB, LDSETLB.
- The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational pseudocode for this instruction.

#### No memory ordering (R == 0)

STSETB <Ws>, [<Xn|SP>]

is equivalent to

LDSETB <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

#### Release (R == 1)

STSETLB <Ws>, [<Xn|SP>]

is equivalent to

LDSETLB <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

### Assembler Symbols

- `<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

### Operation

The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STSETH, STSETLH

Atomic bit set on halfword in memory, without return, atomically loads a 16-bit halfword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- STSETH has no memory ordering semantics.
- STSETLH stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDSETH, LDSETAH, LDSETALH, LDSETLH. This means:

- The encodings in this description are named to match the encodings of LDSETH, LDSETAH, LDSETALH, LDSETLH.
- The description of LDSETH, LDSETAH, LDSETALH, LDSETLH gives the operational pseudocode for this instruction.

and is always the preferred disassembly.

**Release (R == 1)**

STSETLH <Ws>, [<Xn|SP>]

is equivalent to

LDSETLH <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

### Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

### Operation

The description of LDSETH, LDSETAH, LDSETALH, LDSETLH gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STSMAX, STSMAXL

Atomic signed maximum on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

- STSMAX has no memory ordering semantics.
- STSMAXL stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL. This means:

- The encodings in this description are named to match the encodings of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL.
- The description of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL gives the operational pseudocode for this instruction.

STTR

Store Register (unprivileged) stores a word or doubleword from a register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.<E2H, TGE> is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes.

64-bit (size == 11)

STTR <Xt>, [<Xn|SP>{, #<simm}>]

integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '1';
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '1';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
  acctype = AccType_UNPRIV;
else
  acctype = AccType_NORMAL;

integer datasize = 8 << scale;
boolean tag_checked = n != 31;
Operation

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

bits(64) address;
bits(datasize) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, datasize DIV 8, acctype] = data;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STTRB

Store Register Byte (unprivileged) stores a byte from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes.

!![32-bit general-purpose register]

Unscaled offset

STTRB <Wt>, [<Xn|SP>{, #<simm>}]

bits(64) offset = SignExtend(imm9, 64);

Assembler Symbols

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STXP

Store Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords from two registers to a memory location if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and, if the Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. For information about memory accesses see Load/Store addressing modes.

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STXP.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.

1 If the operation fails to update memory.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

• Memory is not updated.
• <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

• If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
• Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
Operation

bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

    data = X[t];

bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, 2) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 2, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
    X[s] = ZeroExtend(status, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
Store Allocation Tags, Zeroing stores an Allocation Tag to two Tag granules of memory, zeroing the associated data locations. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag granule. The Allocation Tag is calculated from the Logical Address Tag in the source register. This instruction generates an Unchecked access.

It has encodings from 3 classes: **Post-index**, **Pre-index** and **Signed offset**

STZG

Store Allocation Tag, Zeroing stores an Allocation Tag to memory, zeroing the associated data location. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

It has encodings from 3 classes: Post-index, Pre-index and Signed offset

Post-index
(Armv8.5)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1  | 0  | 1  | 0  | 0  | 1  | 0  | 1  | 1  | imm9 | 0  | 1  | Xn  | Xt |

Post-index

STZG <Xt|SP>, [<Xn|SP>], #<simm>

integer n = UInt(Xn);
integer t = UInt(Xt);
bits(64) offset = LSL(SignExtend(imm9, 64), LOG2_TAG_GRANULE);
boolean writeback = TRUE;
boolean postindex = TRUE;

Pre-index
(Armv8.5)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1  | 0  | 1  | 0  | 0  | 1  | 0  | 1  | 1  | imm9 | 1  | 1  | Xn  | Xt |

Pre-index

STZG <Xt|SP>, [<Xn|SP>, #<simm>]

integer n = UInt(Xn);
integer t = UInt(Xt);
bits(64) offset = LSL(SignExtend(imm9, 64), LOG2_TAG_GRANULE);
boolean writeback = TRUE;
boolean postindex = FALSE;

Signed offset
(Armv8.5)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 1  | 0  | 1  | 0  | 0  | 1  | 0  | 1  | 1  | imm9 | 1  | 0  | Xn  | Xt |

Signed offset

STZG <Xt|SP>, [<Xn|SP>{, #<simm>}

integer n = UInt(Xn);
integer t = UInt(Xt);
bits(64) offset = LSL(SignExtend(imm9, 64), LOG2_TAG_GRANULE);
boolean writeback = FALSE;
boolean postindex = FALSE;

Assembler Symbols

<Xt|SP> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Xt" field.
Operation

```plaintext
bits(64) address;
SetTagCheckedInstruction(FALSE);
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];
if !postindex then
    address = address + offset;
Mem[address, TAG_GRANULE, AccType_NORMAL] = Zeros(TAG_GRANULE * 8);
basis(64) data = if t == 31 then SP[] else X[t];
basis(4) tag = AArch64.AllocationTagFromAddress(data);
AArch64.MemTag[address, AccType_NORMAL] = tag;
if writeback then
    if postindex then
        address = address + offset;
        if n == 31 then
            SP[] = address;
        else
            X[n] = address;
```
STZGM

Store Tag and Zero Multiple writes a naturally aligned block of N Allocation Tags and stores zero to the associated data locations, where the size of N is identified in DCZID_EL0.BS, and the Allocation Tag written to address A is taken from the source register bits<3:0>.
This instruction is UNDEFINED at EL0.
This instruction generates an Unchecked access.
If ID_AA64PFR1_EL1.MTE != 0b0010, this instruction is UNDEFINED.

Integer
(Armv8.5)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

**SUB (extended register)**

Subtract (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.

<table>
<thead>
<tr>
<th>sf</th>
<th>1 0 0 1 0 1 1 0 0 1</th>
<th>Rm</th>
<th>option</th>
<th>imm3</th>
<th>Rn</th>
<th>Rd</th>
</tr>
</thead>
<tbody>
<tr>
<td>op</td>
<td>S</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**32-bit (sf == 0)**

```plaintext
SUB <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

**64-bit (sf == 1)**

```plaintext
SUB <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then UNDEFINED;
```

**Assembler Symbols**

- `<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>` Is a width specifier, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>010</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>

- `<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
- `<extend>` For the 32-bit variant: is the extension to be applied to the second source operand, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UXTX</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases `<extend>` is required and must be UXTW when "option" is '010'.

SUB (extended register)  Page 507
For the 64-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');
if d == 31 then
  SP[] = result;
else
  X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SUB (immediate)

Subtract (immediate) subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register.

\[
\begin{array}{cccccccccccccccccccccc}
sf & 1 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & sh & imm12 & Op & 5 & Rn & Rd \\
\end{array}
\]

32-bit (sf == 0)

SUB <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}

64-bit (sf == 1)

SUB <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;

<table>
<thead>
<tr>
<th>sh</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LSL #0</td>
</tr>
<tr>
<td>1</td>
<td>LSL #12</td>
</tr>
</tbody>
</table>

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the “imm12” field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

Operation

bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2;
operand2 = NOT(imm);
(result, -) = AddWithCarry(operand1, operand2, '1');
if d == 31 then
  SP[] = result;
else
  X[d] = result;

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
• The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**SUB (shifted register)**

Subtract (shifted register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

This instruction is used by the alias **NEG (shifted register)**.

```
31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0
sf | 1 | 0 | 0 | 1 | 0 | 1 | 1 | shift | 0 | Rm  | imm6 | Rn  | Rd
   op  S
```

**32-bit (sf == 0)**

```plaintext
SUB <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

**64-bit (sf == 1)**

```plaintext
SUB <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if shift == '11' then UNDEFINED;
if sf == '0' && imm6<5> == '1' then UNDEFINED;

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Alias Conditions**

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEG (shifted register)</td>
<td>Rn == '1111'</td>
</tr>
</tbody>
</table>
Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');
X[d] = result;

Operational information

If PSTATE.DIT is 1:
  • The execution time of this instruction is independent of:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
  • The response of this instruction to asynchronous exceptions does not vary based on:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
Subtract with Tag subtracts an immediate value scaled by the Tag granule from the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

### Integer

#### Armv8.5

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

SUBP

Subtract Pointer subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, sign-extends the result to 64-bits, and writes the result to the destination register.

Integer
(Armv8.5)

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 0 0 1 1 1 0 1 0 1 1 0 | Xm 0 0 0 0 0 0 | Xn | Xd

Integer

SUBP <Xd>, <Xn|SP>, <Xm|SP>

integer d = UInt(Xd);
integer n = UInt(Xn);
integer m = UInt(Xm);

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Xd" field.
<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Xn" field.
<Xm|SP> Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Xm" field.

Operation

bits(64) operand1 = if n == 31 then SP[] else X[n];
bits(64) operand2 = if m == 31 then SP[] else X[m];
operand1 = SignExtend(operand1<55:0>, 64);
operand2 = SignExtend(operand2<55:0>, 64);

bits(64) result;
operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');
X[d] = result;
**SUBPS**

Subtract Pointer, setting Flags subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, sign-extends the result to 64-bits, and writes the result to the destination register. It updates the condition flags based on the result of the subtraction.

This instruction is used by the alias **CMPP**.

---

**SUBS (extended register)**

Subtract (extended register), setting flags, subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias **CMP (extended register)**.

<table>
<thead>
<tr>
<th>sf</th>
<th>1</th>
<th>1</th>
<th>0</th>
<th>1</th>
<th>0</th>
<th>1</th>
<th>0</th>
<th>0</th>
<th>1</th>
<th>Rm</th>
<th>option</th>
<th>imm3</th>
<th>Rn</th>
<th>Rd</th>
</tr>
</thead>
<tbody>
<tr>

<td>S</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**32-bit (sf == 0)**

```
SUBS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

**64-bit (sf == 1)**

```
SUBS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

```plaintext
ingiven d = UInt(Rd);
ingiven n = UInt(Rn);
ingiven m = UInt(Rm);
ingiven datasize = if sf == '1' then 64 else 32;
ExtendType extend type = DecodeRegExtend(option);
ingiven shift = UInt(imm3);
if shift > 4 then UNDEFINED;
```

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>` Is a width specifier, encoded in "option":
  - **option** | **<R>**
  - 00x | W
  - 010 | W
  - x11 | X
  - 10x | W
  - 110 | W
- `<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
- `<extend>` For the 32-bit variant: is the extension to be applied to the second source operand, encoded in "option":
  - **option** | **<extend>**
  - 000 | UXTB
  - 001 | UXTH
  - 010 | LSL|UXTW
  - 011 | UXTX
  - 100 | SXTB
  - 101 | SXTX
  - 110 | SXTW
  - 111 | SXTX
If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'. For the 64-bit variant: the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

### Alias Conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMP (extended register)</td>
<td>Rd == '11111'</td>
</tr>
</tbody>
</table>

### Operation

```plaintext
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;
operand2 = NOT(operand2);
(result, nzcv) = AddWithCarry(operand1, operand2, '1');
PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;
```

### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**SUBS (immediate)**

Subtract (immediate), setting flags, subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias **CMP (immediate)**.

<table>
<thead>
<tr>
<th>sf</th>
<th>imm12</th>
<th>Rn</th>
<th>Rd</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**32-bit (sf == 0)**

```
SUBS <Wd>, <Wn|WSP>, #<imm>{, <shift>}
```

**64-bit (sf == 1)**

```
SUBS <Xd>, <Xn|SP>, #<imm>{, <shift>}
```

### Assembler Symbols

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.
- `<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.
- `<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.
- `<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the “imm12” field.
- `<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

<table>
<thead>
<tr>
<th>sh</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LSL #0</td>
</tr>
<tr>
<td>1</td>
<td>LSL #12</td>
</tr>
</tbody>
</table>

### Alias Conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMP (immediate)</td>
<td>Rd == '11111'</td>
</tr>
</tbody>
</table>

### Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2;
bits(4) nzcv;
operand2 = NOT(imm);
(result, nzcv) = AddWithCarry(operand1, operand2, '1');
PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**SUBS (shifted register)**

Subtract (shifted register), setting flags, subtracts an optionally-shifted register value from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the aliases **CMP (shifted register)**, and **NEGS**.

### 32-bit (sf == 0)

\[
\text{SUBS} \ <Wd>, \ <Wn>, \ <Wm>\{, \ <shift> \ #<amount>\}
\]

### 64-bit (sf == 1)

\[
\text{SUBS} \ <Xd>, \ <Xn>, \ <Xm>\{, \ <shift> \ #<amount>\}
\]

### Assembler Symbols

- **<Wd>** is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Wn>** is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- **<Wm>** is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- **<Xd>** is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Xn>** is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- **< Xm>** is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- **<shift>** is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- **<amount>** is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

### Alias Conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CMP (shifted register)</strong></td>
<td>\text{Rd} == '11111'</td>
</tr>
<tr>
<td><strong>NEGS</strong></td>
<td>\text{Rn} == '11111'</td>
</tr>
</tbody>
</table>
Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = \texttt{ShiftReg}(m, \texttt{shift} \_\texttt{type}, \texttt{shift} \_\texttt{amount});
bits(4) nzcv;

operand2 = \texttt{NOT}(operand2);
(result, nzcv) = \texttt{AddWithCarry}(operand1, operand2, '1');

\texttt{PSTATE.<N,Z,C,V>} = nzcv;
X[d] = result;

Operational information

If \texttt{PSTATE.DIT} is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SVC

Supervisor Call causes an exception to be taken to EL1. On executing an SVC instruction, the PE records the exception as a Supervisor Call exception in ESR_ELx, using the EC value 0x15, and the value of the immediate argument.

```
0 1 0 0 0 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
```

System

SVC #<imm>

// Empty.

Assembler Symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

AArch64.CheckForSVCTrap(imm16);
AArch64.CallSupervisor(imm16);
**SWP, SWPA, SWPAL, SWPL**

Swap word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, SWPA and SWPAL load from memory with acquire semantics.
- SWPL and SWPAL store to memory with release semantics.
- SWP has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*. For information about memory accesses see *Load/Store addressing modes*.

- **<Xn|SP>** Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

bits(64) address;
bis(16) data;
bis(16) store_value;

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

store_value = X[s];
data = MemAtomic(address, MemAtomicOp_SWP, store_value, ldacctype, stacctype);
X[t] = ZeroExtend(data, 32);
**SXTB**

Signed Extend Byte extracts an 8-bit value from a register, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of **SBFM**. This means:

- The encodings in this description are named to match the encodings of **SBFM**.
- The description of **SBFM** gives the operational pseudocode for this instruction.

</table>

32-bit (sf == 0 & N == 0)

SXTB <Wd>, <Wn>

is equivalent to

SBFM <Wd>, <Wn>, #0, #7

and is always the preferred disassembly.

64-bit (sf == 1 & N == 1)

SXTB <Xd>, <Wn>

is equivalent to

SBFM <Xd>, <Xn>, #0, #7

and is always the preferred disassembly.

**Assembler Symbols**

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

**Operation**

The description of **SBFM** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SXTH

Sign Extend Halfword extracts a 16-bit value, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

```
<table>
<thead>
<tr>
<th>sf</th>
<th>0 0 1 0 0 1 1 0</th>
<th>N</th>
<th>0 0 0 0 0 0 0 0</th>
<th>0 0 1 1 1 1</th>
</tr>
</thead>
</table>
| opc | immr           | imms
```

32-bit (sf == 0 && N == 0)

SXTH <Wd>, <Wn>

is equivalent to

SBFM <Wd>, <Wn>, #0, #15

and is always the preferred disassembly.

64-bit (sf == 1 && N == 1)

SXTH <Xd>, <Wn>

is equivalent to

SBFM <Xd>, <Xn>, #0, #15

and is always the preferred disassembly.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SXTW

Sign Extend Word sign-extends a word to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

### 64-bit

SXTW \(<Xd>, <Wn>\)

is equivalent to

SBFM \(<Xd>, <Xn>, #0, #31\)

and is always the preferred disassembly.

#### Assembler Symbols

- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

#### Operation

The description of SBFM gives the operational pseudocode for this instruction.

#### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
System instruction. For more information, see Op0 equals 0b01, cache maintenance, TLB maintenance, and address translation instructions for the encodings of System instructions.

This instruction is used by the aliases AT, CFP, CPP, DC, DVP, IC, and TLBI.

Assembler Symbols

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

<Xt> Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

System

SYSL <Xt>, #<op1>, <Cn>, <Cm>, #<op2>

AArch64.CheckSystemAccess('01', op1, CRn, CRm, op2, Rt, L);

integer t = UInt(Rt);

integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

Operation

// No architecturally defined instructions here.
X[t] = AArch64.SysInstrWithResult(1, sys_op1, sys_crn, sys_crm, sys_op2);
TBNZ

Test bit and Branch if Nonzero compares the value of a bit in a general-purpose register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

14-bit signed PC-relative branch offset

TBNZ <R><t>, #<imm>, <label>

integer t = UInt(Rt);

integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bits(64) offset = SignExtend(imm14:'00', 64);

Assembler Symbols

<R> Is a width specifier, encoded in “b5”:

<table>
<thead>
<tr>
<th>b5</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>W</td>
</tr>
<tr>
<td>1</td>
<td>X</td>
</tr>
</tbody>
</table>

In assembler source code an ‘X’ specifier is always permitted, but a ‘W’ specifier is only permitted when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the “Rt“ field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in “b5:b40”.

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as “imm14“ times 4.

Operation

bits(datasize) operand = X[t];

if operand<bit_pos> == op then
  BranchTo(PC[] + offset, BranchType_DIR);

Copyright © 2010-2019 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
TBZ

Test bit and Branch if Zero compares the value of a test bit with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

\[
\begin{array}{cccccccccccccccccccccccc}
\mid \hline \\
\text{b5} & 0 & 1 & 1 & 0 & 1 & 1 & 0 & \text{b40} & \text{imm14} & \text{Rt} \\
\end{array}
\]

14-bit signed PC-relative branch offset

TBZ \text{<R><t>, #<imm>, <label>}

\[
\text{integer } t = \text{UInt}(\text{Rt});
\]
\[
\text{integer datasize} = \text{if b5 == '1' then 64 else 32};
\]
\[
\text{integer bit_pos} = \text{UInt}(\text{b5:b40});
\]
\[
\text{bits(64) offset} = \text{SignExtend(imm14:'00', 64)};
\]

Assembler Symbols

\text{<R>} \quad \text{Is a width specifier, encoded in “b5”:}

\[
\begin{array}{ccc}
\text{b5} & \text{<R>} \\
0 & W \\
1 & X \\
\end{array}
\]

In assembler source code an ‘X’ specifier is always permitted, but a ‘W’ specifier is only permitted when the bit number is less than 32.

\text{<t>} \quad \text{Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the “Rt” field.}

\text{<imm>} \quad \text{Is the bit number to be tested, in the range 0 to 63, encoded in “b5:b40”.

\text{<label>} \quad \text{Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as “imm14” times 4.}

Operation

\[
\text{bits(datasize) operand} = \text{X[t]};
\]
\[
\text{if operand<bit_pos> == op then}
\]
\[
\text{BranchTq(}\text{PC[]} + \text{offset}, \text{BranchType_DIR});
\]
TLBI

TLB Invalidate operation. For more information, see \textit{op0==0b01, cache maintenance, TLB maintenance, and address translation instructions}.

This is an alias of \texttt{SYS}. This means:

- The encodings in this description are named to match the encodings of \texttt{SYS}.
- The description of \texttt{SYS} gives the operational pseudocode for this instruction.

<Xt> Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
Trace Synchronization Barrier. This instruction is a barrier that synchronizes the trace operations of instructions. If ARMv8.4-Trace is not implemented, this instruction executes as a NOP.

System
(Armv8.4)

TST (immediate)

Test bits (immediate), setting the condition flags and discarding the result: Rn AND imm.

This is an alias of ANDS (immediate). This means:

- The encodings in this description are named to match the encodings of ANDS (immediate).
- The description of ANDS (immediate) gives the operational pseudocode for this instruction.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
| sf | 1 | 1 | 1 | 1 | 0 | 0 | 1 | 0 | immr | imms | Rn | 1 | 1 | 1 | 1 | 1 | Rd |
| opc |

32-bit (sf == 0 && N == 0)

TST <Wn>, #<imm>

is equivalent to

ANDS WZR, <Wn>, #<imm>

and is always the preferred disassembly.

64-bit (sf == 1)

TST <Xn>, #<imm>

is equivalent to

ANDS XZR, <Xn>, #<imm>

and is always the preferred disassembly.

Assembler Symbols

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<imm> For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".
For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

Operation

The description of ANDS (immediate) gives the operational pseudocode for this instruction.
TST (shifted register)

Test (shifted register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of ANDS (shifted register). This means:

- The encodings in this description are named to match the encodings of ANDS (shifted register).
- The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

32-bit (sf == 0)

TST <Wn>, <Wm>{, <shift> #<amount>}

is equivalent to

ANDS WZR, <Wn>, <Wm>{, <shift> #<amount>}

and is always the preferred disassembly.

64-bit (sf == 1)

TST <Xn>, <Xm>{, <shift> #<amount>}

is equivalent to

ANDS XZR, <Xn>, <Xm>{, <shift> #<amount>}

and is always the preferred disassembly.

Assembler Symbols

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
- The values of the data supplied in any of its registers.
- The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
UBFIZ

Unsigned Bitfield Insert in Zeros copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, setting the destination bits above and below the bitfield to zero.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

<table>
<thead>
<tr>
<th>sf</th>
<th>1 0 1 0 0 1 1 0</th>
<th>N</th>
<th>immr</th>
<th>imms</th>
<th>Rd</th>
</tr>
</thead>
</table>

32-bit (sf == 0 && N == 0)

UBFIZ <Wd>, <Wn>, #<lsb>, #<width>

is equivalent to

UBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

64-bit (sf == 1 && N == 1)

UBFIZ <Xd>, <Xn>, #<lsb>, #<width>

is equivalent to

UBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

Assembler Symbols

- <Wd> is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <lsb> For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- <width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**UBFM**

Unigned Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly. If \(<\text{imms}\)\> is greater than or equal to \(<\text{immr}\)\>, this copies a bitfield of \((<\text{imms}\>-<\text{immr}\>+1)\) bits starting from bit position \(<\text{immr}\)\> in the source register to the least significant bits of the destination register. If \(<\text{imms}\)\> is less than \(<\text{immr}\)\>, this copies a bitfield of \((<\text{imms}\>+1)\) bits from the least significant bits of the source register to bit position \((\text{regsize}-<\text{immr}\>)\) of the destination register, where \(\text{regsize}\) is the destination register size of 32 or 64 bits. In both cases the destination bits below and above the bitfield are set to zero.

This instruction is used by the aliases `LSL (immediate)`, `LSR (immediate)`, `UBFIZ`, `UBFX`, `UXTB`, and `UXTH`.

### 32-bit \((sf == 0 \&\& N == 0)\)

**UBFM** \(<\text{Wd}\>, <\text{Wn}\>, \#<\text{immr}\>, \#<\text{imms}\>)

### 64-bit \((sf == 1 \&\& N == 1)\)

**UBFM** \(<\text{Xd}\>, <\text{Xn}\>, \#<\text{immr}\>, \#<\text{imms}\>)

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

integer R;
bits(datasize) wmask;
bits(datasize) tmask;

if sf == '1' \&\& N != '1' then UNDEFINED;
if sf == '0' \&\& (N != '0' || immr<5> != '0' || imms<5> != '0') then UNDEFINED;

R = UInt(immr);
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE);
```

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<immr>` For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field. For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.
- `<imms>` For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field. For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

**Alias Conditions**

<table>
<thead>
<tr>
<th>Alias</th>

**32-bit (sf == 0 && N == 0)**

**UBFX** `<Wd>`, `<Wn>`, `#<lsb>`, `#<width>`

is equivalent to

**UBFM** `<Wd>`, `<Wn>`, `#<lsb>`, `{<lsb>+<width>-1}

and is the preferred disassembly when **BFXPreferred(sf, opc<1>, imms, immr)**.

**64-bit (sf == 1 && N == 1)**

**UBFX** `<Xd>`, `<Xn>`, `#<lsb>`, `#<width>`

is equivalent to

**UBFM** `<Xd>`, `<Xn>`, `#<lsb>`, `{<lsb>+<width>-1}

and is the preferred disassembly when **BFXPreferred(sf, opc<1>, imms, immr)**.

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<lsb>` For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
- `<width>` For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

**Operation**

The description of **UBFM** gives the operational pseudocode for this instruction.

**Operational information**

If **PSTATE.DIT** is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Permanently Undefined generates an Undefined Instruction exception (ESR_ELx.EC = 0b000000). The encodings for UDF used in this section are defined as permanently UNDEFINED in the Armv8-A architecture.

```
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
imm16
```

**Integer**

**UDF #<imm>**

```
// The imm16 field is ignored by hardware.
UNDEFINED;
```

**Assembler Symbols**

`<imm>` is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field. The PE ignores the value of this constant.

**Operation**

```
// No operation.
```
UDIV

 Unsigned Divide divides an unsigned integer register value by another unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

result = Int(operand3, TRUE) - (Int(operand1, TRUE) * Int(operand2, TRUE));
X[d] = result<63:0>;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**UMULH**

Unsigned Multiply High multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.

### 64-bit

**UMULH** <Xd>, <Xn>, <Xm>

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
```

**Assembler Symbols**

- <Xd>  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn>  Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- <Xm>  Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

**Operation**

```plaintext
bits(64) operand1 = X[n];
bits(64) operand2 = X[m];

integer result;

result = Int(operand1, TRUE) * Int(operand2, TRUE);

X[d] = result<127:64>;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
unsigned Multiply Long multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This is an alias of **UMADDL**. This means:

- The encodings in this description are named to match the encodings of **UMADDL**.
- The description of **UMADDL** gives the operational pseudocode for this instruction.

  - The values of the NZCV flags.
**WFE**

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any PE in the multiprocessor system. For more information, see *Wait For Event mechanism and Send event*.

As described in *Wait For Event mechanism and Send event*, the execution of a WFE instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level. See:

- *Traps to EL1 of EL0 execution of WFE and WFI instructions.*
- *Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions.*
- *Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions.*

```

WFI

Wait For Interrupt is a hint instruction that indicates that the PE can enter a low-power state and remain there until a
wakeup event occurs. For more information, see Wait For Interrupt.
As described in Wait For Interrupt, the execution of a WFI instruction that would otherwise cause entry to a low-power
state can be trapped to a higher Exception level. See:
- Traps to EL1 of EL0 execution of WFE and WFI instructions.
- Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions.

System

WFI

// Empty.

Operation

if !InterruptPending() then
  if PSTATE.EL == EL0 then
    // Check for traps described by the OS which may be EL1 or EL2.
    AArch64.CheckForWFxTrap(EL1, FALSE);
  if PSTATE.EL IN {EL0, EL1} &amp; EL2Enabled() &amp;&amp; !IsInHost() then
    // Check for traps described by the Hypervisor.
    AArch64.CheckForWFxTrap(EL2, FALSE);
  if HaveEL(EL3) &amp;&amp; PSTATE.EL != EL3 then
    // Check for traps described by the Secure Monitor.
    AArch64.CheckForWFxTrap(EL3, FALSE);
  WaitForInterrupt();
XAFLAG

Convert floating-point condition flags from external format to Arm format. This instruction converts the state of the PSTATE.{N,Z,C,V} flags from an alternative representation required by some software to a form representing the result of an Arm floating-point scalar compare instruction.

System
(Armv8.5)

```

XPACD, XPACI, XPACLRI

Strip Pointer Authentication Code. This instruction removes the pointer authentication code from an address. The address is in the specified general-purpose register for XPACI and XPACD, and is in LR for XPACLRI. The XPACD instruction is used for data addresses, and XPACI and XPACLRI are used for instruction addresses.

It has encodings from 2 classes: Integer and System

**Integer**
(Armv8.3)

```

YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction, see The YIELD instruction.

System

YIELD

// Empty.

Operation

Hint_Yield();
**A64 -- SIMD and Floating-point Instructions (alphabetic order)**

**ABS**: Absolute value (vector).

**ADD (vector)**: Add (vector).

**ADDHN, ADDHN2**: Add returning High Narrow.

**ADDP (scalar)**: Add Pair of elements (scalar).

**ADDP (vector)**: Add Pairwise (vector).

**ADDV**: Add across Vector.

**AESD**: AES single round decryption.

**AESE**: AES single round encryption.

**AESIMC**: AES inverse mix columns.

**AESMC**: AES mix columns.

**AND (vector)**: Bitwise AND (vector).

**BCAX**: Bit Clear and XOR.

**BFCVT**: Floating-point convert from single-precision to BFloat16 format (scalar).

**BFCVTN, BFCVTN2**: Floating-point convert from single-precision to BFloat16 format (vector).

**BFDOT (by element)**: BFloat16 floating-point dot product (vector, by element).

**BFDOT (vector)**: BFloat16 floating-point dot product (vector).

**BFMLALB, BFMLALT (by element)**: BFloat16 floating-point widening multiply-add long (by element).

**BFMLALB, BFMLALT (vector)**: BFloat16 floating-point widening multiply-add long (vector).

**BFMMLA**: BFloat16 floating-point matrix multiply-accumulate into 2x2 matrix.

**BIC (vector, immediate)**: Bitwise bit Clear (vector, immediate).

**BIC (vector, register)**: Bitwise bit Clear (vector, register).

**BIF**: Bitwise Insert if False.

**BIT**: Bitwise Insert if True.

**BSL**: Bitwise Select.

**CLS (vector)**: Count Leading Sign bits (vector).

**CLZ (vector)**: Count Leading Zero bits (vector).

**CMEQ (register)**: Compare bitwise Equal (vector).

**CMEQ (zero)**: Compare bitwise Equal to zero (vector).

**CMGE (register)**: Compare signed Greater than or Equal (vector).

**CMGE (zero)**: Compare signed Greater than or Equal to zero (vector).

**CMGT (register)**: Compare signed Greater than (vector).

**CMGT (zero)**: Compare signed Greater than zero (vector).

**CMHI (register)**: Compare unsigned Higher (vector).

**CMHS (register)**: Compare unsigned Higher or Same (vector).
CMLE (zero): Compare signed Less than or Equal to zero (vector).
CMLT (zero): Compare signed Less than zero (vector).
CMTST: Compare bitwise Test bits nonzero (vector).
CNT: Population Count per byte.
DUP (element): Duplicate vector element to vector or scalar.
DUP (general): Duplicate general-purpose register to vector.
EOR (vector): Bitwise Exclusive OR (vector).
EOR3: Three-way Exclusive OR.
EXT: Extract vector from pair of vectors.
FABD: Floating-point Absolute Difference (vector).
FABS (scalar): Floating-point Absolute value (scalar).
FABS (vector): Floating-point Absolute value (vector).
FACGE: Floating-point Absolute Compare Greater than or Equal (vector).
FACGT: Floating-point Absolute Compare Greater than (vector).
FADD (scalar): Floating-point Add (scalar).
FADD (vector): Floating-point Add (vector).
FADDP (scalar): Floating-point Add Pair of elements (scalar).
FADDP (vector): Floating-point Add Pairwise (vector).
FCADD: Floating-point Complex Add.
FCCMP: Floating-point Conditional quiet Compare (scalar).
FCCMPE: Floating-point Conditional signaling Compare (scalar).
FCMEQ (register): Floating-point Compare Equal (vector).
FCMEQ (zero): Floating-point Compare Equal to zero (vector).
FCMGE (register): Floating-point Compare Greater than or Equal (vector).
FCMGE (zero): Floating-point Compare Greater than or Equal to zero (vector).
FCMG (register): Floating-point Compare Greater than (vector).
FCMG (zero): Floating-point Compare Greater than zero (vector).
FCMLA: Floating-point Complex Multiply Accumulate.
FCMLA (by element): Floating-point Complex Multiply Accumulate (by element).
FCMLE (zero): Floating-point Compare Less than or Equal to zero (vector).
FCMLT (zero): Floating-point Compare Less than zero (vector).
FCMP: Floating-point quiet Compare (scalar).
FCMPE: Floating-point signaling Compare (scalar).
FCSEL: Floating-point Conditional Select (scalar).
FCVT: Floating-point Convert precision (scalar).
FCVTAS (scalar): Floating-point Convert to Signed integer, rounding to nearest with ties to Away (scalar).
FCVTAS (vector): Floating-point Convert to Signed integer, rounding to nearest with ties to Away (vector).
FCVTAU (scalar): Floating-point Convert to Unsigned integer, rounding to nearest with ties to Away (scalar).
FCVTAU (vector): Floating-point Convert to Unsigned integer, rounding to nearest with ties to Away (vector).
FCVTL, FCVTL2: Floating-point Convert to higher precision Long (vector).
FCVTMS (scalar): Floating-point Convert to Signed integer, rounding toward Minus infinity (scalar).
FCVTMS (vector): Floating-point Convert to Signed integer, rounding toward Minus infinity (vector).
FCVTMU (scalar): Floating-point Convert to Unsigned integer, rounding toward Minus infinity (scalar).
FCVTMU (vector): Floating-point Convert to Unsigned integer, rounding toward Minus infinity (vector).
FCVTN, FCVTN2: Floating-point Convert to lower precision Narrow (vector).
FCVTNS (scalar): Floating-point Convert to Signed integer, rounding to nearest with ties to even (scalar).
FCVTNS (vector): Floating-point Convert to Signed integer, rounding to nearest with ties to even (vector).
FCVTNU (scalar): Floating-point Convert to Unsigned integer, rounding to nearest with ties to even (scalar).
FCVTNU (vector): Floating-point Convert to Unsigned integer, rounding to nearest with ties to even (vector).
FCVTPS (scalar): Floating-point Convert to Signed integer, rounding toward Plus infinity (scalar).
FCVTPS (vector): Floating-point Convert to Signed integer, rounding toward Plus infinity (vector).
FCVTPU (scalar): Floating-point Convert to Unsigned integer, rounding toward Plus infinity (scalar).
FCVTPU (vector): Floating-point Convert to Unsigned integer, rounding toward Plus infinity (vector).
FCVTXN, FCVTXN2: Floating-point Convert to lower precision Narrow, rounding to odd (vector).
FCVTZS (scalar, fixed-point): Floating-point Convert to Signed fixed-point, rounding toward Zero (scalar).
FCVTZS (scalar, integer): Floating-point Convert to Signed integer, rounding toward Zero (scalar).
FCVTZS (vector, fixed-point): Floating-point Convert to Signed fixed-point, rounding toward Zero (vector).
FCVTZS (vector, integer): Floating-point Convert to Signed integer, rounding toward Zero (vector).
FCVTZU (scalar, fixed-point): Floating-point Convert to Unsigned fixed-point, rounding toward Zero (scalar).
FCVTZU (scalar, integer): Floating-point Convert to Unsigned integer, rounding toward Zero (scalar).
FCVTZU (vector, fixed-point): Floating-point Convert to Unsigned fixed-point, rounding toward Zero (vector).
FCVTZU (vector, integer): Floating-point Convert to Unsigned integer, rounding toward Zero (vector).
FDIV (scalar): Floating-point Divide (scalar).
FDIV (vector): Floating-point Divide (vector).
FJCVTZS: Floating-point Javascript Convert to Signed fixed-point, rounding toward Zero.
FMADD: Floating-point fused Multiply-Add (scalar).
FMAX (scalar): Floating-point Maximum (scalar).
FMAX (vector): Floating-point Maximum (vector).
FMAXNM (scalar): Floating-point Maximum Number (scalar).
FMAXNM (vector): Floating-point Maximum Number (vector).
FMAXNMP (scalar): Floating-point Maximum Number of Pair of elements (scalar).
FMAXNMP (vector): Floating-point Maximum Number Pairwise (vector).
FMAXNMV: Floating-point Maximum Number across Vector.

FMAXP (scalar): Floating-point Maximum of Pair of elements (scalar).

FMAXP (vector): Floating-point Maximum Pairwise (vector).

FMAXV: Floating-point Maximum across Vector.

FMIN (scalar): Floating-point Minimum (scalar).

FMIN (vector): Floating-point minimum (vector).

FMINNM (scalar): Floating-point Minimum Number (scalar).

FMINNM (vector): Floating-point Minimum Number (vector).

FMINNMP (scalar): Floating-point Minimum Number of Pair of elements (scalar).

FMINNMP (vector): Floating-point Minimum Number Pairwise (vector).

FMINMV: Floating-point Minimum Number across Vector.

FMINP (scalar): Floating-point Minimum of Pair of elements (scalar).

FMINP (vector): Floating-point Minimum Pairwise (vector).

FMINV: Floating-point Minimum across Vector.

FMLA (by element): Floating-point fused Multiply-Add to accumulator (by element).

FMLA (vector): Floating-point fused Multiply-Add to accumulator (vector).

FMLAL, FMLAL2 (by element): Floating-point fused Multiply-Add Long to accumulator (by element).

FMLAL, FMLAL2 (vector): Floating-point fused Multiply-Add Long to accumulator (vector).

FMLS (by element): Floating-point fused Multiply-Subtract from accumulator (by element).

FMLS (vector): Floating-point fused Multiply-Subtract from accumulator (vector).

FMLSL, FMLSL2 (by element): Floating-point fused Multiply-Subtract Long from accumulator (by element).

FMLSL, FMLSL2 (vector): Floating-point fused Multiply-Subtract Long from accumulator (vector).

FMOV (general): Floating-point Move to or from general-purpose register without conversion.

FMOV (register): Floating-point Move register without conversion.

FMOV (scalar, immediate): Floating-point move immediate (scalar).

FMOV (vector, immediate): Floating-point move immediate (vector).

FMSUB: Floating-point Fused Multiply-Subtract (scalar).

FMUL (by element): Floating-point Multiply (by element).

FMUL (scalar): Floating-point Multiply (scalar).

FMUL (vector): Floating-point Multiply (vector).

FMULX: Floating-point Multiply extended.

FMULX (by element): Floating-point Multiply extended (by element).

FNEG (scalar): Floating-point Negate (scalar).

FNEG (vector): Floating-point Negate (vector).

FNMADD: Floating-point Negated fused Multiply-Add (scalar).

FNMSUB: Floating-point Negated fused Multiply-Subtract (scalar).
**FNMUL (scalar)**: Floating-point Multiply-Negate (scalar).

**FRECPE**: Floating-point Reciprocal Estimate.

**FRECPS**: Floating-point Reciprocal Step.

**FRECXP**: Floating-point Reciprocal exponent (scalar).

**FRINT32X (scalar)**: Floating-point Round to 32-bit Integer, using current rounding mode (scalar).

**FRINT32X (vector)**: Floating-point Round to 32-bit Integer, using current rounding mode (vector).

**FRINT32Z (scalar)**: Floating-point Round to 32-bit Integer toward Zero (scalar).

**FRINT32Z (vector)**: Floating-point Round to 32-bit Integer toward Zero (vector).

**FRINT64X (scalar)**: Floating-point Round to 64-bit Integer, using current rounding mode (scalar).

**FRINT64X (vector)**: Floating-point Round to 64-bit Integer, using current rounding mode (vector).

**FRINT64Z (scalar)**: Floating-point Round to 64-bit Integer toward Zero (scalar).

**FRINT64Z (vector)**: Floating-point Round to 64-bit Integer toward Zero (vector).

**FRINTA (scalar)**: Floating-point Round to Integral, to nearest with ties to Away (scalar).

**FRINTA (vector)**: Floating-point Round to Integral, to nearest with ties to Away (vector).

**FRINTI (scalar)**: Floating-point Round to Integral, using current rounding mode (scalar).

**FRINTI (vector)**: Floating-point Round to Integral, using current rounding mode (vector).

**FRINTM (scalar)**: Floating-point Round to Integral, toward Minus infinity (scalar).

**FRINTM (vector)**: Floating-point Round to Integral, toward Minus infinity (vector).

**FRINTN (scalar)**: Floating-point Round to Integral, to nearest with ties to even (scalar).

**FRINTN (vector)**: Floating-point Round to Integral, to nearest with ties to even (vector).

**FRINTP (scalar)**: Floating-point Round to Integral, toward Plus infinity (scalar).

**FRINTP (vector)**: Floating-point Round to Integral, toward Plus infinity (vector).

**FRINTX (scalar)**: Floating-point Round to Integral exact, using current rounding mode (scalar).

**FRINTX (vector)**: Floating-point Round to Integral exact, using current rounding mode (vector).

**FRINTZ (scalar)**: Floating-point Round to Integral, toward Zero (scalar).

**FRINTZ (vector)**: Floating-point Round to Integral, toward Zero (vector).

**FRSORTE**: Floating-point Reciprocal Square Root Estimate.

**FRSORTS**: Floating-point Reciprocal Square Root Step.

**FSORT (scalar)**: Floating-point Square Root (scalar).

**FSORT (vector)**: Floating-point Square Root (vector).

**FSUB (scalar)**: Floating-point Subtract (scalar).

**FSUB (vector)**: Floating-point Subtract (vector).

**INS (element)**: Insert vector element from another vector element.

**INS (general)**: Insert vector element from general-purpose register.

**LD1 (multiple structures)**: Load multiple single-element structures to one, two, three, or four registers.

**LD1 (single structure)**: Load one single-element structure to one lane of one register.
LD1R: Load one single-element structure and Replicate to all lanes (of one register).
LD2 (multiple structures): Load multiple 2-element structures to two registers.
LD2 (single structure): Load single 2-element structure to one lane of two registers.
LD2R: Load single 2-element structure and Replicate to all lanes of two registers.
LD3 (multiple structures): Load multiple 3-element structures to three registers.
LD3 (single structure): Load single 3-element structure to one lane of three registers.
LD3R: Load single 3-element structure and Replicate to all lanes of three registers.
LD4 (multiple structures): Load multiple 4-element structures to four registers.
LD4 (single structure): Load single 4-element structure to one lane of four registers.
LD4R: Load single 4-element structure and Replicate to all lanes of four registers.
LDNP (SIMD&FP): Load Pair of SIMD&FP registers, with Non-temporal hint.
LDP (SIMD&FP): Load Pair of SIMD&FP registers.
LDR (immediate, SIMD&FP): Load SIMD&FP Register (immediate offset).
LDR (literal, SIMD&FP): Load SIMD&FP Register (PC-relative literal).
LDR (register, SIMD&FP): Load SIMD&FP Register (register offset).
LDUR (SIMD&FP): Load SIMD&FP Register (unscaled offset).
MLA (by element): Multiply-Add to accumulator (vector, by element).
MLA (vector): Multiply-Add to accumulator (vector).
MLS (by element): Multiply-Subtract from accumulator (vector, by element).
MLS (vector): Multiply-Subtract from accumulator (vector).
MOV (element): Move vector element to another vector element: an alias of INS (element).
MOV (from general): Move general-purpose register to a vector element: an alias of INS (general).
MOV (scalar): Move vector element to scalar: an alias of DUP (element).
MOV (to general): Move vector element to general-purpose register: an alias of UMOV.
MOVI: Move Immediate (vector).
MUL (by element): Multiply (vector, by element).
MUL (vector): Multiply (vector).
MVN: Bitwise NOT (vector): an alias of NOT.
MVNI: Move inverted Immediate (vector).
NEG (vector): Negate (vector).
NOT: Bitwise NOT (vector).
ORN (vector): Bitwise inclusive OR NOT (vector).
ORR (vector, immediate): Bitwise inclusive OR (vector, immediate).
ORR (vector, register): Bitwise inclusive OR (vector, register).
PMUL: Polynomial Multiply.
PMULL, PMULL2: Polynomial Multiply Long.
RADDH, RADDH2: Rounding Add returning High Narrow.
RAX1: Rotate and Exclusive OR.
RBIT (vector): Reverse Bit order (vector).
REV16 (vector): Reverse elements in 16-bit halfwords (vector).
REV32 (vector): Reverse elements in 32-bit words (vector).
REV64: Reverse elements in 64-bit doublewords (vector).
RSHRN, RSHRN2: Rounding Shift Right Narrow (immediate).
RSUBH, RSUBH2: Rounding Subtract returning High Narrow.
SABA: Signed Absolute difference and Accumulate.
SABAL, SABAL2: Signed Absolute difference and Accumulate Long.
SABD: Signed Absolute Difference.
SABDL, SABDL2: Signed Absolute Difference Long.
SADALP: Signed Add and Accumulate Long Pairwise.
SADDD, SADDL2: Signed Add Long (vector).
SADDLP: Signed Add Long Pairwise.
SADDLV: Signed Add Long across Vector.
SADDW, SADDW2: Signed Add Wide.
SCVT (scalar, fixed-point): Signed fixed-point Convert to Floating-point (scalar).
SCVT (scalar, integer): Signed integer Convert to Floating-point (scalar).
SCVT (vector, fixed-point): Signed fixed-point Convert to Floating-point (vector).
SCVT (vector, integer): Signed integer Convert to Floating-point (vector).
SDOT (by element): Dot Product signed arithmetic (vector, by element).
SDOT (vector): Dot Product signed arithmetic (vector).
SHA1C: SHA1 hash update (choose).
SHA1H: SHA1 fixed rotate.
SHA1M: SHA1 hash update (majority).
SHA1P: SHA1 hash update (parity).
SHA1SU0: SHA1 schedule update 0.
SHA1SU1: SHA1 schedule update 1.
SHA256H: SHA256 hash update (part 1).
SHA256H2: SHA256 hash update (part 2).
SHA256SU0: SHA256 schedule update 0.
SHA256SU1: SHA256 schedule update 1.
SHA512H: SHA512 Hash update part 1.
SHA512H2: SHA512 Hash update part 2.
SHA512SU0: SHA512 Schedule Update 0.
SHA512SU1: SHA512 Schedule Update 1.
SHADD: Signed Halving Add.
SHL: Shift Left (immediate).
SHLL, SHLL2: Shift Left Long (by element size).
SHRN, SHRN2: Shift Right Narrow (immediate).
SHSUB: Signed Halving Subtract.
SLI: Shift Left and Insert (immediate).
SM3PARTW1: SM3PARTW1.
SM3PARTW2: SM3PARTW2.
SM3SS1: SM3SS1.
SM3TT1A: SM3TT1A.
SM3TT1B: SM3TT1B.
SM3TT2A: SM3TT2A.
SM3TT2B: SM3TT2B.
SM4E: SM4 Encode.
SM4EKEY: SM4 Key.
SMAX: Signed Maximum (vector).
S MAXP: Signed Maximum Pairwise.
SMAXV: Signed Maximum across Vector.
SMIN: Signed Minimum (vector).
SMINP: Signed Minimum Pairwise.
SMINV: Signed Minimum across Vector.
SMLSL, SMLSL2 (by element): Signed Multiply-Subtract Long (vector, by element).
SMOV: Signed Move vector element to general-purpose register.
SQABS: Signed saturating Absolute value.
SQADD: Signed saturating Add.
SQDMLSL, SQDMLSL2 (by element): Signed saturating Doubling Multiply-Subtract Long (by element).

SQDMLUL, SQDMLSL2 (by element): Signed saturating Doubling Multiply-Subtract Long (by element).

SQDMLUL (by element): Signed saturating Doubling Multiply-Subtract Long (by element).

SQDMULL, SQDMULL2 (by element): Signed saturating Doubling Multiply Long (by element).

SQNEG: Signed saturating Negate.

SQDMLAH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLAH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQDMLAH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLAH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQDMLUL (by element): Signed saturating Doubling Multiply Long (by element).

SQNEG: Signed saturating Negate.

SQDMLAH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLAH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQDMLAH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLAH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLAH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLAH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLAH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLAH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.

SQDMLALH (by element): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (by element).

SQDMLALH (vector): Signed Saturating Rounding Doubling Multiply-Subtract Multiply returning High half (vector).

SQNEG: Signed saturating Negate.
**ST2 (multiple structures)**: Store multiple 2-element structures from two registers.

**ST2 (single structure)**: Store single 2-element structure from one lane of two registers.

**ST3 (multiple structures)**: Store multiple 3-element structures from three registers.

**ST3 (single structure)**: Store single 3-element structure from one lane of three registers.

**ST4 (multiple structures)**: Store multiple 4-element structures from four registers.

**ST4 (single structure)**: Store single 4-element structure from one lane of four registers.

**STNP (SIMD&FP)**: Store Pair of SIMD&FP registers, with Non-temporal hint.

**STP (SIMD&FP)**: Store Pair of SIMD&FP registers.

**STR (immediate, SIMD&FP)**: Store SIMD&FP register (immediate offset).

**STR (register, SIMD&FP)**: Store SIMD&FP register (register offset).

**STUR (SIMD&FP)**: Store SIMD&FP register (unscaled offset).

**SUB (vector)**: Subtract (vector).

**SUBHN, SUBHN2**: Subtract returning High Narrow.

**SUDOT (by element)**: Dot product with signed and unsigned integers (vector, by element).

**SUQADD**: Signed saturating Accumulate of Unsigned value.

**SXTL, SXTL2**: Signed extend Long: an alias of SSHLL, SSHLL2.

**TBL**: Table vector Lookup.

**TBX**: Table vector lookup extension.

**TRN1**: Transpose vectors (primary).

**TRN2**: Transpose vectors (secondary).

**UABA**: Unsigned Absolute difference and Accumulate.

**UABAL, UABAL2**: Unsigned Absolute difference and Accumulate Long.

**UABD**: Unsigned Absolute Difference (vector).

**UABDL, UABDL2**: Unsigned Absolute Difference Long.

**UADALP**: Unsigned Add and Accumulate Long Pairwise.

**UADDL, UADDL2**: Unsigned Add Long (vector).

**UADDLP**: Unsigned Add Long Pairwise.

**UADDLV**: Unsigned sum Long across Vector.

**UADDDW, UADDW2**: Unsigned Add Wide.

**UCVTF (scalar, fixed-point)**: Unsigned fixed-point Convert to Floating-point (scalar).

**UCVTF (scalar, integer)**: Unsigned integer Convert to Floating-point (scalar).

**UCVTF (vector, fixed-point)**: Unsigned fixed-point Convert to Floating-point (vector).

**UCVTF (vector, integer)**: Unsigned integer Convert to Floating-point (vector).

**UDOT (by element)**: Dot Product unsigned arithmetic (vector, by element).

**UDOT (vector)**: Dot Product unsigned arithmetic (vector).

**UHADD**: Unsigned Halving Add.
UHSUB: Unsigned Halving Subtract.
UMAX: Unsigned Maximum (vector).
UMAXP: Unsigned Maximum Pairwise.
UMAXV: Unsigned Maximum across Vector.
UMIN: Unsigned Minimum (vector).
UMINP: Unsigned Minimum Pairwise.
UMINV: Unsigned Minimum across Vector.
UMLSL, UMLSL2 (by element): Unsigned Multiply-Subtract Long (vector, by element).
UMLSL, UMLSL2 (vector): Unsigned Multiply-Subtract Long (vector).
UMMLA (vector): Unsigned 8-bit integer matrix multiply-accumulate (vector).
UMOV: Unsigned Move vector element to general-purpose register.
UMULL, UMULL2 (by element): Unsigned Multiply Long (vector, by element).
UMULL, UMULL2 (vector): Unsigned Multiply long (vector).
UQADD: Unsigned saturating Add.
UQRSHL: Unsigned saturating Rounding Shift Left (register).
UQRSHRN, UQRSHRN2: Unsigned saturating Rounded Shift Right Narrow (immediate).
UQSHL (immediate): Unsigned saturating Shift Left (immediate).
UQSHL (register): Unsigned saturating Shift Left (register).
UQSHRN, UQSHRN2: Unsigned saturating Shift Right Narrow (immediate).
UQSUB: Unsigned saturating Subtract.
UQXTN, UQXTN2: Unsigned saturating extract Narrow.
URECPE: Unsigned Reciprocal Estimate.
URHADD: Unsigned Rounding Halving Add.
URSHL: Unsigned Rounding Shift Left (register).
URSHR: Unsigned Rounding Shift Right (immediate).
URSORT: Unsigned Reciprocal Square Root Estimate.
URSRA: Unsigned Rounding Shift Right and Accumulate (immediate).
USDOT (by element): Dot Product with unsigned and signed integers (vector, by element).
USDOT (vector): Dot Product with unsigned and signed integers (vector).
USHL: Unsigned Shift Left (register).
USHLL, USHLL2: Unsigned Shift Left Long (immediate).
USHR: Unsigned Shift Right (immediate).
USMMLA (vector): Unsigned and signed 8-bit integer matrix multiply-accumulate (vector).
USQADD: Unsigned saturating Accumulate of Signed value.
USRA: Unsigned Shift Right and Accumulate (immediate).

USUBL, USUBL2: Unsigned Subtract Long.

USUBW, USUBW2: Unsigned Subtract Wide.

UZP1: Unzip vectors (primary).

UZP2: Unzip vectors (secondary).

XAR: Exclusive OR and Rotate.

XTN, XTN2: Extract Narrow.

ZIP1: Zip vectors (primary).

ZIP2: Zip vectors (secondary).
ABS

Absolute value (vector). This instruction calculates the absolute value of each vector element in the source SIMD&FP register, puts the result into a vector, and writes the vector to the destination SIMD&FP register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

```
31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0
0  1  0  1  1  1  1  0  size | 1  0  0  0  0  0  1  0  1  1  1  0  Rn |  Rd
```

Scalar

ASCII 31, 0x0<br>ABS

\[
\text{ABS } <V>d, <V>n
\]

```
integer d = UInt(Rd);
innteger n = UInt(Rn);

</tbody>
</table>

\(<V_n>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
b bits(datasize) operand = \textit{V}[n];
b bits(datasize) result;
integer element;

for e = 0 to elements-1
    \begin{align*}
    element &= \text{SInt} (\text{Elem}[\text{operand}, e, esize]); \\
    \text{if neg then} & \\
    \quad element &= -element; \\
    \text{else} & \\
    \quad element &= \text{Abs}(element); \\
    \text{Elem}[\text{result}, e, esize] &= element^{esize-1:0};
    \end{align*}

\textit{V}[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADD (vector)

Add (vector). This instruction adds corresponding elements in the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

ADD <V><d>, <V><n>, <V><m>

\]

**Operational information**

If \text{PSTATE.DIT} is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADDHN, ADDHN2

Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are truncated. For rounded results, see RADDHN.

The ADDHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the ADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

ADDHN(2)  <Vd>..<Tb>,  <Vn>..<Ta>,  <Vm>.<Ta>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');

Assembler Symbols

2  Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

<table>
<thead>
<tr>
<th>Q</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>[absent]</td>
</tr>
<tr>
<td>1</td>
<td>[present]</td>
</tr>
</tbody>
</table>

<Vd>  Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<Tb>  Is an arrangement specifier, encoded in “size:Q”:

<table>
<thead>
<tr>
<th>size</th>
<th>Q</th>
<th>&lt;Tb&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>00</td>
<td>1</td>
<td>16B</td>
</tr>
<tr>
<td>01</td>
<td>0</td>
<td>4H</td>
</tr>
<tr>
<td>01</td>
<td>1</td>
<td>8H</td>
</tr>
<tr>
<td>10</td>
<td>0</td>
<td>2S</td>
</tr>
<tr>
<td>10</td>
<td>1</td>
<td>4S</td>
</tr>
<tr>
<td>11</td>
<td>x</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

<Vn>  Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta>  Is an arrangement specifier, encoded in “size”:

<table>
<thead>
<tr>
<th>size</th>
<th>&lt;Ta&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>8H</td>
</tr>
<tr>
<td>01</td>
<td>4S</td>
</tr>
<tr>
<td>10</td>
<td>2D</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

<Vm>  Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
Operation

\[

<td>RESERVED</td>
</tr>
<tr>
<td>11</td>
<td>2D</td>
</tr>
</tbody>
</table>

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_ADD, operand, esize);

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**ADDP (vector)**

Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

BFCVT

Floating-point convert from single-precision to BFloat16 format (scalar) converts the single-precision floating-point value in the 32-bit SIMD&FP source register to BFloat16 format and writes the result in the 16-bit SIMD&FP destination register.

Unlike the BFloat16 multiplication instructions, this instruction honors all the control bits in the FPCR that apply to single-precision arithmetic, including the rounding mode. This instruction can generate a floating-point exception that causes a cumulative exception bit in the FPSR to be set, or a synchronous exception to be taken, depending on the enable bits in the FPCR. ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

BFCVTN, BFCVTN2

Floating-point convert from single-precision to BFloat16 format (vector) reads each single-precision element in the SIMD&FP source vector, converts each value to BFloat16 format, and writes the results in the lower or upper half of the SIMD&FP destination vector. The result elements are half the width of the source elements.

The BFCVTN instruction writes the half-width results to the lower half of the destination vector and clears the upper half to zero, while the BFCVTN2 instruction writes the results to the upper half of the destination vector without affecting the other bits in the register.

Unlike the BFloat16 multiplication instructions, this instruction honors all of the control bits in the FPCR that apply to single-precision arithmetic, including the rounding mode. It can also generate a floating-point exception that causes cumulative exception bits in the FPSR to be set, or a synchronous exception to be taken, depending on the enable bits in the FPCR.

BFDOT (by element)

BFloat16 floating-point dot product (vector, by element). This instruction delimits the source vectors into pairs of 16-bit BF16 elements. Each pair of elements in the first source vector is multiplied by the specified pair of elements in the second source vector. The resulting single-precision products are then summed and added destructively to the single-precision element of the destination vector that aligns with the pair of BF16 values in the first source vector. The instruction ignores the FPCR and does not update the FPSR exception status.

The BF16 pair within the second source vector is specified using an immediate index. The index range is from 0 to 3 inclusive. ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

V[d] = result;
BFMMLA

BFLOAT16 floating-point matrix multiply-accumulate into 2x2 matrix. This instruction multiplies the 2x4 matrix of BF16 values held in the first 128-bit source vector by the 4x2 BF16 matrix in the second 128-bit source vector. The resulting 2x2 single-precision matrix product is then added destructively to the 2x2 single-precision matrix in the 128-bit destination vector. This is equivalent to performing a 4-way dot product per destination element. The instruction ignores the FPCR and does not update the FPSR exception status. 

Arm expects that the BFMMLA instruction will deliver a peak BF16 multiply throughput that is at least as high as can be achieved using two BFDOT instructions, with a goal that it should have significantly higher throughput.

BIC (vector, immediate)

Bitwise bit Clear (vector, immediate). This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise AND between each result and the complement of an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
  when ImmediateOp_MOVI
    result = imm;
  when ImmediateOp_MVNI
    result = NOT(imm);
  when ImmediateOp_ORR
    operand = V[rd];
    result = operand OR imm;
  when ImmediateOp_BIC
    operand = V[rd];
    result = operand AND NOT(imm);

V[rd] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**BIC (vector, register)**

Bitwise bit Clear (vector, register). This instruction performs a bitwise AND between the first source SIMD&FP register and the complement of the second source SIMD&FP register, and writes the result to the destination SIMD&FP register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**CLS (vector)**

Count Leading Sign bits (vector). This instruction counts the number of consecutive bits following the most significant bit that are the same as the most significant bit in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The count does not include the most significant bit itself.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    else
        count = CountLeadingZeroBits(Elem[operand, e, esize]);
    Elem[result, e, esize] = count<esize-1:0>;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
CMEQ (register)

Compare bitwise Equal (vector). This instruction compares each vector element from the first source SIMD&FP register with the corresponding vector element from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the \textit{CPACR\_EL1}, \textit{CPTR\_EL2}, and \textit{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: \textit{Scalar} and \textit{Vector}

V[d] = result;
```

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CMGE (register)

Compare signed Greater than or Equal (vector). This instruction compares each vector element in the first source SIMD&FP register with the corresponding vector element in the second source SIMD&FP register and if the first signed integer value is greater than or equal to the second signed integer value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

<table>

    Elem[result, e, esize] = if test_passed then Ones() else Zeros();
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CMHS (register)

Compare unsigned Higher or Same (vector). This instruction compares each vector element in the first source SIMD&FP register with the corresponding vector element in the second source SIMD&FP register and if the first unsigned integer value is greater than or equal to the second unsigned integer value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

</tr>
</tbody>
</table>

For the vector variant: is the number of the SIMD&FP destination register, encoded in the "Rd" field.

For the vector variant: is the name of the SIMD&FP destination register, encoded in the "Rd" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bids(idxdsize) operand = V[n];
bids(datasize) result;
bids(esize) element;

element = Elem[operand, index, esize];
for e = 0 to elements-1
   Elem[result, e, esize] = element;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
DUP (general)

Duplicate general-purpose register to vector. This instruction duplicates the contents of the source general-purpose register into a scalar or each element in a vector, and writes the result to the SIMD&FP destination register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD

DUP <Vd>.,<T>, <R><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;
// imm5<4:size+1> is IGNORED
if size == 3 && Q == '0' then UNDEFINED;
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in “imm5:Q”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>

<tr>
<td>xxx10</td>
<td>W</td>
</tr>
<tr>
<td>xx100</td>
<td>W</td>
</tr>
<tr>
<td>x1000</td>
<td>X</td>
</tr>
</tbody>
</table>

Unspecified bits in "imm5" are ignored but should be set to zero by an assembler.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n];
bits(datasize) result;
for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
EOR3

Three-way Exclusive OR performs a three-way exclusive OR of the values in the three source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when ARMv8.2-SHA is implemented.

Advanced SIMD

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
EXT

Extract vector from pair of vectors. This instruction extracts the lowest vector elements from the second source SIMD&FP register and the highest vector elements from the first source SIMD&FP register, concatenates the results into a vector, and writes the vector to the destination SIMD&FP register vector. The index value specifies the lowest vector element to extract from the first source register, and consecutive elements are extracted from the first, then second, source registers until the destination vector is filled.

The following figure shows an example of the operation of EXT doubleword operation for \( Q = 0 \) and \( \text{imm}4^{<2:0>} = 3 \).

```
\[
\begin{array}{cccccccccccc}
7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
V_m & & & & & & & & V_n & & & & & & & & \\
\end{array}
\]
```

Vd

Depending on the settings in the \texttt{CPACR\_EL1}, \texttt{CPTR\_EL2}, and \texttt{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
\begin{array}{cccccccccccc}
0 & Q & 1 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & Rm & 0 & \text{imm}4 & 0 & Rn & Rd \\
\end{array}
```

### Advanced SIMD

\texttt{EXT <Vd>.<T>, <Vn>.<T>, <Vm>.<T>, #<index>}

integer \( d = \text{UInt}(\text{Rd}); \)
integer \( n = \text{UInt}(\text{Rn}); \)
integer \( m = \text{UInt}(\text{Rm}); \)

if \( Q == '0' \) \&\& \( \text{imm}4^{<3>} == '1' \) then UNDEFINED;

integer datasize = if \( Q == '1' \) then 128 else 64;
integer position = \text{UInt}(\text{imm}4) \ll 3;

</tbody>
</table>

### Assembler Symbols

\(<Vd>\) Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\(<T>\) Is an arrangement specifier, encoded in "Q":

```
\begin{array}{c|c}
Q & <T> \\
0 & 8B \\
1 & 16B \\
\end{array}
```

\(<Vn>\) Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<Vm>\) Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

\(<\text{index}>\) Is the lowest numbered byte element to be extracted, encoded in "Q:imm4":

```
\begin{array}{c|c|c}
Q & \text{imm}4^{<3>} & \text{index} \\
0 & 0 & \text{imm}4^{<2:0>} \\
0 & 1 & \text{RESERVED} \\
1 & \( x \) & \text{imm}4 \\
\end{array}
```

### Operation

```
\texttt{CheckFPAdvSIMDEnabled64();}
\text{bits(datasize) hi} = \text{V}[m];
\text{bits(datasize) lo} = \text{V}[n];
\text{bits(datasize*2) concat} = \text{hi:lo};
\text{V}[d] = \text{concat<position+datasize-1:position>};
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Floating-point Absolute Difference (vector). This instruction subtracts the floating-point values in the elements of the second source SIMD&FP register, from the corresponding floating-point values in the elements of the first source SIMD&FP register, places the absolute value of each result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

case ftype of
  when '00' datasize = 32;
  when '01' datasize = 64;
  when '10' UNDEFINED;
  when '11'
    if HaveFP16Ext() then
      datasize = 16;
    else
      UNDEFINED;

Assembler Symbols

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Dn> Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();

bits(datasize) result;
bits(datasize) operand = V[n];
result = FPAbs(operand);
V[d] = result;
Floating-point Absolute Compare Greater than or Equal (vector). This instruction compares the absolute value of each floating-point value in the first source SIMD&FP register with the absolute value of the corresponding floating-point value in the second source SIMD&FP register and if the first value is greater than or equal to the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

\(V[d] = \text{result}\);
**FACGT**

Floating-point Absolute Compare Greater than (vector). This instruction compares the absolute value of each vector element in the first source SIMD&FP register with the absolute value of the corresponding vector element in the second source SIMD&FP register and if the first value is greater than the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FADD (vector)

Floating-point Add (vector). This instruction adds corresponding vector elements in the two source SIMD&FP registers, writes the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

FADD (scalar)

Floating-point Add (scalar). This instruction adds the floating-point values of the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

bits(datasize) operand2 = V[m];
result = FPAdd(operand1, operand2, FPCR);
V[d] = result;
```

FADDP (scalar)

Floating-point Add Pair of elements (scalar). This instruction adds two floating-point vector elements in the source SIMD&FP register and writes the scalar result into the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

**FADDP (vector)**

Floating-point Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

FCADD

Floating-point Complex Add.
This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with
the more significant element holding the imaginary part of the number and the less significant element holding the
real part of the number. Each element holds a floating-point value. It performs the following computation on the
corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is
  rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in
either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point
exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and
Exception level, an attempt to execute the instruction might be trapped.

  Elem[result, e*2+1, esize] = FPAdd(Elem[operand1, e*2+1, esize], element3, FPCR);

V[d] = result;
FCCMP

Floating-point Conditional quiet Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE.\{N, Z, C, V\} flags. If the condition does not pass then the PSTATE.\{N, Z, C, V\} flags are set to the flag bit specifier.

It raises an Invalid Operation exception only if either operand is a signaling NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<\text{cond}>\quad\text{Is one of the standard conditions, encoded in the "cond" field in the standard way.}

NaNs
The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the **FPSCR** flags being set to N=0, Z=0, C=1, and V=1.

**Operation**

```c
CheckFPAdvSIMEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = V[m];
if ConditionHolds(cond) then
    flags = FPCompare(operand1, operand2, FALSE, FPCR);
PSTATE.<N,Z,C,V> = flags;
```

Copyright © 2010-2019 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
FCCMPE

Floating-point Conditional signaling Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE.\{N, Z, C, V\} flags. If the condition does not pass then the PSTATE.\{N, Z, C, V\} flags are set to the flag bit specifier.

If either operand is any type of NaN, or if either operand is a signaling NaN, the instruction raises an Invalid Operation exception.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**FCMEQ (register)**

Floating-point Compare Equal (vector). This instruction compares each floating-point value from the first source SIMD&FP register, with the corresponding floating-point value from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision, and Vector single-precision and double-precision

    Elem[result, e, esize] = if test_passed then Ones() else Zeros();
V[d] = result;
**FCMEQ (zero)**

Floating-point Compare Equal to zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: **Scalar half precision**, **Scalar single-precision and double-precision**, **Vector half precision** and **Vector single-precision and double-precision**

    Elem[result, e, esize] = if test_passed then Ones() else Zeros();

V[d] = result;
FCMGE (register)

Floating-point Compare Greater than or Equal (vector). This instruction reads each floating-point value in the first source SIMD&FP register and if the value is greater than or equal to the corresponding floating-point value in the second source SIMD&FP register sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    Elem[result, e, esize] = if test_passed then Ones() else Zeros();

V[d] = result;
FCMGE (zero)

Floating-point Compare Greater than or Equal to zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is greater than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

FCMGT (zero)

Floating-point Compare Greater than zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is greater than zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision.

V[d] = result;
**FCMLA (by element)**

Floating-point Complex Multiply Accumulate (by element).

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on complex numbers from the first source register and the destination register with the specified complex number from the second source register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding. This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
FCMLA

Floating-point Complex Multiply Accumulate.
This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with
the more significant element holding the imaginary part of the number and the less significant element holding the
real part of the number. Each element holds a floating-point value. It performs the following computation on the
corresponding complex number element pairs from the two source registers and the destination register:

• Considering the complex number from the second source register on an Argand diagram, the number is
rotated counterclockwise by 0, 90, 180, or 270 degrees.

• The two elements of the transformed complex number are multiplied by:
  ◦ The real element of the complex number from the first source register, if the transformation was a
    rotation by 0 or 180 degrees.
  ◦ The imaginary element of the complex number from the first source register, if the transformation
    was a rotation by 90 or 270 degrees.

• The complex number resulting from that multiplication is added to the complex number from the destination
  register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.
This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in
either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point
exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and
Exception level, an attempt to execute the instruction might be trapped.

FCMLE (zero)

Floating-point Compare Less than or Equal to zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is less than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

      when CompareOp_LT test_passed = FPCompareGT(zero, element, FPCR);
   Elem[result, e, esize] = if test_passed then Ones() else Zeros();

V[d] = result;
Floating-point quiet Compare (scalar). This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the \textit{PSTATE}.\{N, Z, C, V\} flags. It raises an Invalid Operation exception only if either operand is a signaling NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in \textit{FPCR}, the exception results in either a flag being set in \textit{FPSR}, or a synchronous exception being generated. For more information, see \textit{Floating-point exception traps}. Depending on the settings in the \textit{CPACR\_EL1, CPTR\_EL2}, and \textit{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

NaNs
The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1, and V=1.

Operation

```
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = if cmp_with_zero then FPZero('0') else V[m];
PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR);
```

**FCMPE**

Floating-point signaling Compare (scalar). This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the PSTATE. {N, Z, C, V} flags.

If either operand is any type of NaN, or if either operand is a signaling NaN, the instruction raises an Invalid Operation exception.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

```
FCMPE <Dn>, #0.0
```

integer n = UInt(Rn);
integer m = UInt(Rm);  // ignored when opc<0> == '1'

integer datasize;

```sql
case ftype of
  when '00' datasize = 32;
  when '01' datasize = 64;
  when '10' UNDEFINED;
  when '11'
    if HaveFP16Ext() then
      datasize = 16;
    else
      UNDEFINED;
  boolean signal_all_nans = (opc<1> == '1');
  boolean cmp_with_zero = (opc<0> == '1');
```
Assembler Symbols

<Dn>  For the double-precision variant: is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

For the double-precision, zero variant: is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Dm>  Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Hn>  For the half-precision variant: is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

For the half-precision, zero variant: is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Hm>  Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Sn>  For the single-precision variant: is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Sm>  Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

NaNs
The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1, and V=1.

FCMPE raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

Operation

```
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = if cmp_with_zero then FPZero('0') else V[m];
PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR);
```

Floating-point Conditional Select (scalar). This instruction allows the SIMD&FP destination register to take the value from either one or the other of two SIMD&FP source registers. If the condition passes, the first SIMD&FP source register value is taken, otherwise the second SIMD&FP source register value is taken.

Depending on the settings in the \textit{CPACR_EL1}, \textit{CPTR_EL2}, and \textit{CPTR_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- \texttt{<Sm>} Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
- \texttt{<cond>} Is one of the standard conditions, encoded in the "cond" field in the standard way.
Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
result = if ConditionHolds(cond) then V[n] else V[m];
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**FCVT**

Floating-point Convert precision (scalar). This instruction converts the floating-point value in the SIMD&FP source register to the precision for the destination register data type using the rounding mode that is determined by the `FPCR` and writes the result to the SIMD&FP destination register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**FCVTAS (vector)**

Floating-point Convert to Signed integer, rounding to nearest with ties to Away (vector). This instruction converts each element in a vector from a floating-point value to a signed integer value using the Round to Nearest with Ties to Away rounding mode and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: **Scalar half precision**, **Scalar single-precision and double-precision**, **Vector half precision** and **Vector single-precision and double-precision**

### Scalar half precision

FCVTAU (scalar)

Floating-point Convert to Unsigned integer, rounding to nearest with ties to Away (scalar). This instruction converts
the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit unsigned integer using the Round to
Nearest with Ties to Away rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception
results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see
Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and
Exception level, an attempt to execute the instruction might be trapped.

Floating-point Convert to higher precision Long (vector). This instruction reads each element in a vector in the SIMD&FP source register, converts each value to double the precision of the source element using the rounding mode that is determined by the FPCR, and writes each result to the equivalent element of the vector in the SIMD&FP destination register.

Where the operation lengthens a 64-bit vector to a 128-bit vector, the FCVTL2 variant operates on the elements in the top 64 bits of the source register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**FCVTMU (scalar)**

Floating-point Convert to Unsigned integer, rounding toward Minus infinity (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit unsigned integer using the Round towards Minus Infinity rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FCVTN, FCVTN2

Floating-point Convert to lower precision Narrow (vector). This instruction reads each vector element in the SIMD&FP source register, converts each result to half the precision of the source element, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The rounding mode is determined by the FPCR.

The FCVTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the FCVTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Vector single-precision and double-precision

FCVTN(2) <Vd>,<Tb>, <Vn>,<Ta>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16 << UInt(sz);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in "Q":

| Q | 2 |
---|---|
0 | [absent] |
1 | [present] |

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in "sz:Q":

| sz | Q | <Tb> |
---|---|---|
0  | 0 | 4H |
0  | 1 | 8H |
1  | 0 | 2S |
1  | 1 | 4S |

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in "sz":

| sz | <Ta> |
---|---|
0  | 4S |
1  | 2D |
Operation

CheckFPAdvSIMDEnabled64();

bits(2*datasize) operand = V[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = FPConvert(operand, e, 2*esize), FPCR);

Vpart[d, part] = result;
FCVTNS (vector)

Floating-point Convert to Signed integer, rounding to nearest with ties to even (vector). This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round to Nearest rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision.

Scalar half precision (Arm v8.2)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

FCVTNU (scalar)

Floating-point Convert to Unsigned integer, rounding to nearest with ties to even (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit unsigned integer using the Round to Nearest rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.
Half-precision to 32-bit (sf == 0 && ftype == 11) (Armv8.2)

Operation

CheckFPAdvSIMDEnabled64();

bits(fltsize) fltval;
bits(intsize) intval;

fltval = V[n];
intval = FPtoFixed(fltval, 0, TRUE, FPCR, rounding);
X[d] = intval;
FCVTPS (vector)

Floating-point Convert to Signed integer, rounding toward Plus infinity (vector). This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round towards Plus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

X[d] = intval;}
FCVTXN, FCVTXN2

Floating-point Convert to lower precision Narrow, rounding to odd (vector). This instruction reads each vector element in the source SIMD&FP register, narrows each value to half the precision of the source element using the Round to Odd rounding mode, writes the result to a vector, and writes the vector to the destination SIMD&FP register.

This instruction uses the Round to Odd rounding mode which is not defined by the IEEE 754-2008 standard. This rounding mode ensures that if the result of the conversion is inexact the least significant bit of the mantissa is forced to 1. This rounding mode enables a floating-point value to be converted to a lower precision format via an intermediate precision format while avoiding double rounding errors. For example, a 64-bit floating-point value can be converted to a correctly rounded 16-bit floating-point value by first using this instruction to produce a 32-bit value and then using another instruction with the wanted rounding mode to convert the 32-bit value to the final 16-bit floating-point value.

The FCVTXN instruction writes the vector to the lower half of the destination register and clears the upper half, while the FCVTXN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

**FCVTZU (vector, fixed-point)**

Floating-point Convert to Unsigned fixed-point, rounding toward Zero (vector). This instruction converts a scalar or each element in a vector from floating-point to fixed-point unsigned integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see **Floating-point exception traps**.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

**Scalar**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0 |

**FDIV (vector)**

Floating-point Divide (vector). This instruction divides the floating-point values in the elements in the first source SIMD&FP register, by the floating-point values in the corresponding elements in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in *FPCR*, the exception results in either a flag being set in *FPSR*, or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the *CPACR_EL1, CPTR_EL2,* and *CPTR_EL3* registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Half-precision** and **Single-precision and double-precision**

*<Vn>* Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

*<Vm>* Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```plaintext
CheckFPAdvSIMDEnabled64();
```

```plaintext
bits(datasize) operand1 = V[n];

bits(datasize) operand2 = V[m];

bits(datasize) result;

bits(esize) element1;

bits(esize) element2;

for e = 0 to elements-1

   element1 = Elem[operand1, e, esize];
   element2 = Elem[operand2, e, esize];
   Elem[result, e, esize] = FPDIV(element1, element2, FPCR);

V[d] = result;
```
FDIV (scalar)

Floating-point Divide (scalar). This instruction divides the floating-point value of the first source SIMD&FP register by the floating-point value of the second source SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

result = FPDiv(operand1, operand2, FPCR);
V[d] = result;

FDIV (scalar)
FJCVTZS

Floating-point Javascript Convert to Signed fixed-point, rounding toward Zero. This instruction converts the double-precision floating-point value in the SIMD&FP source register to a 32-bit signed integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register. If the result is too large to be accommodated as a signed 32-bit integer, then the result is the integer modulo $2^{32}$, as held in a 32-bit signed integer. This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Assembler Symbols

- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Dn>` Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Dm>` Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
- `<Hd>` Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Hn>` Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Hm>` Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
- `<Sd>` Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Sn>` Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Sm>` Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
Operation

CheckFPAdvSIMDEnabled64();

bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

result = FPMaxNum(operand1, operand2, FPCR);
V[d] = result;
FMAXNMP (scalar)

Floating-point Maximum Number of Pair of elements (scalar). This instruction compares two vector elements in the source SIMD&FP register and writes the largest of the floating-point values as a scalar to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

**Half-precision**

(Armv8.2)

```
0 1 0 1 1 1 1 0 0 0 1 1 0 0 1 0  Rn  Rd

**FMAXNMP (vector)**

Floating-point Maximum Number Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result is the numerical value, otherwise the result is identical to FMAX (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

FMAXV

Floating-point Maximum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision (Armv8.2)

FMAXV <V><d>, <Vn>.<T>

if !HaveFP16Ext() then UNDEFINED;

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16;
integer datasize = if Q == '1' then 128 else 64;

Single-precision and double-precision

FMAXV <V><d>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q != '01' then UNDEFINED;

integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;

Assembler Symbols

FMINNMP (vector)

Floating-point Minimum Number Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of floating-point values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result is the numerical value, otherwise the result is identical to FMIN (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Copyright © 2010-2019 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
**FMINNMV**

Floating-point Minimum Number across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result of the comparison is the numerical value, otherwise the result is identical to \( FMIN(\text{scalar}) \).

This instruction can generate a floating-point exception. Depending on the settings in \( FPSCR \), the exception results in either a flag being set in \( FPSR \) or a synchronous exception being generated. For more information, see **Floating-point exception traps**.

Depending on the settings in the \( CPACR_EL1 \), \( CPTR_EL2 \), and \( CPTR_EL3 \) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Half-precision** and **Single-precision and double-precision**

### Half-precision (Armv8.2)

```
0 Q | 0 | 0 | 1 | 1 | 1 | 0 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0
01
```

### Single-precision and double-precision

```
0 Q | 1 | 0 | 1 | 1 | 1 | 0 | 1 | sz | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0
01
```

**FMINP (vector)**

Floating-point Minimum Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, writes the smaller of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in `FPCR`, the exception results in either a flag being set in `FPSR` or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

FMLA (by element)

Floating-point fused Multiply-Add to accumulator (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the results in the vector elements of the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar, half-precision , Scalar, single-precision and double-precision , Vector, half-precision and Vector, single-precision and double-precision

Scalar, half-precision

FMLS (by element)

Floating-point fused Multiply-Subtract from accumulator (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and subtracts the results from the vector elements of the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in \texttt{FPCR}, the exception results in either a flag being set in \texttt{FPSR} or a synchronous exception being generated. For more information, see \texttt{Floating-point exception traps}.

Depending on the settings in the \texttt{CPACR\_EL1}, \texttt{CPTR\_EL2}, and \texttt{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: \texttt{Scalar, half-precision}, \texttt{Scalar, single-precision and double-precision}, \texttt{Vector, half-precision} and \texttt{Vector, single-precision and double-precision}.

\textbf{Scalar, half-precision (Armv8.2)}

\begin{verbatim}
0 1 0 1 1 1 1 1 0 0 0 0 0 1 0 1 1 1 0 0 0 0 0 0 1 0 1 1 1 0 0 0

FMLS (vector)

Floating-point fused Multiply-Subtract from accumulator (vector). This instruction multiplies corresponding floating-point values in the vectors in the two source SIMD&FP registers, negates the product, adds the result to the corresponding vector element of the destination SIMD&FP register, and writes the result to the destination SIMD&FP register.

A floating-point exception can be generated by this instruction. Depending on the settings in \textit{FPCR}, the exception results in either a flag being set in \textit{FPSR}, or a synchronous exception being generated. For more information, see \textit{Floating-point exception traps}.

Depending on the settings in the \textit{CPACR\_EL1}, \textit{CPTR\_EL2}, and \textit{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: \textit{Half-precision} and \textit{Single-precision and double-precision}

FMLSL, FMLSL2 (by element)

Floating-point fused Multiply-Subtract Long from accumulator (by element). This instruction multiplies the negated vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

ID AA64ISAR0_EL1. FHM indicates whether this instruction is supported.

It has encodings from 2 classes: FMLSL and FMLSL2

FMOV (register)

Floating-point Move register without conversion. This instruction copies the floating-point value in the SIMD&FP source register to the SIMD&FP destination register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FMSUB

Floating-point Fused Multiply-Subtract (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, negates the product, adds that to the value of the third SIMD&FP source register, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPSCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**FMUL (by element)**

Floating-point Multiply (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR** or a synchronous exception being generated. For more information, see **Floating-point exception traps**.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: **Scalar, half-precision**, **Scalar, single-precision and double-precision**, **Vector, half-precision** and **Vector, single-precision and double-precision**

**FMUL (scalar)**

Floating-point Multiply (scalar). This instruction multiplies the floating-point values of the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**FMULX (by element)**

Floating-point Multiply extended (by element). This instruction multiplies the floating-point values in the vector elements in the first source SIMD&FP register by the specified floating-point value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If one value is zero and the other value is infinite, the result is 2.0. In this case, the result is negative if only one of the values is negative, otherwise the result is positive.

This instruction can generate a floating-point exception. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR** or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar, half-precision, Scalar, single-precision and double-precision, Vector, half-precision and Vector, single-precision and double-precision

bits(datasize) operand = V[n];
result = FPNeg(operand);
V[d] = result;
```
Floating-point Negated fused Multiply-Add (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, negates the product, subtracts the value of the third SIMD&FP source register, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Assembler Symbols

- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Dn>` Is the 64-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the "Rn" field.
- `<Dm>` Is the 64-bit name of the second SIMD&FP source register holding the multiplier, encoded in the "Rm" field.
- `<Da>` Is the 64-bit name of the third SIMD&FP source register holding the addend, encoded in the "Ra" field.
- `<Hd>` Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Hn>` Is the 16-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the "Rn" field.
- `<Hm>` Is the 16-bit name of the second SIMD&FP source register holding the multiplier, encoded in the "Rm" field.
<Ha> Is the 16-bit name of the third SIMD&FP source register holding the addend, encoded in the "Ra" field.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Sn> Is the 32-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register holding the multiplier, encoded in the "Rm" field.

<Sa> Is the 32-bit name of the third SIMD&FP source register holding the addend, encoded in the "Ra" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();

bits(datasize) result;
bits(datasize) operanda = V[a];
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

operanda = FPNeg(operanda);
operand1 = FPNeg(operand1);
result = FPMulAdd(operanda, operand1, operand2, FPCR);

V[d] = result;
```

FRECPS

Floating-point Reciprocal Step. This instruction multiplies the corresponding floating-point values in the vectors of the two source SIMD&FP registers, subtracts each of the products from 2.0, places the resulting floating-point values in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPSR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

```

FRINT32X (vector)

Floating-point Round to 32-bit Integer, using current rounding mode (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values that fit into a 32-bit integer size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register. A zero input returns a zero result with the same sign. When one of the result values is not numerically equal to the corresponding input value, an Inexact exception is raised. When an input is infinite, NaN or out-of-range, the instruction returns for the corresponding result value the most negative integer representable in the destination size, and an Invalid Operation floating-point exception is raised.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
**FRINTA (vector)**

Floating-point Round to Integral, to nearest with ties to Away (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the Round to Nearest with Ties to Away rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Half-precision** and **Single-precision and double-precision**

\]

\( V[d] = \text{result}; \)
**FRINTA (scalar)**

Floating-point Round to Integral, to nearest with ties to Away (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the Round to Nearest with Ties to Away rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
  element = Elem[operand, e, esize];
  Elem[result, e, esize] = FPRoundInt(element, FPCR, rounding, exact);

V[d] = result;
FRINTN (scalar)

Floating-point Round to Integral, to nearest with ties to even (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the Round to Nearest rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 1 1 1 1 0 ftype 1 0 0 1 0 0 0 1 0 0 0 0 Rn Rd
```

FRINTZ (scalar)

Floating-point Round to Integral, toward Zero (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**FSUB (vector)**

Floating-point Subtract (vector). This instruction subtracts the elements in the vector in the second source SIMD&FP register, from the corresponding elements in the vector in the first source SIMD&FP register, places each result into elements of a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see **Floating-point exception traps**.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Half-precision** and **Single-precision and double-precision**

### Half-precision

**FSUB** <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

```
if !HaveFP16Ext() then UNDEFINED;

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 16;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean abs = (U == '1');
```

### Single-precision and double-precision

**FSUB** <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz:Q == '10' then UNDEFINED;
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean abs = (U == '1');
```

### Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<**T**> For the half-precision variant: is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4H</td>
</tr>
<tr>
<td>1</td>
<td>8H</td>
</tr>
</tbody>
</table>

For the single-precision and double-precision variant: is an arrangement specifier, encoded in "sz:Q":

<table>
<thead>
<tr>
<th>sz:Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td></td>
</tr>
<tr>
<td>01</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td></td>
</tr>
</tbody>
</table>
<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) diff;
for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    diff = FPSub(element1, element2, FPCR);
    Elem[result, e, esize] = if abs then FPAbs(diff) else diff;
V[d] = result;
```

FSUB (scalar)

Floating-point Subtract (scalar). This instruction subtracts the floating-point value of the second source SIMD&FP register from the floating-point value of the first source SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 0 0 1 1 1 0 ftype 1  Rm 0 0 1 1 1 0  Rd
```

Half-precision (ftype == 11)  
(Armv8.2)

FSUB <Hd>, <Hn>, <Hm>

Single-precision (ftype == 00)

FSUB <Sd>, <Sn>, <Sm>

Double-precision (ftype == 01)

FSUB <Dd>, <Dn>, <Dm>

```plaintext
define d = UInt(Rd);
define n = UInt(Rn);
define m = UInt(Rm);

define datasize;
case ftype of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '10' UNDEFINED;
    when '11'
        if HaveFP16Ext() then
data size = 16;
        else
            UNDEFINED;
```

Assembler Symbols

- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Dn>` Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Dm>` Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
- `<Hd>` Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Hn>` Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Hm>` Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
- `<Sd>` Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

INS (element)

Insert vector element from another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (element).

Advanced SIMD

INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;

integer dst_index = UInt(imm5<4:size+1>);
integer src_index = UInt(imm5<4:size+1>);
integer idxdsize = if imm4<3> == '1' then 128 else 64;
// imm4<size-1:0> is IGNORED

integer esize = 8 << size;

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<index1> Is the destination element index encoded in “imm5”:

```
imm5  <index1>
0000   RESERVED
xxx1   B
xxx10  H
xx100  S
x1000  D
```

<index2> Is the source element index encoded in “imm5:imm4”:

```
imm5  <index2>
0000   RESERVED
xxx1   imm5<4:1>
xxx10  imm5<4:2>
xx100  imm5<4:3>
x1000  imm5<4>
```

Unspecified bits in “imm4” are ignored but should be set to zero by an assembler.
Operation

```
CheckFPAdvSIMDEnabled64();
bits(idxsize) operand = V[n];
bits(128) result;

result = V[d];
Elem[result, dst_index, esize] = Elem[operand, src_index, esize];
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:
  • The execution time of this instruction is independent of:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
  • The response of this instruction to asynchronous exceptions does not vary based on:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
**INS (general)**

Insert vector element from general-purpose register. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register. This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (from general).

---

### Advanced SIMD

**INS <Vd><Ts>[<index>], <R><n>**

```plaintext
d integer d = UInt(Rd);
n integer n = UInt(Rn);
size integer size = LowestSetBit(imm5);
if size > 3 then UNDEFINED;
index integer index = UInt(imm5<4:size+1>);
size esize = 8 << size;
```

---

### Assembler Symbols

- **<Vd>** Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<Ts>** Is an element size specifier, encoded in “imm5”:
  - **imm5**<Ts>:
    - x0000: RESERVED
    - xxx1: B
    - xxx10: H
    - xx100: S
    - x1000: D
- **<index>** Is the element index encoded in “imm5”:
  - **imm5**<index>:
    - x0000: RESERVED
    - xxx1: imm5<4:1>
    - xxx10: imm5<4:2>
    - xx100: imm5<4:3>
    - x1000: imm5<4>
- **<R>** Is the width specifier for the general-purpose source register, encoded in “imm5”:
  - **imm5**<R>:
    - x0000: RESERVED
    - xxx1: W
    - xxx10: W
    - xx100: W
    - x1000: X
- **<n>** Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the “Rn” field.
**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n];
bits(128) result;

result = V[d];
Elem[result, index, esize] = element;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**LD1 (multiple structures)**

Load multiple single-element structures to one, two, three, or four registers. This instruction loads multiple single-element structures from memory and writes the result to one, two, three, or four SIMD&FP registers. Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **No offset** and **Post-index**

**No offset**

    else
        X[n] = address + offs;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LD1 (single structure)

Load one single-element structure to one lane of one register. This instruction loads a single-element structure from memory and writes the result to the specified lane of the SIMD&FP register without affecting the other bits of the register.

Depending on the settings in the \texttt{CPACR\_EL1}, \texttt{CPTR\_EL2}, and \texttt{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: \texttt{No offset} and \texttt{Post-index}

\textbf{No offset}

    else
        X[n] = address + offs;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LD1R

Load one single-element structure and Replicate to all lanes (of one register). This instruction loads a single-element structure from memory and replicates the structure to all the lanes of the SIMD&FP register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

### Operands

<table>
<thead>
<tr>
<th>Rm</th>
<th>size</th>
<th>Rn</th>
<th>Rt</th>
</tr>
</thead>
<tbody>
<tr>

<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

#### No offset

LD1R {<Vt>..<T>}, [<Xn|SP>]

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
boolean tag_checked = wback || n != 31;

#### Post-index

### Immediate offset (Rm == 11111)

LD1R {<Vt>..<T>}, [<Xn|SP>], <imm>

### Register offset (Rm != 11111)

LD1R {<Vt>..<T>}, [<Xn|SP>], <Xm>

#### Assembler Symbols

- `<Vt>` is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<T>` is an arrangement specifier, encoded in "size:Q":
  
<table>
<thead>
<tr>
<th>size</th>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>00</td>
<td>1</td>
<td>16B</td>
</tr>
<tr>
<td>01</td>
<td>0</td>
<td>4H</td>
</tr>
<tr>
<td>01</td>
<td>1</td>
<td>8H</td>
</tr>
<tr>
<td>10</td>
<td>0</td>
<td>2S</td>
</tr>
<tr>
<td>10</td>
<td>1</td>
<td>4S</td>
</tr>
<tr>
<td>11</td>
<td>0</td>
<td>1D</td>
</tr>
<tr>
<td>11</td>
<td>1</td>
<td>2D</td>
</tr>
</tbody>
</table>

- `<Xn|SP>` is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm> Is the post-index immediate offset, encoded in “size”:

<table>
<thead>
<tr>
<th>size</th>
<th>&lt;imm&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>#1</td>
</tr>
<tr>
<td>01</td>
<td>#2</td>
</tr>
<tr>
<td>10</td>
<td>#4</td>
</tr>
<tr>
<td>11</td>
<td>#8</td>
</tr>
</tbody>
</table>

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

**Shared Decode**

```plaintext

EndIf

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LD2 (multiple structures)

Load multiple 2-element structures to two registers. This instruction loads multiple 2-element structures from memory and writes the result to the two SIMD&FP registers, with de-interleaving.

For an example of de-interleaving, see LD3 (multiple structures).

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

**No offset**

LD2R

Load single 2-element structure and Replicate to all lanes of two registers. This instruction loads a 2-element structure from memory and replicates the structure to all the lanes of the two SIMD&FP registers. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |

|-----------------------------------------------|----------------|----------------|
| L | R | opcode | S               |

Immediate offset (Rm == 11111)

LD2R { <Vt>, <Vt2>, [Xn|SP] }, [imm]

Register offset (Rm != 11111)

LD2R { <Vt>, <Vt2>, [Xn|SP] }, [imm]

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
boolean tag_checked = wback || n != 31;

Assembler Symbols

<vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

<T> Is an arrangement specifier, encoded in "size:Q":

<table>
<thead>
<tr>
<th>size</th>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>00</td>
<td>1</td>
<td>16B</td>
</tr>
<tr>
<td>01</td>
<td>0</td>
<td>4H</td>
</tr>
<tr>
<td>01</td>
<td>1</td>
<td>8H</td>
</tr>
<tr>
<td>10</td>
<td>0</td>
<td>2S</td>
</tr>
<tr>
<td>10</td>
<td>1</td>
<td>4S</td>
</tr>
<tr>
<td>11</td>
<td>0</td>
<td>1D</td>
</tr>
<tr>
<td>11</td>
<td>1</td>
<td>2D</td>
</tr>
</tbody>
</table>

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.
Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Is the post-index immediate offset, encoded in “size”:

<table>
<thead>
<tr>
<th>size</th>
<th>&lt;imm&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>#2</td>
</tr>
<tr>
<td>01</td>
<td>#4</td>
</tr>
<tr>
<td>10</td>
<td>#8</td>
</tr>
<tr>
<td>11</td>
<td>#16</td>
</tr>
</tbody>
</table>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

### Shared Decode

```plaintext
text
```
if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

CheckFPAdvSIMDEnabled64();

bits(64) address;
bits(64) offs;
bits(128) rval;
bits(esize) element;
constant integer ebytes = esize DIV 8;

    address = SP[];
else
    address = X[n];

offs = Zeros();
if replicate then
    // load and replicate to all elements
    for s = 0 to selem-1
        element = Mem[address+offs, ebytes, AccType_VEC];
        offs = offs + ebytes;
        t = (t + 1) MOD 32;
else
    // load/store one element per register
    for s = 0 to selem-1
        rval = V[t];
        if memop == MemOp_LOAD then
            // insert into one lane of 128-bit register
            Elem[rval, index, esize] = Mem[address+offs, ebytes, AccType_VEC];
        else
            // memop == MemOp_STORE
            // extract from one lane of 128-bit register
            Mem[address+offs, ebytes, AccType_VEC] = Elem[rval, index, esize];
        offs = offs + ebytes;
        t = (t + 1) MOD 32;

if wback then
    if m != 31 then
        offs = X[m];
    if n == 31 then
        SP[] = address + offs;
    else
        X[n] = address + offs;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LD3 (multiple structures)

Load multiple 3-element structures to three registers. This instruction loads multiple 3-element structures from memory and writes the result to the three SIMD&FP registers, with de-interleaving.

The following figure shows an example of the operation of de-interleaving of a LD3.16 (multiple 3-element structures) instruction:

A is a packed array of 3-element structures.
Each element is a 16-bit halfword.

Depending on the settings in the *CPACR_EL1, CPTR_EL2*, and *CPTR_EL3* registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **No offset** and **Post-index**

**No offset**

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LD4 (multiple structures)

Load multiple 4-element structures to four registers. This instruction loads multiple 4-element structures from memory and writes the result to the four SIMD&FP registers, with de-interleaving.

For an example of de-interleaving, see LD3 (multiple structures).

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDNP (SIMD&FP)**

Load Pair of SIMD&FP registers, with Non-temporal hint. This instruction loads a pair of SIMD&FP registers from memory, issuing a hint to the memory system that the access is non-temporal. The address that is used for the load is calculated from a base register value and an optional immediate offset.

For information about non-temporal pair instructions, see *[Load/Store SIMD and Floating-point Non-temporal pair](#)*. Depending on the settings in the *CPACR_EL1, CPTR_EL2*, and *CPTR_EL3* registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler Symbols

- `<Bt>` Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<Dt>` Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<Ht>` Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<Qt>` Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<St>` Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<Wm>` When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<Xm>` When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<extend>` For the 8-bit variant: is the index extend specifier, encoded in "option";
For the 128-bit, 16-bit, 32-bit and 64-bit variant: is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

<amount> For the 8-bit variant: is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

For the 16-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#1</td>
</tr>
</tbody>
</table>

For the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#2</td>
</tr>
</tbody>
</table>

For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#3</td>
</tr>
</tbody>
</table>

For the 128-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#4</td>
</tr>
</tbody>
</table>

Shared Decode

integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
MemOp memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = 8 << scale;
boolean tag_checked = memop != MemOp_PREFETCH;

        V[t] = data;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDUR (SIMD&FP)

Load SIMD&FP Register (unscaled offset). This instruction loads a SIMD&FP register from memory. The address that is used for the load is calculated from a base register value and an optional immediate offset. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

V[d] = result;
Operational information

If PSTATE.DT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (scalar)

Move vector element to scalar. This instruction duplicates the specified vector element in the SIMD&FP source register into a scalar, and writes the result to the SIMD&FP destination register. Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of `DUP (element)`. This means:

- The encodings in this description are named to match the encodings of `DUP (element)`.
- The description of `DUP (element)` gives the operational pseudocode for this instruction.

Scalar

MOV `<V>`<d>, `<Vn>`.<`T`>[`<index>`]

is equivalent to

DUP `<V>`<d>, `<Vn>`.<`T`>[`<index>`]

and is always the preferred disassembly.

Assembler Symbols

`<V>` Is the destination width specifier, encoded in “imm5”:

<table>
<thead>
<tr>
<th><code>imm5</code></th>
<th><code>&lt;V&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>B</td>
</tr>
<tr>
<td>xxx10</td>
<td>H</td>
</tr>
<tr>
<td>xx100</td>
<td>S</td>
</tr>
<tr>
<td>x1000</td>
<td>D</td>
</tr>
</tbody>
</table>

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<T>` Is the element width specifier, encoded in “imm5”:

<table>
<thead>
<tr>
<th><code>imm5</code></th>
<th><code>&lt;T&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>B</td>
</tr>
<tr>
<td>xxx10</td>
<td>H</td>
</tr>
<tr>
<td>xx100</td>
<td>S</td>
</tr>
<tr>
<td>x1000</td>
<td>D</td>
</tr>
</tbody>
</table>

`<index>` Is the element index encoded in “imm5”:

<table>
<thead>
<tr>
<th><code>imm5</code></th>
<th><code>&lt;index&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td><code>imm5&lt;4:1&gt;</code></td>
</tr>
<tr>
<td>xxx10</td>
<td><code>imm5&lt;4:2&gt;</code></td>
</tr>
<tr>
<td>xx100</td>
<td><code>imm5&lt;4:3&gt;</code></td>
</tr>
<tr>
<td>x1000</td>
<td><code>imm5&lt;4&gt;</code></td>
</tr>
</tbody>
</table>

Operation

The description of `DUP (element)` gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
The values of the data supplied in any of its registers.

The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (element)

Move vector element to another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register. This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of INS (element). This means:

- The encodings in this description are named to match the encodings of INS (element).
- The description of INS (element) gives the operational pseudocode for this instruction.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 | 1 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | imm5 | 0 | imm4 | 1 | Rn | Rd

Advanced SIMD

MOV <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

is equivalent to

INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

and is always the preferred disassembly.

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Ts> Is an element size specifier, encoded in “imm5”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>&lt;Ts&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>B</td>
</tr>
<tr>
<td>xxx10</td>
<td>H</td>
</tr>
<tr>
<td>xx100</td>
<td>S</td>
</tr>
<tr>
<td>x1000</td>
<td>D</td>
</tr>
</tbody>
</table>

<index1> Is the destination element index encoded in “imm5”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>&lt;index1&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>imm5&lt;4:1&gt;</td>
</tr>
<tr>
<td>xxxx10</td>
<td>imm5&lt;4:2&gt;</td>
</tr>
<tr>
<td>xx100</td>
<td>imm5&lt;4:3&gt;</td>
</tr>
<tr>
<td>x1000</td>
<td>imm5&lt;4&gt;</td>
</tr>
</tbody>
</table>

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<index2> Is the source element index encoded in “imm5:imm4”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>&lt;index2&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>imm4&lt;3:0&gt;</td>
</tr>
<tr>
<td>xxxx10</td>
<td>imm4&lt;3:1&gt;</td>
</tr>
<tr>
<td>xx100</td>
<td>imm4&lt;3:2&gt;</td>
</tr>
<tr>
<td>x1000</td>
<td>imm4&lt;3&gt;</td>
</tr>
</tbody>
</table>

Unspecified bits in “imm4” are ignored but should be set to zero by an assembler.

Operation

The description of INS (element) gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

MOV (from general)

Move general-purpose register to a vector element. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of INS (general). This means:

- The encodings in this description are named to match the encodings of INS (general).
- The description of INS (general) gives the operational pseudocode for this instruction.

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

Advanced SIMD

MOV <Vd>.<Ts>[<index>], <R><n>

is equivalent to

INS <Vd>.<Ts>[<index>], <R><n>

and is always the preferred disassembly.

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ts> Is an element size specifier, encoded in “imm5”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>&lt;Ts&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>B</td>

<td>imm5&lt;4:2&gt;</td>
</tr>
<tr>
<td>xx100</td>
<td>imm5&lt;4:3&gt;</td>
</tr>
<tr>
<td>x1000</td>
<td>imm5&lt;4&gt;</td>
</tr>
</tbody>
</table>

<R> Is the width specifier for the general-purpose source register, encoded in “imm5”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>W</td>
</tr>
<tr>
<td>xxx10</td>
<td>W</td>
</tr>
<tr>
<td>xx100</td>
<td>W</td>
</tr>
<tr>
<td>x1000</td>
<td>X</td>
</tr>
</tbody>
</table>

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the “Rn” field.

Operation

The description of INS (general) gives the operational pseudocode for this instruction.
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**MOV (vector)**

Move vector. This instruction copies the vector in the source SIMD&FP register into the destination SIMD&FP register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of `ORR (vector, register)`. This means:

- The encodings in this description are named to match the encodings of `ORR (vector, register)`.`
- The description of `ORR (vector, register)` gives the operational pseudocode for this instruction.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Q  | 0  | 0  | 1  | 1  | 0  | 1  | 0  | 1  | Rm | 0  | 0  | 0  | 1  | 1  | 1  | Rn | 1  | Rd |

### Three registers of the same type

MOV `<Vd>`. `<T>`, `<Vn>`. `<T>`

is equivalent to

`ORR `<Vd>`. `<T>`, `<Vn>`. `<T>`, `<Vn>`. `<T>`

and is the preferred disassembly when `Rm == Rn`.

### Assembler Symbols

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in "Q":
  - `Q `<T>
    - 0 | 8B
    - 1 | 16B
- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

### Operation

The description of `ORR (vector, register)` gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**MOV (to general)**

Move vector element to general-purpose register. This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of `UMOV`. This means:

- The encodings in this description are named to match the encodings of `UMOV`.
- The description of `UMOV` gives the operational pseudocode for this instruction.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Q  | 0  | 1  | 1  | 0  | 0  | 0  | 0  | x  | x  | x  | 0  | 0  | 0  | 0  | 1  | 1  | 1  | 1  | Rn | Rd |

**32-bit (Q == 0 && imm5 == xx100)**

MOV `<Wd>`, `<Vn>.S[<index>]`

is equivalent to

UMOV `<Wd>`, `<Vn>.S[<index>]`

and is always the preferred disassembly.

**64-reg,UMOV-64-reg (Q == 1 && imm5 == x1000)**

MOV `<Xd>`, `<Vn>.D[<index>]`

is equivalent to

UMOV `<Xd>`, `<Vn>.D[<index>]`

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- `<index>` For the 32-bit variant: is the element index encoded in "imm5<4:3>".
  For the 64-reg,UMOV-64-reg variant: is the element index encoded in "imm5<4>".

**Operation**

The description of `UMOV` gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Move Immediate (vector). This instruction places an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

  when '10x10' operation = ImmediateOp_ORR;
  when '10x11' operation = ImmediateOp_BIC;
  when '110x0' operation = ImmediateOp_MOVI;
  when '110x1' operation = ImmediateOp_MVNI;
  when '1110x' operation = ImmediateOp_MOVI;
  when '11110' operation = ImmediateOp_MOVI;
  when '11111' operation = ImmediateOp_MOVI;

  // FMOV Dn,#imm is in main FP instruction set
  if op == '0' then UNDEFINED;
  operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```
Assembler Symbols

<DD> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<imm> Is a 64-bit immediate 'aaaaaaaaabbbbbbbbbccccccccdceddddeeeefgggggghhhhhhh', encoded in "a:b:c:e:f:g:h".

<T> For the 8-bit variant: is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>1</td>
<td>16B</td>
</tr>
</tbody>
</table>

For the 16-bit variant: is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4H</td>
</tr>
<tr>
<td>1</td>
<td>8H</td>
</tr>
</tbody>
</table>

For the 32-bit variant: is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>25H</td>
</tr>
<tr>
<td>1</td>
<td>45H</td>
</tr>
</tbody>
</table>

<imm8> Is an 8-bit immediate encoded in "a:b:c:e:f:g:h".

<amount> For the 16-bit shifted immediate variant: is the shift amount encoded in "cmode<1>":

<table>
<thead>
<tr>
<th>cmode&lt;1&gt;</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>

case operation of
  when ImmediateOp_MOVI
    result = imm;
  when ImmediateOp_MVNI
    result = NOT(imm);
  when ImmediateOp_ORR
    operand = V[rd];
    result = operand OR imm;
  when ImmediateOp_BIC
    operand = V[rd];
    result = operand AND NOT(imm);

V[rd] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MUL (by element)

Multiply (vector, by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  if poly then
    product = PolynomialMult(element1, element2)<esize-1:0>;
  else
    product = (UInt(element1)*UInt(element2))<esize-1:0>;
  Elem[result, e, esize] = product;
V[d] = result;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MVN

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of NOT. This means:

- The encodings in this description are named to match the encodings of NOT.
- The description of NOT gives the operational pseudocode for this instruction.

### Vector

MVN <Vd>.<T>, <Vn>.<T>

is equivalent to

NOT <Vd>.<T>, <Vn>.<T>

and is always the preferred disassembly.

### Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>1</td>
<td>16B</td>
</tr>
</tbody>
</table>

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

### Operation

The description of NOT gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**MVNI**

Move inverted Immediate (vector). This instruction places the inverse of an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

### 16-bit shifted immediate (cmode == 10x0)

MVNI `<Vd>.<T>, #<imm8>{, LSL #<amount>}`

### 32-bit shifted immediate (cmode == 0xx0)

MVNI `<Vd>.<T>, #<imm8>{, LSL #<amount>}`

### 32-bit shifting ones (cmode == 110x)

MVNI `<Vd>.<T>, #<imm8>, MSL #<amount>`

```plaintext
type integer rd = UInt(Rd);

type integer datasize = if Q == '1' then 128 else 64;

type bits(datasize) imm;

type bits(64) imm64;

enum ImmediateOp operation;

case cmode:op of
  when '0xx01' operation = ImmediateOp_MVNI;
  when '0xx11' operation = ImmediateOp_BIC;
  when '10x01' operation = ImmediateOp_MVNI;
  when '10x11' operation = ImmediateOp_BIC;
  when '110x1' operation = ImmediateOp_MVNI;
  when '1110x' operation = ImmediateOp_MOVI;
  when '11111' operation = ImmediateOp_MOVI;

  // FMOV Dn,#imm is in main FP instruction set
  if Q == '0' then UNDEFINED;

  operation = ImmediateOp_MOVI;

  imm64 = AdvSIMDEncodeImm(op, cmode, a:b:c:d:e:f:g:h);

  imm = Replicate(imm64, datasize DIV 64);
```

### Assembler Symbols

- `<Vd>` is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` For the 16-bit variant: is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th><code>&lt;T&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4H</td>
</tr>
<tr>
<td>1</td>
<td>8H</td>
</tr>
</tbody>
</table>

For the 32-bit variant: is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th><code>&lt;T&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2S</td>
</tr>
<tr>
<td>1</td>
<td>4S</td>
</tr>
</tbody>
</table>

- `<imm8>` Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".
- `<amount>` For the 16-bit shifted immediate variant: is the shift amount encoded in "cmode<1>":
For the 32-bit shifted immediate variant: is the shift amount encoded in “cmode<2:1>”:

<table>
<thead>
<tr>
<th>cmode&lt;2:1&gt;</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
</tr>
<tr>
<td>01</td>
<td>8</td>
</tr>
<tr>
<td>10</td>
<td>16</td>
</tr>
<tr>
<td>11</td>
<td>24</td>
</tr>
</tbody>
</table>

defaulting to 0 if LSL is omitted.

For the 32-bit shifting ones variant: is the shift amount encoded in “cmode<0>”:

<table>
<thead>
<tr>
<th>cmode&lt;0&gt;</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
</tr>
<tr>
<td>1</td>
<td>16</td>
</tr>
</tbody>
</table>

defaulting to 0 if LSL is omitted.

Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);
    when ImmediateOp_ORR
        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);

V[rd] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
NEG (vector)

Negate (vector). This instruction reads each vector element from the source SIMD&FP register, negates each value, puts the result into a vector, and writes the vector to the destination SIMD&FP register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 1 1 1 1 1 1 0 size 1 0 0 0 0 0 1 0 1 1 1 0 Rd
Rn

Scalar

NEG <V>d, <V>n

integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean neg = (U == '1');

Vector

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 1 1 1 1 1 0 size 1 0 0 0 0 0 1 0 1 1 1 0 Rd
Rn

Vector

NEG <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean neg = (U == '1');

Assembler Symbols

<V> Is a width specifier, encoded in “size”:

<table>
<thead>
<tr>
<th>size</th>
<th>&lt;V&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x</td>
<td>RESERVED</td>
</tr>
<tr>
<td>10</td>
<td>RESERVED</td>
</tr>
<tr>
<td>11</td>
<td>D</td>
</tr>
</tbody>
</table>

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in “size:Q”: 
<table>
<thead>
<tr>
<th>size</th>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>00</td>
<td>1</td>
<td>16B</td>

<tr>
<td>10</td>
<td>1</td>
<td>4S</td>
</tr>
<tr>
<td>11</td>
<td>0</td>
<td>RESERVED</td>
</tr>
<tr>
<td>11</td>
<td>1</td>
<td>2D</td>
</tr>
</tbody>
</table>

<Vn>  Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;

for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    Elem[result, e, esize] = element<esize-1:0>;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**NOT**

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register. Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MVN.

![Vector NOT](#)

### Assembler Symbols

```

32-bit (cmode == 0xx1)

```
ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

### Assembler Symbols

- `<Vd>` is the name of the SIMD&FP register, encoded in the "Rd" field.
- `<T>` is an arrangement specifier, encoded in “Q”:
  - For the 16-bit variant:
    ```
    Q <T>
    0  4H
    1  8H
    ```
  - For the 32-bit variant:
    ```
    Q <T>
    0  2S
    1  4S
    ```
- `<imm8>` is an 8-bit immediate encoded in “a:b:c:d:e:f:g:h”.
- `<amount>` is the shift amount encoded in “cmode<1>”:
  - For the 16-bit variant:
    ```
    cmode<1> <amount>
    0  0
    1  8
    ```
  - For the 32-bit variant:
    ```
    cmode<2:1> <amount>
    ```
### Operation

```plaintext
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
  when ImmediateOp_MOVI
    result = imm;
  when ImmediateOp_MVNI
    result = NOT(imm);
  when ImmediateOp_ORR
    operand = V[rd];
    result = operand OR imm;
  when ImmediateOp_BIC
    operand = V[rd];
    result = operand AND NOT(imm);

V[rd] = result;
```

### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**ORR (vector, register)**

Bitwise inclusive OR (vector, register). This instruction performs a bitwise OR between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (vector).

bits(dataSize) operand1 = V[n];
bits(dataSize) operand2 = V[m];
result = operand1 OR operand2;
V[d] = result;
```

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
PMUL

Polynomial Multiply. This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

For information about multiplying polynomials see Polynomial arithmetic over \{0, 1\}.

Depending on the settings in the \texttt{CPACR_EL1}, \texttt{CPTR_EL2}, and \texttt{CPTR_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type

\texttt{PMUL \langle Vd\rangle.<T>, \langle Vn\rangle.<T>, \langle Vm\rangle.<T>}

integer \(d = \texttt{UInt}(Rd)\);
integer \(n = \texttt{UInt}(Rn)\);

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
PMULL, PMULL2

Polynomial Multiply Long. This instruction multiplies corresponding elements in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

For information about multiplying polynomials see *Polynomial arithmetic over \{0, 1\}*. The PMULL instruction extracts each source vector from the lower half of each source register, while the PMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the *CPACR_EL1, CPTR_EL2*, and *CPTR_EL3* registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    Elem[result, e, 2*esize] = PolynomialMult(element1, element2);
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
RADDHN, RADDHN2

Rounding Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The results are rounded. For truncated results, see ADDHN.

The RADDHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
RAX1

Rotate and Exclusive OR rotates each 64-bit element of the 128-bit vector in a source SIMD&FP register left by 1, performs a bitwise exclusive OR of the resulting 128-bit vector and the vector in another source SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when ARMv8.2-SHA is implemented.

Advanced SIMD
(Armv8.2)

RSHRN, RSHRN2

Rounding Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the vector in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see \textit{SHRN}.

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the \textit{CPACR\_EL1, CPTR\_EL2}, and \textit{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

</tbody>
</table>

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;
Vpart[d, part] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
RSUBHN, RSUBHN2

Rounding Subtract returning High Narrow. This instruction subtracts each vector element of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see SUBHN.

The RSUBHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSUBHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Three registers, not all the same type

  absdiff = Abs(element1-element2)<2*esize-1:0>;
  Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + absdiff;
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Signed Add and Accumulate Long Pairwise. This instruction adds pairs of adjacent signed integer values from the vector in the source SIMD&FP register and accumulates the results into the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SCVTF (vector, fixed-point)

Signed fixed-point Convert to Floating-point (vector). This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the \texttt{FPCR}, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in \texttt{FPCR}, the exception results in either a flag being set in \texttt{FPSR}, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the \texttt{CPACR_EL1}, \texttt{CPTR_EL2}, and \texttt{CPTR_EL3} registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

</tr>
</tbody>
</table>

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
  element = Elem[operand, e, esize];
  Elem[result, e, esize] = FixedToFP(element, fracbits, unsigned, FPCR, rounding);
V[d] = result;
SCVTF (vector, integer)

Signed integer Convert to Floating-point (vector). This instruction converts each element in a vector from signed integer to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

**Scalar half precision**

```

**Assembler Symbols**

- `<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Hd>` Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Sd>` Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
Operation

`CheckFPAdvSIMDEnabled64();`

`bits(fltsize) fltval;`
`bits(intsize) intval;`

`intval = X[n];`
`fltval = FixedToFP(intval, 0, FALSE, FPCR, rounding);`
`V[d] = fltval;`
SDOT (by element)

Dot Product signed arithmetic (vector, by element). This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an **OPTIONAL** instruction. From Armv8.4 it is mandatory for all implementations to support it.

`ID_AA64ISAR0_EL1`.DP indicates whether this instruction is supported.

**Vector (Armv8.2)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0   | Q  | 0  | 1  | 1  | 1  | 1  | size | L  | M  | Rm  | 1  | 1  | 1  | 0  | H  | 0  | Rn  | Rd |

**Vector**

`SDOT <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.4B[<index>]`

- if !HaveDOTPExt() then UNDEFINED;
- if size != '10' then UNDEFINED;
- boolean signed = (U == '0');

integer n = UInt(Rn);
integer m = UInt(M:Rm);
integer index = UInt(H:L);

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

**Assembler Symbols**

- `<Vd>` Is the name of the SIMD&FP third source and destination register, encoded in the "Rd" field.
- `<Ta>` Is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th><code>&lt;Ta&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2S</td>
</tr>
<tr>
<td>1</td>
<td>4S</td>
</tr>
</tbody>
</table>

- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Tb>` Is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th><code>&lt;Tb&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>1</td>
<td>16B</td>
</tr>
</tbody>
</table>

- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "M:Rm" fields.
- `<index>` Is the element index, encoded in the "H:L" fields.
Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(128) operand2 = V[m];
bits(datasize) result = V[d];
for e = 0 to elements-1
    integer res = 0;
    integer element1, element2;
    for i = 0 to 3
        if signed then
            element1 = SInt(Elem[operand1, 4*e+i, esize DIV 4]);
            element2 = SInt(Elem[operand2, 4*index+i, esize DIV 4]);
        else
            element1 = UInt(Elem[operand1, 4*e+i, esize DIV 4]);
            element2 = UInt(Elem[operand2, 4*index+i, esize DIV 4]);
        res = res + element1 * element2;
    Elem[result, e, esize] = Elem[result, e, esize] + res;
V[d] = result;
```
**SDOT (vector)**

Dot Product signed arithmetic (vector). This instruction performs the dot product of the four signed 8-bit elements in each 32-bit element of the first source register with the four signed 8-bit elements of the corresponding 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

Depending on the settings in the \textit{CPACR\_EL1, CPTR\_EL2,} and \textit{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an \textit{OPTIONAL} instruction. From Armv8.4 it is mandatory for all implementations to support it.

\textit{ID\_AA64ISAR0\_EL1}.DP indicates whether this instruction is supported.

SHA512SU1

SHA512 Schedule Update 1 takes the values from the three source SIMD&FP registers and produces a 128-bit output value that combines the gamma1 functions of two iterations of the SHA512 schedule update that are performed after the first 16 iterations within a block. It returns this value to the destination SIMD&FP register. This instruction is implemented only when ARMv8.2-SHA is implemented.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SHADD

Signed Halving Add. This instruction adds corresponding signed integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SRHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

</tbody>
</table>

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
for e = 0 to elements-1
    Elem[result, e, esize] = LSL(Elem[operand, e, esize], shift);
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**SHLL, SHLL2**

Shift Left Long (by element size). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, left shifts each result by the element size, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. The SHLL instruction extracts vector elements from the lower half of the source register, while the SHLL2 instruction extracts vector elements from the upper half of the source register. Depending on the settings in the **CPACR_EL1, CPTR_EL2, and CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

</tbody>
</table>
Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(2*datasize) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SHRN, SHRN2

Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are truncated. For rounded results, see RSHRN.

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |

bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;

Vpart[d, part] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SHSUB

Signed Halving Subtract. This instruction subtracts the elements in the vector in the second source SIMD&FP register from the corresponding elements in the vector in the first source SIMD&FP register, shifts each result right one bit, places each result into elements of a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type

SHSUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

</tr>
</tbody>
</table>

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer diff;
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    diff = element1 - element2;
    Elem[result, e, esize] = diff<esize:1>;
V[d] = result;

Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
SLI

Shift Left and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, left
shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the
destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing
value. Bits shifted out of the left of each vector element in the source register are lost.
The following figure shows an example of the operation of shift left by 3 for an 8-bit vector element.

![Example Figure]

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and
Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

**Scalar**

SM3TT1A

SM3TT1A takes three 128-bit vectors from three source SIMD&FP registers and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a three-way exclusive OR of the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:
- The bottom 32-bit element of the first source vector, Vd, that was used for the three-way exclusive OR.
- The result of the exclusive OR of the top 32-bit element of the second source vector, Vn, with a rotation left by 12 of the top 32-bit element of the first source vector.
- A 32-bit element indexed out of the third source vector, Vm.

The result of this addition is returned as the top element of the result. The other elements of the result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 9.

This instruction is implemented only when ARMv8.2-SM is implemented.

- The 32-bit element held in the top 32 bits of the second source vector, Vn.
- A 32-bit element indexed out of the third source vector, Vm.

A three-way exclusive OR is performed of the result of this addition, the result of the addition rotated left by 9, and the result of the addition rotated left by 17. The result of this exclusive OR is returned as the top element of the returned result. The other elements of this result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 19.

This instruction is implemented only when ARMv8.2-SM is implemented.

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SM4E

SM4 Encode takes input data as a 128-bit vector from the first source SIMD&FP register, and four iterations of the round key held as the elements of the 128-bit vector in the second source SIMD&FP register. It encrypts the data by four rounds, in accordance with the SM4 standard, returning the 128-bit result to the destination SIMD&FP register. This instruction is implemented only when ARMv8.2-SM is implemented.

boolean min = (op == '1');

**Assembler Symbols**

`<V>` Is the destination width specifier, encoded in “size”:
```
<table>
<thead>
<tr>
<th>size</th>
<th>&lt;V&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>B</td>
</tr>
<tr>
<td>01</td>
<td>H</td>
</tr>
<tr>
<td>10</td>
<td>S</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>
```

`<d>` Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

`<T>` Is an arrangement specifier, encoded in “size:Q”:
```
<table>
<thead>
<tr>
<th>size</th>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>00</td>
<td>1</td>
<td>16B</td>
</tr>
<tr>

<tr>
<td>10</td>
<td>0</td>
<td>RESERVED</td>
</tr>
<tr>
<td>10</td>
<td>1</td>
<td>45</td>
</tr>
<tr>
<td>11</td>
<td>x</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>
```

**Operation**

`CheckFPAdvSIMDEnabled64();`

```
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
   element = Int(Elem[operand, e, esize], unsigned);
   maxmin = if min then Min(maxmin, element) else Max(maxmin, element);
```

```
V[d] = maxmin<esize-1:0>;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SMLAL, SMLAL2 (by element)

Signed Multiply-Add Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element in the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are signed integer values.

The SMLAL instruction extracts vector elements from the lower half of the first source register, while the SMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>RESERVED</td>
</tr>
<tr>
<td>01</td>
<td>H:L:M</td>
</tr>
<tr>
<td>10</td>
<td>H:L</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxdsize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<<2*esize-1:0;  
    if sub_op then
        Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
    else
        Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] + product;

V[d] = result;
```

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SMLAL, SMLAL2 (vector)

Signed Multiply-Add Long (vector). This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLAL instruction extracts each source vector from the lower half of each source register, while the SMLAL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the **CPACR_EL1, CPTR_EL2, and CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        accum = Elem[operand3, e, 2*esize] - product;
    else
        accum = Elem[operand3, e, 2*esize] + product;
    Elem[result, e, 2*esize] = accum;
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SMMLA (vector)

Signed 8-bit integer matrix multiply-accumulate. This instruction multiplies the 2x8 matrix of signed 8-bit integer values in the first source vector by the 8x2 matrix of signed 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2 to Armv8.5, this is an **OPTIONAL** instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. **ID_AA64ISAR1_EL1.I8MM** indicates whether this instruction is supported.

Vector
(Armv8.6)

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, 2*esize] = (element1*element2)<2*esize-1:0>;
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SQABS

Signed saturating Absolute value. This instruction reads each vector element from the source SIMD&FP register, puts the absolute value of the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

\[

SQDMLAL, SQDMLAL2 (by element)

Signed saturating Doubling Multiply-Add Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQDMLAL instruction extracts vector elements from the lower half of the first source register, while the SQDMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

**SQDMLAL, SQDMLAL2 (vector)**

Signed saturating Doubling Multiply-Add Long. This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set. The SQDMLAL instruction extracts each source vector from the lower half of each source register, while the SQDMLAL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

### Scalar

| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

  if sub_op then
    accum = SInt(Elem[operand3, e, 2*esize]) - SInt(product);
  else
    accum = SInt(Elem[operand3, e, 2*esize]) + SInt(product);
  (Elem[result, e, 2*esize], sat2) = SignedSatQ(accum, 2 * esize);
  if sat1 || sat2 then FPSR.QC = '1';

V[d] = result;
SQDMLSL, SQDMLSL2 (by element)

Signed saturating Doubling Multiply-Subtract Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and subtracts the final results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQDMLSL instruction extracts vector elements from the lower half of the first source register, while the SQDMLSL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

**SQDMLSL, SQDMLSL2 (vector)**

Signed saturating Doubling Multiply-Subtract Long. This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, doubles the results, and subtracts the final results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit `FPSR.QC` is set.

The `SQDMLSL` instruction extracts each source vector from the lower half of each source register, while the `SQDMLSL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

SQDMULH (by element)

Signed saturating Doubling Multiply returning High half (by element). This instruction multiplies each vector element in the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see \texttt{SQRDMULH}.

Depending on the settings in the \texttt{CPACR_EL1}, \texttt{CPTR_EL2}, and \texttt{CPTR_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: \texttt{Scalar} and \texttt{Vector}.

\textbf{Scalar}

\begin{verbatim}
<table>
<thead>
<tr>
<th>0 1 0 1 1 1 1 1</th>

    (Elem[result, e, esize], sat) = SignedSatQ(product >> esize, esize);
    if sat then FPSR.QC = '1';
V[d] = result;
SQDMULH (vector)

Signed saturating Doubling Multiply returning High half. This instruction multiplies the values of corresponding elements of the two source SIMD&FP registers, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SQRDMLULH.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

SQDMULL, SQDMULL2 (by element)

Signed saturating Doubling Multiply Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the final results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQDMULL instruction extracts the first source vector from the lower half of the first source register, while the SQDMULL2 instruction extracts the first source vector from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

**SQNEG**

Signed saturating Negate. This instruction reads each vector element from the source SIMD&FP register, negates each value, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit **FPSR.QC** is set.

Depending on the settings in the **CPACR_EL1, CPTR_EL2, and CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

### Scalar

Scalar encoding:

```
<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22</th>
<th>21 20 19 18 17 16 15 14 13 12</th>
<th>11 10 9 8 7 6 5 4 3 2</th>
<th>1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 1 1 1 1 1 1 0</td>
<td>size 1 0 0 0 0</td>
<td>0 0 1 1 1 1 0</td>
<td>Rn</td>
</tr>
</tbody>
</table>
```

Scalar

```
Scalar SQNEG <V>d, <V>n>
```

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean neg = (U == '1');
```

### Vector

Vector encoding:

```
<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22</th>
<th>21 20 19 18 17 16 15 14 13 12</th>
<th>11 10 9 8 7 6 5 4 3 2</th>
<th>1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 Q 1 0 1 1 1 0</td>
<td>size 1 0 0 0 0</td>
<td>0 0 1 1 1 1 0</td>
<td>Rn</td>

SQRDMULH (by element)

Signed saturating Rounding Doubling Multiply returning High half (by element). This instruction multiplies each vector element in the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see SQRDMULH.

If any of the results overflows, they are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Copyright © 2010-2019 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
**SQRSHL**

Signed saturating Rounding Shift Left (register). This instruction takes each vector element in the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see *SQSHL*.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the *CPACR_EL1*, *CPTR_EL2*, and *CPTR_EL3* registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: *Scalar* and *Vector*

SQRSHRN, SQRSHRN2

Signed saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SQRSHRN.

The SQRSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

</tbody>
</table>
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;
for e = 0 to elements-1
  element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
  (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
  if sat then FPSR.QC = '1';
Vpart[d, part] = result;
**SQRSHRUN, SQRSHRUN2**

Signed saturating Rounded Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are rounded. For truncated results, see **SQRSHRUN**.

The **SQRSHRUN** instruction writes the vector to the lower half of the destination register and clears the upper half, while the **SQRSHRUN2** instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit **FPSR.QC** is set.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

SQSHL (register)

Signed saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see $$SQRSHL$$.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit $$FPSR.QC$$ is set.

Depending on the settings in the $$CPACR_EL1$$, $$CPTR_EL2$$, and $$CPTR_EL3$$ registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

**SQSHLU**

Signed saturating Shift Left Unsigned (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, shifts each value by an immediate value, saturates the shifted result to an unsigned integer value, places the result in a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see `UQRSHL`.

If saturation occurs, the cumulative saturation bit `FPSR.QC` is set.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

### Scalar

<table>

SQSHRN, SQSHRN2

Signed saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts and truncates each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. For rounded results, see **SQSRHN**.

The SQSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit **FPSR.QC** is set.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

**Scalar**

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
