Arm® A64 Instruction Set Architecture, for Arm A-class
Future Architecture Technologies in the A architecture profile
Product Status

This release covers multiple versions of the architecture. The content relating to different versions is given different quality ratings.

The information related to v8.7 of the architecture and features FEAT_CSRE and FEAT_BRBE are at Alpha quality. Alpha quality means that most major features of the specification are described in the manual, some features and details might be missing.

The information related to versions of the architecture introduced before v8.7 of the architecture and for the remaining features (FEAT_SVE2, FEAT_TME, FEAT_TRBE and FEAT_ETE), which was also published in previous releases, is at BET quality. BET quality means that all major features of the specification are described, some details might be missing.

Web Address

http://www.arm.com
A64 -- Base Instructions (alphabetic order)

**ADC**: Add with Carry.

**ADCS**: Add with Carry, setting flags.

**ADD (extended register)**: Add (extended register).

**ADD (immediate)**: Add (immediate).

**ADD (shifted register)**: Add (shifted register).

**ADDG**: Add with Tag.

**ADDS (extended register)**: Add (extended register), setting flags.

**ADDS (immediate)**: Add (immediate), setting flags.

**ADDS (shifted register)**: Add (shifted register), setting flags.

**ADR**: Form PC-relative address.

**ADRP**: Form PC-relative address to 4KB page.

**AND (immediate)**: Bitwise AND (immediate).

**AND (shifted register)**: Bitwise AND (shifted register).

**ANDS (immediate)**: Bitwise AND (immediate), setting flags.

**ANDS (shifted register)**: Bitwise AND (shifted register), setting flags.

**ASR (immediate)**: Arithmetic Shift Right (immediate): an alias of SBFM.

**ASR (register)**: Arithmetic Shift Right (register): an alias of ASRV.

**ASRV**: Arithmetic Shift Right Variable.

**AT**: Address Translate: an alias of SYS.

**AUTDA, AUTDZA**: Authenticate Data address, using key A.

**AUTDB, AUTDZB**: Authenticate Data address, using key B.

**AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA**: Authenticate Instruction address, using key A.

**AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB**: Authenticate Instruction address, using key B.

**AXFLAG**: Convert floating-point condition flags from Arm to external format.

**B**: Branch.

**B.cond**: Branch conditionally.

**BFC**: Bitfield Clear: an alias of BFM.

**BFI**: Bitfield Insert: an alias of BFM.

**BFM**: Bitfield Move.

**BFXIL**: Bitfield extract and insert at low end: an alias of BFM.

**BIC (shifted register)**: Bitwise Bit Clear (shifted register).

**BICS (shifted register)**: Bitwise Bit Clear (shifted register), setting flags.

**BL**: Branch with Link.

**BLR**: Branch with Link to Register.
BLRAA, BLRAAZ, BLRAB, BLRABZ: Branch with Link to Register, with pointer authentication.

BR: Branch to Register.

BRAA, BRAAZ, BRAB, BRABZ: Branch to Register, with pointer authentication.

BRK: Breakpoint instruction.

BTI: Branch Target Identification.

CAS, CASA, CASAL, CASL: Compare and Swap word or doubleword in memory.

CASB, CASAB, CASALB, CASLB: Compare and Swap byte in memory.

CASH, CASAH, CASALH, CASLH: Compare and Swap halfword in memory.

CASP, CASPA, CASPAL, CASPL: Compare and Swap Pair of words or doublewords in memory.

CBNZ: Compare and Branch on Nonzero.

CBZ: Compare and Branch on Zero.

CCMN (immediate): Conditional Compare Negative (immediate).

CCMN (register): Conditional Compare Negative (register).

CCMP (immediate): Conditional Compare (immediate).

CCMP (register): Conditional Compare (register).

CFINV: Invert Carry Flag.

CFP: Control Flow Prediction Restriction by Context: an alias of SYS.

CINC: Conditional Increment: an alias of CSINC.

CINV: Conditional Invert: an alias of CSINV.

CLREX: Clear Exclusive.

CLS: Count Leading Sign bits.

CLZ: Count Leading Zeros.

CMN (immediate): Compare Negative (immediate): an alias of ADDS (immediate).

CMP (immediate): Compare (immediate): an alias of SUBS (immediate).

CMPP: Compare with Tag: an alias of SUBPS.

CNEG: Conditional Negate: an alias of CSNEG.

CPP: Cache Prefetch Prediction Restriction by Context: an alias of SYS.

CRC32CB, CRC32CH, CRC32CW, CRC32CX: CRC32C checksum.

CSDB: Consumption of Speculative Data Barrier.

CSEL: Conditional Select.

CSET: Conditional Set: an alias of CSINC.
CSETM: Conditional Set Mask: an alias of CSINV.

CSINC: Conditional Select Increment.

CSINV: Conditional Select Invert.

CSNEG: Conditional Select Negation.

DC: Data Cache operation: an alias of SYS.

DCPS1: Debug Change PE State to EL1..

DCPS2: Debug Change PE State to EL2..

DCPS3: Debug Change PE State to EL3.

DGH: Data Gathering Hint.

DMB: Data Memory Barrier.

DRPS: Debug restore process state.

DSB: Data Synchronization Barrier.

DVP: Data Value Prediction Restriction by Context: an alias of SYS.

EON (shifted register): Bitwise Exclusive OR NOT (shifted register).

EOR (immediate): Bitwise Exclusive OR (immediate).

EOR (shifted register): Bitwise Exclusive OR (shifted register).

ERET: Exception Return.

ERETAA, ERETAB: Exception Return, with pointer authentication.

ESB: Error Synchronization Barrier.

EXTR: Extract register.

GMI: Tag Mask Insert.

HINT: Hint instruction.

HLT: Halt instruction.

HVC: Hypervisor Call.

IC: Instruction Cache operation: an alias of SYS.

IRG: Insert Random Tag.

ISB: Instruction Synchronization Barrier.

LD64B: Single-copy Atomic 64-byte Load.

LDADD, LDADDA, LDADDAL, LDADDL: Atomic add on word or doubleword in memory.

LDADDB, LDADDAB, LDADDALB, LDADDLB: Atomic add on byte in memory.

LDADDH, LDADDAH, LDADDALH, LDADDLH: Atomic add on halfword in memory.

LDAPR: Load-Acquire RCpc Register.

LDAPRB: Load-Acquire RCpc Register Byte.

LDAPRH: Load-Acquire RCpc Register Halfword.

LDAPUR: Load-Acquire RCpc Register (unscaled).

LDAPURB: Load-Acquire RCpc Register Byte (unscaled).
LDAPURH: Load-Acquire RCpc Register Halfword (unscaled).
LDAPURSB: Load-Acquire RCpc Register Signed Byte (unscaled).
LDAPURSH: Load-Acquire RCpc Register Signed Halfword (unscaled).
LDAPURSW: Load-Acquire RCpc Register Signed Word (unscaled).
LDAR: Load-Acquire Register.
LDARB: Load-Acquire Register Byte.
LDARH: Load-Acquire Register Halfword.
LDAXP: Load-Acquire Exclusive Pair of Registers.
LDAXR: Load-Acquire Exclusive Register.
LDAXRB: Load-Acquire Exclusive Register Byte.
LDAXRH: Load-Acquire Exclusive Register Halfword.
LDCLR, LDCLRA, LDCLRAL, LDCLRL: Atomic bit clear on word or doubleword in memory.
LDCLR, LDCLRAB, LDCLRALB, LDCLRLB: Atomic bit clear on byte in memory.
LDCLRH, LDCLRALH, LDCLRLH: Atomic bit clear on halfword in memory.
LDEOR, LDEORA, LDEORAL, LDEORL: Atomic exclusive OR on word or doubleword in memory.
LDEORB, LDEORAB, LDEORALB, LDEORLB: Atomic exclusive OR on byte in memory.
LDEORH, LDEORAH, LDEORALH, LDEORLH: Atomic exclusive OR on halfword in memory.
LDG: Load Allocation Tag.
LDGM: Load Tag Multiple.
LDLAR: Load LOAcquire Register.
LDLARB: Load LOAcquire Register Byte.
LDLARH: Load LOAcquire Register Halfword.
LDNP: Load Pair of Registers, with non-temporal hint.
LDP: Load Pair of Registers.
LDPSW: Load Pair of Registers Signed Word.
LDR (immediate): Load Register (immediate).
LDR (literal): Load Register (literal).
LDR (register): Load Register (register).
LDRAA, LDRAB: Load Register, with pointer authentication.
LDRB (immediate): Load Register Byte (immediate).
LDRB (register): Load Register Byte (register).
LDRH (immediate): Load Register Halfword (immediate).
LDRH (register): Load Register Halfword (register).
LDRSB (immediate): Load Register Signed Byte (immediate).
LDRSB (register): Load Register Signed Byte (register).
LDRSH (immediate): Load Register Signed Halfword (immediate).
LDRSH (register): Load Register Signed Halfword (register).

LDRSW (immediate): Load Register Signed Word (immediate).

LDRSW (literal): Load Register Signed Word (literal).

LDRSW (register): Load Register Signed Word (register).

LDSET, LDSETA, LDSETL, LDSETL: Atomic bit set on word or doubleword in memory.

LDSETB, LDSETAB, LDSETLB, LDSETLB: Atomic bit set on byte in memory.

LDSETH, LDSETHA, LDSETLH, LDSETHL: Atomic bit set on halfword in memory.

LDMAX, LDMAXA, LDMAXAL, LDMAXL: Atomic signed maximum on word or doubleword in memory.

LDMAXB, LDMAXAB, LDMAXALB, LDMAXLB: Atomic signed maximum on byte in memory.

LDMAXH, LDMAXAH, LDMAXALH, LDMAXLH: Atomic signed maximum on halfword in memory.

LDMIN, LDMINA, LDMINAL, LDMINL: Atomic signed minimum on word or doubleword in memory.

LDMINB, LDMINAB, LDMINALB, LDMINLB: Atomic signed minimum on byte in memory.

LDMINH, LDMINAH, LDMINALH, LDMINLH: Atomic signed minimum on halfword in memory.

LDTR: Load Register (unprivileged).

LDTRB: Load Register Byte (unprivileged).

LDTRH: Load Register Halfword (unprivileged).

LDTRSB: Load Register Signed Byte (unprivileged).

LDTRSH: Load Register Signed Halfword (unprivileged).

LDTRSW: Load Register Signed Word (unprivileged).

LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL: Atomic unsigned maximum on word or doubleword in memory.

LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB: Atomic unsigned maximum on byte in memory.

LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH: Atomic unsigned maximum on halfword in memory.

LDUMIN, LDUMINA, LDUMINAL, LDUMINL: Atomic unsigned minimum on word or doubleword in memory.

LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB: Atomic unsigned minimum on byte in memory.

LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH: Atomic unsigned minimum on halfword in memory.

LDUR: Load Register (unscaled).

LDURB: Load Register Byte (unscaled).

LDURH: Load Register Halfword (unscaled).

LDURSB: Load Register Signed Byte (unscaled).

LDURSH: Load Register Signed Halfword (unscaled).

LDURSW: Load Register Signed Word (unscaled).

LDXP: Load Exclusive Pair of Registers.

LDXR: Load Exclusive Register.

LDXRB: Load Exclusive Register Byte.

LDXRH: Load Exclusive Register Halfword.

LSL (immediate): Logical Shift Left (immediate): an alias of UBFM.
**LSL (register)**: Logical Shift Left (register): an alias of LSLV.

**LSLV**: Logical Shift Left Variable.

**LSR (immediate)**: Logical Shift Right (immediate): an alias of UBFM.

**LSR (register)**: Logical Shift Right (register): an alias of LSRV.

**LSRV**: Logical Shift Right Variable.

**MADD**: Multiply-Add.

**MNEG**: Multiply-Negate: an alias of MSUB.

**MOV (bitmask immediate)**: Move (bitmask immediate): an alias of ORR (immediate).

**MOV (inverted wide immediate)**: Move (inverted wide immediate): an alias of MOVN.

**MOV (register)**: Move (register): an alias of ORR (shifted register).

**MOV (to/from SP)**: Move between register and stack pointer: an alias of ADD (immediate).

**MOV (wide immediate)**: Move (wide immediate): an alias of MOVZ.

**MOVK**: Move wide with keep.

**MOVN**: Move wide with NOT.

**MOVZ**: Move wide with zero.

**MRS**: Move System Register.

**MSR (immediate)**: Move immediate value to Special Register.

**MSR (register)**: Move general-purpose register to System Register.

**MSUB**: Multiply-Subtract.

**MUL**: Multiply: an alias of MADD.

**MVN**: Bitwise NOT: an alias of ORN (shifted register).

**NEG (shifted register)**: Negate (shifted register): an alias of SUB (shifted register).

**NEGS**: Negate, setting flags: an alias of SUBS (shifted register).

**NGC**: Negate with Carry: an alias of SBC.

**NGCS**: Negate with Carry, setting flags: an alias of SBCS.

**NOP**: No Operation.

**ORN (shifted register)**: Bitwise OR NOT (shifted register).

**ORR (immediate)**: Bitwise OR (immediate).

**ORR (shifted register)**: Bitwise OR (shifted register).

**PACDA, PACDZA**: Pointer Authentication Code for Data address, using key A.

**PACDB, PACDBZ**: Pointer Authentication Code for Data address, using key B.

**PACGA**: Pointer Authentication Code, using Generic key.

**PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA**: Pointer Authentication Code for Instruction address, using key A.

**PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB**: Pointer Authentication Code for Instruction address, using key B.

**PRFM (immediate)**: Prefetch Memory (immediate).

**PRFM (literal)**: Prefetch Memory (literal).
**PRFM (register)**: Prefetch Memory (register).

**PRFUM**: Prefetch Memory (unscaled offset).

**PSB CSYNC**: Profiling Synchronization Barrier.

**PSSBB**: Physical Speculative Store Bypass Barrier.

**RBIT**: Reverse Bits.

**RET**: Return from subroutine.

**RETA, RETAB**: Return from subroutine, with pointer authentication.

**REV**: Reverse Bytes.

**REV16**: Reverse bytes in 16-bit halfwords.

**REV32**: Reverse bytes in 32-bit words.

**REV64**: Reverse Bytes: an alias of REV.

**RMIF**: Rotate, Mask Insert Flags.

**ROR (immediate)**: Rotate right (immediate): an alias of EXTR.

**ROR (register)**: Rotate Right (register): an alias of RORV.

**RORV**: Rotate Right Variable.

**SB**: Speculation Barrier.

**SBC**: Subtract with Carry.

**SBCS**: Subtract with Carry, setting flags.

**SBFIZ**: Signed Bitfield Insert in Zero: an alias of SBFM.

**SBFM**: Signed Bitfield Move.

**SBFX**: Signed Bitfield Extract: an alias of SBFM.

**SDIV**: Signed Divide.

**SETF8, SETF16**: Evaluation of 8 or 16 bit flag values.

**SEV**: Send Event.

**SEVL**: Send Event Local.

**SMADDL**: Signed Multiply-Add Long.

**SMC**: Secure Monitor Call.

**SMNEGL**: Signed Multiply-Negate Long: an alias of SMSUBL.

**SMSUBL**: Signed Multiply-Subtract Long.

**SMULH**: Signed Multiply High.

**SMULL**: Signed Multiply Long: an alias of SMADDL.

**SSBB**: Speculative Store Bypass Barrier.

**ST2G**: Store Allocation Tags.

**ST64B**: Single-copy Atomic 64-byte Store without Return.

**ST64BV**: Single-copy Atomic 64-byte Store with Return.

**ST64BV0**: Single-copy Atomic 64-byte EL0 Store with Return.
STADD, STADDL: Atomic add on word or doubleword in memory, without return: an alias of LDADD, LDADDA, LDADDAL, LDADDDL.

STADDB, STADDLB: Atomic add on byte in memory, without return: an alias of LDADDB, LDADDAB, LDADDALB, LDADDLB.

STADDH, STADDLH: Atomic add on halfword in memory, without return: an alias of LDADDH, LDADDAH, LDADDALH, LDADDLH.

STCLR, STCLRL: Atomic bit clear on word or doubleword in memory, without return: an alias of LDCLR, LDCLRA, LDCLRAL, LDCLRL.

STCLRB, STCLRLB: Atomic bit clear on byte in memory, without return: an alias of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB.

STCLRH, STCLRLH: Atomic bit clear on halfword in memory, without return: an alias of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH.

STEOR, STEORL: Atomic exclusive OR on word or doubleword in memory, without return: an alias of LDEOR, LDEORA, LDEORAL, LDEORL.

STEORB, STEORLB: Atomic exclusive OR on byte in memory, without return: an alias of LDEORB, LDEORAB, LDEORALB, LDEORLB.

STEORH, STEORLH: Atomic exclusive OR on halfword in memory, without return: an alias of LDEORH, LDEORAH, LDEORALH, LDEORLH.

STG: Store Allocation Tag.

STGM: Store Tag Multiple.

STGP: Store Allocation Tag and Pair of registers.

STLLR: Store LORelease Register.

STLLRB: Store LORelease Register Byte.

STLLRH: Store LORelease Register Halfword.

STLR: Store-Release Register.

STLRB: Store-Release Register Byte.

STLRH: Store-Release Register Halfword.

STLUR: Store-Release Register (unscaled).

STLURB: Store-Release Register Byte (unscaled).

STLURH: Store-Release Register Halfword (unscaled).

STLXP: Store-Release Exclusive Pair of registers.

STLXR: Store-Release Exclusive Register.

STLXRB: Store-Release Exclusive Register Byte.

STLXRH: Store-Release Exclusive Register Halfword.

STNP: Store Pair of Registers, with non-temporal hint.

STP: Store Pair of Registers.

STR (immediate): Store Register (immediate).

STR (register): Store Register (register).

STRB (immediate): Store Register Byte (immediate).

STRB (register): Store Register Byte (register).

STRH (immediate): Store Register Halfword (immediate).
**STRH (register)**: Store Register Halfword (register).

**STSET, STSETL**: Atomic bit set on word or doubleword in memory, without return: an alias of LDSET, LDSETA, LDSETAL, LDSETL.

**STSETB, STSETLB**: Atomic bit set on byte in memory, without return: an alias of LDSETB, LDSETAB, LDSETALB, LDSETLB.

**STSETH, STSETLH**: Atomic bit set on halfword in memory, without return: an alias of LDSETH, LDSETAH, LDSETALH, LDSETLH.

**STSMAX, STSMAXL**: Atomic signed maximum on word or doubleword in memory, without return: an alias of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL.

**STSMAXB, STSMAXLB**: Atomic signed maximum on byte in memory, without return: an alias of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB.

**STSMAXH, STSMAXLH**: Atomic signed maximum on halfword in memory, without return: an alias of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH.

**STSMIN, STSMINL**: Atomic signed minimum on word or doubleword in memory, without return: an alias of LDSMIN, LDSMINA, LDSMINAL, LDSMINL.

**STSMINB, STSMINLB**: Atomic signed minimum on byte in memory, without return: an alias of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB.

**STSMINH, STSMINLH**: Atomic signed minimum on halfword in memory, without return: an alias of LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH.

**STTR**: Store Register (unprivileged).

**STTRB**: Store Register Byte (unprivileged).

**STTRH**: Store Register Halfword (unprivileged).

**STUMAX, STUMAXL**: Atomic unsigned maximum on word or doubleword in memory, without return: an alias of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL.

**STUMAXB, STUMAXLB**: Atomic unsigned maximum on byte in memory, without return: an alias of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB.

**STUMAXH, STUMAXLH**: Atomic unsigned maximum on halfword in memory, without return: an alias of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH.

**STUMIN, STUMINL**: Atomic unsigned minimum on word or doubleword in memory, without return: an alias of LDUMIN, LDUMINA, LDUMINAL, LDUMINL.

**STUMINB, STUMINLB**: Atomic unsigned minimum on byte in memory, without return: an alias of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB.

**STUMINH, STUMINLH**: Atomic unsigned minimum on halfword in memory, without return: an alias of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH.

**STUR**: Store Register (unscaled).

**STURB**: Store Register Byte (unscaled).

**STURH**: Store Register Halfword (unscaled).

**STXP**: Store Exclusive Pair of registers.

**STXR**: Store Exclusive Register.

**STXRB**: Store Exclusive Register Byte.

**STXRH**: Store Exclusive Register Halfword.

**STZ2G**: Store Allocation Tags, Zeroing.

**STZG**: Store Allocation Tag, Zeroing.

**STZGM**: Store Tag and Zero Multiple.
**SUB (extended register)**: Subtract (extended register).

**SUB (immediate)**: Subtract (immediate).

**SUB (shifted register)**: Subtract (shifted register).

**SUBG**: Subtract with Tag.

**SUBP**: Subtract Pointer.

**SUBPS**: Subtract Pointer, setting Flags.

**SUBS (extended register)**: Subtract (extended register), setting flags.

**SUBS (immediate)**: Subtract (immediate), setting flags.

**SUBS (shifted register)**: Subtract (shifted register), setting flags.

**SVC**: Supervisor Call.

**SWP, SWPA, SWPAL, SWPL**: Swap word or doubleword in memory.

**SWPB, SWPAB, SWPALB, SWPLB**: Swap byte in memory.

**SWPH, SWPAH, SWPALH, SWPLH**: Swap halfword in memory.

**SXTR**: Signed Extend Byte: an alias of SBFM.

**SXTH**: Sign Extend Halfword: an alias of SBFM.

**SXTW**: Sign Extend Word: an alias of SBFM.

**SYS**: System instruction.

**SYSL**: System instruction with result.

**TBNZ**: Test bit and Branch if Nonzero.

**TBZ**: Test bit and Branch if Zero.

**TCANCEL**: Cancel current transaction.

**TCOMMIT**: Commit current transaction.

**TLBI**: TLB Invalidate operation: an alias of SYS.

**TSB CSYNC**: Trace Synchronization Barrier.

**TST (immediate)**: Test bits (immediate): an alias of ANDS (immediate).

**TST (shifted register)**: Test (shifted register): an alias of ANDS (shifted register).

**TSTART**: Start transaction.

**TTEST**: Test transaction state.

**UBFIZ**: Unsigned Bitfield Insert in Zero: an alias of UBFM.

**UBFM**: Unsigned Bitfield Move.

**UBFX**: Unsigned Bitfield Extract: an alias of UBFM.

**UDF**: Permanently Undefined.

**UDIV**: Unsigned Divide.

**UMADDL**: Unsigned Multiply-Add Long.

**UMNEGL**: Unsigned Multiply-Negate Long: an alias of UMSUBL.

**UMSUBL**: Unsigned Multiply-Subtract Long.
**UMULH**: Unsigned Multiply High.

**UMULL**: Unsigned Multiply Long: an alias of UMADDL.

**UXTB**: Unsigned Extend Byte: an alias of UBFM.

**UXTH**: Unsigned Extend Halfword: an alias of UBFM.

**WFE**: Wait For Event.

**WFET**: Wait For Event with Timeout.

**WFI**: Wait For Interrupt.

**WFIT**: Wait For Interrupt with Timeout.

**XAFLAG**: Convert floating-point condition flags from external format to Arm format.

**XPACD, XPACI, XPACLRI**: Strip Pointer Authentication Code.

**YIELD**: YIELD.
ADC

Add with Carry adds two register values and the Carry flag value, and writes the result to the destination register.

<table>
<thead>
<tr>
<th>sf</th>
<th>0 0 1 1 0 1 0 0 0 0</th>
<th>Rm</th>
<th>0 0 0 0 0 0 0</th>
<th>Rn</th>
<th>Rd</th>
</tr>
</thead>
<tbody>

<td></td>
</tr>
</tbody>
</table>

32-bit (sf == 0)

ADC <Wd>, <Wn>, <Wm>

64-bit (sf == 1)

ADC <Xd>, <Xn>, <Xm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

(result, -) = AddWithCarry(operand1, operand2, PSTATE.C);
X[d] = result;

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADCS

Add with Carry, setting flags, adds two register values and the Carry flag value, and writes the result to the destination register. It updates the condition flags based on the result.

<table>
<thead>
<tr>
<th>sf</th>
<th>0</th>

32-bit (sf == 0)

ADCS <Wd>, <Wn>, <Wm>

64-bit (sf == 1)

ADCS <Xd>, <Xn>, < Xm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcv;
(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);
PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

ADD (extended register)

Add (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
  sf 0 0 0 1 0 1 1 0 0 1    Rm  |  op |  option  |  imm3  |  Rn  |  Rd
```

32-bit (sf == 0)

ADD <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

64-bit (sf == 1)

ADD <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

```python
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then UNDEFINED;
```

Assembler Symbols

- `<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>` Is a width specifier, encoded in "option":

<table>
<thead>
<tr>
<th><code>option</code></th>
<th><code>&lt;R&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>010</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>

- `<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
- `<extend>` For the 32-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th><code>option</code></th>
<th><code>&lt;extend&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UXTX</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases `<extend>` is required and must be UXTW when "option" is '010'.
For the 64-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
(result, -) = AddWithCarry(operand1, operand2, '0');
if d == 31 then
  SP[] = result;
else
  X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADD (immediate)

Add (immediate) adds a register value and an optionally-shifted immediate value, and writes the result to the destination register.

This instruction is used by the alias MOV (to/from SP).

<table>
<thead>
<tr>
<th>sf</th>
<th>0</th>
<th>0</th>
<th>1</th>
<th>0</th>
<th>0</th>
<th>0</th>

</tbody>
</table>
```

- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

```plaintext
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
(result, -) = AddWithCarry(operand1, operand2, '0');
X[d] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**ADDG**

Add with Tag adds an immediate value scaled by the Tag granule to the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

**Integer (Armv8.5)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1  | 0  | 1  | 0  | 0  | 1  | 1  | 0  | uimm6 | [0](0) | uimm4 | Xn | Xd |

ADDG <Xd|SP>, <Xn|SP>, #<uimm6>, #<uimm4>

if !HaveMTEExt() then UNDEFINED;
integer d = UInt(Xd);
integer n = UInt(Xn);
bits(64) offset = LSL(ZeroExtend(uimm6, 64), LOG2_TAG_GRANULE);

**Assembler Symbols**

- `<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Xd" field.
- `<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer; encoded in the “Xn” field.
- `<uimm6>` Is an unsigned immediate, a multiple of 16 in the range 0 to 1008, encoded in the "uimm6" field.
- `<uimm4>` Is an unsigned immediate, in the range 0 to 15, encoded in the “uimm4" field.

**Operation**

bits(64) operand1 = if n == 31 then SP[] else X[n];
bits(4) start_tag = AArch64.AllocationTagFromAddress(operand1);
bits(16) exclude = GCR_EL1.Exclude;
bits(64) result;
bits(4) rtag;
if AArch64.AllocationTagAccessIsEnabled(AccType_NORMAL) then
  rtag = AArch64.ChooseNonExcludedTag(start_tag, uimm4, exclude);
else
  rtag = '0000';
(result, -) = AddWithCarry(operand1, offset, '0');</p>
result = AArch64.AddressWithAllocationTag(result, AccType_NORMAL, rtag);
if d == 31 then
  SP[] = result;
else
  X[d] = result;
ADDS (extended register)

Add (extended register), setting flags, adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMN (extended register).

<table>
<thead>
<tr>
<th>sf</th>
<th>1</th>
<th>0</th>
<th>1</th>

</table>

32-bit (sf == 0)

ADDS <Wd>, <Wn|WSP>, <Wm>{, <extend> {=#<amount>}}

64-bit (sf == 1)

ADDS <Xd>, <Xn|SP>, <R><m>{, <extend> {=#<amount>}}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then UNDEFINED;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>010</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UTX</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

ADDS (extended register)
For the 64-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

### Alias Conditions

```

**Assembler Symbols**

- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<label>` is the program label whose address is to be calculated. Its offset from the address of this instruction, in the range +/-1MB, is encoded in “immhi:immlo”.

**Operation**

```
integer d = UInt(Rd);
bits(64) imm;
imm = SignExtend(immhi:immlo, 64);

bits(64) base = PC[];
X[d] = base + imm;
```
ADRP

Form PC-relative address to 4KB page adds an immediate value that is shifted left by 12 bits, to the PC value to form a PC-relative address, with the bottom 12 bits masked out, and writes the result to the destination register.

ADRP <Xd>, <label>

integer d = UInt(Rd);
bits(64) imm;

imm = SignExtend(immhi:immlo:Zeros(12), 64);

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<label> Is the program label whose 4KB page address is to be calculated. Its offset from the page address of this instruction, in the range +/-4GB, is encoded as "immhi:immlo" times 4096.

Operation

bits(64) base = PC[];
base<11:0> = Zeros(12);

X[d] = base + imm;

AND (immediate)

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

32-bit (sf == 0)

ASR <Wd>, <Wn>, <Wm>

is equivalent to

ASRV <Wd>, <Wn>, <Wm>

and is always the preferred disassembly.

64-bit (sf == 1)

ASR <Xd>, <Xn>, <Xm>

is equivalent to

ASRV <Xd>, <Xn>, <Xm>

and is always the preferred disassembly.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of ASRV gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of the sign bit in the upper bits and zeros in the lower bits, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

### 32-bit (sf == 0 && N == 0 && imms == 011111)

ASR <Wd>, <Wn>, #<shift>

is equivalent to

SBFM <Wd>, <Wn>, #<shift>, #31

and is always the preferred disassembly.

### 64-bit (sf == 1 && N == 1 && imms == 111111)

ASR <Xd>, <Xn>, #<shift>

is equivalent to

SBFM <Xd>, <Xn>, #<shift>, #63

and is always the preferred disassembly.

#### Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <shift> For the 32-bit variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.

#### Operation

The description of SBFM gives the operational pseudocode for this instruction.

#### Operational information

</tbody>
</table>

`<op1>`

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

`<Cm>`

Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

`<op2>`

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

`<Xt>`

Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

### Operation

The description of `SYS` gives the operational pseudocode for this instruction.
AUTDA, AUTDZA

Authenticate Data address, using key A. This instruction authenticates a data address, using a modifier and key A. The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDA.
- The value zero, for AUTDZA.

If the authentication fails, the upper bits of the address are restored to enable subsequent use of the address. If the authentication passes, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

**Integer (Armv8.3)**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

**AUTDA (Z == 0)**

AUTDA <Xd>, <Xn|SP>

**AUTDZA (Z == 1 && Rn == 11111)**

AUTDZA <Xd>

```plaintext
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HavePACExt() then
    UNDEFINED;
if Z == '0' then // AUTDA
    if n == 31 then source_is_sp = TRUE;
    else // AUTDZA
        if n != 31 then UNDEFINED;
```

**Assembler Symbols**

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

**Operation**

```plaintext
if HavePACExt() then
    if source_is_sp then
        X[d] = AuthDA(X[d], SP[], FALSE);
    else
        X[d] = AuthDA(X[d], X[n], FALSE);
```
AUTDB, AUTDZB

Authenticate Data address, using key B. This instruction authenticates a data address, using a modifier and key B. The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDB.
- The value zero, for AUTDZB.

If the authentication fails, the upper bits of the address are corrupted and any subsequent use of the address results in a Translation fault.

**AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA**

Authenticate Instruction address, using key A. This instruction authenticates an instruction address, using a modifier and key A.

The address is:
- In the general-purpose register that is specified by <Xd> for AUTIA and AUTIZA.
- In X17, for AUTIA1716.
- In X30, for AUTIASP and AUTIAZ.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTIA.
- The value zero, for AUTIZA and AUTIAZ.
- In X16, for AUTIA1716.
- In SP, for AUTIASP.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

It has encodings from 2 classes: **Integer** and **System**

AXFLAG

Convert floating-point condition flags from Arm to external format. This instruction converts the state of the PSTATE.{N,Z,C,V} flags from a form representing the result of an Arm floating-point scalar compare instruction to an alternative representation required by some software.

System (Armv8.5)

```
0 1 0 1 0 1 0 0 0 0 0 0 0 0 0 1 0 0 1 0 0 1 0 0 0 0 0 0 0 1 1 1 1 1
```

```plaintext
AXFLAG

if !HaveFlagFormatExt() then UNDEFINED;

Operation

bit Z = PSTATE.Z OR PSTATE.V;
bite C = PSTATE.C AND NOT(PSTATE.V);

PSTATE.N = '0';
PSTATE.Z = Z;
PSTATE.C = C;
PSTATE.V = '0';
```
B.cond

Branch conditionally to a label at a PC-relative offset, with a hint that this is not a subroutine call or return.

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 1 0 1 0 1 0</td>
</tr>
</tbody>
</table>

B.<cond> <label>

bits(64) offset = SignExtend(imm19:'00', 64);

Assembler Symbols

<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

if ConditionHolds(cond) then
    BranchTo(PC[] + offset, BranchType_DIR);

Copyright © 2010-2020 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
Branch causes an unconditional branch to a label at a PC-relative offset, with a hint that this is not a subroutine call or return.

```
0 | 0 0 0 1 0 1 |
---|-------------|
imm26
```

**Assembler Symbols**

```<label>`
Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as “imm26" times 4.

**Operation**

```
BranchTo(PC[] + offset, BranchType_DIR);
```
BFC

Bitfield Clear sets a bitfield of <width> bits at bit position <lsb> of the destination register to zero, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.

Leaving other bits unchanged
(Armv8.2)

32-bit (sf == 0 && N == 0)

BFC <Wd>, #<lsb>, #<width>

is equivalent to

BFM <Wd>, WZR, #(-<lsb> MOD 32), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

64-bit (sf == 1 && N == 1)

BFC <Xd>, #<lsb>, #<width>

is equivalent to

BFM <Xd>, XZR, #(-<lsb> MOD 64), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <lsb> For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- <width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
BFI

Bitfield Insert copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 & N == 0)

BFI <Wd>, <Wn>, #<lsb>, #<width>

is equivalent to

BFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

64-bit (sf == 1 & N == 1)

BFI <Xd>, <Xn>, #<lsb>, #<width>

is equivalent to

BFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<lsb> For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.

For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.

<width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly.

If \(<imm>\) is greater than or equal to \(<imm>\), this copies a bitfield of \((<imm>-<imm>)+1\) bits starting from bit position \(<imm>\) in the source register to the least significant bits of the destination register.

If \(<imm>\) is less than \(<imm>\), this copies a bitfield of \((<imm>+1\) bits from the least significant bits of the source register to bit position \((regsize-<imm>)\) of the destination register, where \(regsize\) is the destination register size of 32 or 64 bits.

In both cases the other bits of the destination register remain unchanged.

This instruction is used by the aliases BFC, BFI, and BFXIL.

###Assembler Symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<imm>\) For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the "imm" field.
  - For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the "imm" field.
- \(<imms>\) For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field.
  - For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

is equivalent to

BFM <Xd>, <Xn>, #<lsb>, #{<lsb>+<width>-1}

and is the preferred disassembly when UInt(imms) >= UInt(immr).

Assembler Symbols

- **<Wd>**: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Wn>**: Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- **<Xd>**: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Xn>**: Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- **<lsb>**: For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
- **<width>**: For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**BIC (shifted register)**

Bitwise Bit Clear (shifted register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

<table>
<thead>
<tr>
<th>sf</th>
<th>0</th>
<th>0</th>

</tr>
</tbody>
</table>

32-bit (sf == 0)

BIC <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit (sf == 1)

BIC <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

```plaintext
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
operand2 = NOT(operand2);
result = operand1 AND operand2;
X[d] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
BICS (shifted register)

Bitwise Bit Clear (shifted register), setting flags, performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

- For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

**Operation**

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
operand2 = NOT(operand2);
result = operand1 AND operand2;
PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';
X[d] = result;
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
BL

Branch with Link branches to a PC-relative offset, setting the register X30 to PC+4. It provides a hint that this is a subroutine call.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 | 0 0 1 0 1 | imm26
```

```
BL <label>

bits(64) offset = SignExtend(imm26:'00', 64);
```

**Assembler Symbols**

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as “imm26” times 4.

**Operation**

```
if HaveCSRExt() && CallStackRecordingActive() then
    AddCallStackRecord();
X[30] = PC[] + 4;
BranchTo(PC[] + offset, BranchType_DIRCALL);
```

Copyright © 2010-2020 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
BLR

Branch with Link to Register calls a subroutine at an address in a register, setting register X30 to PC+4.

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1   | 1  | 0  | 1  | 1  | 0  | 0  | 0  | 0  | 1  | 1  | 1  | 1  | 1  | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
```

BLR `<Xn>`

integer n = UInt(Rn);

**Assembler Symbols**

`<Xn>` Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the “Rn” field.

**Operation**

```
bits(64) target = X[n];

if HaveCSRExt() && CallStackRecordingActive() then
    AddCallStackRecord();
    X[30] = PC[] + 4;

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '10';
BranchTo(target, BranchType_INDCALL);
```

BLRAA, BLRAAZ, BLRAB, BLRABZ

Branch with Link to Register, with pointer authentication. This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and calls a subroutine at the authenticated address, setting register X30 to PC+4.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xm|SP> for BLRAA and BLRAB.
- The value zero, for BLRAAZ and BLRABZ.

Key A is used for BLRAA and BLRAAZ, and key B is used for BLRAB and BLRABZ.
If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

Integer (Armv8.3)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Key A, zero modifier (Z == 0 && M == 0 && Rm == 11111)

BLRAAZ <Xn>

Key A, register modifier (Z == 1 && M == 0)

BLRAA <Xn>, <Xm|SP>

Key B, zero modifier (Z == 0 && M == 1 && Rm == 11111)

BLRABZ <Xn>

Key B, register modifier (Z == 1 && M == 1)

BLRAB <Xn>, <Xm|SP>

```java
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean use_key_a = (M == '0');
boolean source_is_sp = ((Z == '1') && (m == 31));

if !HavePACExt() then
    UNDEFINED;
if Z == '0' && m != 31 then
    UNDEFINED;
```

Assembler Symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

<Xm|SP> Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.
Operation

bits(64) target = X[n];

bits(64) modifier = if source_is_sp then SP[] else X[m];

if use_key_a then
    target = AuthIA(target, modifier, TRUE);
else
    target = AuthIB(target, modifier, TRUE);

if HaveCSRExt() && CallStackRecordingActive() then
    AddCallStackRecord();
X[30] = PC[] + 4;

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '10';
BranchTo(target, BranchType_INDCALL);

Internal version only: isa v32.12, AdvSIMD v29.04, pseudocode v2020-09_xml, sve v2020-09_rc2b ; Build timestamp: 2020-09-30T20:20

Copyright © 2010-2020 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
Branch to Register branches unconditionally to an address in a register, with a hint that this is not a subroutine return.

```
BR <Xn>

integer n = UInt(Rn);
```

**Assembler Symbols**

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

**Operation**

```
bits(64) target = X[n];

// Value in BTypeNext will be used to set PSTATE.BTYPE
if InGuardedPage then
  if n == 16 || n == 17 then
    BTypeNext = '01';
  else
    BTypeNext = '11';
else
  BTypeNext = '01';
BranchTo(target, BranchType_INDIR);
```

BRAA, BRAAZ, BRAB, BRABZ

Branch to Register, with pointer authentication. This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and branches to the authenticated address. The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xm|SP> for BRAA and BRAB.
- The value zero, for BRAAZ and BRABZ.

Key A is used for BRAA and BRAAZ, and key B is used for BRAB and BRABZ.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

Integer
(ARMv8.3)

|    | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Key A, zero modifier (Z == 0 & M == 0 & Rm == 11111)

BRAAZ <Xn>

Key A, register modifier (Z == 1 & M == 0)

BRAA <Xn>, <Xm|SP>

Key B, zero modifier (Z == 0 & M == 1 & Rm == 11111)

BRABZ <Xn>

Key B, register modifier (Z == 1 & M == 1)

BRAB <Xn>, <Xm|SP>

```java
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean use_key_a = (M == '0');
boolean source_is_sp = (Z == '1') && (m == 31);
if !HavePACExt() then
    UNDEFINED;
if Z == '0' && m != 31 then
    UNDEFINED;
```

Assembler Symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

<Xm|SP> Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.
Operation

bits(64) target = X[n];

bits(64) modifier = if source_is_sp then SP[] else X[m];

if use_key_a then
    target = AuthIA(target, modifier, TRUE);
else
    target = AuthIB(target, modifier, TRUE);

// Value in BTypeNext will be used to set PSTATE.BTYPE
if InGuardedPage then
    if n == 16 || n == 17 then
        BTypeNext = '01';
    else
        BTypeNext = '11';
else
    BTypeNext = '01';
BranchTo(target, BranchType_INDIR);
Breakpoint instruction. A BRK instruction generates a Breakpoint Instruction exception. The PE records the exception in ESR_ELx, using the EC value 0x3c, and captures the value of the immediate argument in ESR_ELx.ISS.

BRK #<imm>

if HaveBTIExt() then
    SetBTypeCompatible(TRUE);

Assembler Symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

AArch64.SoftwareBreakpoint(imm16);
BTI

Branch Target Identification. A BTI instruction is used to guard against the execution of instructions which are not the intended target of a branch.

Outside of a guarded memory region, a BTI instruction executes as a NOP. Within a guarded memory region while PSTATE.BTYPE != 0b00, a BTI instruction compatible with the current value of PSTATE.BTYPE will not generate a Branch Target Exception and will allow execution of subsequent instructions within the memory region.

The operand <targets> passed to a BTI instruction determines the values of PSTATE.BTYPE which the BTI instruction is compatible with.

Within a guarded memory region, while PSTATE.BTYPE != 0b00, all instructions will generate a Branch Target Exception, other than BRK, BTI, HLT, PACIASP, and PACIBSP, which may not. See the individual instructions for details.

CAS, CASA, CASAL, CASL

Compare and Swap word or doubleword in memory reads a 32-bit word or 64-bit doubleword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- CASA and CASAL load from memory with acquire semantics.
- CASL and CASAL store to memory with release semantics.
- CAS has neither acquire nor release semantics.

For more information about memory ordering semantics see *Load-Acquire, Store-Release.*

For information about memory accesses see *Load/Store addressing modes.*

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, or <Xs>, is restored to the value held in the register before the instruction was executed.

**Assembler Symbols**

\(<Ws>\) Is the 32-bit name of the general-purpose register to be compared and loaded, encoded in the "Rs" field.

\(<Wt>\) Is the 32-bit name of the general-purpose register to be conditionally stored, encoded in the "Rt" field.

\(<Xs>\) Is the 64-bit name of the general-purpose register to be compared and loaded, encoded in the "Rs" field.

\(<Xt>\) Is the 64-bit name of the general-purpose register to be conditionally stored, encoded in the "Rt" field.

\(<Xn|SP>\) Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Operation

bits(64) address;
bits(datasize) comparevalue;
bits(datasize) newvalue;
bits(datasize) data;

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

comparevalue = X[s];
newvalue = X[t];

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = MemAtomicCompareAndSwap(address, comparevalue, newvalue, ldacctype, stacctype);
X[s] = ZeroExtend(data, regsize);
CASB, CASAB, CASALB, CASLB

Compare and Swap byte in memory reads an 8-bit byte from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- CASAB and CASALB load from memory with acquire semantics.
- CASLB and CASALB store to memory with release semantics.
- CASB has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Store-Release.
For information about memory accesses see Load/Store addressing modes.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is restored to the values held in the register before the instruction was executed.

data = MemAtomicCompareAndSwap(address, comparevalue, newvalue, ldacctype, stacctype);

X[s] = ZeroExtend(data, 32);
CASH, CASAH, CASALH, CASLH

Compare and Swap halfword in memory reads a 16-bit halfword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- CASAH and CASALH load from memory with acquire semantics.
- CASLH and CASALH store to memory with release semantics.
- CAS has neither acquire nor release semantics.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*. For information about memory accesses see *Load/Store addressing modes*.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is restored to the values held in the register before the instruction was executed.

Conditional Compare Negative (immediate) sets the value of the condition flags to the result of the comparison of a register value and a negated immediate value if the condition is TRUE, and an immediate value otherwise.

### 32-bit (sf == 0)

```
CCMN <Wn>, #<imm>, #<nzcv>, <cond>
```

### 64-bit (sf == 1)

```
CCMN <Xn>, #<imm>, #<nzcv>, <cond>
```

```
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(4) flags = nzcv;
bits(datasize) imm = ZeroExtend(imm5, datasize);
```

### Assembler Symbols

- `<Wn>`: Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xn>`: Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<imm>`: Is a five bit unsigned (positive) immediate encoded in the "imm5" field.
- `<nzcv>`: Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.
- `<cond>`: Is one of the standard conditions, encoded in the "cond" field in the standard way.

### Operation

```
bits(datasize) operand1 = X[n];
if ConditionHolds(cond) then
    (\-, flags) = AddWithCarry(operand1, imm, '0');
PSTATE.<N,Z,C,V> = flags;
```

### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CCMN (register)

Conditional Compare Negative (register) sets the value of the condition flags to the result of the comparison of a register value and the inverse of another register value if the condition is TRUE, and an immediate value otherwise.

32-bit (sf == 0)

CCMN <Wn>, <Wm>, #<nzcv>, <cond>

64-bit (sf == 1)

CCMN <Xn>, < Xm>, #<nzcv>, <cond>

**CFP RCTX, <Xt>**

is equivalent to

**SYS #3, C7, C3, #4, <Xt>**

and is always the preferred disassembly.

**Assembler Symbols**

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

**Operation**

The description of SYS gives the operational pseudocode for this instruction.
CINC

Conditional Increment returns, in the destination register, the value of the source register incremented by 1 if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSINC. This means:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode for this instruction.

<table>
<thead>

</tbody>
</table>

32-bit (sf == 0)

CINC <Wd>, <Wn>, <cond>

is equivalent to

CSINC <Wd>, <Wn>, <Wn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

64-bit (sf == 1)

CINC <Xd>, <Xn>, <cond>

is equivalent to

CSINC <Xd>, <Xn>, <Xn>, invert(<cond>)

and is the preferred disassembly when Rn == Rm.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINC gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CINV

Conditional Invert returns, in the destination register, the bitwise inversion of the value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSINV. This means:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode for this instruction.

integer result;
bits(datasize) operand1 = X[n];
result = CountLeadingZeroBits(operand1);
X[d] = result<datasize-1:0>;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CMN (extended register)

Compare Negative (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (extended register). This means:

- The encodings in this description are named to match the encodings of ADDS (extended register).
- The description of ADDS (extended register) gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CMN <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

is equivalent to

ADDS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}

and is always the preferred disassembly.

64-bit (sf == 1)

CMN <Xn|SP>, <R><m>{, <extend> {#<amount>}}

is equivalent to

ADDS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>01x</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in “option”:
If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UXTX</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

The description of ADDS (extended register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CMN (immediate)

Compare Negative (immediate) adds a register value and an optionally-shifted immediate value. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (immediate). This means:

- The encodings in this description are named to match the encodings of ADDS (immediate).
- The description of ADDS (immediate) gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CMN <Wn|WSP>, #<imm>{, <shift>}

is equivalent to

ADDS WZR, <Wn|WSP>, #<imm> {, <shift>}

and is always the preferred disassembly.

64-bit (sf == 1)

CMN <Xn|SP>, #<imm>{, <shift>}

is equivalent to

ADDS XZR, <Xn|SP>, #<imm> {, <shift>}

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the “imm12” field.
<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

<table>
<thead>
<tr>
<th>sh</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LSL #0</td>
</tr>
<tr>
<td>1</td>
<td>LSL #12</td>
</tr>
</tbody>
</table>

Operation

The description of ADDS (immediate) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CMN (shifted register)

Compare Negative (shifted register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (shifted register). This means:

- The encodings in this description are named to match the encodings of ADDS (shifted register).
- The description of ADDS (shifted register) gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CMN <Wn>, <Wm>{, <shift> #<amount>}

is equivalent to

ADDS WZR, <Wn>, <Wm> {, <shift> #<amount>}

and is always the preferred disassembly.

64-bit (sf == 1)

CMN <Xn>, <Xm>{, <shift> #<amount>}

is equivalent to

ADDS XZR, <Xn>, <Xm> {, <shift> #<amount>}

and is always the preferred disassembly.

Assembler Symbols

- <Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- <amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

The description of ADDS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
**CMP (extended register)**

Compare (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This is an alias of **SUBS (extended register)**. This means:

- The encodings in this description are named to match the encodings of **SUBS (extended register)**.
- The description of **SUBS (extended register)** gives the operational pseudocode for this instruction.

### 32-bit (sf == 0)

**CMP** `<Wn|WSP>, <Wm>{, <extend> {#<amount>}}`

is equivalent to

**SUBS** WZR, `<Wn|WSP>, <Wm>{, <extend> {#<amount>}}`

and is always the preferred disassembly.

### 64-bit (sf == 1)

**CMP** `<Xn|SP>, <R><m>{, <extend> {#<amount>}}`

is equivalent to

**SUBS** XZR, `<Xn|SP>, <R><m>{, <extend> {#<amount>}}`

and is always the preferred disassembly.

### Assembler Symbols

- `<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>` Is a width specifier, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>010</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>

- `<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
- `<extend>` For the 32-bit variant: is the extension to be applied to the second source operand, encoded in "option":

---

**CMP (extended register)**

Page 101
If “Rn” is ‘11111’ (WSP) and “option” is ‘010’ then LSL is preferred, but may be omitted when “imm3” is ‘000’. In all other cases <extend> is required and must be UXTW when "option" is ‘010’.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in “option”:

<table>
<thead>
<tr>
<th>Option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTB</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UXTX</td>
</tr>
<tr>
<td>100</td>
<td>SXTH</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If “Rn” is ‘11111’ (SP) and “option” is ‘011’ then LSL is preferred, but may be omitted when "imm3" is ‘000’. In all other cases <extend> is required and must be UXTX when "option" is ‘011’.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

The description of SUBS (extended register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CMP (immediate)

Compare (immediate) subtracts an optionally-shifted immediate value from a register value. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (immediate). This means:

- The encodings in this description are named to match the encodings of SUBS (immediate).
- The description of SUBS (immediate) gives the operational pseudocode for this instruction.

### 32-bit (sf == 0)

```plaintext
CMP <Wn|WSP>, #<imm>{, <shift>}
```

is equivalent to

```plaintext
SUBS WZR, <Wn|WSP>, #<imm> {, <shift>}
```

and is always the preferred disassembly.

### 64-bit (sf == 1)

```plaintext
CMP <Xn|SP>, #<imm>{, <shift>}
```

is equivalent to

```plaintext
SUBS XZR, <Xn|SP>, #<imm> {, <shift>}
```

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wn|WSP>`: Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Xn|SP>`: Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<imm>`: Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
- `<shift>`: Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in "sh":

<table>
<thead>
<tr>
<th>sh</th>
<th>&lt;shift&gt;</th>

**32-bit (sf == 0)**

\[
\text{CMP } \langle Wn \rangle, \langle Wm \rangle\{, \langle shift \rangle \#\langle amount \rangle\}
\]

is equivalent to

\[
\text{SUBS WZR, } \langle Wn \rangle, \langle Wm \rangle \{, \langle shift \rangle \#\langle amount \rangle\}
\]

and is always the preferred disassembly.

**64-bit (sf == 1)**

\[
\text{CMP } \langle Xn \rangle, \langle Xm \rangle\{, \langle shift \rangle \#\langle amount \rangle\}
\]

is equivalent to

\[
\text{SUBS XZR, } \langle Xn \rangle, \langle Xm \rangle \{, \langle shift \rangle \#\langle amount \rangle\}
\]

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":
  
<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

The description of **SUBS (shifted register)** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
CMPP

Compare with Tag subtracts the 56-bit address held in the second source register from the 56-bit address held in the first source register, updates the condition flags based on the result of the subtraction, and discards the result.

This is an alias of SUBPS. This means:

- The encodings in this description are named to match the encodings of SUBPS.
- The description of SUBPS gives the operational pseudocode for this instruction.

**Integer**

CMPP <Xn|SP>, <Xm|SP>

is equivalent to

SUBPS XZR, <Xn|SP>, <Xm|SP>

and is always the preferred disassembly.

**Assembler Symbols**

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the “Xn” field.

<Xm|SP> Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the “Xm” field.

**Operation**

The description of SUBPS gives the operational pseudocode for this instruction.
CNEG

Conditional Negate returns, in the destination register, the negated value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSNEG. This means:

- The encodings in this description are named to match the encodings of CSNEG.
- The description of CSNEG gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CNEG \(<W_d>, <W_n>, <\text{cond}>\)

is equivalent to

CSNEG \(<W_d>, <W_n>, <W_n>, \text{invert}(<\text{cond}>)\)

and is the preferred disassembly when \(R_n == R_m\).

64-bit (sf == 1)

CNEG \(<X_d>, <X_n>, <\text{cond}>\)

is equivalent to

CSNEG \(<X_d>, <X_n>, <X_n>, \text{invert}(<\text{cond}>)\)

and is the preferred disassembly when \(R_n == R_m\).

Assembler Symbols

- \(<W_d>\) is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<W_n>\) is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- \(<X_d>\) is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<X_n>\) is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- \(<\text{cond}>\) is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSNEG gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Cache Prefetch Prediction Restriction by Context prevents cache allocation predictions, based on information gathered from earlier execution within a particular execution context, from allowing later speculative execution within that context to be observable through side-channels.

For more information, see **CPP RCTX, Cache Prefetch Prediction Restriction by Context**.

This is an alias of **SYS**. This means:

- The encodings in this description are named to match the encodings of **SYS**.
- The description of **SYS** gives the operational pseudocode for this instruction.

**System**

(ARMv8.5)

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 0 1 0 1 0 0 0 0 1 0 1 1 0 1 1 1 0 0 1 1 1 1 1 1 1 0

L  op1  CRn  CRm  op2  Rt
```

**CPP RCTX, <Xt>**

is equivalent to

**SYS #3, C7, C3, #7, <Xt>**

and is always the preferred disassembly.

**Assembler Symbols**

**<Xt>** Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

**Operation**

The description of **SYS** gives the operational pseudocode for this instruction.
CRC32B, CRC32H, CRC32W, CRC32X

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

In Armv8-A, this is an OPTIONAL instruction, and in Armv8.1 it is mandatory for all implementations to implement it. ID AA64ISAR0_EL1. CRC32 indicates whether this instruction is supported.

<table>

integer m = UInt(Rm);
if sf == '1' & sz != '11' then UNDEFINED;
if sf == '0' & sz == '11' then UNDEFINED;
integer size = 8 << UInt(sz);

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.
<Wm> Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.

Operation

bits(32) acc = X[n];  // accumulator
bits(size) val = X[m];  // input value
bits(32) poly = 0x04C11DB7<31:0>;
bits(32+size) tempacc = BitReverse(acc):Zeros(size);
bits(size+32) tempval = BitReverse(val):Zeros(32);

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CRC32CB, CRC32CH, CRC32CW, CRC32CX

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x1EDC6F41 is used for the CRC calculation.

In Armv8-A, this is an **OPTIONAL** instruction, and in Armv8.1 it is mandatory for all implementations to implement it. 

**ID_AA64ISAR0_EL1**. CRC32 indicates whether this instruction is supported.

```

integer m = UInt(Rm);
if sf == '1' & sz != '11' then UNDEFINED;
if sf == '0' & sz == '11' then UNDEFINED;
integer size = 8 << UInt(sz);
```

**Assembler Symbols**

- **<Wd>** Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.
- **<Wn>** Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.
- **<Xm>** Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.
- **<Wm>** Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.

**Operation**

```plaintext
bits(32) acc = X[n];  // accumulator
bits(size) val = X[m];  // input value
bits(32) poly = 0x1EDC6F41<31:0>;

bits(32+size) tempacc = BitReverse(acc) ⊕ Zeros(size);
bits(size+32) tempval = BitReverse(val) ⊕ Zeros(32);

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d] = BitReverse(Poly32Mod2(tempacc XOR tempval, poly));
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Consumption of Speculative Data Barrier is a memory barrier that controls speculative execution and data value prediction.

No instruction other than branch instructions appearing in program order after the CSDB can be speculatively executed using the results of any:

- Data value predictions of any instructions.
- PSTATE.{N,Z,C,V} predictions of any instructions other than conditional branch instructions appearing in program order before the CSDB that have not been architecturally resolved.
- Predictions of SVE predication state for any SVE instructions.

For purposes of the definition of CSDB, PSTATE.{N,Z,C,V} is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or PSTATE.{N,Z,C,V} predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

   op   Rm   cond   o2   Rn

32-bit (sf == 0)

CSET <Wd>, <cond>

is equivalent to

CSINC <Wd>, WZR, WZR, invert(<cond>)

and is always the preferred disassembly.

64-bit (sf == 1)

CSET <Xd>, <cond>

is equivalent to

CSINC <Xd>, XZR, XZR, invert(<cond>)

and is always the preferred disassembly.

Assembler Symbols

<Wd>           Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd>           Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<cond>         Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINC gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CSETM

Conditional Set Mask sets all bits of the destination register to 1 if the condition is TRUE, and otherwise sets all bits to 0.

This is an alias of CSINV. This means:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode for this instruction.

32-bit (sf == 0)

CSETM <Wd>, <cond>

is equivalent to

CSINV <Wd>, WZR, WZR, invert(<cond>)

and is always the preferred disassembly.

64-bit (sf == 1)

CSETM <Xd>, <cond>

is equivalent to

CSINV <Xd>, XZR, XZR, invert(<cond>)

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<cond> Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINV gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CSINC

Conditional Select Increment returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register incremented by 1.

This instruction is used by the aliases CINC, and CSET.

32-bit (sf == 0)

CSINC <Wd>, <Wn>, <Wm>, <cond>

64-bit (sf == 1)

CSINC <Xd>, <Xn>, <Xm>, <cond>

    result = operand1;
else
    result = NOT(operand2);
result = result + 1;
X[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
• The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
Data Cache operation. For more information, see \texttt{op0==0b01, cache maintenance, TLB maintenance, and address translation instructions}.

This is an alias of \texttt{SYS}. This means:

- The encodings in this description are named to match the encodings of \texttt{SYS}.
- The description of \texttt{SYS} gives the operational pseudocode for this instruction.

<dc_op> Is a DC instruction name, as listed for the DC system instruction group, encoded in "op1:CRm:op2":

\begin{center}
\begin{tabular}{ccccccc}
\textbf{op1} & \textbf{CRm} & \textbf{op2} & \textbf{<dc_op>} & \textbf{Architectural Feature} \\

\end{tabular}
\end{center}

\texttt{<op1>} Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

\texttt{<Cm>} Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

\texttt{<op2>} Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

\texttt{<Xt>} Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

The description of \texttt{SYS} gives the operational pseudocode for this instruction.
DCPS1

Debug Change PE State to EL1, when executed in Debug state:
- If executed at EL0 changes the current Exception level and SP to EL1 using SP_EL1.
- Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS1 instruction is:
- EL1 if the instruction is executed at EL0.
- Otherwise, the Exception level at which the instruction is executed.

When the target Exception level of a DCPS1 instruction is ELx, on executing this instruction:
- \( ELR_{ELx} \) becomes UNKNOWN.
- \( SPSR_{ELx} \) becomes UNKNOWN.
- \( ESR_{ELx} \) becomes UNKNOWN.
- \( DLR_{EL0} \) and \( DSPSR_{EL0} \) become UNKNOWN.
- The endianness is set according to \( SCTLR_{ELx} \) EE.

This instruction is UNDEFINED at EL0 in Non-secure state if EL2 is implemented and \( HCR_{EL2}.TGE == 1 \).

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see DCPS.

**Assembler Symbols**

\(<\text{imm}>\)

Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

**Operation**

\[
\text{DCPSInstruction}(\text{LL});
\]
DCPS2

Debug Change PE State to EL2, when executed in Debug state:

• If executed at EL0 or EL1 changes the current Exception level and SP to EL2 using SP_EL2.
• Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS2 instruction is:

• EL2 if the instruction is executed at an exception level that is not EL3.
• EL3 if the instruction is executed at EL3.

When the target Exception level of a DCPS2 instruction is ELx, on executing this instruction:

• ELR_ELx becomes UNKNOWN.
• SPSR_ELx becomes UNKNOWN.
• ESR_ELx becomes UNKNOWN.
• DLR_EL0 and DSPSR_EL0 become UNKNOWN.
• The endianness is set according to SCTLR_ELx EE.

This instruction is UNDEFINED at the following exception levels:

• All exception levels if EL2 is not implemented.
• At EL0 and EL1 if EL2 is disabled in the current Security state.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see DCPS.

Assembler Symbols

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

DCPSInstruction(LL);

if !Halted() then UNDEFINED;
DCPS3

Debug Change PE State to EL3, when executed in Debug state:

• If executed at EL3 selects SP_EL3.
• Otherwise, changes the current Exception level and SP to EL3 using SP_EL3.

The target exception level of a DCPS3 instruction is EL3.

On executing a DCPS3 instruction:

• ELR_EL3 becomes UNKNOWN.
• SPSR_EL3 becomes UNKNOWN.
• ESR_EL3 becomes UNKNOWN.
• DLR_EL0 and DSPSR_EL0 become UNKNOWN.
• The endianness is set according to SCTLR_EL3.EE.

This instruction is UNDEFINED at all exception levels if either:

• EDSCR.SDD == 1.
• EL3 is not implemented.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see DCPS.

Assembler Symbols

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the
"imm16" field.

Operation

DCPSInstruction(LL);

Internal version only: isa v32.12, AdvSIMD v29.04, pseudocode v2020-09_xml, sve v2020-09_rc2b ; Build timestamp: 2020-09-30T20:20

  when '01' types = MBReqTypes_Reads;
  when '10' types = MBReqTypes_Writes;
  when '11' types = MBReqTypes_All;

Assembler Symbols

<option> Specifies the limitation on the barrier operation. Values are:

SY
Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = 0b1111.

ST
Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1110.

LD
Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1101.

ISH
Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b1011.

ISHST
Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1010.

ISHLD
Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1001.

NSH
Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = 0b0111.

NSHST
Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0110.

NSHLD
Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.
OSH
Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.

OSHST
Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.

OSHLD
Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of CRm that are not listed above are reserved, and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) or see Data Synchronization Barrier (DSB).

<imm>
Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the “CRm” field.

Operation

DataMemoryBarrier(domain, types);
DRPS

Debug restore process state.

```
1 1 0 1 0 1 1 0 1 0 1 1 1 1 1 0 0 0 0 0 1 1 1 1 1 0 0 0 0 0
```

if !Halted() || PSTATE.EL == EL0 then UNDEFINED;

Operation

DRPSInstruction();
DSB

Data Synchronization Barrier is a memory barrier that ensures the completion of memory accesses, see Data Synchronization Barrier.

It has encodings from 2 classes: Memory barrier and Memory nXS barrier

Memory barrier

<table>

  when '01' domain = MBRegDomain_Nonshareable;
  when '10' domain = MBRegDomain_InnerShareable;
  when '11' domain = MBRegDomain_FullSystem;

case CRm<1:0> of
  when '00' types = MBRegTypes_All; domain = MBRegDomain_FullSystem;
  when '01' types = MBRegTypes_Reads;
  when '10' types = MBRegTypes_Writes;
  when '11' types = MBRegTypes_All;

Memory nXS barrier

(Armv8.7)

<table>
<thead>
<tr>
<th>CRm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

DSB <option>nXS|#<imm>

Assembler Symbols

<option> For the memory barrier variant: specifies the limitation on the barrier operation. Values are:

SY
Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = 0b1111.

ST
Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1110.

LD
Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1101.

ISH
Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b1011.

ISHST
Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1010.
ISHLD

Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1001.

NSH

Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = 0b0111.

NSHST

Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0110.

NSHLD

Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.

OSH

Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.

OSHST

Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.

OSHLD

Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of CRm, other than the values 0b0000 and 0b0100, that are not listed above are reserved, and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) or see Data Synchronization Barrier (DSB).

The value 0b0000 is used to encode SSBB and the value 0b0100 is used to encode PSSBB.

For the memory nXS barrier variant: specifies the limitation on the barrier operation. Values are:

SY

Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm<3:2> = 0b11.

ISH

Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm<3:2> = 0b10.

NSH

Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm<3:2> = 0b01.

OSH

Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm<3:2> = 0b00.

<imm>

For the memory barrier variant: is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

For the memory nXS barrier variant: is a 5-bit unsigned immediate, encoded in “CRm<3:2>”:

<table>
<thead>
<tr>
<th>CRm&lt;3:2&gt;</th>
<th>&lt;imm&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>16</td>
</tr>
<tr>
<td>01</td>
<td>20</td>
</tr>
<tr>
<td>10</td>
<td>24</td>
</tr>
<tr>
<td>11</td>
<td>28</td>
</tr>
</tbody>
</table>
Operation

if HaveTME() && TSTATE.depth > 0 then
  FailTransaction(TMFailure_ERR, FALSE);
  DataSynchronizationBarrier(domain, types);

Internal version only: isa v32.12, AdvSIMD v29.04, pseudocode v2020-09_xml, sve v2020-09_rc2b ; Build timestamp: 2020-09-30T20:20

DVP RCTX, <Xt>

is equivalent to

SYS #3, C7, C3, #5, <Xt>

and is always the preferred disassembly.

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.
EON (shifted register)

Bitwise Exclusive OR NOT (shifted register) performs a bitwise Exclusive OR NOT of a register value and an optionally-shifted register value, and writes the result to the destination register.

\[
\begin{array}{cccccccccccccccc}
\hline
sf & 1 & 0 & 0 & 1 & 0 & 1 & 0 & | & shift & 1 & | & Rm & | & imm6 & | & Rn & | & Rd & \\
opc & N
\end{array}
\]

32-bit (sf == 0)

EON \(<Wd>, \,<Wn>, \,<Wm>{, \,<\text{shift} \, #<\text{amount}>}\)

64-bit (sf == 1)

EON \(<Xd>, \,<Xn>, \,<Xm>{, \,<\text{shift} \, #<\text{amount}>}\)

integer \(d\) = \(\text{UInt}(Rd)\);
integer \(n\) = \(\text{UInt}(Rn)\);
integer \(m\) = \(\text{UInt}(Rm)\);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;

\begin{itemize}
  \item \textbf{ShiftType} \(\text{shift}\)\_\text{type} = \text{DecodeShift}(\text{shift});
  \item integer \(\text{shift}\)\_\text{amount} = \text{UInt}(\text{imm6});
\end{itemize}

Assembler Symbols

\begin{itemize}
  \item \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
  \item \(<Wn>\) Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
  \item \(<Wm>\) Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
  \item \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
  \item \(<Xn>\) Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
  \item \(<Xm>\) Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
  \item \(<\text{shift}>\) Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":
\end{itemize}

\[
\begin{array}{c|c}
\text{shift} & \langle\text{shift}\rangle \\
\hline
00 & LSL \\
01 & LSR \\
10 & ASR \\
11 & ROR \\
\end{array}
\]

\begin{itemize}
  \item \(<\text{amount}>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  \item For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
\end{itemize}

Operation

\[
\begin{align*}
\text{bits(datasize)} \, \text{operand1} &= \bar{x}[n]; \\
\text{bits(datasize)} \, \text{operand2} &= \text{ShiftReg}(m, \text{shift}\_\text{type}, \text{shift}\_\text{amount}); \\
\text{operand2} &= \text{NOT}(\text{operand2}); \\
\text{result} &= \text{operand1} \text{ EOR } \text{operand2}; \\
x[d] &= \text{result};
\end{align*}
\]
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
**EOR (immediate)**

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register.

### 32-bit \((sf == 0 && N == 0)\)

EOR \(<Wd|WSP>, <Wn>, #<imm>\)

### 64-bit \((sf == 1)\)

EOR \(<Xd|SP>, <Xn>, #<imm>\)

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;
if sf == '0' && N != '0' then UNDEFINED;
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

**Assembler Symbols**

- `<Wd|WSP>`  Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Wn>`  Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Xd|SP>`  Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xn>`  Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<imm>`  For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".
  For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = X[n];
result = operand1 EOR imm;
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
EOR (shifted register)

Bitwise Exclusive OR (shifted register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

<table>
<thead>
<tr>
<th>sf</th>
<th>0</th>
<th>0</th>
<th>1</th>

32-bit (sf == 0)

EOR <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit (sf == 1)

EOR <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then UNDEFINED;

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

\[
\text{bits(datasize) operand1} = X[n];
\text{bits(datasize) operand2} = \text{ShiftReg}(m, shift\_type, shift\_amount);
\text{result} = \text{operand1 EOR operand2};
\text{X[d]} = \text{result};
\]

Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
ERET

Exception Return using the ELR and SPSR for the current Exception level. When executed, the PE restores \texttt{PSTATE} from the SPSR, and branches to the address held in the ELR.

The PE checks the SPSR for the current Exception level for an illegal return event. See \textit{Illegal return events from AArch64 state}.

\texttt{ERET} is \texttt{UNDEFINED} at \texttt{EL0}.

\begin{verbatim}
1 1 0 1 0 1 1 0 1 0 0 1 1 1 1 1 0 0 0 0 1 1 1 1 0 0 0 0 0
A M Rn op4
\end{verbatim}

**Operation**

\begin{verbatim}
\texttt{AArch64.CheckForERetTrap(FALSE, TRUE);}  
\texttt{bits(64) target = ELR[];}  
\texttt{AArch64.ExceptionReturn(target, SPSR[]);}
\end{verbatim}
ERETAA, ERETABB

Exception Return, with pointer authentication. This instruction authenticates the address in ELR, using SP as the modifier and the specified key, the PE restores PSTATE from the SPSR for the current Exception level, and branches to the authenticated address.

Key A is used for ERETAA, and key B is used for ERETAB.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to ELR.

The PE checks the SPSR for the current Exception level for an illegal return event. See Illegal return events from AArch64 state.

ERETAA and ERETAB are UNDEFINED at EL0.

Operation

AArch64.CheckForERetTrap(TRUE, use_key_a);

bits(64) target;

if use_key_a then

target = AuthIA(ELR[], SP[], TRUE);
else

target = AuthIB(ELR[], SP[], TRUE);

AArch64.ExceptionReturn(target, SPSR[]);
Error Synchronization Barrier is an error synchronization event that might also update DISR_EL1 and VDISR_EL2. This instruction can be used at all Exception levels and in Debug state. In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. See Error Synchronization Barrier in the Arm(R) Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for Armv8-A architecture profile. If the RAS Extension is not implemented, this instruction executes as a NOP.

System
(Armv8.2)

```
if !HaveRASExt() then EndOfInstruction();
```

Operation

```
if HaveTME() && TSTATE.depth > 0 then
    FailTransaction(TMFailure_ERR, FALSE);
    SynchronizeErrors();
    AArch64.ESBOperation();
if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then AArch64.vESBOperation();
    TakeUnmaskedSErrorInterrupts();
```
**EXTR**

Extract register extracts a register from a pair of registers.

This instruction is used by the alias **ROR (immediate)**.

HVC

Hypervisor Call causes an exception to EL2. Non-secure software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is UNDEFINED:

- At EL0.
- At EL1 if EL2 is not enabled in the current Security state.
- When SCR_EL3.HCE is set to 0.

On executing an HVC instruction, the PE records the exception as a Hypervisor Call exception in ESR_ELx, using the EC value 0x16, and the value of the immediate argument.

ISB

Instruction Synchronization Barrier flushes the pipeline in the PE and is a context synchronization event. For more information, see Instruction Synchronization Barrier (ISB).

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 0 1 0 1 0 0 0 1 0 1 1 0 1 1 0 1 1 1 1
```

```
ISB {<option>|#<imm>}
```

// No additional decoding required

**Assembler Symbols**

- `<option>` Specifies an optional limitation on the barrier operation. Values are:
  - **SY**
    
    Full system barrier operation, encoded as CRm = 0b1111. Can be omitted.

    All other encodings of CRm are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

- `<imm>` Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

**Operation**

```
InstructionSynchronizationBarrier();
```

LD64B

Single-copy Atomic 64-byte Load derives an address from a base register value, loads eight 64-bit doublewords from a memory location, and writes them to consecutive registers, Xt to X(t+7). The data that is loaded is atomic and is required to be 64-byte aligned.

LDADD, LDADDA, LDADDAL, LDADDL

Atomic add on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDADDA and LDADDAL load from memory with acquire semantics.
- LDADDL and LDADDAL store to memory with release semantics.
- LDADD has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

This instruction is used by the alias STADD, STADDL.

LDAPR

Load-Acquire RCpc Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from the derived address in memory, and writes it to a register.

The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release*, except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see *Load/Store addressing modes*.

** LDAPRH  
<Wt>, [<Xn|SP> {,#0}]**

integer n = UInt(Rn);
integer t = UInt(Rt);
boolean tag_checked = n != 31;

### Assembler Symbols

- `<Wt>` Is the 32-bit name of the general-purpose register to be loaded, encoded in the “Rt” field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

### Operation

bits(64) address;
bits(16) data;

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];
data = Mem[address, 2, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);

### Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDAPUR

Load-Acquire RCpc Register (unscaled) calculates an address from a base register and an immediate offset, loads a
32-bit word or 64-bit doubleword from memory, zero-extends it, and writes it to a register.

The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release*,
except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release,
  created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does
  not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see *Load/Store addressing modes*.

X[t] = ZeroExtend(data, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDAXP

Load-Acquire Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and is single-copy atomic for each doubleword at doubleword granularity. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

32-bit (sz == 0)

LDAXP <Wt1>, <Wt2>, [<Xn|SP>{,#0}]

64-bit (sz == 1)

LDAXP <Xt1>, <Xt2>, [<Xn|SP>{,#0}]

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);
integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;

boolean rt_unknown = FALSE;
if t == t2 then
  Constraint c = ConstraineUnpredictable(Unpredictable_LDPOVERLAP);
  assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
  case c of
    when Constraint_UNKNOWN rt unknown = TRUE; // result is UNKNOWN
    when Constraint_UNDEF UNDEFINED;
    when Constraint_NOP EndOfInstruction();

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDAXP.

Assembler Symbols

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDEORB, LDEORAB, LDEORALB, LDEORLB

Atomic exclusive OR on byte in memory atomically loads an 8-bit byte from memory, performs an exclusive OR with
the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is
returned in the destination register.

- If the destination register is not WZR, LDEORAB and LDEORALB load from memory with acquire semantics.
- LDEORLB and LDEORALB store to memory with release semantics.
- LDEORB has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Store-Release.
For information about memory accesses see Load/Store addressing modes.

This instruction is used by the alias STEORB, STEORLB.

LDP `<Xt1>`, `<Xt2>`, `[<Xn|SP>]`, `#<imm>`

boolean wback = FALSE;
boolean postindex = FALSE;
For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDP*.

**Assembler Symbols**

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> For the 32-bit post-index and 32-bit pre-index variant: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the "imm7" field as <imm>/4.

For the 32-bit signed offset variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4.

For the 64-bit post-index and 64-bit pre-index variant: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the "imm7" field as <imm>/8.

For the 64-bit signed offset variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDR (immediate)**

Load Register (immediate) loads a word or doubleword from memory and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see *Load/Store addressing modes*. The Unsigned offset variant scales the immediate offset value by the size of the value accessed before adding it to the base register value.

It has encodings from 3 classes: Post-index, Pre-index and Unsigned offset

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
```
**LDRAA, LDRAB**

Load Register, with pointer authentication. This instruction authenticates an address from a base register using a modifier of zero and the specified key, adds an immediate offset to the authenticated address, and loads a 64-bit doubleword from memory at this resulting address into a register.

Key A is used for LDRAA, and key B is used for LDRAB.

If the authentication passes, the PE behaves the same as for an LDR instruction. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the base register, unless the pre-indexed variant of the instruction is used. In this case, the address that is written back to the base register does not include the pointer authentication code.

For information about memory accesses, see *Load/Store addressing modes*.

**Unscaled offset**

(Armv8.3)

```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRH (immediate)*.

**Assembler Symbols**

- `<Wt>`: Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>`: Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<simm>`: Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
- `<pimm>`: Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
Shared Decode

integer n = UInt(Rn);
integer t = UInt(Rt);

boolean tag_checked = wback || n != 31;
boolean wb_unknown = FALSE;

if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE; // writeback is suppressed
        when Constraint_UNKNOWN wb unknown = TRUE; // writeback is UNKNOWN
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();

Operation

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

if !postindex then
    address = address + offset;

data = Mem[address, 1, AccType_NORMAL];
X[t] = ZeroExtend(data, 32);

if wback then
    if wb unknown then
        address = bits(64) UNKNOWN;
    elsif postindex then
        address = address + offset;
    if n == 31 then
        SP[] = address;
    else
        X[n] = address;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDRB (register)**

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it, and writes it to a register. For information about memory accesses, see Load/Store addressing modes.

Extended register (option != 011)

\[ \text{LDRB} \ <Wt>, \ [<Xn|SP>, \ (<Wm>|<Xm>), \ <extend> \ {<amount>}] \]

Shifted register (option == 011)

\[ \text{LDRB} \ <Wt>, \ [<Xn|SP>, \ <Xm>{, \ LSL <amount>}] \]

if option<1> == '0' then UNDEFINED; // sub-word index

\[ \text{ExtendType extend_type} = \text{DecodeRegExtend}(\text{option}); \]

**Assembler Symbols**

- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<Wm>` When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<Xm>` When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<extend>` Is the index extend specifier, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

`<amount>` Is the index shift amount, it must be #0, encoded in “S” as 0 if omitted, or as 1 if present.

**Shared Decode**

```java
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```
Operation

bits(64) offset = ExtendReg(m, extend_type, 0);
if HaveMTEExt() then
    SetTagCheckedInstruction(TRUE);

bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];
address = address + offset;

data = Mem[address, 1, AccType_NORMAL];
X[t] = ZeroExtend(data, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDRH `<Wt>`, `(<Xn|SP>, (<Wm>|<Xm>)\{, <extend> {<amount>}})`

if option<1> == '0' then UNDEFINED; // sub-word index

**ExtendType** extend_type = DecodeRegExtend(option);

integer shift = if S == '1' then 1 else 0;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

**Assembler Symbols**

- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<Wm>` When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<Xm>` When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<extend>` Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when `<amount>` is omitted, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th><code>&lt;extend&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

- `<amount>` Is the index shift amount, optional only when `<extend>` is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

<table>
<thead>
<tr>
<th>S</th>
<th><code>&lt;amount&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#1</td>
</tr>
</tbody>
</table>

ExtendType  extend_type = DecodeRegExtend(option);  
```

**Assembler Symbols**

- `<Wt>` is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xt>` is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<Wm>` is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<Xm>` is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<extend>` is the index extend specifier, encoded in “option”:
  
<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

- `<amount>` is the index shift amount, it must be #0, encoded in “S” as 0 if omitted, or as 1 if present.

< Xt > Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTW</td>
</tr>
<tr>
<td>001</td>
<td>LSL</td>
</tr>
<tr>
<td>010</td>
<td>SXTW</td>
</tr>
<tr>
<td>011</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#2</td>
</tr>
</tbody>
</table>

Shared Decode

integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
Operation

bits(64) offset = ExtendReg(m, extend_type, shift);
if HaveMTEExt() then
    SetTagCheckedInstruction(TRUE);

bits(64) address;
bits(32) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[ ];
else
    address = X[n];

address = address + offset;

data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDSET, LDSETA, LDSETAL, LDSETL

Atomic bit set on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDSETA and LDSETAL load from memory with acquire semantics.
- LDSETL and LDSETAL store to memory with release semantics.
- LDSET has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

This instruction is used by the alias STSET, STSETL.

LDSMIN, LDSMINA, LDSMINAL, LDSMINL

Atomic signed minimum on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDSMINA and LDSMINAL load from memory with acquire semantics.
- LDSMINL and LDSMINAL store to memory with release semantics.
- LDSMIN has neither acquire nor release semantics.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*. For information about memory accesses see *Load/Store addressing modes*.

This instruction is used by the alias **STSMIN, STSMINL**.

LDTR

Load Register (unprivileged) loads a word or doubleword from memory, and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:
- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes.

LDTRSW

Load Register Signed Word (unprivileged) loads a word from memory, sign-extends it to 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.E2H, TGE is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL**

Atomic unsigned maximum on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, LDUMAXA and LDUMAXAL load from memory with acquire semantics.
- LDUMAXL and LDUMAXAL store to memory with release semantics.
- LDUMAX has neither acquire nor release semantics.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*. For information about memory accesses see *Load/Store addressing modes*.

This instruction is used by the alias **STUMAX, STUMAXL**.

    address = X[n];

data = MemAtomic(address, MemAtomicOp_UMIN, value, ldacctype, stacctype);

if t != 31 then
    X[t] = ZeroExtend(data, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDUR

Load Register (unscaled) calculates an address from a base register and an immediate offset, loads a 32-bit word or 64-bit doubleword from memory, zero-extends it, and writes it to a register. For information about memory accesses, see Load/Store addressing modes.

### 32-bit (size == 10)

LDUR <Wt>, [<Xn|SP>{, #<simm>}]  

### 64-bit (size == 11)

LDUR <Xt>, [<Xn|SP>{, #<simm>}]  

integer scale = UInt(size);  
bits(64) offset = SignExtend(imm9, 64);

#### Assembler Symbols

- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<simm>` Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

#### Shared Decode

integer n = UInt(Rn);  
integer t = UInt(Rt);  
integer regsize;

regsize = if size == '11' then 64 else 32;  
integer datasize = 8 << scale;  
boolean tag_checked = n != 31;

#### Operation

if HaveMTEExt() then  
    SetTagCheckedInstruction(tag_checked);

bits(64) address;  
bits(datasize) data;

if n == 31 then  
    CheckSPAlignment();  
    address = SP[];  
else  
    address = X[n];

address = address + offset;

data = Mem[address, datasize DIV 8, AccType_NORMAL];  
X[t] = ZeroExtend(data, regsize);
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDURB

Load Register Byte (unscaled) calculates an address from a base register and an immediate offset, loads a byte from memory, zero-extends it, and writes it to a register. For information about memory accesses, see Load/Store addressing modes.

```
|   31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|---------------------------------|--------|--------|----|

X[t] = SignExtend(data, 64);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDXP

Load Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit
doublewords from memory, and writes them to two registers. A 32-bit pair requires the address to be doubleword
aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned
and is single-copy atomic for each doubleword at doubleword granularity. The PE marks the physical address being
accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See
Synchronization and semaphores. For information about memory accesses see Load/Store addressing modes.

32-bit (sz == 0)

LDXP <Wt1>, <Wt2>, [<Xn|SP>{,#0}]

64-bit (sz == 1)

LDXP <Xt1>, <Xt2>, [<Xn|SP>{,#0}]

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;

boolean rt_unknown = FALSE;
if t == t2 then
    Constraint c = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt unknown = TRUE; // result is UNKNOWN
        when Constraint_UNDEF UNDEFINED;
        when Constraint_NOP EndOfInstruction();

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on
UNPREDICTABLE behaviors, and particularly LDXP.

Assembler Symbols

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LSL (register)**

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This is an alias of `LSLV`. This means:

- The encodings in this description are named to match the encodings of `LSLV`.
- The description of `LSLV` gives the operational pseudocode for this instruction.

### 32-bit (sf == 0)

```
LSL <Wd>, <Wn>, <Wm>
```

is equivalent to

```
LSLV <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

### 64-bit (sf == 1)

```
LSL <Xd>, <Xn>, <Xm>
```

is equivalent to

```
LSLV <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

**Operation**

The description of `LSLV` gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 && N == 0 && imms != 011111)

LSL <Wd>, <Wn>, #<shift>

is equivalent to

UBFM <Wd>, <Wn>, #(-<shift> MOD 32), #(31-<shift>)

and is the preferred disassembly when imms + 1 == immr.

64-bit (sf == 1 && N == 1 && imms != 111111)

LSL <Xd>, <Xn>, #<shift>

is equivalent to

UBFM <Xd>, <Xn>, #(-<shift> MOD 64), #(63-<shift>)

and is the preferred disassembly when imms + 1 == immr.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <shift> For the 32-bit variant: is the shift amount, in the range 0 to 31.
- For the 64-bit variant: is the shift amount, in the range 0 to 63.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**LSLV**

Logical Shift Left Variable shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This instruction is used by the alias **LSL (register)**.

<table>
<thead>
<tr>

**32-bit (sf == 0)**

\[
\text{LSLV } <Wd>, <Wn>, <Wm>
\]

**64-bit (sf == 1)**

\[
\text{LSLV } <Xd>, <Xn>, <Xm>
\]

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

**Assembler Symbols**

- `<Wd>` is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Wm>` is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
- `<Xd>` is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- `<Xm>` is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand2 = X[m];
result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Logical Shift Right (register) shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This is an alias of \textit{LSRV}. This means:

- The encodings in this description are named to match the encodings of \textit{LSRV}.
- The description of \textit{LSRV} gives the operational pseudocode for this instruction.

\begin{verbatim}
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
sf | 0 0 1 1 0 1 0 1 1 0 | Rm | 0 0 1 0 | 0 1 | Rn | Rd

op2
\end{verbatim}

**32-bit (sf == 0)**

\texttt{LSR <Wd>, <Wn>, <Wm>}

is equivalent to

\texttt{LSRV <Wd>, <Wn>, <Wm>}

and is always the preferred disassembly.

**64-bit (sf == 1)**

\texttt{LSR <Xd>, <Xn>, <Xm>}

is equivalent to

\texttt{LSRV <Xd>, <Xn>, <Xm>}

and is always the preferred disassembly.

**Assembler Symbols**

\begin{itemize}
\item \texttt{<Wd>} Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
\item \texttt{<Wn>} Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
\item \texttt{<Wm>} Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
\item \texttt{<Xd>} Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
\item \texttt{<Xn>} Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
\item \texttt{<Xm>} Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.
\end{itemize}

**Operation**

The description of \textit{LSRV} gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
LSR (immediate)

Logical Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

<table>

</table>

Operation

bits(destsize) operand1 = X[n];
bits(destsize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;

result = UInt(operand3) + (UInt(operand1) * UInt(operand2));

X[d] = result<destsize-1:0>;
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MNEG

Multiply-Negate multiplies two register values, negates the product, and writes the result to the destination register.

This is an alias of MSUB. This means:

- The encodings in this description are named to match the encodings of MSUB.
- The description of MSUB gives the operational pseudocode for this instruction.

32-bit (sf == 0)

MNEG \(<Wd>, <Wn>, <Wm>\)

is equivalent to

MSUB \(<Wd>, <Wn>, <Wm>, WZR\)

and is always the preferred disassembly.

64-bit (sf == 1)

MNEG \(<Xd>, <Xn>, < Xm>\)

is equivalent to

MSUB \(<Xd>, <Xn>, < Xm>, XZR\)

and is always the preferred disassembly.

Assembler Symbols

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \(<Wm>\) Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- \(<Xm>\) Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of MSUB gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**MOV (to/from SP)**

Move between register and stack pointer: \( Rd = Rn \).

This is an alias of **ADD (immediate)**. This means:

- The encodings in this description are named to match the encodings of **ADD (immediate)**.
- The description of **ADD (immediate)** gives the operational pseudocode for this instruction.

| sf | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | Rn | Rd |
| op | S | sh | imm12 |

### 32-bit (sf == 0)

\[
\text{MOV } <\text{Wd}|\text{WSP}>, <\text{Wn}|\text{WSP}>
\]

is equivalent to

\[
\text{ADD } <\text{Wd}|\text{WSP}>, <\text{Wn}|\text{WSP}>, \#0
\]

and is the preferred disassembly when \( (Rd == '11111' || Rn == '11111') \).

### 64-bit (sf == 1)

\[
\text{MOV } <\text{Xd}|\text{SP}>, <\text{Xn}|\text{SP}>
\]

is equivalent to

\[
\text{ADD } <\text{Xd}|\text{SP}>, <\text{Xn}|\text{SP}>, \#0
\]

and is the preferred disassembly when \( (Rd == '11111' || Rn == '11111') \).

**Assembler Symbols**

- `<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

**Operation**

The description of **ADD (immediate)** gives the operational pseudocode for this instruction.
MOV (inverted wide immediate)

Move (inverted wide immediate) moves an inverted 16-bit immediate value to a register.

This is an alias of MOVN. This means:

- The encodings in this description are named to match the encodings of MOVN.
- The description of MOVN gives the operational pseudocode for this instruction.

<table>
<thead>
<tr>
<th>sf</th>
<th>0 0 1 0 0 1 0 1</th>
<th>hw</th>
<th>imm16</th>
<th>Rd</th>
</tr>
</thead>
</table>

32-bit (sf == 0 & hw == 0x)

MOV <Wd>, #<imm>

is equivalent to

MOVN <Wd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when ! (IsZero(imm16) && hw != '00') && ! IsOnes(imm16).

64-bit (sf == 1)

MOV <Xd>, #<imm>

is equivalent to

MOVN <Xd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when ! (IsZero(imm16) && hw != '00').

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<imm> For the 32-bit variant: is a 32-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw", but excluding 0xffff0000 and 0x0000ffff

For the 64-bit variant: is a 64-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw".

<shift> For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.

For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

The description of MOVN gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (wide immediate)

Move (wide immediate) moves a 16-bit immediate value to a register.

This is an alias of MOVZ. This means:

- The encodings in this description are named to match the encodings of MOVZ.
- The description of MOVZ gives the operational pseudocode for this instruction.

<table>

32-bit (sf == 0 & hw == 0x)

MOV <Wd>, #<imm>

is equivalent to

MOVZ <Wd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when ! (IsZero(imm16) && hw != '00').

64-bit (sf == 1)

MOV <Xd>, #<imm>

is equivalent to

MOVZ <Xd>, #<imm16>, LSL #<shift>

and is the preferred disassembly when ! (IsZero(imm16) && hw != '00').

Assembler Symbols

- **<Wd>**
  - Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

- **<Xd>**
  - Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

- **<imm>**
  - For the 32-bit variant: is a 32-bit immediate which can be encoded in "imm16:hw".
    - For the 64-bit variant: is a 64-bit immediate which can be encoded in "imm16:hw".

- **<shift>**
  - For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.
    - For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

The description of MOVZ gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (bitmask immediate)

Move (bitmask immediate) writes a bitmask immediate value to a register.

This is an alias of ORR (immediate). This means:

- The encodings in this description are named to match the encodings of ORR (immediate).
- The description of ORR (immediate) gives the operational pseudocode for this instruction.

32-bit (sf == 0 & N == 0)

MOV <Wd|WSP>, #<imm>

is equivalent to

ORR <Wd|WSP>, WZR, #<imm>

and is the preferred disassembly when \(!\) MoveWidePreferred(sf, N, imms, immr).

64-bit (sf == 1)

MOV <Xd|SP>, #<imm>

is equivalent to

ORR <Xd|SP>, XZR, #<imm>

and is the preferred disassembly when \(!\) MoveWidePreferred(sf, N, imms, immr).

Assembler Symbols

\(<\text{Wd}\text{|WSP}>\quad \text{Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.}\)
\(<\text{Xd}\text{|SP}>\quad \text{Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.}\)
\(<\text{imm}>\quad \text{For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr", but excluding values which could be encoded by MOVZ or MOVN.}\)
\(<\text{imm}>\quad \text{For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr", but excluding values which could be encoded by MOVZ or MOVN.}\)

Operation

The description of ORR (immediate) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (register)

Move (register) copies the value in a source register to the destination register.

This is an alias of **ORR (shifted register)**. This means:

- The encodings in this description are named to match the encodings of **ORR (shifted register)**.
- The description of **ORR (shifted register)** gives the operational pseudocode for this instruction.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
| sf | 0 1 | 0 1 0 0 0 | Rm | 0 0 0 0 0 1 1 1 1 1 | Rd |
| opt | shift | N | imm6 | Rn |

### 32-bit (sf == 0)

MOV `<Wd>`, `<Wm>`

is equivalent to

**ORR `<Wd>`, WZR, `<Wm>`**

and is always the preferred disassembly.

### 64-bit (sf == 1)

MOV `<Xd>`, `<Xm>`

is equivalent to

**ORR `<Xd>`, XZR, `<Xm>`**

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

**Operation**

The description of **ORR (shifted register)** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**MOVK**

Move wide with keep moves an optionally-shifted 16-bit immediate value into a register, keeping other bits unchanged.

```
<table>
<thead>
<tr>
<th>sf</th>
<th>hw</th>
<th>imm16</th>
<th>Rd</th>
</tr>
</thead>
</table>
```

32-bit (sf == 0 && hw == 0x)

```
MOVK <Wd>, #<imm>{, LSL #<shift>}
```

64-bit (sf == 1)

```
MOVK <Xd>, #<imm>{, LSL #<shift>}
```

```
integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
integer pos;
if sf == '0' && hw<1> == '1' then UNDEFINED;
pos = UInt(hw:'0000');
```

**Assembler Symbols**

- **<Wd>** Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Xd>** Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<imm>** Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
- **<shift>** For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.
  
  For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

**Operation**

```
bits(datasize) result;
result = X[d];
result<pos+15:pos> = imm16;
X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOVN

Move wide with NOT moves the inverse of an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (inverted wide immediate).

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
sf 0 0 1 0 0 1 0 1 hw imm16 Rd
```

**Asmblr Symbols**

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<imm> Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

<shift> For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.

For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

**Alias Conditions**

<table>

<td>! (IsZero(imm16) &amp; hw != '00') &amp; ! IsOnes(imm16)</td>
</tr>
</tbody>
</table>

**Operation**

```
bits(datasize) result;
result = Zeros();
result<pos+15:pos> = imm16;
result = NOT(result);
X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
• The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  • The values of the data supplied in any of its registers.
  • The values of the NZCV flags.
**MOVZ**

Move wide with zero moves an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias **MOV (wide immediate)**.

<table>
<thead>
<tr>
<th>sf</th>
<th>1 0 0 0 0 1 0 1</th>

</tbody>
</table>

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

<Cn> Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.

<Cm> Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

Operation

```
X[t] = AArch64.SysRegRead(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2);
```
MSR (immediate)

Move immediate value to Special Register moves an immediate value to selected bits of the PSTATE. For more information, see *Process state, PSTATE*.

The bits that can be written by this instruction are:

- PSTATE.D, PSTATE.A, PSTATE.I, PSTATE.F, and PSTATE.SP.
- If ARMv8.0-SSBS is implemented, PSTATE.SSBS.
- If ARMv8.1-PAN is implemented, PSTATE.PAN.
- If ARMv8.2-UAO is implemented, PSTATE.UAO.
- If ARMv8.4-DIT is implemented, PSTATE.DIT.
- If ARMv8.5-MemTag is implemented, PSTATE.TCO.
- If FEAT_CSRE is implemented, PSTATE.CSR.

```
31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0

MSR (register)

Move general-purpose register to System Register allows the PE to write an AArch64 System register from a general-purpose register:

```
  31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  10  9  8  7  6  5  4  3  2  1  0
  1  1  0  1  0  1  0  0  0  1  o0  op1  CRn  CRm  op2  Rt  L
```

MSR (<systemreg>|S<op0>_op1_<Cn>_Cm_<op2>), <Xt>

AArch64.CheckSystemAccess ('1':o0, op1, CRn, CRm, op2, Rt, L);

integer t = UInt(Rt);
integer sys_op0 = 2 + UInt(o0);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);

Assembler Symbols

- `<systemreg>` is a System register name, encoded in the "o0:op1:CRn:CRm:op2".
- `<op0>` is an unsigned immediate, encoded in "o0":
<table>
<thead>
<tr>
<th>&lt;op0&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
- `<op1>` is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- `<Cn>` is a name ‘Cn’, with ‘n’ in the range 0 to 15, encoded in the "CRn" field.
- `<Cm>` is a name ‘Cm’, with ‘m’ in the range 0 to 15, encoded in the "CRm" field.
- `<op2>` is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
- `<Xt>` is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

AArch64.SysRegWrite(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, X[t]);
MSUB

Multiply-Subtract multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register.

This instruction is used by the alias MNEG.

| sf | 0 0 0 1 1 0 1 0 0 0 | Rm | 1 | Ra | Rn | Rd |
|----|----------------------|----|----|----|----|
|    | 00                  |

32-bit (sf == 0)

MSUB <Wd>, <Wn>, <Wm>, <Wa>

64-bit (sf == 1)

MSUB <Xd>, <Xn>, < Xm>, <Xa>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Wa> Is the 32-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Alias Conditions

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>MNEG</td>
<td>Ra == '11111'</td>
</tr>
</tbody>
</table>

Operation

bits(destsize) operand1 = X[n];
bits(destsize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;
result = UInt(operand3) - (UInt(operand1) * UInt(operand2));
X[d] = result<destsize-1:0>
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MUL

Multiply: Rd = Rn * Rm.

This is an alias of MADD. This means:

- The encodings in this description are named to match the encodings of MADD.
- The description of MADD gives the operational pseudocode for this instruction.

32-bit (sf == 0)

MUL <Wd>, <Wn>, <Wm>

is equivalent to

MADD <Wd>, <Wn>, <Wm>, WZR

and is always the preferred disassembly.

64-bit (sf == 1)

MUL <Xd>, <Xn>, <Xm>

is equivalent to

MADD <Xd>, <Xn>, <Xm>, XZR

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of MADD gives the operational pseudocode for this instruction.
**MVN**

Bitwise NOT writes the bitwise inverse of a register value to the destination register.

This is an alias of ORN (shifted register). This means:

- The encodings in this description are named to match the encodings of ORN (shifted register).
- The description of ORN (shifted register) gives the operational pseudocode for this instruction.

<table>
<thead>
<tr>
<th>sf</th>
<th>0</th>
<th>1</th>
<th>0</th>
<th>1</th>
<th>0</th>
<th>1</th>
<th>0</th>
<th>shift</th>
<th>1</th>
<th>Rm</th>
<th>1</th>
<th>1</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**32-bit (sf == 0)**

MVN <Wd>, <Wm>{, <shift> #<amount>}

is equivalent to

ORN <Wd>, WZR, <Wm>{, <shift> #<amount>}

and is always the preferred disassembly.

**64-bit (sf == 1)**

MVN <Xd>, <Xm>{, <shift> #<amount>}

is equivalent to

ORN <Xd>, XZR, <Xm>{, <shift> #<amount>}

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

The description of ORN (shifted register) gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
• The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
NEG (shifted register)

Negate (shifted register) negates an optionally-shifted register value, and writes the result to the destination register.

This is an alias of SUB (shifted register). This means:

- The encodings in this description are named to match the encodings of SUB (shifted register).
- The description of SUB (shifted register) gives the operational pseudocode for this instruction.

### 32-bit (sf == 0)

$$\text{NEG} <Wd>, <Wm>{, <shift> \#<amount>}$$

is equivalent to

$$\text{SUB} <Wd>, WZR, <Wm>{, <shift> \#<amount>}$$

and is always the preferred disassembly.

### 64-bit (sf == 1)

$$\text{NEG} <Xd>, <Xm>{, <shift> \#<amount>}$$

is equivalent to

$$\text{SUB} <Xd>, XZR, <Xm>{, <shift> \#<amount>}$$

and is always the preferred disassembly.

### Assembler Symbols

- `<Wd>`: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wm>`: Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<Xd>`: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xm>`: Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<shift>`: Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- `<amount>`: For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

### Operation

The description of SUB (shifted register) gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
- The values of the data supplied in any of its registers.
- The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v32.12, AdvSIMD v29.04, pseudocode v2020-09_xml, sve v2020-09_rc2b ; Build timestamp: 2020-09-30T20:20

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**32-bit (sf == 0)**

NEGS <Wd>, <Wm>{, <shift> #<amount>}

is equivalent to

SUBS <Wd>, WZR, <Wm> {, <shift> #<amount>}

and is always the preferred disassembly.

**64-bit (sf == 1)**

NEGS <Xd>, <Xm>{, <shift> #<amount>}

is equivalent to

SUBS <Xd>, XZR, <Xm> {, <shift> #<amount>}

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.
- `<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>

<td>RESERVED</td>
</tr>
</tbody>
</table>

- `<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Operation**

The description of **SUBS (shifted register)** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
NGC

Negate with Carry negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register.

This is an alias of SBC. This means:

- The encodings in this description are named to match the encodings of SBC.
- The description of SBC gives the operational pseudocode for this instruction.

32-bit (sf == 0)

NGC <Wd>, <Wm>

is equivalent to

SBC <Wd>, WZR, <Wm>

and is always the preferred disassembly.

64-bit (sf == 1)

NGC <Xd>, <Xm>

is equivalent to

SBC <Xd>, XZR, <Xm>

and is always the preferred disassembly.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wm> Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xm> Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SBC gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
NGCS

Negate with Carry, setting flags, negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register. It updates the condition flags based on the result.

This is an alias of SBCS. This means:

- The encodings in this description are named to match the encodings of SBCS.
- The description of SBCS gives the operational pseudocode for this instruction.

| sf | 1 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | Rm | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | Rd |

32-bit (sf == 0)

NGCS <Wd>, <Wm>

is equivalent to

SBCS <Wd>, WZR, <Wm>

and is always the preferred disassembly.

64-bit (sf == 1)

NGCS <Xd>, <Xm>

is equivalent to

SBCS <Xd>, XZR, <Xm>

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wm> Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xm> Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SBCS gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
NOP

No Operation does nothing, other than advance the value of the program counter by 4. This instruction can be used for instruction alignment purposes.

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

NOP

// Empty.

// do nothing

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ORN (shifted register)

Bitwise OR NOT (shifted register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MVN.

32-bit (sf == 0)

ORN <Wd>, <Wn>, <Wm>{, <shift> #<amount>}

64-bit (sf == 1)

ORN <Xd>, <Xn>, < Xm>{, <shift> #<amount>}

Assembler Symbols

| <Wd>   | Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field. |

X[d] &= \text{result};
\end{align*}
\]

Operational information

If \text{PSTATE.DIT} is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the \text{NZCV} flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the \text{NZCV} flags.
PACDA, PACDZA

Pointer Authentication Code for Data address, using key A. This instruction computes and inserts a pointer authentication code for a data address, using a modifier and key A.
The address is in the general-purpose register that is specified by <Xd>.
The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDA.
- The value zero, for PACDZA.

Integer
(Armv8.3)

else // PACDZB
    if n != 31 then UNDEFINED;

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

if source_is_sp then
    X[d] = AddPACDB(X[d], SP[]);
else
    X[d] = AddPACDB(X[d], X[n]);
PACGA

Pointer Authentication Code, using Generic key. This instruction computes the pointer authentication code for an address in the first source register, using a modifier in the second source register, and the Generic key. The computed pointer authentication code is returned in the upper 32 bits of the destination register.

Integer

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm|SP> Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Rm" field.

Operation

if source_is_sp then
    X[d] = AddPACGA(X[n], SP[{}]);
else
    X[d] = AddPACGA(X[n], X[m]);
PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA

Pointer Authentication Code for Instruction address, using key A. This instruction computes and inserts a pointer authentication code for an instruction address, using a modifier and key A.

The address is:
- In the general-purpose register that is specified by <Xd> for PACIA and PACIZA.
- In X17, for PACIA1716.
- In X30, for PACIASP and PACIAZ.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACIA.
- The value zero, for PACIZA and PACIAZ.
- In X16, for PACIA1716.
- In SP, for PACIASP.

It has encodings from 2 classes: Integer and System

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

if HavePACExt() then
  if source_is_sp then
    X[d] = AddPACIA(X[d], SP());
  else
    X[d] = AddPACIA(X[d], X[n]);
PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB

Pointer Authentication Code for Instruction address, using key B. This instruction computes and inserts a pointer authentication code for an instruction address, using a modifier and key B.

The address is:
- In the general-purpose register that is specified by <Xd> for PACIB and PACIZB.
- In X17, for PACIB1716.
- In X30, for PACIBSP and PACIBZ.

The modifier is:
- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACIB.
- The value zero, for PACIZB and PACIBZ.
- In X16, for PACIB1716.
- In SP, for PACIBSP.

It has encodings from 2 classes: Integer and System

    X[d] = AddPACIB(X[d], SP[]);
  else
    X[d] = AddPACIB(X[d], X[n]);
PRFM (immediate)

Prefetch Memory (immediate) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory. For information about memory accesses, see Load/Store addressing modes.

```

|   |   | 1 | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | imm12 |     | Rn  |     | Rt  |
```

PRFM (<prfop>|#<imm5>), [<Xn|SP>{, #<pimm}]}

```
bits(64) offset = LSL(ZeroExtend(imm12, 64), 3);
```

Assembler Symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.

- **PLD**
  - Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.

- **PLI**
  - Preload instructions, encoded in the "Rt<4:3>" field as 0b01.

- **PST**
  - Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.

<target> is one of:

- **L1**
  - Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.

- **L2**
  - Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.

- **L3**
  - Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

<policy> is one of:

- **KEEP**
  - Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.

- **STRM**
  - Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory.

For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<pimm> Is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

Shared Decode

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```
Operation

if HaveMTEExt() then
    SetTagCheckedInstruction(FALSE);

bits(64) address;
if n == 31 then
    address = SP[];
else
    address = X[n];

address = address + offset;

Prefetch(address, t<4:0>);
PRFM (literal)

Prefetch Memory (literal) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory. For information about memory accesses, see Load/Store addressing modes.

integer t = Uint(Rt);
bias(64) offset;
offset = SignExtend(imm19:'00', 64);

Assembler Symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.
<type> is one of:
PLD Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
PLI Preload instructions, encoded in the "Rt<4:3>" field as 0b01.
PST Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.
<target> is one of:
L1 Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
L2 Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
L3 Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.
<policy> is one of:
KEEP Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
STRM Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory. For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<label> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.
Operation

```c
bits(64) address = PC[] + offset;
if HaveMTEExt() then
    SetTagCheckedInstruction(FALSE);
Prefetch(address, t<4:0>);
```

PRFM (register)

Prefetch Memory (register) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory.

For information about memory accesses, see Load/Store addressing modes.

    - Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.
  - L2
    - Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
  - L3
    - Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

- <policy> is one of:
  - KEEP
    - Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
  - STRM
    - Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory.

For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field.

This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in "option":

For other encodings of the "Rm" field, use <imm5>.
<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>

</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#3</td>
</tr>
</tbody>
</table>

**Shared Decode**

```plaintext
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```

**Operation**

```plaintext
bits(64) offset = ExtendReg(m, extend_type, shift);
if HaveMTEExt() then
    SetTagCheckedInstruction(FALSE);

bits(64) address;
if n == 31 then
    address = SP[{}];
else
    address = X[n];

address = address + offset;
Prefetch(address, t<4:0>);
```
Prefetch Memory (unscaled offset) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFUM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory. For information about memory accesses, see Load/Store addressing modes.

For information about memory accesses, see Load/Store addressing modes.

### Assembler Symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>. 

- **PLD**: Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.
- **PLI**: Preload instructions, encoded in the "Rt<4:3>" field as 0b01.

- **L2**: Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.
- **L3**: Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

<policy> is one of:

- **KEEP**: Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.
- **STRM**: Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see Prefetch memory. For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field. This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

### Shared Decode

```c
integer n = UInt(Rn);
integer t = UInt(Rt);
```

```c
size opc
PRFUM (<prfop>|#<imm5>), [<Xn|SP>{, #<simm>})

bits(64) offset = SignExtend(imm9, 64);
```
Operation

if HaveMTEExt() then
    SetTagCheckedInstruction(FALSE);

bits(64) address;

if n == 31 then
    address = SP[];
else
    address = X[n];

address = address + offset;

Prefetch(address, t<4:0>);
PSB CSYNC

Profiling Synchronization Barrier. This instruction is a barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. A following DSB instruction completes when the writes to the profiling buffer have completed.

If the Statistical Profiling Extension is not implemented, this instruction executes as a NOP.

System
(Armv8.2)

if !HaveStatisticalProfiling() then EndOfInstruction();

Operation

ProfilingSynchronizationBarrier();

Internal version only: isa v32.12, AdvSIMD v29.04, pseudocode v2020-09_xml, sve v2020-09_rc2b ; Build timestamp: 2020-09-30T20:20

PSSBB

Physical Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same physical address.

The semantics of the Physical Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the PSSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the PSSBB.

- When a load to a location appears in program order before the PSSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order after the PSSBB.

\[
\begin{array}{cccccccccccccccccccc}
\hline
1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\]

CRm opc

// No additional decoding required

Operation

SpeculativeStoreBypassBarrierToPA();

Internal version only: isa v32.12, AdvSIMD v29.04, pseudocode v2020-09.xml, sve v2020-09_rc2b ; Build timestamp: 2020-09-30T20:20

RBIT

Reverse Bits reverses the bit order in a register.

32-bit (sf == 0)

RBIT <Wd>, <Wn>

64-bit (sf == 1)

RBIT <Xd>, <Xn>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

bits(datasize) operand = X[n];
bits(datasize) result;
for i = 0 to datasize-1
    result<datasize-1-i> = operand<i>;
X[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**RET**

Return from subroutine branches unconditionally to an address in a register, with a hint that this is a subroutine return.

\[
\begin{array}{cccccccccccccccccccc}
\hline
1 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & Rn & 0 & 0 & 0 & 0 & 0 & Rm
\end{array}
\]

\[\text{RET } \{<Xn>\}\]

integer \(n = \text{UInt}(\text{Rn});\)

**Assembler Symbols**

\(<Xn>\) Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the “Rn” field. Defaults to X30 if absent.

**Operation**

bits(64) \(\text{target} = X[n];\)

if \(\text{HaveCSRExt}() \&\& \text{CallStackRecordingActive}()\) then
  \(\text{RemoveCallStackRecord}();\)

// Value in BTypeNext will be used to set PSTATE.BTYPE
BTypeNext = '00';

\(\text{BranchTo(target, BranchType\_RET);}\)

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**RETA A, RETAB**

Return from subroutine, with pointer authentication. This instruction authenticates the address that is held in LR, using SP as the modifier and the specified key, branches to the authenticated address, with a hint that this instruction is a subroutine return.

Key A is used for RETAA, and key B is used for RETAB.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to LR.

---

REV64

Reverse Bytes reverses the byte order in a 64-bit general-purpose register. When assembling for Armv8.2, an assembler must support this pseudo-instruction. It is optional whether an assembler supports this pseudo-instruction when assembling for an architecture earlier than Armv8.2.

This is a pseudo-instruction of REV. This means:

- The encodings in this description are named to match the encodings of REV.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of REV gives the operational pseudocode for this instruction.

sf opc

64-bit

REV64 <Xd>, <Xn>

is equivalent to

REV <Xd>, <Xn>

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of REV gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
RMIF

Performs a rotation right of a value held in a general purpose register by an immediate value, and then inserts a selection of the bottom four bits of the result of the rotation into the PSTATE flags, under the control of a second immediate mask.

Integer (Armv8.4)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| 1  | 0  | 1  | 1  | 0  | 1  | 0  | 0  | 0  | 0  | 0  | imm6 | 0  | 0  | 0  | 0  | 1  | Rn | 0  | mask |

sf

RMIF <Xn>, #<shift>, #<mask>

if !HaveFlagManipulateExt() then UNDEFINED;
integer lsb = UInt(imm6);
integer n = UInt(Rn);

Assembler Symbols

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<shift> Is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
<mask> Is the flag bit mask, an immediate in the range 0 to 15, which selects the bits that are inserted into the NZCV condition flags, encoded in the "mask" field.

Operation

bits(4) tmp;
bits(64) tmpreg = X[n];
tmp = (tmpreg:tmpreg)<lsb+3:lsb>;
if mask<3> == '1' then PSTATE.N = tmp<3>;
if mask<2> == '1' then PSTATE.Z = tmp<2>;
if mask<1> == '1' then PSTATE.C = tmp<1>;
if mask<0> == '1' then PSTATE.V = tmp<0>;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ROR (immediate)

Rotate right (immediate) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This is an alias of EXTR. This means:

- The encodings in this description are named to match the encodings of EXTR.
- The description of EXTR gives the operational pseudocode for this instruction.

| sf | 0 0 1 1 1 | N 0 | Rm | imms | Rn | Rd |

32-bit (sf == 0 && N == 0 && imms == 0xxxxx)

ROR <Wd>, <Ws>, #<shift>

is equivalent to

EXTR <Wd>, <Ws>, <Ws>, #<shift>

and is the preferred disassembly when Rn == Rm.

64-bit (sf == 1 && N == 1)

ROR <Xd>, <Xs>, #<shift>

is equivalent to

EXTR <Xd>, <Xs>, <Xs>, #<shift>

and is the preferred disassembly when Rn == Rm.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Ws> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xs> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
- <shift> For the 32-bit variant: is the amount by which to rotate, in the range 0 to 31, encoded in the "imms" field.
  For the 64-bit variant: is the amount by which to rotate, in the range 0 to 63, encoded in the "imms" field.

Operation

The description of EXTR gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This is an alias of RORV. This means:

- The encodings in this description are named to match the encodings of RORV.
- The description of RORV gives the operational pseudocode for this instruction.

32-bit (sf == 0)

ROR <Wd>, <Wn>, <Wm>

is equivalent to

RORV <Wd>, <Wn>, <Wm>

and is always the preferred disassembly.

64-bit (sf == 1)

ROR <Xd>, <Xn>, <Xm>

is equivalent to

RORV <Xd>, <Xn>, <Xm>

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of RORV gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Rotate Right Variable provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ROR (register).

32-bit (sf == 0)

RORV <Wd>, <Wn>, <Wm>

64-bit (sf == 1)

RORV <Xd>, <Xn>, <Xm>

ShiftType shift_type = DecodeShift(op2);

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

bits(datasize) result;
bits(datasize) operand2 = X[m];
result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SB

Speculation Barrier is a barrier that controls speculation. The semantics of the Speculation Barrier are that the execution, until the barrier completes, of any instruction that appears later in the program order than the barrier:

- Cannot be performed speculatively to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception.

In particular, any instruction that appears later in the program order than the barrier cannot cause a speculative allocation into any caching structure where the allocation of that entry could be indicative of any data value present in memory or in the registers.

The SB instruction:

- Cannot be speculatively executed as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception. The potentially exception generating instruction can complete once it is known not to be speculative, and all data values generated by instructions appearing in program order before the SB instruction have their predicted values confirmed.

When the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after an uncompleted SB instruction, the SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched.

```
1 1 0 1 0 1 0 0 0 0 1 1 0 0 1 1 |(0) (0) (0) |1 1 1 1 1 1 1
```

```
SB
if !HaveSBExt() then UNDEFINED;
```

**Operation**

```
SpeculationBarrier();
```
SBC

Subtract with Carry subtracts a register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

This instruction is used by the alias NGC.

  - The values of the NZCV flags.
SBFIZ

Signed Bitfield Insert in Zeros copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, setting the destination bits below the bitfield to zero, and the bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 && N == 0)

SBFIZ <Wd>, <Wn>, #<lsb>, #<width>

is equivalent to

SBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

64-bit (sf == 1 && N == 1)

SBFIZ <Xd>, <Xn>, #<lsb>, #<width>

is equivalent to

SBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)

and is the preferred disassembly when UInt(imms) < UInt(immr).

Assembler Symbols

<Wr>  Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wr>  Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Wr>  Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wr>  Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb> For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.
<lsb> For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
<width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
<width> For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
Signed Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly. If \(<\text{imms}>\) is greater than or equal to \(<\text{immr}>\), this copies a bitfield of \((<\text{imms}>-<\text{immr}>+1)\) bits starting from bit position \(<\text{immr}>\) in the source register to the least significant bits of the destination register. If \(<\text{imms}>\) is less than \(<\text{immr}>\), this copies a bitfield of \((<\text{imms}>+1)\) bits from the least significant bits of the source register to bit position \((\text{regsize}-<\text{immr}>)\) of the destination register, where \text{regsize} is the destination register size of 32 or 64 bits. In both cases the destination bits below the bitfield are set to zero, and the bits above the bitfield are set to a copy of the most significant bit of the bitfield.

This instruction is used by the aliases ASR (immediate), SBFIZ, SBFX, SXTB, SXTH, and SXTW.

### Operation

```plaintext
bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = ROR(src, R) AND wmask;

// determine extension bits (sign, zero or dest register)
bits(datasize) top = Replicate(src<S>);

// combine extension bits and result bits
X[d] = (top AND NOT(tmask)) OR (bot AND tmask);
```

### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SBFX

Signed Bitfield Extract copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 & N == 0)

SBFX <Wd>, <Wn>, #<lsb>, #<width>

is equivalent to

SBFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)

and is the preferred disassembly when BFXPreferred(sf, opc<1>, imms, immr).

64-bit (sf == 1 & N == 1)

SBFX <Xd>, <Xn>, #<lsb>, #<width>

is equivalent to

SBFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)

and is the preferred disassembly when BFXPreferred(sf, opc<1>, imms, immr).

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb> For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
<width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Signed Divide divides a signed integer register value by another signed integer register value, and writes the result to the destination register. The condition flags are not affected.

32-bit (sf == 0)

SDIV <Wd>, <Wn>, <Wm>

64-bit (sf == 1)

SDIV <Xd>, <Xn>, < Xm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
integer result;
if IsZero(operand2) then
  result = 0;
else
  result = RoundTowardsZero(Real(Int(operand1, FALSE)) / Real(Int(operand2, FALSE)));
X[d] = result<datasize-1:0>;

Copyright © 2010-2020 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
**SETF8, SETF16**

Set the PSTATE.NZV flags based on the value in the specified general-purpose register. SETF8 treats the value as an 8 bit value, and SETF16 treats the value as an 16 bit value.

The PSTATE.C flag is not affected by these instructions.

**Integer**

(Armv8.4)

```plaintext
bits(32) tmpreg = X[n];
PSTATE.N = tmpreg<msb>;
PSTATE.Z = if (tmpreg<msb:0> == Zeros(msb + 1)) then '1' else '0';
PSTATE.V = tmpreg<msb+1> EOR tmpreg<msb>;
//PSTATE.C unchanged;
```

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SEV

Send Event is a hint instruction. It causes an event to be signaled to all PEs in the multiprocessor system. For more information, see *Wait for Event mechanism and Send event*.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
 1 1 0 1 0 1 0 0 0 0 1 0 0 0 1 0 0 0 1 0 0 0 0 1 0 0 0 0 0 0 0 1 0 0 0 1 0 0 1 1 1 1 1

SEV

// Empty.

Operation

SendEvent();
```
Send Event Local is a hint instruction that causes an event to be signaled locally without requiring the event to be signaled to other PEs in the multiprocessor system. It can prime a wait-loop which starts with a WFE instruction.

SEVL

CRm  op2

Operation

SendEventLocal();
SMADDL

Signed Multiply-Add Long multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMULL.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Operation

bits(32) operand1 = X[n];
bits(32) operand2 = X[m];
bits(64) operand3 = X[a];

integer result;
result = Int(operand3, FALSE) + (Int(operand1, FALSE) * Int(operand2, FALSE));

X[d] = result<63:0>;

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SMC

Secure Monitor Call causes an exception to EL3.
SMC is available only for software executing at EL1 or higher. It is UNDEFINED in EL0.
If the values of HCR_EL2.TSC and SCR_EL3.SMD are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception, recording it in ESR_ELx, using the EC value 0x17, that is taken to EL3.
If the value of HCR_EL2.TSC is 1 and EL2 is enabled in the current Security state, execution of an SMC instruction at EL1 generates an exception that is taken to EL2, regardless of the value of SCR_EL3.SMD. For more information, see Traps to EL2 of Non-secure EL1 execution of SMC instructions.
If the value of HCR_EL2.TSC is 0 and the value of SCR_EL3.SMD is 1, the SMC instruction is UNDEFINED.

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

```

SMC #<imm>

// Empty.

Assembler Symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field.

Operation

```
AArch64.CheckForSMCUndefOrTrap(imm16);
AArch64.CallSecureMonitor(imm16);
```
SMNEGL

Signed Multiply-Negate Long multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This is an alias of SMSUBL. This means:

- The encodings in this description are named to match the encodings of SMSUBL.
- The description of SMSUBL gives the operational pseudocode for this instruction.

```
   31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
   | 0 0 1 1 0 1 1 0 0 1 | Rm | 1 1 1 1 1 1 | Rn  | Rd |
   | U 0 0 | Ra |

SMNEGL <Xd>, <Wn>, <Wm>

is equivalent to

SMSUBL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of SMSUBL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Signed Multiply-Subtract Long multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMNEGL.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

SSBB

Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the SSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the SSBB.
- When a load to a location appears in program order before the SSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order after the SSBB.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 0 1 0 1 0 0 0 0 0 1 1 0 0 1 1 0 0 0 0 1 0 0 1 1 1 1 1
```

SSBB

// No additional decoding required

**Operation**

`SpeculativeStoreBypassBarrierToVA();`

ST2G

Store Allocation Tags stores an Allocation Tag to two Tag granules of memory. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

It has encodings from 3 classes: Post-index, Pre-index and Signed offset

**Post-index**
**(Armv8.5)**

STADD, STADDL

Atomic add on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory.

- STADD does not have release semantics.
- STADDL stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDADD, LDADDA, LDADDAL, LDADDL. This means:

- The encodings in this description are named to match the encodings of LDADD, LDADDA, LDADDAL, LDADDL.
- The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational pseudocode for this instruction.

**Integer**

(Armv8.1)

32-bit LDADD alias (size == 10 && R == 0)

STADD <Ws>, [<Xn|SP>]

is equivalent to

LDADD <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

32-bit LDADDL alias (size == 10 && R == 1)

STADDL <Ws>, [<Xn|SP>]

is equivalent to

LDADDL <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

64-bit LDADD alias (size == 11 && R == 0)

STADD <Xs>, [<Xn|SP>]

is equivalent to

LDADD <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

64-bit LDADDL alias (size == 11 && R == 1)

STADDL <Xs>, [<Xn|SP>]

is equivalent to

LDADDL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.
Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDADD, LDADDA, LDADDAL, LDADDI, gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STADDB, STADDBL

Atomic add on byte in memory, without return, atomically loads an 8-bit byte from memory, adds the value held in a register to it, and stores the result back to memory.

- STADDB does not have release semantics.
- STADDBL stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDADDB, LDADDAB, LDADDALB, LDADDLB. This means:

- The encodings in this description are named to match the encodings of LDADDB, LDADDAB, LDADDALB, LDADDLB.
- The description of LDADDB, LDADDAB, LDADDALB, LDADDLB gives the operational pseudocode for this instruction.

LDADDB <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Release (R == 1)

STADDBL <Ws>, [<Xn|SP>]

is equivalent to

LDADDLB <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDADDB, LDADDAB, LDADDALB, LDADDLB gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STADDH, STADDLH

Atomic add on halfword in memory, without return, atomically loads a 16-bit halfword from memory, adds the value held in a register to it, and stores the result back to memory.

- STADDH does not have release semantics.
- STADDLH stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDADDH, LDADDAH, LDADDALH, LDADDLH. This means:

- The encodings in this description are named to match the encodings of LDADDH, LDADDAH, LDADDALH, LDADDLH.
- The description of LDADDH, LDADDAH, LDADDALH, LDADDLH gives the operational pseudocode for this instruction.

Integer

STADDH <Ws>, [<Xn|SP>]

is equivalent to

LDADDH <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Release (R == 1)

STADDLH <Ws>, [<Xn|SP>]

is equivalent to

LDADDLH <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler Symbols

<Ws>      Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xn|SP>   Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDADDH, LDADDAH, LDADDALH, LDADDLH gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STCLR, STCLRL

Atomic bit clear on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit
doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and
stores the result back to memory.

- STCLR does not have release semantics.
- STCLRL stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDCLR, LDCLRA, LDCLRAL, LDCLRL. This means:

- The encodings in this description are named to match the encodings of LDCLR, LDCLRA, LDCLRAL, LDCLRL.
- The description of LDCLR, LDCLRA, LDCLRAL, LDCLRL gives the operational pseudocode for this
  instruction.

LDCLR <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

**64-bit LDCLRL alias (size == 11 && R == 1)**

STCLRL <Xs>, [<Xn|SP>]

is equivalent to

LDCLRL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.
Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDCLR, LDCLRA, LDCLRAL, LDCLRL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**STCLRB, STCLRLB**

Atomic bit clear on byte in memory, without return, atomically loads an 8-bit byte from memory, performs a bitwise
AND with the complement of the value held in a register on it, and stores the result back to memory.

- STCLRB does not have release semantics.
- STCLRLB stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about memory accesses see *Load/Store addressing modes*.

This is an alias of **LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB**. This means:

- The encodings in this description are named to match the encodings of **LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB**.
- The description of **LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB** gives the operational pseudocode for this instruction.

is equivalent to

**LDCLRB** `<Ws>, WZR, [<Xn|SP>]`

and is always the preferred disassembly.

**Release (R == 1)**

**STCLRLB** `<Ws>, [<Xn|SP>]`

is equivalent to

**LDCLRLB** `<Ws>, WZR, [<Xn|SP>]`

and is always the preferred disassembly.

### Assembler Symbols

- `<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

### Operation

The description of **LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB** gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STCLRH, STCLRLH

Atomic bit clear on halfword in memory, without return, atomically loads a 16-bit halfword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

- STCLRH does not have release semantics.
- STCLRLH stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH. This means:

- The encodings in this description are named to match the encodings of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH.
- The description of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH gives the operational pseudocode for this instruction.

No memory ordering (R == 0)

STCLRH <Ws>, [<Xn|SP>]

is equivalent to

LDCLRH <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Release (R == 1)

STCLRLH <Ws>, [<Xn|SP>]

is equivalent to

LDCLRLH <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STEOR, STEORL

Atomic exclusive OR on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, performs an exclusive OR with the value held in a register on it, and stores the result back to memory.

- STEOR does not have release semantics.
- STEORL stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDEOR, LDEORA, LDEORAL, LDEORL. This means:

- The encodings in this description are named to match the encodings of LDEOR, LDEORA, LDEORAL, LDEORL.
- The description of LDEOR, LDEORA, LDEORAL, LDEORL gives the operational pseudocode for this instruction.

### Assembler Symbols

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Xt" field.
<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Xt2" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Xn" field.
For the post-index and pre-index variant: is the signed immediate offset, a multiple of 16 in the range -1024 to 1008, encoded in the "simm7" field.

For the signed offset variant: is the optional signed immediate offset, a multiple of 16 in the range -1024 to 1008, defaulting to 0 and encoded in the "simm7" field.

Operation

```plaintext
bits(64) address;
b bits(64) data1;
b bits(64) data2;
SetTagCheckedInstruction(FALSE);
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];
data1 = X[t];
data2 = X[t2];
if !postindex then
    address = address + offset;
Mem[address, 8, AccType_NORMAL] = data1;
Mem[address+8, 8, AccType_NORMAL] = data2;
AArch64.MemTag[address, AccType_NORMAL] = AArch64.AllocationTagFromAddress(address);
if writeback then
    if n == 31 then
        address = address + offset;
        if n == 31 then
            SP[] = address;
        else
            X[n] = address;
    else
        X[n] = address;
```
STLLR

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STLXP

Store-Release Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords to a memory location if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and, if the Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

32-bit (sz == 0)

STLXP <Ws>, <Wt1>, <Wt2>, [<Xn|SP>{,#0}]

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STLXP.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the “Rs” field. The value returned is:
0 If the operation updates memory.
1 If the operation fails to update memory.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the “Rt” field.
Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment
If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

        status = ExclusiveMonitorsStatus();
    \text{X}[s] = ZeroExtend(status, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STLXR

Store-Release Exclusive Register stores a 32-bit word or a 64-bit doubleword to memory if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:
0 If the operation updates memory.
1 If the operation fails to update memory.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- \(<Ws>\) is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```plaintext
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;
if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);
if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];
if rt_unknown then
    data = bits(elsize) UNKNOWN;
else
    data = X[t];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, dbytes) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, dbytes, AccType_ORDEREDATOMIC] = data;
    status = ExclusiveMonitorsStatus();
    X[s] = ZeroExtend(status, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STLXRB

Store-Release Exclusive Register Byte stores a byte from a 32-bit register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

**Assembler Symbols**

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.

1 If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Aborts and alignment**

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.
If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

**Operation**

```plaintext
bits(64) address;
bits(16) data;

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];

if rt_unknown then
    data = bits(16) UNKNOWN;
else
    data = X[t];

bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, 2) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 2, AccType_ORDEREDATOMIC] = data;
    status = ExclusiveMonitorsStatus();
    X[s] = ZeroExtend(status, 32);
```

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STNP

Store Pair of Registers, with non-temporal hint, calculates an address from a base register value and an immediate offset, and stores two 32-bit words or two 64-bit doublewords to the calculated address, from two registers. For information about memory accesses, see Load/Store addressing modes. For information about Non-temporal pair instructions, see Load/Store Non-temporal pair.

- `<Wt>`: Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>`: Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<Wm>`: When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<Xm>`: When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
- `<extend>`: Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when `<amount>` is omitted. encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

- `<amount>`: Is the index shift amount, optional only when `<extend>` is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

<table>
<thead>
<tr>
<th>S</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#0</td>
</tr>
<tr>
<td>1</td>
<td>#1</td>
</tr>
</tbody>
</table>

Shared Decode

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```
Operation

bits(64) offset = $\text{ExtendReg}(m, \text{extend type, shift})$;
if $\text{HaveMTEExt}()$ then
  $\text{SetTagCheckedInstruction}(\text{TRUE})$;

bits(64) address;
bits(16) data;

if $n == 31$ then
  $\text{CheckSPAlignment}();$
  address = $\text{SP}[]$;
else
  address = $\text{X}[n]$;

address = address + offset;

data = $\text{X}[t]$;
$\text{Mem}[\text{address, 2, AccType\_NORMAL}] = \text{data}$;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STSET, STSETL

Atomic bit set on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- STSET does not have release semantics.
- STSETL stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about memory accesses see *Load/Store addressing modes*.

This is an alias of **LDSET, LDSETA, LDSETAL, LDSETL**. This means:

- The encodings in this description are named to match the encodings of **LDSET, LDSETA, LDSETAL, LDSETL**.
- The description of **LDSET, LDSETA, LDSETAL, LDSETL** gives the operational pseudocode for this instruction.

### Integer (Armv8.1)

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

```

**32-bit LDSET alias (size == 10 && R == 0)**

STSET <Ws>, [<Xn|SP>]

is equivalent to

LDSET <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

**32-bit LDSETL alias (size == 10 && R == 1)**

STSETL <Ws>, [<Xn|SP>]

is equivalent to

LDSETL <Ws>, WZR, [<Xn|SP>]

and is always the preferred disassembly.

**64-bit LDSET alias (size == 11 && R == 0)**

STSET <Xs>, [<Xn|SP>]

is equivalent to

LDSET <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.

**64-bit LDSETL alias (size == 11 && R == 1)**

STSETL <Xs>, [<Xn|SP>]

is equivalent to

LDSETL <Xs>, XZR, [<Xn|SP>]

and is always the preferred disassembly.
Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**STSETB, STSETLB**

Atomic bit set on byte in memory, without return, atomically loads an 8-bit byte from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- STSETB does not have release semantics.
- STSETLB stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about memory accesses see *Load/Store addressing modes*.

This is an alias of **LDSETB, LDSETAB, LDSETALB, LDSETLB**. This means:

- The encodings in this description are named to match the encodings of **LDSETB, LDSETAB, LDSETALB, LDSETLB**.
- The description of **LDSETB, LDSETAB, LDSETALB, LDSETLB** gives the operational pseudocode for this instruction.

#### No memory ordering (R == 0)

**STSMINH <Ws>, [<Xn|SP>]**

is equivalent to

**LDSMINH <Ws>, WZR, [<Xn|SP>]**

and is always the preferred disassembly.

#### Release (R == 1)

**STSMINLH <Ws>, [<Xn|SP>]**

is equivalent to

**LDSMINLH <Ws>, WZR, [<Xn|SP>]**

and is always the preferred disassembly.

### Assembler Symbols

- **<Ws>** is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- **<Xn|SP>** is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

### Operation

The description of LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STTR

Store Register (unprivileged) stores a word or doubleword from a register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is \{1, 1\}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes.

32-bit (size == 10)

STTR <Wt>, [<Xn|SP>{, #<simm>}]

64-bit (size == 11)

STTR <Xt>, [<Xn|SP>{, #<simm>}]

integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '1';
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '1';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
  acctype = AccType_UNPRIV;
else
  acctype = AccType_NORMAL;

integer datasize = 8 << scale;
boolean tag_checked = n != 31;
Operation

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

bits(64) address;
bits(datasize) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, datasize DIV 8, acctype] = data;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STTRB

Store Register Byte (unprivileged) stores a byte from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the **Effective value** of PSTATE.UAO is 0 and either:
- The instruction is executed at EL1.
- The instruction is executed at EL2 when the **Effective value** of HCR_EL2.E2H, TGE is \{1, 1\}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see **Load/Store addressing modes**.

**STTRB <Wt>, [<Xn|SP>{, #<simm}>]**

```
bits(64) offset = SignExtend(imm9, 64);
```

**Assembler Symbols**

- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<simm>` Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

**Shared Decode**

```python
integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !(EL2Enabled()) && HaveNVExt() && HCR_EL2.<NV,NV1> == '11';
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '11';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
    acctype = AccType_UNPRIV;
else
    acctype = AccType_NORMAL;

boolean tag_checked = n != 31;
```

**Operation**

```python
if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, 1, acctype] = data;
```
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STTRH

Store Register Halfword (unprivileged) stores a halfword from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see Load/Store addressing modes.

imm9 Rn Rt
```

STTRH <Wt>, [<Xn|SP>{{, #<simm>}}]

```
bits(64) offset = SignExtend(imm9, 64);
```

**Assembler Symbols**

- `<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<simm>` Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

**Shared Decode**

```c
integer n = UInt(Rn);
integer t = UInt(Rt);

unpriv_at_el1 = PSTATE.EL == EL1 && !EL2Enabled() && HaveNVExt() && HCR_EL2.<NV,NV1> == '11';
unpriv_at_el2 = PSTATE.EL == EL2 && HaveVirtHostExt() && HCR_EL2.<E2H,TGE> == '11';

user_access_override = HaveUAOExt() && PSTATE.UAO == '1';
if !user_access_override && (unpriv_at_el1 || unpriv_at_el2) then
    accetype = AccType_UNPRIV;
else
    accetype = AccType_NORMAL;

boolean tag_checked = n != 31;
```

**Operation**

```c
if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

bits(64) address;
b bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, 2, accetype] = data;
```
Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STUMAX, STUMAXL

Atomic unsigned maximum on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

- STUMAX does not have release semantics.
- STUMAXL stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about memory accesses see Load/Store addressing modes.

This is an alias of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL. This means:

- The encodings in this description are named to match the encodings of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL.
- The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational pseudocode for this instruction.

**No memory ordering (R == 0)**

**STUMINH <Ws>, [<Xn|SP>]**

is equivalent to

**LDUMINH <Ws>, WZR, [<Xn|SP>]**

and is always the preferred disassembly.

**Release (R == 1)**

**STUMINLH <Ws>, [<Xn|SP>]**

is equivalent to

**LDUMINLH <Ws>, WZR, [<Xn|SP>]**

and is always the preferred disassembly.

**Assembler Symbols**

- **<Ws>** is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
- **<Xn|SP>** is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

**Operation**

The description of **LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STUR

Store Register (unscaled) calculates an address from a base register value and an immediate offset, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about memory accesses, see Load/Store addressing modes.

**STXP**

Store Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords from two registers to a memory location if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and, if the Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. For information about memory accesses see *Load/Store addressing modes*.

### 32-bit (sz == 0)

**STXP** `<Ws>, <Wt1>, <Wt2>, [<Xn|SP>{,#0}]`

### 64-bit (sz == 1)

**STXP** `<Ws>, <Xt1>, <Xt2>, [<Xn|SP>{,#0}]`

```plaintext
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2); // ignored by load/store single register
integer s = UInt(Rs);   // ignored by all loads and store-release

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
boolean tag_checked = n != 31;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t || (s == t2) then
  Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
  assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
  case c of
    when Constraint_UNKNOWN rt unknown = TRUE;  // store UNKNOWN value
    when Constraint_NONE rt unknown = FALSE;   // store original value
    when Constraint_UNDEF UNDEFINED;
    when Constraint_NOP EndOfInstruction();
  case c of
    when Constraint_UNKNOWN rn unknown = TRUE;  // address is UNKNOWN
    when Constraint_NONE rn unknown = FALSE;   // address is original base
    when Constraint_UNDEF UNDEFINED;
    when Constraint_NOP EndOfInstruction();
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly **STXP**.

**Assembler Symbols**

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.

1 If the operation fails to update memory.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment
If a synchronous Data Abort exception is generated by the execution of this instruction:
• Memory is not updated.
• <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:
• If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
• Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;

if HaveMTEExt() then
  SetTagCheckedInstruction(tag_checked);

if n == 31 then
  CheckSPAlignment();
  address = SP[];
elsif rn_unknown then
  address = bits(64) UNKNOWN;
else
  address = X[n];

if rt_unknown then
  data = bits(datasize) UNKNOWN;
else
  bits(datasize DIV 2) el1 = X[t];
  bits(datasize DIV 2) el2 = X[t2];
  data = if BigEndian(AccType_ATOMIC) then el1:el2 else el2:el1;
  bit status = '1';
  // Check whether the Exclusives monitors are set to include the
  // physical memory locations corresponding to virtual address
  // range [address, address+dbytes-1].
  if AArch64.ExclusiveMonitorsPass(address, dbytes) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, dbytes, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
  X[s] = ZeroExtend(status, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STXR

Store Exclusive Register stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. For information about memory accesses see Load/Store addressing modes.

    when Constraint_NOP EndOfInstruction();

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.

1 If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.
Operation

bits(64) address;
bright(16) data;

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);
if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn Unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];

if rt Unknown then
    data = bits(16) UNKNOWN;
else
    data = X[t];

bit status = '1';
// Check whether the Exclusives monitors are set to include the physical memory locations corresponding to virtual address range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, 2) then
    // This atomic write will be rejected if it does not refer to the same physical locations after address translation.
    Mem[address, 2, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
    X[s] = ZeroExtend(status, 32);

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
STZ2G

Store Allocation Tags, Zeroing stores an Allocation Tag to two Tag granules of memory, zeroing the associated data locations. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

It has encodings from 3 classes: Post-index, Pre-index and Signed offset.

SUB (extended register)

Subtract (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.

32-bit ($sf == 0$)

```
SUB <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {<$amount>}}
```

64-bit ($sf == 1$)

```
SUB <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {<$amount>}}
```

integer $d = UInt(Rd)$;
integer $n = UInt(Rn)$;
integer $m = UInt(Rm)$;
integer $datasize = if sf == '1' then 64 else 32$;
$ExtendType extend_type = DecodeRegExtend(option)$;
integer $shift = UInt(imm3)$;
if $shift > 4$ then UNDEFINED;

Assembler Symbols

- `<Wd|WSP>` is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Wn|WSP>` is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>` is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd|SP>` is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xn|SP>` is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>` is a width specifier, encoded in "option":
  - option <R>
    - 00x W
    - 010 W
    - x11 X
    - 10x W
    - 110 W

- `<m>` is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
- `<extend>` is the extension to be applied to the second source operand, encoded in "option":
  - option <extend>
    - 000 UXTB
    - 001 UXTH
    - 010 LSL|UXTW
    - 011 UXTX
    - 100 SXTB
    - 101 SXTH
    - 110 SXTW
    - 111 SXTX

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in "option":

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);

operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');

if d == 31 then
  SP[] = result;
else
  X[d] = result;

Operational information

If PSTATE.DIT is 1:
  • The execution time of this instruction is independent of:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
  • The response of this instruction to asynchronous exceptions does not vary based on:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
**SUB (immediate)**

Subtract (immediate) subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register.

<table>
<thead>
<tr>
<th>sf</th>
<th>0</th>
<th>1</th>
<th>0</th>
<th>0</th>
<th>0</th>

  when '0' imm = ZeroExtend(imm12, datasize);
  when '1' imm = ZeroExtend(imm12:Zeros(12), datasize);
```

**Assembler Symbols**

- `<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
- `<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
- `<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in "sh":

<table>
<thead>
<tr>
<th>sh</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LSL #0</td>
</tr>
<tr>
<td>1</td>
<td>LSL #12</td>
</tr>
</tbody>
</table>

**Operation**

```plaintext
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2;

operand2 = NOT(imm);
(result, -) = AddWithCarry(operand1, operand2, '1');

if d == 31 then
  SP[] = result;
else
  X[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
• The values of the NZCV flags.
  • The response of this instruction to asynchronous exceptions does not vary based on:
    • The values of the data supplied in any of its registers.
    • The values of the NZCV flags.
**SUB (shifted register)**

Subtract (shifted register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

This instruction is used by the alias **NEG (shifted register)**.

### 32-bit (sf == 0)

```
SUB <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

### 64-bit (sf == 1)

```
SUB <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

```python
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
datasize = if sf == '1' then 64 else 32;

if shift == '11' then UNDEFINED;
if sf == '0' & imm6<5> == '1' then UNDEFINED;

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

**Assembler Symbols**

- **<Wd>** Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Wn>** Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- **<Wm>** Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- **<Xd>** Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- **<Xn>** Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- **<Xm>** Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- **<shift>** Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

- **<amount>** For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  
  For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

**Alias Conditions**

<table>
<thead>
<tr>
<th>Alias</th>
<th>Is preferred when</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEG (shifted register)</td>
<td>Rn == '11111'</td>
</tr>
</tbody>
</table>
Operation

bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, ‘1’);

X[d] = result;

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Subtract with Tag subtracts an immediate value scaled by the Tag granule from the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

**Integer**

**SUBS (extended register)**

Subtract (extended register), setting flags, subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias **CMP (extended register)**.

**32-bit (sf == 0)**

```
SUBS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

**64-bit (sf == 1)**

```
SUBS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then UNDEFINED;
```

**Assembler Symbols**

- `<Wd>`: Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn|WSP>`: Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<Wm>`: Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- `<Xd>`: Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn|SP>`: Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
- `<R>`: Is a width specifier, encoded in "option":
  ```plaintext
<table>
<thead>
<tr>
<th>option</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00x</td>
<td>W</td>
</tr>
<tr>
<td>010</td>
<td>W</td>
</tr>
<tr>
<td>x11</td>
<td>X</td>
</tr>
<tr>
<td>10x</td>
<td>W</td>
</tr>
<tr>
<td>110</td>
<td>W</td>
</tr>
</tbody>
</table>
  ```
- `<m>`: Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.
- `<extend>`: For the 32-bit variant: is the extension to be applied to the second source operand, encoded in "option":
  ```plaintext
<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>LSL</td>
</tr>
<tr>
<td>011</td>
<td>UXTW</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SCTX</td>
</tr>
</tbody>
</table>
  ```
If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in “option”:

<table>
<thead>
<tr>
<th>option</th>
<th>&lt;extend&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>UXTB</td>
</tr>
<tr>
<td>001</td>
<td>UXTH</td>
</tr>
<tr>
<td>010</td>
<td>UXTW</td>
</tr>
<tr>
<td>011</td>
<td>LSL</td>
</tr>
<tr>
<td>100</td>
<td>SXTB</td>
</tr>
<tr>
<td>101</td>
<td>SXTH</td>
</tr>
<tr>
<td>110</td>
<td>SXTW</td>
</tr>
<tr>
<td>111</td>
<td>SXTX</td>
</tr>
</tbody>
</table>

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

### Alias Conditions

PSTATE.<N,Z,C,V> = nzcv;
X[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SVC

Supervisor Call causes an exception to be taken to EL1.
On executing an SVC instruction, the PE records the exception as a Supervisor Call exception in ESR_ELx, using the EC value 0x15, and the value of the immediate argument.

```
  31  30  29  28  27  26  25  24  23  22  21  20  19  18  17  16  15  14  13  12  11  10  9  8  7  6  5  4  3  2  1  0
+--------------------------------------------------+
| 1  1  0  1  0  0  0  0 | imm16 | 0  0  0  0  1 |
```

SVC #<imm>

// Empty.

Assembler Symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
AArch64.CheckForSVCTrap(imm16);
AArch64.CallSupervisor(imm16);
```
SWP, SWPA, SWPAL, SWPL

Swap word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, SWPA and SWPAL load from memory with acquire semantics.
- SWPL and SWPAL store to memory with release semantics.
- SWP has neither acquire nor release semantics.

For more information about memory ordering semantics see Load-Acquire, Store-Release. For information about memory accesses see Load/Store addressing modes.

X[t] = ZeroExtend(data, regsize);
### SWPB, SWPAB, SWPALB, SWPLB

Swap byte in memory atomically loads an 8-bit byte from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, SWPAB and SWPALB load from memory with acquire semantics.
- SWPLB and SWPALB store to memory with release semantics.
- SWPB has neither acquire nor release semantics.

For more information about memory ordering semantics see [Load-Acquire, Store-Release](#).

For information about memory accesses see [Load/Store addressing modes](#).

SXTB

Signed Extend Byte extracts an 8-bit value from a register, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 && N == 0)

SXTB <Wd>, <Wn>

is equivalent to

SBFM <Wd>, <Wn>, #0, #7

and is always the preferred disassembly.

64-bit (sf == 1 && N == 1)

SXTB <Xd>, <Wn>

is equivalent to

SBFM <Xd>, <Xn>, #0, #7

and is always the preferred disassembly.

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SXTH

Sign Extend Halfword extracts a 16-bit value, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of **SBFM**. This means:

- The encodings in this description are named to match the encodings of **SBFM**.
- The description of **SBFM** gives the operational pseudocode for this instruction.

### 32-bit (sf == 0 & N == 0)

**SXTH** `<Wd>, <Wn>`

is equivalent to

**SBFM** `<Wd>, <Wn>, #0, #15`

and is always the preferred disassembly.

### 64-bit (sf == 1 & N == 1)

**SXTH** `<Xd>, <Wn>`

is equivalent to

**SBFM** `<Xd>, <Xn>, #0, #15`

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- `<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

**Operation**

The description of **SBFM** gives the operational pseudocode for this instruction.

**Operational information**

integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys.crm = UInt(CRm);
```

**Assembler Symbols**

- `<Xt>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
- `<op1>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
- `<Cn>` Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
- `<Cm>` Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
- `<op2>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

**Operation**

// No architecturally defined instructions here.
`X[t] = AArch64.SysInstrWithResult(1, sys_op1, sys_crn, syscrm, sys_op2);`
Programmable table lookup in one or two vector table (zeroing).

Reads each element of the second source (index) vector and uses its value to select an indexed element from a table of elements consisting of one or two consecutive vector registers, where the first or only vector holds the lower numbered elements, and places the indexed table element in the destination vector element corresponding to the index vector element. If an index value is greater than or equal to the number of vector elements then it places zero in the corresponding destination vector element.

Since the index values can select any element in a vector this operation is not naturally vector length agnostic.

It has encodings from 2 classes: SVE and SVE2

SVE

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|---------------------------------|-----------------|-----------------|
| 0 0 0 0 0 1 0 1 size | Zm | 0 0 1 1 0 0 | Zn | Zd |

if !HaveSVE() then UNDEFINED;
integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
boolean double_table = FALSE;

SVE2

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|---------------------------------|-----------------|-----------------|
| 0 0 0 0 0 1 0 1 size | Zm | 0 0 1 0 1 0 | Zn | Zd |

TBL <Zd>..<T>, { <Zn1>..<T>, <Zn2>..<T> }, <Zm>..<T>

if !HaveSVE2() then UNDEFINED;
integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer m = UInt(Zm);
integer d = UInt(Zd);
boolean double_table = TRUE;

Assembler Symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in “size”:

<table>
<thead>
<tr>
<th>size</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>B</td>
</tr>
<tr>
<td>01</td>
<td>H</td>
</tr>
<tr>
<td>10</td>
<td>S</td>
</tr>
<tr>
<td>11</td>
<td>D</td>
</tr>
</tbody>
</table>

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<Zn1> Is the name of the first scalable vector register of a multi-vector sequence, encoded in the "Zn" field.

<Zn2> Is the name of the second scalable vector register of a multi-vector sequence, encoded in the "Zn" field.

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.
Operation

```c
CheckSVEEnabled();
integer elements = VL DIV esize;
bits(VL) indexes = Z[m];
bits(VL) result;
integer table_size = if double_table then VL*2 else VL;
integer table elems = table_size DIV esize;
bits(table_size) table;

if double_table then
    bits(VL) top = Z[(n + 1) MOD 32];
    bits(VL) bottom = Z[n];
    table = (top:bottom)<table_size-1:0>;
else
    table = Z[n];

for e = 0 to elements-1
    integer idx = UInt(Elem[indexes, e, esize]);
    Elem[result, e, esize] = if idx < table elems then Elem[table, idx, esize] else Zeros();
Z[d] = result;
```

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
TBNZ

Test bit and Branch if Nonzero compares the value of a bit in a general-purpose register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| b5 | 0  | 1  | 1  | 0  | 1  | 1  | 1  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| op |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

TBNZ <R><t>, #<imm>, <label>

integer t = UInt(Rt);

integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bits(64) offset = SignExtend(imm14:'00', 64);

Assembler Symbols

<op> Is a width specifier, encoded in “b5”:

<table>
<thead>
<tr>
<th>b5</th>
<th>&lt;op&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>W</td>
</tr>
<tr>
<td>1</td>
<td>X</td>
</tr>
</tbody>
</table>

In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

Operation

bits(datasize) operand = X[t];

if operand<bit_pos> == op then
    BranchTo(PC[] + offset, BranchType_DIR);

Internal version only: isa v32.12, AdvSIMD v29.04, pseudocode v2020-09_xml, sve v2020-09_rc2b ; Build timestamp: 2020-09-30T20:20

<tbody>
<tr>
<td>b5</td>
<td>W</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

Operation

bits(datasize) operand = X[t];

if operand<bit_pos> == op then
    BranchTo( PC[ ] + offset, BranchType_DIR);
TCANCEL

This instruction exits Transactional state and discards all state modifications that were performed transactionally. Execution continues at the instruction that follows the TSTART instruction of the outer transaction. The destination register of the TSTART instruction of the outer transaction is written with the immediate operand of TCANCEL.

System
(FEAT_TME)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

TCANCEL #<imm>

if !HaveTME() then UNDEFINED;
boolean retry = (imm16<15> == '1');
bits(15) reason = imm16<14:0>;

Assembler Symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

CheckTMEEnabled();

if TSTATE.depth > 0 then
   FailTransaction(TMFailure_CNCL, retry, FALSE, reason);
TCOMMIT

This instruction commits the current transaction. If the current transaction is an outer transaction, then Transactional state is exited, and all state modifications performed transactionally are committed to the architectural state. TCOMMIT takes no inputs and returns no value. Execution of TCOMMIT is UNDEFINED in Non-transactional state.

**TST (immediate)**

Test bits (immediate), setting the condition flags and discarding the result: \( Rn \ AND \ imm \).

This is an alias of **ANDS (immediate)**. This means:

- The encodings in this description are named to match the encodings of **ANDS (immediate)**.
- The description of **ANDS (immediate)** gives the operational pseudocode for this instruction.

```
+---------+-----+------+
| sf      | N   | immr |
+---------+-----+------+
```

32-bit (\( sf == 0 \) \&\& \( N == 0 \))

TST \(<Wn>, #<imm>\)

is equivalent to

**ANDS** WZR, \(<Wn>, #<imm>\)

and is always the preferred disassembly.

64-bit (\( sf == 1 \))

TST \(<Xn>, #<imm>\)

is equivalent to

**ANDS** XZR, \(<Xn>, #<imm>\)

and is always the preferred disassembly.

**Assembler Symbols**

- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<imm>\) For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr".
  For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

**Operation**

The description of **ANDS (immediate)** gives the operational pseudocode for this instruction.
TST (shifted register)

Test (shifted register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of ANDS (shifted register). This means:

- The encodings in this description are named to match the encodings of ANDS (shifted register).
- The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

### 32-bit (sf == 0)

TST \(<Wn>, <Wm>{, <shift> #<amount>}\)

is equivalent to

ANDS WZR, \(<Wn>, <Wm>{, <shift> #<amount>}\)

and is always the preferred disassembly.

### 64-bit (sf == 1)

TST \(<Xn>, <Xm>{, <shift> #<amount>}\)

is equivalent to

ANDS XZR, \(<Xn>, <Xm>{, <shift> #<amount>}\)

and is always the preferred disassembly.

### Assembler Symbols

- \(<Wn>\) is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Wm>\) is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<Xn>\) is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
- \(<Xm>\) is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
- \(<shift>\) is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

<table>
<thead>
<tr>
<th>shift</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>LSL</td>
</tr>
<tr>
<td>01</td>
<td>LSR</td>
</tr>
<tr>
<td>10</td>
<td>ASR</td>
</tr>
<tr>
<td>11</td>
<td>ROR</td>
</tr>
</tbody>
</table>

- \(<amount>\) For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.
  - For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

### Operation

The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
• The values of the data supplied in any of its registers.
• The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
TSTART

This instruction starts a new transaction. If the transaction started successfully, the destination register is set to zero. If the transaction failed or was canceled, then all state modifications that were performed transactionally are discarded and the destination register is written with a non-zero value that encodes the cause of the failure.

System
(FEAT_TME)

1 1 0 1 0 1 0 1 0 0 1 0 0 0 1 1 0 0 1 1 0 0 0 0 0 1 1 | Rt

TSTART <Xt>

if !HaveTME() then UNDEFINED;
integer t = UInt(Rt);

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
Operation

CheckTMEEnabled();

boolean IsEL1Regime;
case PSTATE.ELOf
  when EL0
    IsEL1Regime = S1TranslationRegime() == EL1;
    if IsEL1Regime then
      tme = SCTLR_EL1.TME0;

UBFIZ

Unsigned Bitfield Insert in Zeros copies a bitfield of \(<width>\) bits from the least significant bits of the source register to bit position \(<lsb>\) of the destination register, setting the destination bits above and below the bitfield to zero.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
sf 1 0 1 0 0 1 1 0 N | immr | imms | Rn | Rd
opc
```

32-bit (sf == 0 && N == 0)

UBFIZ \(<Wd>, <Wn>, #<lsb>, #<width>\)

is equivalent to

UBFM \(<Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)\)

and is the preferred disassembly when UInt(imms) < UInt(immr).

64-bit (sf == 1 && N == 1)

UBFIZ \(<Xd>, <Xn>, #<lsb>, #<width>\)

is equivalent to

UBFM \(<Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)\)

and is the preferred disassembly when UInt(imms) < UInt(immr).

**Assembler Symbols**

- \(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- \(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- \(<lsb>\) For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
- \(<width>\) For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

**Operation**

The description of UBFM gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
UBFM

Unsigned Bitfield Move is usually accessed via one of its aliases, which are always preferred for disassembly. If \( \text{immr} \) is greater than or equal to \( \text{imms} \), this copies a bitfield of \( (\text{imms} - \text{immr} + 1) \) bits starting from bit position \( \text{immr} \) in the source register to the least significant bits of the destination register. If \( \text{imms} \) is less than \( \text{immr} \), this copies a bitfield of \( (\text{imms} + 1) \) bits from the least significant bits of the source register to bit position \( \text{regsize} - \text{immr} \) of the destination register, where \( \text{regsize} \) is the destination register size of 32 or 64 bits. In both cases the destination bits above and below the bitfield are set to zero.

This instruction is used by the aliases \text{LSL (immediate)}, \text{LSR (immediate)}, \text{UBFIZ}, \text{UBFX}, \text{UXTB}, and \text{UXTH}.

32-bit (\( \text{sf} = 0 \&\& \text{N} = 0 \))

\[
\text{UBFM} \ <Wd>, <Wn>, \ #\text{immr}, \ #\text{imms} 
\]

64-bit (\( \text{sf} = 1 \&\& \text{N} = 1 \))

\[
\text{UBFM} \ <Xd>, <Xn>, \ #\text{immr}, \ #\text{imms} 
\]

Assembler Symbols

\(<Wd>\) Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Wn>\) Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

\(<Xd>\) Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

\(<Xn>\) Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

\(<\text{immr}>\) For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field. For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.

\(<\text{imms}>\) For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field. For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

</table>

### Operation

```c
bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = ROR(src, R) AND wmask;

// combine extension bits and result bits
X[d] = bot AND tmask;
```

### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
UBFX

Unsigned Bitfield Extract copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to zero.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.

32-bit (sf == 0 && N == 0)

UBFX <Wd>, <Wn>, #<lsb>, #<width>

is equivalent to

UBFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)

and is the preferred disassembly when BFXPreferred(sf, opc<1>, imms, immr).

64-bit (sf == 1 && N == 1)

UBFX <Xd>, <Xn>, #<lsb>, #<width>

is equivalent to

UBFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)

and is the preferred disassembly when BFXPreferred(sf, opc<1>, imms, immr).

Assembler Symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <lsb> For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
  For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
- <width> For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
  For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Permanently Undefined generates an Undefined Instruction exception (ESR_ELx.EC = 0b000000). The encodings for UDF used in this section are defined as permanently UNDEFINED in the Armv8-A architecture.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

UDF #<imm>

// The imm16 field is ignored by hardware.
UNDEFINED;

Assembler Symbols

<imm> is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field. The PE ignores the value of this constant.

Operation

// No operation.
### UDIV

Unsigned Divide divides an unsigned integer register value by another unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

**32-bit**

UXTH `<Wd>`, `<Wn>`

is equivalent to

**UBFM** `<Wd>`, `<Wn>`, #0, #15

and is always the preferred disassembly.

**Assembler Symbols**

- `<Wd>` is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- `<Wn>` is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

**Operation**

The description of **UBFM** gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any PE in the multiprocessor system. For more information, see *Wait For Event mechanism and Send event*.

As described in *Wait For Event mechanism and Send event*, the execution of a WFE instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level. See:

- **Traps to EL1 of EL0 execution of WFE and WFI instructions.**
- **Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions.**
- **Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions.**

```

**WFET**

Wait For Event with Timeout is a hint instruction that indicates that the PE can enter a low-power state and remain there until either a local timeout event or a wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any PE in the multiprocessor system. For more information, see *Wait For Event mechanism and Send event*.

As described in *Wait For Event mechanism and Send event*, the execution of a WFET instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions.
- Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions.

WFIT

Wait For Interrupt with Timeout is a hint instruction that indicates that the PE can enter a low-power state and remain there until either a local timeout event or a wakeup event occurs. For more information, see Wait For Interrupt. As described in Wait For Interrupt, the execution of a WFIT instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level. See:

- Traps to EL1 of EL0 execution of WFE and WFI instructions.
- Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions.
- Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions.

System
(Armv8.7)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

WFIT <Xt>

if !HaveFeatWFxT() then UNDEFINED;

integer d = UINT(Rd);

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rd" field.

Operation

bits(64) operand = X[d];
integer localtimeout = UINT(operand);

if Halted() && ConstrainUnpredictableBool(Unpredictable_WFxTDEBUG) then
  EndOfInstruction();

Hint_WFI(localtimeout);
XAFLAG

Convert floating-point condition flags from external format to Arm format. This instruction converts the state of the PSTATE.{N,Z,C,V} flags from an alternative representation required by some software to a form representing the result of an Arm floating-point scalar compare instruction.

System
(Armv8.5)

if !HaveFlagFormatExt() then UNDEFINED;

Operation

bit N = NOT(PSTATE.C) AND NOT(PSTATE.Z);
bzet Z = PSTATE.Z AND PSTATE.C;
bzet C = PSTATE.C OR PSTATE.Z;
bzet V = NOT(PSTATE.C) AND PSTATE.Z;
PSTATE.N = N;
PSTATE.Z = Z;
PSTATE.C = C;
PSTATE.V = V;
XPACD, XPACI, XPACLRI

Strip Pointer Authentication Code. This instruction removes the pointer authentication code from an address. The address is in the specified general-purpose register for XPACI and XPACD, and is in LR for XPACLRI. The XPACD instruction is used for data addresses, and XPACI and XPACLRI are used for instruction addresses.

It has encodings from 2 classes: Integer and System

```java
integer d = 30;
boolean data = FALSE;
```

### Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

### Operation

```java
if HavePACExt() then
    X[d] = Strip(X[d], data);
```
YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction, see The YIELD instruction.

```
// Empty.

// Operation

Hint_Yield();
```

A64 -- SIMD and Floating-point Instructions (alphabetic order)

**ABS**: Absolute value (vector).

**ADD (vector)**: Add (vector).

**ADDHN, ADDHN2**: Add returning High Narrow.

**ADDP (scalar)**: Add Pair of elements (scalar).

**ADDP (vector)**: Add Pairwise (vector).

**ADDV**: Add across Vector.

**AESD**: AES single round decryption.

**AESE**: AES single round encryption.

**AESIMC**: AES inverse mix columns.

**AESMC**: AES mix columns.

**AND (vector)**: Bitwise AND (vector).

**BCAX**: Bit Clear and XOR.

**BFCVT**: Floating-point convert from single-precision to BFloat16 format (scalar).

**BFCVTN, BFCVTN2**: Floating-point convert from single-precision to BFloat16 format (vector).

**BFDOT (by element)**: BFloat16 floating-point dot product (vector, by element).

**BFDOT (vector)**: BFloat16 floating-point dot product (vector).

**BFMLALB, BFMLALT (by element)**: BFloat16 floating-point widening multiply-add long (by element).

**BFMLALB, BFMLALT (vector)**: BFloat16 floating-point widening multiply-add long (vector).

**BFMMLA**: BFloat16 floating-point matrix multiply-accumulate into 2x2 matrix.

**BIC (vector, immediate)**: Bitwise bit Clear (vector, immediate).

**BIC (vector, register)**: Bitwise bit Clear (vector, register).

**BIF**: Bitwise Insert if False.

**BIT**: Bitwise Insert if True.

**BSL**: Bitwise Select.

**CLS (vector)**: Count Leading Sign bits (vector).

**CLZ (vector)**: Count Leading Zero bits (vector).

**CMEQ (register)**: Compare bitwise Equal (vector).

**CMEQ (zero)**: Compare bitwise Equal to zero (vector).

**CMGE (register)**: Compare signed Greater than or Equal (vector).

**CMGE (zero)**: Compare signed Greater than or Equal to zero (vector).

**CMGT (register)**: Compare signed Greater than (vector).

**CMGT (zero)**: Compare signed Greater than zero (vector).

**CMHI (register)**: Compare unsigned Higher (vector).

**CMHS (register)**: Compare unsigned Higher or Same (vector).
CMLE (zero): Compare signed Less than or Equal to zero (vector).
CMLT (zero): Compare signed Less than zero (vector).
CMST: Compare bitwise Test bits nonzero (vector).
CNT: Population Count per byte.
DUP (element): Duplicate vector element to vector or scalar.
DUP (general): Duplicate general-purpose register to vector.
EOR (vector): Bitwise Exclusive OR (vector).
EOR3: Three-way Exclusive OR.
EXT: Extract vector from pair of vectors.
FABD: Floating-point Absolute Difference (vector).
FABS (scalar): Floating-point Absolute value (scalar).
FABS (vector): Floating-point Absolute value (vector).
FACGE: Floating-point Absolute Compare Greater than or Equal (vector).
FACGT: Floating-point Absolute Compare Greater than (vector).
FADD (scalar): Floating-point Add (scalar).
FADD (vector): Floating-point Add (vector).
FADDP (scalar): Floating-point Add Pair of elements (scalar).
FADDP (vector): Floating-point Add Pairwise (vector).
FCADD: Floating-point Complex Add.
FCCMP: Floating-point Conditional quiet Compare (scalar).
FCCMPE: Floating-point Conditional signaling Compare (scalar).
FCMEQ (register): Floating-point Compare Equal (vector).
FCMEQ (zero): Floating-point Compare Equal to zero (vector).
FCMGE (register): Floating-point Compare Greater than or Equal (vector).
FCMGE (zero): Floating-point Compare Greater than or Equal to zero (vector).
FCMGTE (register): Floating-point Compare Greater than (vector).
FCMGTE (zero): Floating-point Compare Greater than zero (vector).
FCMLA: Floating-point Complex Multiply Accumulate.
FCMLA (by element): Floating-point Complex Multiply Accumulate (by element).
FCMLE (zero): Floating-point Compare Less than or Equal to zero (vector).
FCMLT (zero): Floating-point Compare Less than zero (vector).
FCMP: Floating-point quiet Compare (scalar).
FCMPE: Floating-point signaling Compare (scalar).
FCSEL: Floating-point Conditional Select (scalar).
FCVT: Floating-point Convert precision (scalar).
FCVTAS (scalar): Floating-point Convert to Signed integer, rounding to nearest with ties to Away (scalar).
FCVTAS (vector): Floating-point Convert to Signed integer, rounding to nearest with ties to Away (vector).
FCVTAU (scalar): Floating-point Convert to Unsigned integer, rounding to nearest with ties to Away (scalar).
FCVTAU (vector): Floating-point Convert to Unsigned integer, rounding to nearest with ties to Away (vector).
FCVTL, FCVTL2: Floating-point Convert to higher precision Long (vector).
FCVTMS (scalar): Floating-point Convert to Signed integer, rounding toward Minus infinity (scalar).
FCVTMS (vector): Floating-point Convert to Signed integer, rounding toward Minus infinity (vector).
FCVTMU (scalar): Floating-point Convert to Unsigned integer, rounding toward Minus infinity (scalar).
FCVTMU (vector): Floating-point Convert to Unsigned integer, rounding toward Minus infinity (vector).
FCVTN, FCVTN2: Floating-point Convert to lower precision Narrow (vector).
FCVTNS (scalar): Floating-point Convert to Signed integer, rounding to nearest with ties to even (scalar).
FCVTNS (vector): Floating-point Convert to Signed integer, rounding to nearest with ties to even (vector).
FCVTNU (scalar): Floating-point Convert to Unsigned integer, rounding to nearest with ties to even (scalar).
FCVTNU (vector): Floating-point Convert to Unsigned integer, rounding to nearest with ties to even (vector).
FCVTPS (scalar): Floating-point Convert to Signed integer, rounding toward Plus infinity (scalar).
FCVTPS (vector): Floating-point Convert to Signed integer, rounding toward Plus infinity (vector).
FCVTPU (scalar): Floating-point Convert to Unsigned integer, rounding toward Plus infinity (scalar).
FCVTPU (vector): Floating-point Convert to Unsigned integer, rounding toward Plus infinity (vector).
FCVTXN, FCVTXN2: Floating-point Convert to lower precision Narrow, rounding to odd (vector).
FCVTZS (scalar, fixed-point): Floating-point Convert to Signed fixed-point, rounding toward Zero (scalar).
FCVTZS (scalar, integer): Floating-point Convert to Signed integer, rounding toward Zero (scalar).
FCVTZS (vector, fixed-point): Floating-point Convert to Signed fixed-point, rounding toward Zero (vector).
FCVTZS (vector, integer): Floating-point Convert to Signed integer, rounding toward Zero (vector).
FCVTZU (scalar, fixed-point): Floating-point Convert to Unsigned fixed-point, rounding toward Zero (scalar).
FCVTZU (scalar, integer): Floating-point Convert to Unsigned integer, rounding toward Zero (scalar).
FCVTZU (vector, fixed-point): Floating-point Convert to Unsigned fixed-point, rounding toward Zero (vector).
FCVTZU (vector, integer): Floating-point Convert to Unsigned integer, rounding toward Zero (vector).
FDIV (scalar): Floating-point Divide (scalar).
FDIV (vector): Floating-point Divide (vector).
FCVTZS: Floating-point Javascript Convert to Signed fixed-point, rounding toward Zero.
FMADD: Floating-point fused Multiply-Add (scalar).
FMAX (scalar): Floating-point Maximum (scalar).
FMAX (vector): Floating-point Maximum (vector).
FMAXNM (scalar): Floating-point Maximum Number (scalar).
FMAXNM (vector): Floating-point Maximum Number (vector).
FMAXNMP (scalar): Floating-point Maximum Number of Pair of elements (scalar).
FMAXNMP (vector): Floating-point Maximum Number Pairwise (vector).
FMAXNMV: Floating-point Maximum Number across Vector.

FMAXP (scalar): Floating-point Maximum of Pair of elements (scalar).

FMAXP (vector): Floating-point Maximum Pairwise (vector).

FMAXV: Floating-point Maximum across Vector.

FMINP (scalar): Floating-point Minimum of Pair of elements (scalar).

FMINP (vector): Floating-point Minimum Pairwise (vector).

FMINV: Floating-point Minimum across Vector.

FMINNM: Floating-point Minimum Number (scalar).

FMINNM (vector): Floating-point Minimum Number Pairwise (vector).

FMINNMV: Floating-point Minimum Number across Vector.

FMINNMP (scalar): Floating-point Minimum Number of Pair of elements (scalar).

FMINNMP (vector): Floating-point Minimum Number Pairwise (vector).

FMLA (by element): Floating-point fused Multiply-Add to accumulator (by element).

FMLA (vector): Floating-point fused Multiply-Add to accumulator (vector).

FMLAL, FMLAL2 (by element): Floating-point fused Multiply-Add Long to accumulator (by element).

FMLAL, FMLAL2 (vector): Floating-point fused Multiply-Add Long to accumulator (vector).

FLMS (by element): Floating-point fused Multiply-Subtract from accumulator (by element).

FLMS (vector): Floating-point fused Multiply-Subtract from accumulator (vector).

FMLSL, FMLSL2 (by element): Floating-point fused Multiply-Subtract Long from accumulator (by element).

FMLSL, FMLSL2 (vector): Floating-point fused Multiply-Subtract Long from accumulator (vector).

FMOV (general): Floating-point Move to or from general-purpose register without conversion.

FMOV (register): Floating-point Move register without conversion.

FMOV (scalar, immediate): Floating-point move immediate (scalar).

FMOV (vector, immediate): Floating-point move immediate (vector).

FMULX: Floating-point Multiply extended.

FMULX (by element): Floating-point Multiply extended (by element).

FNEG (scalar): Floating-point Negate (scalar).

FNEG (vector): Floating-point Negate (vector).

FNMSUB: Floating-point Negated fused Multiply-Subtract (scalar).
FNMUL (scalar): Floating-point Multiply-Negate (scalar).
FRECPE: Floating-point Reciprocal Estimate.
FRECPS: Floating-point Reciprocal Step.
FRECPSX: Floating-point Reciprocal exponent (scalar).
FRINT32X (scalar): Floating-point Round to 32-bit Integer, using current rounding mode (scalar).
FRINT32X (vector): Floating-point Round to 32-bit Integer, using current rounding mode (vector).
FRINT32Z (scalar): Floating-point Round to 32-bit Integer toward Zero (scalar).
FRINT32Z (vector): Floating-point Round to 32-bit Integer toward Zero (vector).
FRINT64X (scalar): Floating-point Round to 64-bit Integer, using current rounding mode (scalar).
FRINT64X (vector): Floating-point Round to 64-bit Integer, using current rounding mode (vector).
FRINT64Z (scalar): Floating-point Round to 64-bit Integer toward Zero (scalar).
FRINT64Z (vector): Floating-point Round to 64-bit Integer toward Zero (vector).
FRINTA (scalar): Floating-point Round to Integral, to nearest with ties to Away (scalar).
FRINTA (vector): Floating-point Round to Integral, to nearest with ties to Away (vector).
FRINTI (scalar): Floating-point Round to Integral, using current rounding mode (scalar).
FRINTI (vector): Floating-point Round to Integral, using current rounding mode (vector).
FRINTM (scalar): Floating-point Round to Integral, toward Minus infinity (scalar).
FRINTM (vector): Floating-point Round to Integral, toward Minus infinity (vector).
FRINTN (scalar): Floating-point Round to Integral, to nearest with ties to even (scalar).
FRINTN (vector): Floating-point Round to Integral, to nearest with ties to even (vector).
FRINTP (scalar): Floating-point Round to Integral, toward Plus infinity (scalar).
FRINTP (vector): Floating-point Round to Integral, toward Plus infinity (vector).
FRINTX (scalar): Floating-point Round to Integral exact, using current rounding mode (scalar).
FRINTX (vector): Floating-point Round to Integral exact, using current rounding mode (vector).
FRINTZ (scalar): Floating-point Round to Integral, toward Zero (scalar).
FRINTZ (vector): Floating-point Round to Integral, toward Zero (vector).
FRSQRTE: Floating-point Reciprocal Square Root Estimate.
FRSQRTS: Floating-point Reciprocal Square Root Step.
FSORT (scalar): Floating-point Square Root (scalar).
FSORT (vector): Floating-point Square Root (vector).
FSUB (scalar): Floating-point Subtract (scalar).
FSUB (vector): Floating-point Subtract (vector).
INS (element): Insert vector element from another vector element.
INS (general): Insert vector element from general-purpose register.
LD1 (multiple structures): Load multiple single-element structures to one, two, three, or four registers.
LD1 (single structure): Load one single-element structure to one lane of one register.
LD1R: Load one single-element structure and Replicate to all lanes (of one register).
LD2 (multiple structures): Load multiple 2-element structures to two registers.
LD2 (single structure): Load single 2-element structure to one lane of two registers.
LD2R: Load single 2-element structure and Replicate to all lanes of two registers.
LD3 (multiple structures): Load multiple 3-element structures to three registers.
LD3 (single structure): Load single 3-element structure to one lane of three registers.
LD3R: Load single 3-element structure and Replicate to all lanes of three registers.
LD4 (multiple structures): Load multiple 4-element structures to four registers.
LD4 (single structure): Load single 4-element structure to one lane of four registers.
LD4R: Load single 4-element structure and Replicate to all lanes of four registers.
LDNP (SIMD&FP): Load Pair of SIMD&FP registers, with Non-temporal hint.
LDP (SIMD&FP): Load Pair of SIMD&FP registers.
LDR (immediate, SIMD&FP): Load SIMD&FP Register (immediate offset).
LDR (literal, SIMD&FP): Load SIMD&FP Register (PC-relative literal).
LDR (register, SIMD&FP): Load SIMD&FP Register (register offset).
LDUR (SIMD&FP): Load SIMD&FP Register (unscaled offset).
MLA (by element): Multiply-Add to accumulator (vector, by element).
MLA (vector): Multiply-Add to accumulator (vector).
MLS (by element): Multiply-Subtract from accumulator (vector, by element).
MLS (vector): Multiply-Subtract from accumulator (vector).
MOV (element): Move vector element to another vector element: an alias of INS (element).
MOV (from general): Move general-purpose register to a vector element: an alias of INS (general).
MOV (scalar): Move vector element to scalar: an alias of DUP (element).
MOV (to general): Move vector element to general-purpose register: an alias of UMOV.
MOVI: Move Immediate (vector).
MUL (by element): Multiply (vector, by element).
MUL (vector): Multiply (vector).
MVN: Bitwise NOT (vector): an alias of NOT.
MVNI: Move inverted Immediate (vector).
NEG (vector): Negate (vector).
NOT: Bitwise NOT (vector).
ORN (vector): Bitwise inclusive OR NOT (vector).
ORR (vector, immediate): Bitwise inclusive OR (vector, immediate).
ORR (vector, register): Bitwise inclusive OR (vector, register).
PMUL: Polynomial Multiply.
PMULL, PMULL2: Polynomial Multiply Long.
RADDHN, RADDHN2: Rounding Add returning High Narrow.
RAX1: Rotate and Exclusive OR.
RBIT (vector): Reverse Bit order (vector).
REV16 (vector): Reverse elements in 16-bit halfwords (vector).
REV32 (vector): Reverse elements in 32-bit words (vector).
REV64: Reverse elements in 64-bit doublewords (vector).
RSHRN, RSHRN2: Rounding Shift Right Narrow (immediate).
RSUBHN, RSUBHN2: Rounding Subtract returning High Narrow.
SABA: Signed Absolute difference and Accumulate.
SABAL, SABAL2: Signed Absolute difference and Accumulate Long.
SABD: Signed Absolute Difference.
SABDL, SABDL2: Signed Absolute Difference Long.
SADALP: Signed Add and Accumulate Long Pairwise.
SADDL, SADDL2: Signed Add Long (vector).
SADLP: Signed Add Long Pairwise.
SADDLV: Signed Add Long across Vector.
SADDW, SADDW2: Signed Add Wide.
SCVTF (scalar, fixed-point): Signed fixed-point Convert to Floating-point (scalar).
SCVTF (scalar, integer): Signed integer Convert to Floating-point (scalar).
SCVTF (vector, fixed-point): Signed fixed-point Convert to Floating-point (vector).
SCVTF (vector, integer): Signed integer Convert to Floating-point (vector).
SDOT (by element): Dot Product signed arithmetic (vector, by element).
SDOT (vector): Dot Product signed arithmetic (vector).
SHA1C: SHA1 hash update (choose).
SHA1H: SHA1 fixed rotate.
SHA1M: SHA1 hash update (majority).
SHA1P: SHA1 hash update (parity).
SHA1SU0: SHA1 schedule update 0.
SHA1SU1: SHA1 schedule update 1.
SHA256H: SHA256 hash update (part 1).
SHA256H2: SHA256 hash update (part 2).
SHA256SU0: SHA256 schedule update 0.
SHA256SU1: SHA256 schedule update 1.
SHA512H: SHA512 Hash update part 1.
SHA512H2: SHA512 Hash update part 2.
SHA512SU0: SHA512 Schedule Update 0.
SHA512SU1: SHA512 Schedule Update 1.
SHADD: Signed Halving Add.
SHL: Shift Left (immediate).
SHLL, SHLL2: Shift Left Long (by element size).
SHRN, SHRN2: Shift Right Narrow (immediate).
SHSUB: Signed Halving Subtract.
SLI: Shift Left and Insert (immediate).
SM3PARTW1: SM3PARTW1.
SM3PARTW2: SM3PARTW2.
SM3SS1: SM3SS1.
SM3TT1A: SM3TT1A.
SM3TT1B: SM3TT1B.
SM3TT2A: SM3TT2A.
SM3TT2B: SM3TT2B.
SM4E: SM4 Encode.
SM4EKEY: SM4 Key.
SMAX: Signed Maximum (vector).
SMAXP: Signed Maximum Pairwise.
SMAXV: Signed Maximum across Vector.
SMIN: Signed Minimum (vector).
SMINP: Signed Minimum Pairwise.
SMINV: Signed Minimum across Vector.
SMLSL, SMLSL2 (by element): Signed Multiply-Subtract Long (vector, by element).
SMMLA (vector): Signed 8-bit integer matrix multiply-accumulate (vector).
SMOV: Signed Move vector element to general-purpose register.
SQABS: Signed saturating Absolute value.
SQADD: Signed saturating Add.
SQDMLSL, SQDMLSL2 (by element): Signed saturating Doubling Multiply-Subtract Long (by element).

SQDMULH (by element): Signed saturating Doubling Multiply returning High half (by element).

SQDMULH (vector): Signed saturating Doubling Multiply returning High half.

SQDMULL, SQDMULL2 (by element): Signed saturating Doubling Multiply Long (by element).

SQNEG: Signed saturating Negate.

SQDMULH (by element): Signed saturating Doubling Multiply returning High half (by element).

SQDMULH (vector): Signed saturating Doubling Multiply returning High half.

SQDMULL, SQDMULL2 (by element): Signed saturating Doubling Multiply Long (by element).

SQNEG: Signed saturating Negate.

SQRDMLAH (by element): Signed Saturating Rounding Doubling Multiply Accumulate returning High Half (by element).

SQRDMLAH (vector): Signed Saturating Rounding Doubling Multiply Accumulate returning High Half (vector).

SQRDMLSH (by element): Signed Saturating Rounding Doubling Multiply Subtract returning High Half (by element).

SQRDMLSH (vector): Signed Saturating Rounding Doubling Multiply Subtract returning High Half (vector).

SORSHL: Signed saturating Rounding Shift Left (register).

SORSHRN, SORSHRN2: Signed saturating Rounding Shift Right Narrow (immediate).

SORSHRUN, SORSHRUN2: Signed saturating Rounding Shift Right Unsigned Narrow (immediate).

SOSHL (immediate): Signed saturating Shift Left (immediate).

SOSHL (register): Signed saturating Shift Left (register).

SOSHLU: Signed saturating Shift Left Unsigned (immediate).

SOSHRN, SOSHRN2: Signed saturating Shift Right Narrow (immediate).

SOSHRUN, SOSHRUN2: Signed saturating Shift Right Unsigned Narrow (immediate).

SQSUB: Signed saturating Subtract.

SOXTN, SOXTN2: Signed saturating extract Narrow.

SOXTUN, SOXTUN2: Signed saturating extract Unsigned Narrow.

SRHADD: Signed Rounding Halving Add.

SRI: Shift Right and Insert (immediate).

SRSHL: Signed Rounding Shift Left (register).

SRSHR: Signed Rounding Shift Right (immediate).

SRSRA: Signed Rounding Shift Right and Accumulate (immediate).

SSHL: Signed Shift Left (register).

SSHL, SSHLL2: Signed Shift Left Long (immediate).

SSHR: Signed Shift Right (immediate).

SSRA: Signed Shift Right and Accumulate (immediate).

SSUBL, SSUBL2: Signed Subtract Long.

SSUBW, SSUBW2: Signed Subtract Wide.

ST1 (multiple structures): Store multiple single-element structures from one, two, three, or four registers.

ST1 (single structure): Store a single-element structure from one lane of one register.
ST2 (multiple structures): Store multiple 2-element structures from two registers.
ST2 (single structure): Store single 2-element structure from one lane of two registers.
ST3 (multiple structures): Store multiple 3-element structures from three registers.
ST3 (single structure): Store single 3-element structure from one lane of three registers.
ST4 (multiple structures): Store multiple 4-element structures from four registers.
ST4 (single structure): Store single 4-element structure from one lane of four registers.
STNP (SIMD&FP): Store Pair of SIMD&FP registers, with Non-temporal hint.
STP (SIMD&FP): Store Pair of SIMD&FP registers.
STR (immediate, SIMD&FP): Store SIMD&FP register (immediate offset).
STR (register, SIMD&FP): Store SIMD&FP register (register offset).
STUR (SIMD&FP): Store SIMD&FP register (unscaled offset).
SUB (vector): Subtract (vector).
SUBHN, SUBHN2: Subtract returning High Narrow.
SUDOT (by element): Dot product with signed and unsigned integers (vector, by element).
SUQADD: Signed saturating Accumulate of Unsigned value.
TBL: Table vector Lookup.
TBX: Table vector lookup extension.
TRN1: Transpose vectors (primary).
TRN2: Transpose vectors (secondary).
UABA: Unsigned Absolute difference and Accumulate.
UABAL, UABAL2: Unsigned Absolute difference and Accumulate Long.
UABD: Unsigned Absolute Difference (vector).
UABDL, UABDL2: Unsigned Absolute Difference Long.
UADALP: Unsigned Add and Accumulate Long Pairwise.
UADDL, UADDL2: Unsigned Add Long (vector).
UADLP: Unsigned Add Long Pairwise.
UADDLV: Unsigned sum Long across Vector.
UADDW, UADDW2: Unsigned Add Wide.
UCVTF (scalar, fixed-point): Unsigned fixed-point Convert to Floating-point (scalar).
UCVTF (scalar, integer): Unsigned integer Convert to Floating-point (scalar).
UCVTF (vector, fixed-point): Unsigned fixed-point Convert to Floating-point (vector).
UCVTF (vector, integer): Unsigned integer Convert to Floating-point (vector).
UDOT (by element): Dot Product unsigned arithmetic (vector, by element).
UDOT (vector): Dot Product unsigned arithmetic (vector).
UHADD: Unsigned Halving Add.
UHSUB: Unsigned Halving Subtract.
UMAX: Unsigned Maximum (vector).
UMAXP: Unsigned Maximum Pairwise.
UMAXV: Unsigned Maximum across Vector.
UMIN: Unsigned Minimum (vector).
UMINP: Unsigned Minimum Pairwise.
UMINV: Unsigned Minimum across Vector.
UMLSL, UMLSL2 (by element): Unsigned Multiply-Subtract Long (vector, by element).
UMLSL, UMLSL2 (vector): Unsigned Multiply-Subtract Long (vector).
UMMLA (vector): Unsigned 8-bit integer matrix multiply-accumulate (vector).
UMOV: Unsigned Move vector element to general-purpose register.
UMULL, UMULL2 (by element): Unsigned Multiply Long (vector, by element).
UMULL, UMULL2 (vector): Unsigned Multiply long (vector).
UQADD: Unsigned saturating Add.
UQRSHL: Unsigned saturating Rounding Shift Left (register).
UQRSHRN, UQRSHRN2: Unsigned saturating Rounded Shift Right Narrow (immediate).
UQSHL (immediate): Unsigned saturating Shift Left (immediate).
UQSHL (register): Unsigned saturating Shift Left (register).
UQSHRN, UQSHRN2: Unsigned saturating Shift Right Narrow (immediate).
UQSUB: Unsigned saturating Subtract.
UQXTN, UQXTN2: Unsigned saturating extract Narrow.
URECPE: Unsigned Reciprocal Estimate.
URHADD: Unsigned Rounding Halving Add.
URSHL: Unsigned Rounding Shift Left (register).
URSHR: Unsigned Rounding Shift Right (immediate).
URSORTE: Unsigned Reciprocal Square Root Estimate.
URSRRA: Unsigned Rounding Shift Right and Accumulate (immediate).
USDOT (by element): Dot Product with unsigned and signed integers (vector, by element).
USDOT (vector): Dot Product with unsigned and signed integers (vector).
USHL: Unsigned Shift Left (register).
USHLL, USHLL2: Unsigned Shift Left Long (immediate).
USHR: Unsigned Shift Right (immediate).
USMMLA (vector): Unsigned and signed 8-bit integer matrix multiply-accumulate (vector).
USQADD: Unsigned saturating Accumulate of Signed value.
**USRA**: Unsigned Shift Right and Accumulate (immediate).

**USUBL, USUBL2**: Unsigned Subtract Long.

**USUBW, USUBW2**: Unsigned Subtract Wide.

**UXTL, UXTL2**: Unsigned extend Long: an alias of USHLL, USHLL2.

**UZP1**: Unzip vectors (primary).

**UZP2**: Unzip vectors (secondary).

**XAR**: Exclusive OR and Rotate.

**XTN, XTN2**: Extract Narrow.

**ZIP1**: Zip vectors (primary).

**ZIP2**: Zip vectors (secondary).
ABS

Absolute value (vector). This instruction calculates the absolute value of each vector element in the source SIMD&FP register, puts the result into a vector, and writes the vector to the destination SIMD&FP register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

### Scalar

V[d] = result;
```

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ADDHN, ADDHN2

Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are truncated. For rounded results, see RADDHN.

The ADDHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the ADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
0 | Q | 0 | 0 | 1 | 1 | 0 | size | 1 | Rm | 0 | 1 | 0 | 0 | 0 | Rn | Rd |
```

ADDHN(2) <Vd>..<Tb>, <Vn>..<Ta>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

```
Q 2
0   [absent]
1   [present]
```

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in “size.Q”:

```
size   Q   <Tb>
00     0   8B
00     1   16B
01     0   4H
01     1   8H
10     0   2S
10     1   4S
11     x   RESERVED
```

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in “size”:

```
size   <Ta>
00     8H
01     4S
10     2D
11     RESERVED
```

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
Operation

CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;

for e = 0 to elements-1
   element1 = Elem[operand1, e, 2*esize];
   element2 = Elem[operand2, e, 2*esize];
   if sub_op then
      sum = element1 - element2;
   else
      sum = element1 + element2;
   sum = sum + round_const;
   Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;

Operational information

If PSTATE.DIT is 1:
   • The execution time of this instruction is independent of:
      ◦ The values of the data supplied in any of its registers.
      ◦ The values of the NZCV flags.
   • The response of this instruction to asynchronous exceptions does not vary based on:
      ◦ The values of the data supplied in any of its registers.
      ◦ The values of the NZCV flags.
ADDP (scalar)

Add Pair of elements (scalar). This instruction adds two vector elements in the source SIMD&FP register and writes the scalar result into the destination SIMD&FP register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 1 0 1 1 1 1 0 | size | 1 1 0 0 0 | 1 1 0 1 1 1 0 | Rn | Rd
```

ADDP <V><d>, <Vn>.<T>

integer d = UInt(Rd);

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_ADD, operand, esize);

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**ADDP (vector)**

Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
0  Q  0  0  1  1  1  0  size  1  Rm  1  0  1  1  1  1  Rn  Rd
```

ADDP `<Vd>`..<T>, `<Vn>`..<T>, `<Vm`..<T>

integer d = `UInt(Rd)`;
integer n = `UInt(Rn)`;
integer m = `UInt(Rm)`;
if size:Q == '110' then UNDEFINED;
integer esize = 8 << `UInt(size)`;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

### Assembler Symbols

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in "size:Q":

<table>
<thead>
<tr>
<th>size</th>
<th>Q</th>
<th>&lt;T&gt;</th>

  \end{itemize}
\end{itemize}
**BCAX**

Bit Clear and Exclusive OR performs a bitwise AND of the 128-bit vector in a source SIMD&FP register and the complement of the vector in another source SIMD&FP register, then performs a bitwise exclusive OR of the resulting vector and the vector in a third source SIMD&FP register, and writes the result to the destination SIMD&FP register. This instruction is implemented only when `FEAT_SHA3` is implemented.

**Advanced SIMD**

`AArch64.CheckFPAdvSIMDEnabled()`;

bits(128) Vm = V[m];
bits(128) Vn = V[n];
bits(128) Va = V[a];

V[d] = Vn EOR (Vm AND NOT(Va));

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Floating-point convert from single-precision to BFloat16 format (scalar) converts the single-precision floating-point value in the 32-bit SIMD&FP source register to BFloat16 format and writes the result in the 16-bit SIMD&FP destination register.

Unlike the BFloat16 multiplication instructions, this instruction honors all the control bits in the FPCR that apply to single-precision arithmetic, including the rounding mode. This instruction can generate a floating-point exception that causes a cumulative exception bit in the FPSR to be set, or a synchronous exception to be taken, depending on the enable bits in the FPCR, ID_AA64ISAR1_EL1. BF16 indicates whether this instruction is supported.

Single-precision to BFloat16
(Armv8.6)

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|

BFCVT <Hd>, <Sn>

if !HaveBF16Ext() then UNDEFINED;
integer n = UInt(Rn);
integer d = UInt(Rd);

Assembler Symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();

bits(32) operand = V[n];
FPCRType fpcr = FPCR[];
boolean merge = IsMerging(fpcr);
bits(128) result = if merge then V[d] else Zeros();

Elem[result, 0, 16] = FPConvertBF(operand, fpcr);
V[d] = result;
BFCVTN, BFCVTN2

Floating-point convert from single-precision to BFloat16 format (vector) reads each single-precision element in the SIMD&FP source vector, converts each value to BFloat16 format, and writes the results in the lower or upper half of the SIMD&FP destination vector. The result elements are half the width of the source elements.

The BFCVTN instruction writes the half-width results to the lower half of the destination vector and clears the upper half to zero, while the BFCVTN2 instruction writes the results to the upper half of the destination vector without affecting the other bits in the register.

Unlike the BFloat16 multiplication instructions, this instruction honors all of the control bits in the FPCR that apply to single-precision arithmetic, including the rounding mode. It can also generate a floating-point exception that causes cumulative exception bits in the FPSR to be set, or a synchronous exception to be taken, depending on the enable bits in the FPCR.

BFDOT (by element)

BFloat16 floating-point dot product (vector, by element). This instruction delimits the source vectors into pairs of 16-bit BF16 elements. Each pair of elements in the first source vector is multiplied by the specified pair of elements in the second source vector. The resulting single-precision products are then summed and added destructively to the single-precision element of the destination vector that aligns with the pair of BF16 values in the first source vector. The instruction ignores the FPCR and does not update the FPSR exception status.

The BF16 pair within the second source vector is specified using an immediate index. The index range is from 0 to 3 inclusive. ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

V[d] = result;
**BFDOT (vector)**

BFloat16 floating-point dot product (vector). This instruction delimits the source vectors into pairs of 16-bit BF16 elements. Within each pair; the elements in the first source vector are multiplied by the corresponding elements in the second source vector. The resulting single-precision products are then summed and added destructively to the single-precision element of the destination vector that aligns with the pair of BF16 values in the first source vector. The instruction ignores the FPCR and does not update the FPSR exception status.

```

V[d] = result;
BFMLALB, BFMLALT (by element)

BFLOAT16 floating-point widening multiply-add long (by element) widens the even-numbered (bottom) or odd-numbered (top) 16-bit elements in the first source vector, and the indexed element in the second source vector from BFLOAT16 to single-precision format. The instruction then multiplies and adds these values to the overlapping single-precision elements of the destination vector.

This performs a fused multiply-add without intermediate rounding that honors all of the control bits in the FPCR that apply to single-precision arithmetic, including the rounding mode. It can also generate a floating-point exception that causes cumulative exception bits in the FPSR to be set, or a synchronous exception to be taken, depending on the enable bits in the FPCR. ID_AA64ISAR1_EL1. BF16 indicates whether this instruction is supported.

BFMMLA

BFLOAT16 floating-point matrix multiply-accumulate into 2x2 matrix. This instruction multiplies the 2x4 matrix of BF16 values held in the first 128-bit source vector by the 4x2 BF16 matrix in the second 128-bit source vector. The resulting 2x2 single-precision matrix product is then added destructively to the 2x2 single-precision matrix in the 128-bit destination vector. This is equivalent to performing a 4-way dot product per destination element. The instruction ignores the FPCR and does not update the FPSR exception status.

Arm expects that the BFMMLA instruction will deliver a peak BF16 multiply throughput that is at least as high as can be achieved using two BFDOT instructions, with a goal that it should have significantly higher throughput.

Vector

BSL

Bitwise Select. This instruction sets each bit in the destination SIMD&FP register to the corresponding bit from the first source SIMD&FP register when the original destination bit was 1, otherwise from the second source SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

![Register Bit Representation]

BSL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> Is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>1</td>
<td>16B</td>
</tr>
</tbody>
</table>

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();

bits(datasize) operand1;
bits(datasize) operand3;
bits(datasize) operand4 = V[n];

operand1 = V[m];
operand3 = V[d];
V[d] = operand1 EOR ((operand1 EOR operand4) AND operand3);

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
CLS (vector)

Count Leading Sign bits (vector). This instruction counts the number of consecutive bits following the most significant bit that are the same as the most significant bit in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The count does not include the most significant bit itself.

Depending on the settings in the \textit{CPACR\_EL1}, \textit{CPTR\_EL2}, and \textit{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

count = 0

t = '0'

\textbf{Asm:}

\begin{verbatim}
CLS <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

CountOp countop = if U == '1' then CountOp_CLZ else CountOp_CLS;

<Asm>

integer count;
for e = 0 to elements-1
    if countop == CountOp_CLS then
        count = CountLeadingSignBits(Elem[operand, e, esize]);
    else
        count = CountLeadingZeroBits(Elem[operand, e, esize]);
    Elem[result, e, esize] = count<esize-1:0>;
V[d] = result;

debug(X, V);
\end{verbatim}

\textbf{Operational information}

If PSTATE.DIT is 1:
\begin{itemize}
  \item The execution time of this instruction is independent of:
    \begin{itemize}
      \item The values of the data supplied in any of its registers.
      \item The values of the NZCV flags.
    \end{itemize}
  \item The response of this instruction to asynchronous exceptions does not vary based on:
    \begin{itemize}
      \item The values of the data supplied in any of its registers.
    \end{itemize}
\end{itemize}
The values of the NZCV flags.
CLZ (vector)

Count Leading Zero bits (vector). This instruction counts the number of consecutive zeros, starting from the most significant bit, in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
CMEQ (register)

Compare bitwise Equal (vector). This instruction compares each vector element from the first source SIMD&FP register with the corresponding vector element from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Compare signed Greater than (vector). This instruction compares each vector element in the first source SIMD&FP register with the corresponding vector element in the second source SIMD&FP register and if the first signed integer value is greater than the second signed integer value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

**CMTST**

Compare bitwise Test bits nonzero (vector). This instruction reads each vector element in the first source SIMD&FP register, performs an AND with the corresponding vector element in the second source SIMD&FP register, and if the result is not zero, sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

### Scalar

  \end{tabular}
- **<Vn>** Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- **<Vm>** Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

\begin{verbatim}
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand2;
bits(datasize) operand3;
bits(datasize) operand4 = \texttt{V}[n];
operand1 = \texttt{V}[m];
operand2 = \texttt{Zeros}();
operand3 = \texttt{Ones}();
\texttt{V}[d] = operand1 \texttt{EOR ((operand2 EOR operand4) AND operand3);};
\end{verbatim}

**Operational information**

If PSTATE.DIT is 1:
\begin{itemize}
  \item The execution time of this instruction is independent of:
    \begin{itemize}
      \item The values of the data supplied in any of its registers.
      \item The values of the NZCV flags.
    \end{itemize}
  \item The response of this instruction to asynchronous exceptions does not vary based on:
    \begin{itemize}
      \item The values of the data supplied in any of its registers.
      \item The values of the NZCV flags.
    \end{itemize}
\end{itemize}
Extract vector from pair of vectors. This instruction extracts the lowest vector elements from the second source SIMD&FP register and the highest vector elements from the first source SIMD&FP register, concatenates the results into a vector, and writes the vector to the destination SIMD&FP register vector. The index value specifies the lowest vector element to extract from the first source register, and consecutive elements are extracted from the first, then second, source registers until the destination vector is filled.

The following figure shows an example of the operation of EXT doubleword operation for $Q = 0$ and $imm4<2:0> = 3$.

Depending on the settings in the $CPACR_EL1$, $CPTR_EL2$, and $CPTR_EL3$ registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) hi = V[m];
bits(datasize) lo = V[n];
bits(datasize*2) concat = hi:lo;
V[d] = concat<position+ datasize-1:position>;
```
Operational information

If PSTATE.DIT is 1:

• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
Floating-point Absolute Difference (vector). This instruction subtracts the floating-point values in the elements of the second source SIMD&FP register, from the corresponding floating-point values in the elements of the first source SIMD&FP register, places the absolute value of each result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: **Scalar half precision**, **Scalar single-precision and double-precision**, **Vector half precision** and **Vector single-precision and double-precision**

**FACGE**

Floating-point Absolute Compare Greater than or Equal (vector). This instruction compares the absolute value of each floating-point value in the first source SIMD&FP register with the absolute value of the corresponding floating-point value in the second source SIMD&FP register and if the first value is greater than or equal to the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the **CPACR_EL1, CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: **Scalar half precision**, **Scalar single-precision and double-precision**, **Vector half precision** and **Vector single-precision and double-precision**

```
FADD (vector)

Floating-point Add (vector). This instruction adds corresponding vector elements in the two source SIMD&FP registers, writes the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

FADDP (vector)

Floating-point Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Copyright © 2010-2020 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
**FCADD**

Floating-point Complex Add.
This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Copyright © 2010-2020 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.
**FCCMP**

Floating-point Conditional quiet Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the \( \text{PSTATE} \).\{N, Z, C, V\} flags. If the condition does not pass then the \( \text{PSTATE} \).\{N, Z, C, V\} flags are set to the flag bit specifier.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in \( \text{FPCR} \), the exception results in either a flag being set in \( \text{FPSR} \), or a synchronous exception being generated. For more information, see [Floating-point exception traps](#).

Depending on the settings in the \( \text{CPACR\_EL1} \), \( \text{CPTR\_EL2} \), and \( \text{CPTR\_EL3} \) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

\text{FCCMP } \langle \text{Dn} \rangle, \langle \text{Dm} \rangle, \#\langle \text{nzcv} \rangle, \langle \text{cond} \rangle
\]

integer \( n = \text{UInt}(\text{Rn}) \);

integer \( m = \text{UInt}(\text{Rm}) \);

integer datasize;

```plaintext
case ftype of
  when '00' datasize = 32;
  when '01' datasize = 64;
  when '10' UNDEFINED;
  when '11'
    if \( \text{HaveFP16Ext}() \) then
      datasize = 16;
    else
      UNDEFINED;

bits(4) flags = nzcv;
```

**Assembler Symbols**

\(<\text{Dn}>\) Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<\text{Dm}>\) Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

\(<\text{Hn}>\) Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<\text{Hm}>\) Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

\(<\text{Sn}>\) Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

\(<\text{Sm}>\) Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

\(<\text{nzcv}>\) Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

\(<\text{cond}>\) Is one of the standard conditions, encoded in the "cond" field in the standard way.
Operation

```c
CheckFPAdvSIMEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = V[m];
if ConditionHolds(cond) then
    flags = FPCmp(operand1, operand2, FALSE, FPCR[]);
PSTATE.<N,Z,C,V> = flags;
```

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the PSTATE condition flags to N=0, Z=0, C=1, and V=1.
FCCMPE

Floating-point Conditional signaling Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the *PSTATE*.\{N, Z, C, V\} flags. If the condition does not pass then the *PSTATE*.\{N, Z, C, V\} flags are set to the flag bit specifier.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in *FPCR*, the exception results in either a flag being set in *FPSR*, or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the *CPACR_EL1*, *CPTR_EL2*, and *CPTR_EL3* registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- `<cond>` Is one of the standard conditions, encoded in the "cond" field in the standard way.
Operation

CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = V[m];
if ConditionHolds(cond) then
    flags = FPCmpared(operand1, operand2, TRUE, FPCR[]);
PSTATE.<N,Z,C,V> = flags;

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the PSTATE condition flags to N=0, Z=0, C=1, and V=1.
Floating-point Compare Equal (vector). This instruction compares each floating-point value from the first source SIMD&FP register, with the corresponding floating-point value from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FCMGE (register)

Floating-point Compare Greater than or Equal (vector). This instruction reads each floating-point value in the first source SIMD&FP register and if the value is greater than or equal to the corresponding floating-point value in the second source SIMD&FP register sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in \textit{FPCR}, the exception results in either a flag being set in \textit{FPSR}, or a synchronous exception being generated. For more information, see \textit{Floating-point exception traps}.

Depending on the settings in the \textit{CPACR\_EL1}, \textit{CPTR\_EL2}, and \textit{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: \textit{Scalar half precision}, \textit{Scalar single-precision and double-precision}, \textit{Vector half precision} and \textit{Vector single-precision and double-precision}

**FCMGT (zero)**

Floating-point Compare Greater than zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is greater than zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

**FCMLA (by element)**

Floating-point Complex Multiply Accumulate (by element).
This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with
the more significant element holding the imaginary part of the number and the less significant element holding the
real part of the number. Each element holds a floating-point value. It performs the following computation on complex
numbers from the first source register and the destination register with the specified complex number from the
second source register:

- Considering the complex number from the second source register on an Argand diagram, the number is
  rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a
    rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation
    was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination
  register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.
This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in
either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point
exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and
Exception level, an attempt to execute the instruction might be trapped.

V[d] = result;
```
FCMLE (zero)

Floating-point Compare Less than or Equal to zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is less than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

### Scalar half precision

Assembler Symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<V> Is a width specifier, encoded in “sz”:

<table>
<thead>
<tr>
<th>sz</th>
<th>&lt;V&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>S</td>
</tr>
<tr>
<td>1</td>
<td>D</td>
</tr>
</tbody>
</table>

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the half-precision variant: is an arrangement specifier, encoded in “Q”: 
For the single-precision and double-precision variant: is an arrangement specifier, encoded in “sz:<T>”:

<table>
<thead>
<tr>
<th>sz</th>
<th>Q</th>
<th>&lt;T&gt;</th>

</tr>
<tr>
<td>0</td>
<td>1</td>
<td>RESERVE</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>2D</td>
</tr>
</tbody>
</table>

\(<V_n>\) Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = \(V[n]\);
bits(datasize) result;
bits(esize) zero = FPZero('0');
bits(esize) element;
boolean test_passed;
for e = 0 to elements-1
    element = Elem[operand, e, esize];
    case comparison of
        when CompareOp_GT test_passed = FPCompareGT(element, zero, FPCR[]);
        when CompareOp_GE test_passed = FPCompareGE(element, zero, FPCR[]);
        when CompareOp_EQ test_passed = FPCompareEQ(element, zero, FPCR[]);
        when CompareOp_LE test_passed = FPCompareGE(zero, element, FPCR[]);
        when CompareOp_LT test_passed = FPCompareGT(zero, element, FPCR[]);
    Elem[result, e, esize] = if test_passed then Ones() else Zeros();
V[d] = result;
```
**FCMLT (zero)**

Floating-point Compare Less than zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is less than zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

    Elem[result, e, esize] = if test_passed then Ones() else Zeros();
V[d] = result;
```

Floating-point quiet Compare (scalar). This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the \textit{PSTATE}.\{N, Z, C, V\} flags. This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in \textit{FPCR}, the exception results in either a flag being set in \textit{FPSR}, or a synchronous exception being generated. For more information, see \textit{Floating-point exception traps}.

Depending on the settings in the \textit{CPACR\_EL1}, \textit{CPTR\_EL2}, and \textit{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```
integer n = \textit{UInt}(Rn);
integer m = \textit{UInt}(Rm);    // ignored when \textit{opc}<0> == '1'

Assembler Symbols

\(<Dn>\) For the double-precision variant: is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

For the double-precision, zero variant: is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

\(<Dm>\) Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

\(<Hn>\) For the half-precision variant: is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

For the half-precision, zero variant: is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

\(<Hm>\) Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

\(<Sn>\) For the single-precision variant: is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

\(<Sm>\) Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();

\(\text{bits(datasize) operand1} = V[n];\)
\(\text{bits(datasize) operand2};\)

\(\text{operand2} = \text{if cmp_with_zero then FPUzero('0') else V[m]};\)

\(\text{PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR[]);}\)

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of \(<, ==, >\) or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the \(\text{PSTATE}\) condition flags to \(N=0, Z=0, C=1,\) and \(V=1.\)
FCMPE

Floating-point signaling Compare (scalar). This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the \text{PSTATE}.\{N, Z, C, V\} flags.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in \text{FPCR}, the exception results in either a flag being set in \text{FPSR}, or a synchronous exception being generated. For more information, see \textit{Floating-point exception traps}.

Depending on the settings in the \text{CPACR\_EL1}, \text{CPTR\_EL2}, and \text{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;
operand2 = if cmp_with_zero then FPZero('0') else V[m];
PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR[]);

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the PSTATE condition flags to N=0, Z=0, C=1, and V=1.
FCSEL

Floating-point Conditional Select (scalar). This instruction allows the SIMD&FP destination register to take the value from either one or the other of two SIMD&FP source registers. If the condition passes, the first SIMD&FP source register value is taken, otherwise the second SIMD&FP source register value is taken.

Depending on the settings in the \texttt{CPACR\_EL1}, \texttt{CPTR\_EL2}, and \texttt{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- \texttt{<Sm>} Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
- \texttt{<cond>} Is one of the standard conditions, encoded in the "cond" field in the standard way.
Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
result = if ConditionHolds(cond) then V[n] else V[m];
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
FCVT

Floating-point Convert precision (scalar). This instruction converts the floating-point value in the SIMD&FP source register to the precision for the destination register data type using the rounding mode that is determined by the \texttt{FPCR} and writes the result to the SIMD&FP destination register.

Depending on the settings in the \texttt{CPACR\_EL1}, \texttt{CPTR\_EL2}, and \texttt{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FCVTAS (vector)

Floating-point Convert to Signed integer, rounding to nearest with ties to Away (vector). This instruction converts each element in a vector from a floating-point value to a signed integer value using the Round to Nearest with Ties to Away rounding mode and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see *Floating-point exception traps*.

Depending on the settings in the **CPACR_EL1, CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: **Scalar half precision**, **Scalar single-precision and double-precision**, **Vector half precision** and **Vector single-precision and double-precision**

**Scalar half precision**

FCVTL, FCVTL2

Floating-point Convert to higher precision Long (vector). This instruction reads each element in a vector in the SIMD&FP source register, converts each value to double the precision of the source element using the rounding mode that is determined by the FPCR, and writes each result to the equivalent element of the vector in the SIMD&FP destination register.

Where the operation lengthens a 64-bit vector to a 128-bit vector, the FCVTL2 variant operates on the elements in the top 64 bits of the source register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

|(sz:Q) <Tb> |
|----------|---------------|
| 0 0      | 4H             |
| 0 1      | 8H             |
| 1 0      | 2S             |
| 1 1      | 4S             |

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in “sz”:

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in “sz:Q”:

Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(2*datasize) result;

for e = 0 to elements-1
    Elem[result, e, 2*esize] = FPConvert(Elem[operand, e, esize], FPCR[]);
V[d] = result;
```

Internal version only: isa v32.12, AdvSIMD v29.04, pseudocode v2020-09_xml, sve v2020-09_rc2b ; Build timestamp: 2020-09-30T20:20
FCVTMS (vector)

Floating-point Convert to Signed integer, rounding toward Minus infinity (vector). This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round towards Minus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

Scalar half precision
(Armv8.2)

```
FCVTMS <Hd>, <Hn>
if !HaveFP16Ext() then UNDEFINED;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer esize = 16;
integer datasize = esize;
integer elements = 1;
FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Scalar single-precision and double-precision

```
FCVTMS <V>d>, <V>n>
integer d = UInt(Rd);
integer n = UInt(Rn);
integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;
FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Vector half precision
(Armv8.2)

```
FCVTMS (vector)
Page 737
```
FCVTMS <Vd>.<T>, <Vn>.<T>

if !HaveFP16Ext() then UNDEFINED;

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');

Vector single-precision and double-precision

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Dn> Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.
Operation

CheckFPAdvSIMDEnabled64();

FPCRTypelfpcr = FPCR[];
bits(fltsize) fltval;
bits(intsize) intval;

fltval = V[n];
intval = FPToFixed(fltval, 0, TRUE, fpcr, rounding);
X[d] = intval;
FCVTN, FCVTN2

Floating-point Convert to lower precision Narrow (vector). This instruction reads each vector element in the SIMD&FP source register, converts each result to half the precision of the source element, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The rounding mode is determined by the FPCR.

The FCVTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the FCVTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

FCVTNS (scalar)

Floating-point Convert to Signed integer, rounding to nearest with ties to even (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round to Nearest rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FCVTXN, FCVTXN2

Floating-point Convert to lower precision Narrow, rounding to odd (vector). This instruction reads each vector element in the source SIMD&FP register, narrows each value to half the precision of the source element using the Round to Odd rounding mode, writes the result to a vector, and writes the vector to the destination SIMD&FP register.

This instruction uses the Round to Odd rounding mode which is not defined by the IEEE 754-2008 standard. This rounding mode ensures that if the result of the conversion is inexact the least significant bit of the mantissa is forced to 1. This rounding mode enables a floating-point value to be converted to a lower precision format via an intermediate precision format while avoiding double rounding errors. For example, a 64-bit floating-point value can be converted to a correctly rounded 16-bit floating-point value by first using this instruction to produce a 32-bit value and then using another instruction with the wanted rounding mode to convert the 32-bit value to the final 16-bit floating-point value.

The FCVTXN instruction writes the vector to the lower half of the destination register and clears the upper half, while the FCVTXN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Operation

CheckFPAdvanceSIMDEnabled64();
bits(datosize) operand = V[n];
bits(esize) element;
FPCRType fpcr = FPCR[];
boolean merge = elements == 1 && IsMerging(fpcr);
bits(128) result = if merge then V[d] else Zeros();
for e = 0 to elements-1
   element = Elem[operand, e, esize];
   Elem[result, e, esize] = FPToFixed(element, fracbits, unsigned, fpcr, rounding);
V[d] = result;
FCVTZS (vector, integer)

Floating-point Convert to Signed integer, rounding toward Zero (vector). This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision, Scalar single-precision and double-precision, Vector half precision and Vector single-precision and double-precision

   element = Elem[operand, e, esize];
   Elem[result, e, esize] = FPToFixed(element, 0, unsigned, fpcr, rounding);
V[d] = result;
FCVTZU (scalar, fixed-point)

Floating-point Convert to Unsigned fixed-point, rounding toward Zero (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit fixed-point unsigned integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

FDIV (vector)

Floating-point Divide (vector). This instruction divides the floating-point values in the elements in the first source SIMD&FP register, by the floating-point values in the corresponding elements in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

**Half-precision**

- `<Sm>` Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
Operation

CheckFPAdvSIMDEnabled64();

bits(esize) operand1 = V[n];
bits(esize) operand2 = V[m];

FPCRType fpcr = FPCR[];
boolean merge = IsMerging(fpcr);
bits(128) result = if merge then V[n] else Zeros();

Elem[result, 0, esize] = FPDiv(operand1, operand2, FPCR[]);

V[d] = result;
Floating-point Javascript Convert to Signed fixed-point, rounding toward Zero. This instruction converts the double-precision floating-point value in the SIMD&FP source register to a 32-bit signed integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register. If the result is too large to be represented as a signed 32-bit integer, then the result is the integer modulo $2^{32}$, as held in a 32-bit signed integer. This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### FMADD

Floating-point fused Multiply-Add (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, adds the product to the value of the third SIMD&FP source register, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FMAXNM (vector)

Floating-point Maximum Number (vector). This instruction compares corresponding vector elements in the two source SIMD&FP registers, writes the larger of the two floating-point values into a vector, and writes the vector to the destination SIMD&FP register.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result placed in the vector is the numerical value, otherwise the result is identical to FMAX (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

FMAXNMP (vector)

Floating-point Maximum Number Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result is the numerical value, otherwise the result is identical to FMAX (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

**FMIN (scalar)**

Floating-point Minimum (scalar). This instruction compares the first and second source SIMD&FP register values, and writes the smaller of the two floating-point values to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FMINNMP (vector)

Floating-point Minimum Number Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of floating-point values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result is the numerical value, otherwise the result is identical to FMIN (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

FLOATING MINIMUM NUMBER ACROSS VECTOR (FMINNMV)

This instruction compares all the vector elements in the source SIMD&FP register and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are floating-point values.

NaNs are handled according to the IEEE 754-2008 standard. If one vector element is numeric and the other is a quiet NaN, the result of the comparison is the numerical value, otherwise the result is identical to FMIN (scalar).

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision.

**Half-precision**

(ARMv8.2)

```plaintext
0 | Q | 0 | 0 | 1 | 1 | 1 | 0 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0 |
```

**Single-precision and double-precision**

```plaintext
0 | Q | 1 | 0 | 1 | 1 | 1 | 0 | 1 | sz | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0 |
```

FMINP (vector)

Floating-point Minimum Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, writes the smaller of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values. This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FMLA (vector)

Floating-point fused Multiply-Add to accumulator (vector). This instruction multiplies corresponding floating-point values in the vectors in the two source SIMD&FP registers, adds the product to the corresponding vector element of the destination SIMD&FP register, and writes the result to the destination SIMD&FP register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision

(Armv8.2)

```

FMLA <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

if !HaveFP16Ext() then UNDEFINED;

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 16;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean sub_op = (a == '1');
```

Single-precision and double-precision

```

FMLA <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz:Q == '10' then UNDEFINED;
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean sub_op = (op == '1');
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

FMLAL, FMLAL2 (by element)

Floating-point fused Multiply-Add Long to accumulator (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

ID_AA64ISAR0_EL1.FHM indicates whether this instruction is supported.

It has encodings from 2 classes: FMLAL and FMLAL2

V[d] = result;
```
FMLS (by element)

Floating-point fused Multiply-Subtract from accumulator (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and subtracts the results from the vector elements of the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar, half-precision, Scalar, single-precision and double-precision, Vector, half-precision and Vector, single-precision and double-precision.

Scalar, half-precision

FMLS (vector)

Floating-point fused Multiply-Subtract from accumulator (vector). This instruction multiplies corresponding floating-point values in the vectors in the two source SIMD&FP registers, negates the product, adds the result to the corresponding vector element of the destination SIMD&FP register, and writes the result to the destination SIMD&FP register.

A floating-point exception can be generated by this instruction. Depending on the settings in $FPCR$, the exception results in either a flag being set in $FPSR$, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the $CPACR_EL1$, $CPTR_EL2$, and $CPTR_EL3$ registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

**Half-precision (Armv8.2)**

FMLSL, FMLSL2 (by element)

Floating-point fused Multiply-Subtract Long from accumulator (by element). This instruction multiplies the negated vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped. In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

ID AA64ISAR0_EL1. FHM indicates whether this instruction is supported.

It has encodings from 2 classes: FMLSL and FMLSL2

FMOV (vector, immediate)

Floating-point move immediate (vector). This instruction copies an immediate floating-point constant into every element of the SIMD&FP destination register.
Depending on the settings in the \textit{CPACR\_EL1}, \textit{CPTR\_EL2}, and \textit{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: \textit{Half-precision} and \textit{Single-precision and double-precision}

\textbf{Half-precision}
\textit{(Armv8.2)}

\begin{verbatim}
                                  0 |  Q |  0  |  1  |  1  |  1  |  1  |  0  |  0  |  0  |  0  |  0  | Rd

FMOV <Vd>.<T>, #<imm>
if !HaveFP16Ext() then UNDEFINED;
integer rd = UInt(Rd);
integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
imm8 = a:b:c:d:e:f:g:h;
imm16 = imm8<7>:NOT(imm8<6>):Replicate(imm8<6>, 2):imm8<5:0>:Zeros(6);
imm = Replicate(imm16, datasize DIV 16);
\end{verbatim}

\textbf{Single-precision and double-precision}

\begin{verbatim}
                                  0 |  Q | op |  0  |  1  |  1  |  1  |  0  |  0  |  0  |  0  | Rd

Single-precision (op == 0)
FMOV <Vd>.<T>, #<imm>
Double-precision (Q == 1 && op == 1)
FMOV <Vd>.2D, #<imm>
\end{verbatim}

Assembler Symbols

\begin{verbatim}
<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<T> For the half-precision variant: is an arrangement specifier, encoded in "Q";
\end{verbatim}
For the single-precision variant: is an arrangement specifier, encoded in “Q”:

<table>
<thead>
<tr>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4H</td>
</tr>
<tr>
<td>1</td>
<td>8H</td>
</tr>
</tbody>
</table>

<imm> Is a signed floating-point constant with 3-bit exponent and normalized 4 bits of precision, encoded in “a:b:c:d:e:f:g:h”. For details of the range of constants available and the encoding of <imm>, see Modified immediate constants in A64 floating-point instructions.

Operation

```c
CheckFPAdvSIMDEnabled64();

V[rd] = imm;
```

FMOV (scalar, immediate)

Floating-point move immediate (scalar). This instruction copies a floating-point immediate constant into the SIMD&FP destination register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FMSUB

Floating-point Fused Multiply-Subtract (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, negates the product, adds that to the value of the third SIMD&FP source register, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FMUL (by element)

Floating-point Multiply (by element). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in \textit{FPSCR}, the exception results in either a flag being set in \textit{FPSR} or a synchronous exception being generated. For more information, see \textit{Floating-point exception traps}.

Depending on the settings in the \textit{CPACR_EL1}, \textit{CPTR_EL2}, and \textit{CPTR_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: \textit{Scalar, half-precision}, \textit{Scalar, single-precision and double-precision}, \textit{Vector, half-precision} and \textit{Vector, single-precision and double-precision}

FMULX (by element)

Floating-point Multiply extended (by element). This instruction multiplies the floating-point values in the vector elements in the first source SIMD&FP register by the specified floating-point value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If one value is zero and the other value is infinite, the result is 2.0. In this case, the result is negative if only one of the values is negative, otherwise the result is positive.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar, half-precision, Scalar, single-precision and double-precision, Vector, half-precision and Vector, single-precision and double-precision

Floating-point Negated fused Multiply-Subtract (scalar). This instruction multiplies the values of the first two SIMD&FP source registers, subtracts the value of the third SIMD&FP source register, and writes the result to the destination SIMD&FP register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

\( V[d] = result; \)
FRINT32X (vector)

Floating-point Round to 32-bit Integer, using current rounding mode (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values that fit into a 32-bit integer size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register. A zero input returns a zero result with the same sign. When one of the result values is not numerically equal to the corresponding input value, an Inexact exception is raised. When an input is infinite, NaN or out-of-range, the instruction returns for the corresponding result value the most negative integer representable in the destination size, and an Invalid Operation floating-point exception is raised.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**FRINT32Z (vector)**

Floating-point Round to 32-bit Integer toward Zero (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values that fit into a 32-bit integer size using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A zero input returns a zero result with the same sign. When one of the result values is not numerically equal to the corresponding input value, an Inexact exception is raised. When an input is infinite, NaN or out-of-range, the instruction returns for the corresponding result value the most negative integer representable in the destination size, and an Invalid Operation floating-point exception is raised.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FRINT32Z (scalar)

Floating-point Round to 32-bit Integer toward Zero (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value that fits into a 32-bit integer size using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A zero input returns a zero result with the same sign. When the result value is not numerically equal to the {corresponding} input value, an Inexact exception is raised. When the input is infinite, NaN or out-of-range, the instruction returns {for the corresponding result value} the most negative integer representable in the destination size, and an Invalid Operation floating-point exception is raised.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FRINTA (vector)

Floating-point Round to Integral, to nearest with ties to Away (vector). This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the Round to Nearest with Ties to Away rounding mode, and writes the result to the SIMD&FP destination register. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

\end{array}
\]

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
  element = Elem[operand, e, esize];
  Elem[result, e, esize] = FPRoundInt(element, FPCR[], rounding, exact);

V[d] = result;
FRINTA (scalar)

Floating-point Round to Integral, to nearest with ties to Away (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the Round to Nearest with Ties to Away rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in 

FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FRINTZ (scalar)

Floating-point Round to Integral, toward Zero (scalar). This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FRRSQTS

Floating-point Reciprocal Square Root Step. This instruction multiplies corresponding floating-point values in the vectors of the two source SIMD&FP registers, subtracts each of the products from 3.0, divides these results by 2.0, places the results into a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

endcase
```

**Assembler Symbols**

- **<Dd>** Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<Dn>** Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.
- **<Hd>** Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<Hn>** Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
- **<Sd>** Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<Sn>** Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.
Operation

CheckFPAdvSIMDEnabled64();

FPCRTYPE fpcr = FPCR[];
boolean merge = IsMerging(fpcr);
bits(128) result = if merge then V[d] else Zeros();

bits(ewise) operand = V[n];

Elem[result, 0, esize] = FPSqrt(operand, fpcr);

V[d] = result;
FSUB (vector)

Floating-point Subtract (vector). This instruction subtracts the elements in the vector in the second source SIMD&FP register, from the corresponding elements in the vector in the first source SIMD&FP register, places each result into elements of a vector, and writes the vector to the destination SIMD&FP register. This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
Operation

CheckFPAdvSIMDEnabled64();
bits(esize) operand1 = V[n];
bits(esize) operand2 = V[m];

FPCRType fpcr = FPCR[];
boolean merge = IsMerging(fpcr);
bits(128) result = if merge then V[n] else Zeros();

Elem(result, 0, esize) = FPSub(operand1, operand2, fpcr);
V[d] = result;
INS (element)

Insert vector element from another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias `MOV (element)`.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 1 1 0 1 1 0 0 0 0 | imm5 | 0 | imm4 | 1 | Rd | Rn
```

`INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]`

- `integer d = UInt(Rd);`
- `integer n = UInt(Rn);`
- `integer size = LowestSetBit(imm5);`
- `if size > 3 then UNDEFINED;`
- `integer dst_index = UInt(imm5<4:size+1>);`
- `integer src_index = UInt(imm4<3:size>);`
- `integer idxdxsize = if imm4<3> == '1' then 128 else 64;`
- `// imm4<size-1:0> is IGNORED`
- `integer esize = 8 << size;`

Assembler Symbols

- **<Vd>** Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<Ts>** Is an element size specifier, encoded in “imm5”:
  
<table>
<thead>
<tr>
<th>imm5</th>
<th>&lt;Ts&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>RESERVED</td>
</tr>
<tr>

<tr>
<td>xxx10</td>
<td>H</td>
</tr>
<tr>
<td>xx100</td>
<td>S</td>
</tr>
<tr>
<td>x1000</td>
<td>D</td>
</tr>
</tbody>
</table>

- **<index1>** Is the destination element index encoded in “imm5”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>&lt;index1&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>imm5&lt;4:1&gt;</td>
</tr>
<tr>
<td>xxx10</td>
<td>imm5&lt;4:2&gt;</td>
</tr>
<tr>
<td>xx100</td>
<td>imm5&lt;4:3&gt;</td>
</tr>
<tr>
<td>x1000</td>
<td>imm5&lt;4&gt;</td>
</tr>
</tbody>
</table>

- **<Vn>** Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- **<index2>** Is the source element index encoded in “imm5:imm4”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>&lt;index2&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x0000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>imm4&lt;3:0&gt;</td>
</tr>
<tr>
<td>xxx10</td>
<td>imm4&lt;3:1&gt;</td>
</tr>
<tr>
<td>xx100</td>
<td>imm4&lt;3:2&gt;</td>
</tr>
<tr>
<td>x1000</td>
<td>imm4&lt;3&gt;</td>
</tr>
</tbody>
</table>

Unspecified bits in “imm4” are ignored but should be set to zero by an assembler.
Operation

\[
\text{CheckFPAdvSIMDEnabled64}();
\]
\[
\text{bits(idxdsize) operand} = \text{V}[n];
\]
\[
\text{bits(128) result};

\[
\text{result} = \text{V}[d];
\]
\[
\text{Elem}[\text{result, dst\_index, esize}] = \text{Elem}[\text{operand, src\_index, esize}];
\]
\[
\text{V}[d] = \text{result};
\]

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
INS (general)

Insert vector element from general-purpose register. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the \texttt{CPACR\_EL1}, \texttt{CPTR\_EL2}, and \texttt{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias \texttt{MOV (from general)}.

integer \( \text{size} = \texttt{LowestSetBit}(\text{imm5}); \)

if \( \text{size} > 3 \) then UNDEFINED;
integer \( \text{index} = \texttt{UInt}(\text{imm5}<4:\text{size}+1>); \)

integer \( \text{esize} = 8 \ll \text{size}; \)

\textbf{Assembler Symbols}

\texttt{<Vd>} \quad Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

\texttt{<Ts>} \quad Is an element size specifier, encoded in “imm5”:

\begin{center}
\begin{tabular}{c|c}
\hline
\texttt{imm5} & \texttt{<Ts>} \\
\hline
x0000 & RESERVED \\
xxx1 & B \\
xxx10 & H \\
x100 & S \\
x1000 & D \\
\hline
\end{tabular}
\end{center}

\texttt{<index>} \quad Is the element index encoded in “imm5”:

\begin{center}
\begin{tabular}{c|c}
\hline
\texttt{imm5} & \texttt{<index>} \\
\hline
x0000 & RESERVED \\
xxx1 & \texttt{imm5}<4:1> \\
xxx10 & \texttt{imm5}<4:2> \\
x100 & \texttt{imm5}<4:3> \\
x1000 & \texttt{imm5}<4> \\
\hline
\end{tabular}
\end{center}

\texttt{<R>} \quad Is the width specifier for the general-purpose source register, encoded in “imm5”:

\begin{center}
\begin{tabular}{c|c}
\hline
\texttt{imm5} & \texttt{<R>} \\
\hline
x0000 & RESERVED \\
xxx1 & W \\
xxx10 & W \\
x100 & W \\
x1000 & X \\
\hline
\end{tabular}
\end{center}

\texttt{<n>} \quad Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.
Operation

\(\text{CheckFPAdvSIMDEnabled64}()\);
bits(esize) element = \(X[n]\);
bits(128) result;

result = \(V[d]\);
\(\text{Elem}[\text{result, index, esize}] = \text{element}\);
\(V[d] = \text{result}\);

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
LD1 (multiple structures)

Load multiple single-element structures to one, two, three, or four registers. This instruction loads multiple single-element structures from memory and writes the result to one, two, three, or four SIMD&FP registers.

Depending on the settings in the \texttt{CPACR\_EL1}, \texttt{CPTR\_EL2}, and \texttt{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: \texttt{No offset} and \texttt{Post-index}

**No offset**

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LD1 (single structure)

Load one single-element structure to one lane of one register. This instruction loads a single-element structure from memory and writes the result to the specified lane of the SIMD&FP register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

boolean tag_checked = wback || n != 31;

**Assembler Symbols**

- `<Vt>` Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<T>` Is an arrangement specifier, encoded in “size:Q”:

```
  size | Q | <T>
  00   0 | 8B
  00   1 | 16B
  01   0 | 4H
  01   1 | 8H
  10   0 | 2S
  10   1 | 4S
  11   0 | 1D
  11   1 | 2D
```

- `<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<imm>` Is the post-index immediate offset, encoded in “size”:
size | <imm>
--- | ---
00 | #1
01 | #2
10 | #4
11 | #8

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LD2R

Load single 2-element structure and Replicate to all lanes of two registers. This instruction loads a 2-element structure from memory and replicates the structure to all the lanes of the two SIMD&FP registers. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

### No offset

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LD3 (multiple structures)

Load multiple 3-element structures to three registers. This instruction loads multiple 3-element structures from memory and writes the result to the three SIMD&FP registers, with de-interleaving.

The following figure shows an example of the operation of de-interleaving of a LD3.16 (multiple 3-element structures) instruction:

A is a packed array of 3-element structures. Each element is a 16-bit halfword.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

Assembler Symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.
<Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.
<index> For the 8-bit variant: is the element index, encoded in "Q:S:size".
For the 16-bit variant: is the element index, encoded in "Q:S:size<1>".
For the 32-bit variant: is the element index, encoded in "Q:S".
For the 64-bit variant: is the element index, encoded in "Q".
<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LD3R

Load single 3-element structure and Replicate to all lanes of three registers. This instruction loads a 3-element structure from memory and replicates the structure to all the lanes of the three SIMD&FP registers. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index.

### No offset

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LD4 (multiple structures)**

Load multiple 4-element structures to four registers. This instruction loads multiple 4-element structures from memory and writes the result to the four SIMD&FP registers, with de-interleaving.

For an example of de-interleaving, see LD3 (multiple structures).

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

**No offset**

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LD4R

Load single 4-element structure and Replicate to all lanes of four registers. This instruction loads a 4-element structure from memory and replicates the structure to all the lanes of the four SIMD&FP registers. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

|   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

| L | R  | opcode | S    |

Immediate offset (Rm == 11111)

LD4R { <Vt>,<T>, <Vt2>,<T>, <Vt3>,<T>, <Vt4>,<T> }, [<Xn|SP>], <imm>

Register offset (Rm != 11111)

LD4R { <Vt>,<T>, <Vt2>,<T>, <Vt3>,<T>, <Vt4>,<T> }, [<Xn|SP>], <Xm>

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
boolean tag_checked = wback || n != 31;

Assembler Symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
<T> Is an arrangement specifier, encoded in "size:Q":

<table>
<thead>
<tr>
<th>size</th>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>00</td>
<td>1</td>
<td>16B</td>
</tr>
<tr>
<td>01</td>
<td>0</td>
<td>4H</td>
</tr>
<tr>
<td>01</td>
<td>1</td>
<td>8H</td>
</tr>
<tr>
<td>10</td>
<td>0</td>
<td>2S</td>
</tr>
<tr>
<td>10</td>
<td>1</td>
<td>4S</td>
</tr>
<tr>
<td>11</td>
<td>0</td>
<td>1D</td>
</tr>
<tr>
<td>11</td>
<td>1</td>
<td>2D</td>
</tr>
</tbody>
</table>

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.
<Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.
<Vt4> Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.
Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Is the post-index immediate offset, encoded in “size”:

<table>
<thead>
<tr>
<th>size</th>
<th>&lt;imm&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>#4</td>
</tr>
<tr>
<td>01</td>
<td>#8</td>
</tr>
<tr>
<td>10</td>
<td>#16</td>
</tr>
<tr>
<td>11</td>
<td>#32</td>
</tr>
</tbody>
</table>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
**LDNP (SIMD&FP)**

Load Pair of SIMD&FP registers, with Non-temporal hint. This instruction loads a pair of SIMD&FP registers from memory, issuing a hint to the memory system that the access is non-temporal. The address that is used for the load is calculated from a base register value and an optional immediate offset.

For information about non-temporal pair instructions, see *Load/Store SIMD and Floating-point Non-temporal pair*. Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Depending on the configuration, the instruction may have different behaviors.

### 32-bit (opc == 00)

```
LDNP <St1>, <St2>, [<Xn|SP>{, #<imm>}]
```

### 64-bit (opc == 01)

```
LDNP <Dt1>, <Dt2>, [<Xn|SP>{, #<imm>}]
```

### 128-bit (opc == 10)

```
LDNP <Qt1>, <Qt2>, [<Xn|SP>{, #<imm>}]
```

// Empty.

For information about the CONstrained UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDNP (SIMD&FP)*.

**Assembler Symbols**

- `<Dt1>` is the 64-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<Dt2>` is the 64-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.
- `<Qt1>` is the 128-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<Qt2>` is the 128-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.
- `<St1>` is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.
- `<St2>` is the 32-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.
- `<Xn|SP>` is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- `<imm>` is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as `<imm>/4`.

For the 64-bit variant:

- For the 32-bit variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as `<imm>/8`.

For the 128-bit variant: is the optional signed immediate byte offset, a multiple of 16 in the range -1024 to 1008, defaulting to 0 and encoded in the "imm7" field as `<imm>/16`.

Assembler Symbols

<Bt> Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<Dt> Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<It> Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<Qt> Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<St> Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.

<pimm> For the 8-bit variant: is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For the 16-bit variant: is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

For the 32-bit variant: is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4.

For the 64-bit variant: is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

For the 128-bit variant: is the optional positive immediate byte offset, a multiple of 16 in the range 0 to 65520, defaulting to 0 and encoded in the "imm12" field as <pimm>/16.

Shared Decode

```plaintext
integer n = UInt(Rn);
integer t = UInt(Rt);
MemOp memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = 8 << scale;
boolean tag_checked = memop != MemOp_PREFETCH && (wback || n != 31);
```
Operation

if HaveMTEExt() then
    SetTagCheckedInstruction(tag_checked);

CheckFPAdvSIMDEnabled64();

bits(64) address;
bits(datasize) data;

if n == 31 then
    CheckSPAlignment();

    else
        X[n] = address;

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.
LDR (literal, SIMD&FP)

Load SIMD&FP Register (PC-relative literal). This instruction loads a SIMD&FP register from memory. The address that is used for the load is calculated from the PC value and an immediate offset.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

integer elements = datasize DIV esize;

boolean sub_op = (o2 == '1');
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in "size:Q":

```
size   Q   <T>
00     x   RESERVED
01     0   4H
01     1   8H
10     0   2S
10     1   4S
11     x   RESERVED
```

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in "size:M:Rm":

```
size   <Vm>
00     RESERVED
01     0:Rm
10     M:Rm
11     RESERVED
```

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in "size":

```
size   <Ts>
00     RESERVED
01     H
10     S
11     RESERVED
```

<index> Is the element index, encoded in "size:L:H:M":

```
### Operation

CheckFPAdvSIMDEnabled64();

```c
bits(datasize) operand1 = V[n];
bits(idxdsize) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) product;

element2 = UInt(Elem[operand2, index, esize]);
for e = 0 to elements-1
    element1 = UInt(Elem[operand1, e, esize]);
    product = (element1*element2)<esize-1:0>;
    if sub_op then
        Elem[result, e, esize] = Elem[operand3, e, esize] - product;
    else
        Elem[result, e, esize] = Elem[operand3, e, esize] + product;
V[d] = result;
```

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Multiply-Subtract from accumulator (vector). This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, and subtracts the results from the vector elements of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    else
        Elem[result, e, esize] = Elem[operand3, e, esize] + product;
V[d] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (scalar)

Move vector element to scalar. This instruction duplicates the specified vector element in the SIMD&FP source register into a scalar, and writes the result to the SIMD&FP destination register.

Depending on the settings in the \textit{CPACR\_EL1}, \textit{CPTR\_EL2}, and \textit{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of \textit{DUP (element)}. This means:

- The encodings in this description are named to match the encodings of \textit{DUP (element)}.
- The description of \textit{DUP (element)} gives the operational pseudocode for this instruction.

\begin{verbatim}
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
0 1 0 1 1 1 1 0 0 0 0 | imm5 | 0 0 0 0 0 1 | Rn | Rd
\end{verbatim}

\texttt{MOV <V><d>, <Vn>.<T>[<index>]}

is equivalent to

\texttt{DUP <V><d>, <Vn>.<T>[<index>]}

and is always the preferred disassembly.

\textbf{Assembler Symbols}

- \texttt{<V>} Is the destination width specifier, encoded in “imm5”:
  \begin{verbatim}
  imm5  <V>
  \end{verbatim}
  \begin{itemize}
  \item x0000: RESERVED
  \item xxx1: B
  \item xxx10: H
  \item xx100: S
  \item x1000: D
  \end{itemize}

- \texttt{<d>} Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

- \texttt{<Vn>} Is the name of the SIMD&FP source register, encoded in the "Rn" field.

- \texttt{<T>} Is the element width specifier, encoded in “imm5”:
  \begin{verbatim}
  imm5  <T>
  \end{verbatim}
  \begin{itemize}
  \item x0000: RESERVED
  \item xxx1: B
  \item xxx10: H
  \item xx100: S
  \item x1000: D
  \end{itemize}

- \texttt{<index>} Is the element index encoded in “imm5”:
  \begin{verbatim}
  imm5  <index>
  \end{verbatim}
  \begin{itemize}
  \item x0000: RESERVED
  \item xxx1: imm5<4:1>
  \item xxx10: imm5<4:2>
  \item xx100: imm5<4:3>
  \item x1000: imm5<4>
  \end{itemize}

\textbf{Operation}

The description of \textit{DUP (element)} gives the operational pseudocode for this instruction.

\textbf{Operational information}

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  \begin{itemize}
  \item The values of the data supplied in any of its registers.
  \item The values of the NZCV flags.
  \end{itemize}
- The response of this instruction to asynchronous exceptions does not vary based on:
- The values of the data supplied in any of its registers.
- The values of the NZCV flags.
MOV (element)

Move vector element to another vector element. This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register. This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of `INS (element)`. This means:

- The encodings in this description are named to match the encodings of `INS (element)`.
- The description of `INS (element)` gives the operational pseudocode for this instruction.

```
|0|1|1|0|1|1|0|0|0|imm5|0|imm4|1|Rn|Rd|
```

MOV `<Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]`

is equivalent to

`INS `<Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]`

and is always the preferred disassembly.

Assembler Symbols

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Ts>` Is an element size specifier, encoded in "imm5":
  - `imm5 <Ts>`
    - x0000: RESERVED
    - xxx1: B
    - xxx10: H
    - xx100: S
    - x1000: D
- `<index1>` Is the destination element index encoded in “imm5”:  
  - `imm5 <index1>`
    - x0000: RESERVED
    - xxx1: imm5<4:1>
    - xxx10: imm5<4:2>
    - xx100: imm5<4:3>
    - x1000: imm5<4>
- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- `<index2>` Is the source element index encoded in “imm5:imm4”:
  - `imm5 <index2>`
    - x0000: RESERVED
    - xxx1: imm4<3:0>
    - xxx10: imm4<3:1>
    - xx100: imm4<3:2>
    - x1000: imm4<3>

Unspecified bits in "imm4" are ignored but should be set to zero by an assembler.

Operation

The description of `INS (element)` gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
MOV (from general)

Move general-purpose register to a vector element. This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.
This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.
Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of `INS (general)`. This means:

- The encodings in this description are named to match the encodings of `INS (general)`.
- The description of `INS (general)` gives the operational pseudocode for this instruction.

```plaintext
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0  | 1  | 0  | 0  | 1  | 1  | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

MOV <Vd>.<Ts>[<index>], <R><n>

is equivalent to

`INS <Vd>.<Ts>[<index>], <R><n>`

and is always the preferred disassembly.

**Assembler Symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<Ts>` Is an element size specifier, encoded in “imm5”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>&lt;Ts&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>B</td>
</tr>
<tr>
<td>xxx10</td>
<td>H</td>
</tr>
<tr>
<td>xx100</td>
<td>S</td>
</tr>
<tr>
<td>x1000</td>
<td>D</td>
</tr>
</tbody>
</table>

- `<index>` Is the element index encoded in “imm5”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>&lt;index&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>imm5&lt;4:1&gt;</td>
</tr>
<tr>
<td>xxx10</td>
<td>imm5&lt;4:2&gt;</td>
</tr>
<tr>
<td>xx100</td>
<td>imm5&lt;4:3&gt;</td>
</tr>
<tr>
<td>x1000</td>
<td>imm5&lt;4&gt;</td>
</tr>
</tbody>
</table>

- `<R>` Is the width specifier for the general-purpose source register, encoded in “imm5”:

<table>
<thead>
<tr>
<th>imm5</th>
<th>&lt;R&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>x000</td>
<td>RESERVED</td>
</tr>
<tr>
<td>xxxx1</td>
<td>W</td>
</tr>
<tr>
<td>xxx10</td>
<td>W</td>
</tr>
<tr>
<td>xx100</td>
<td>W</td>
</tr>
<tr>
<td>x1000</td>
<td>X</td>
</tr>
</tbody>
</table>

- `<n>` Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

**Operation**

The description of `INS (general)` gives the operational pseudocode for this instruction.

**Operational information**

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
MOV (vector)

Move vector. This instruction copies the vector in the source SIMD&FP register into the destination SIMD&FP register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of ORR (vector, register). This means:

- The encodings in this description are named to match the encodings of ORR (vector, register).
- The description of ORR (vector, register) gives the operational pseudocode for this instruction.

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

MOV <Vd>.<T>, <Vn>.<T>

is equivalent to

ORR <Vd>.<T>, <Vn>.<T>, <Vn>.<T>

and is the preferred disassembly when Rm == Rn.

Assembler Symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in “Q”:

<table>
<thead>
<tr>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>1</td>
<td>16B</td>
</tr>
</tbody>
</table>

- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

Operation

The description of ORR (vector, register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOV (to general)

Move vector element to general-purpose register. This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of UMOV. This means:

- The encodings in this description are named to match the encodings of UMOV.
- The description of UMOV gives the operational pseudocode for this instruction.

32-bit (Q == 0 && imm5 == xx100)

MOV <Wd>, <Vn>.S[<index>]

is equivalent to

UMOV <Wd>, <Vn>.S[<index>]

and is always the preferred disassembly.

64-reg,UMOV-64-reg (Q == 1 && imm5 == x1000)

MOV <Xd>, <Vn>.D[<index>]

is equivalent to

UMOV <Xd>, <Vn>.D[<index>]

and is always the preferred disassembly.

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<index> For the 32-bit variant: is the element index encoded in "imm5<4:3>".

For the 64-reg,UMOV-64-reg variant: is the element index encoded in "imm5<4>".

Operation

The description of UMOV gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MOVI

Move Immediate (vector). This instruction places an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

cccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccccc
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MUL (by element)

Multiply (vector, by element). This instruction multiplies the vector elements in the first source SIMD&FP register by
the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the
destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and
Exception level, an attempt to execute the instruction might be trapped.

        product = (UInt(element1)*UInt(element2))<esize-1:0>;
    Elem[result, e, esize] = product;
V[d] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**MVN**

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register. Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of **NOT**. This means:

- The encodings in this description are named to match the encodings of **NOT**.
- The description of **NOT** gives the operational pseudocode for this instruction.

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |
| 0 | 0 | 1 | 1 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 1 | 0 | Rn | Rd |

**MVN** `<Vd>.<T>`, `<Vn>.<T>`

is equivalent to

**NOT** `<Vd>.<T>`, `<Vn>.<T>`

and is always the preferred disassembly.

**Assembler Symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- `<T>` Is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th><code>&lt;T&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8B</td>
</tr>
<tr>
<td>1</td>
<td>16B</td>
</tr>
</tbody>
</table>

- `<Vn>` Is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

The description of **NOT** gives the operational pseudocode for this instruction.

**Operational information**

If `PSTATE.DIT` is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
MVNI

Move inverted Immediate (vector). This instruction places the inverse of an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the $\text{CPACR\_EL1}$, $\text{CPTR\_EL2}$, and $\text{CPTR\_EL3}$ registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### 16-bit shifted immediate (cmode == 10x0)

$$\text{MVNI} \ <Vd>.<T>, \ #\langle\text{imm8}\rangle\{, \ \text{LSL} \ #\langle\text{amount}\rangle\}$$

### 32-bit shifted immediate (cmode == 0xx0)

$$\text{MVNI} \ <Vd>.<T>, \ #\langle\text{imm8}\rangle\{, \ \text{LSL} \ #\langle\text{amount}\rangle\}$$

### 32-bit shifting ones (cmode == 110x)

$$\text{MVNI} \ <Vd>.<T>, \ #\langle\text{imm8}\rangle, \ \text{MSL} \ #\langle\text{amount}\rangle$$

integer rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;  
bits(datasize) imm;  
bits(64) imm64;

```plaintext

imm = Replicate(imm64, datasize DIV 64);

### Assembler Symbols

- **<Vd>** Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- **<T>** For the 16-bit variant: is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4H</td>
</tr>
<tr>
<td>1</td>
<td>8H</td>
</tr>
</tbody>
</table>

For the 32-bit variant: is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th>&lt;T&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>45</td>
</tr>
</tbody>
</table>

- **<imm8>** Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".
- **<amount>** For the 16-bit shifted immediate variant: is the shift amount encoded in "cmode<1>":

`
defaulting to 0 if LSL is omitted.

For the 32-bit shifted immediate variant: is the shift amount encoded in “cmode<2:1>”:

<table>
<thead>
<tr>
<th>cmode&lt;2:1&gt;</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
</tr>
<tr>
<td>01</td>
<td>8</td>
</tr>
<tr>
<td>10</td>
<td>16</td>
</tr>
<tr>
<td>11</td>
<td>24</td>
</tr>
</tbody>
</table>

defaulting to 0 if LSL is omitted.

For the 32-bit shifting ones variant: is the shift amount encoded in “cmode<0>”:

<table>
<thead>
<tr>
<th>cmode&lt;0&gt;</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
</tr>
<tr>
<td>1</td>
<td>16</td>
</tr>
</tbody>
</table>

Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
  when ImmediateOp_MOVI
    result = imm;
  when ImmediateOp_MVNI
    result = NOT(imm);
  when ImmediateOp_ORR
    operand = V[rd];
    result = operand OR imm;
  when ImmediateOp_BIC
    operand = V[rd];
    result = operand AND NOT(imm);

V[rd] = result;
```

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
NEG (vector)

Negate (vector). This instruction reads each vector element from the source SIMD&FP register, negates each value, puts the result into a vector, and writes the vector to the destination SIMD&FP register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

<table>
<thead>
<tr>

<Vn> is the name of the SIMD&FP source register, encoded in the "Rn" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
for e = 0 to elements-1
  element = SInt(Elem[operand, e, esize]);
  if neg then
    element = -element;
  else
    element = Abs(element);
  Elem[result, e, esize] = element<esize-1:0>;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**NOT**

Bitwise NOT (vector). This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register. Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias `MVN`.

```
NOT <Vd>,<T>, <Vn>,<T>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
```

**Assembler Symbols**

- `<Vd>` Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

`imm` = `Replicate`(imm64, `datasize DIV 64`);

---

**Assembler Symbols**

- `<Vd>` Is the name of the SIMD&FP register, encoded in the "Rd" field.
- `<T>` For the 16-bit variant: is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th><code>&lt;T&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4H</td>
</tr>
<tr>
<td>1</td>
<td>8H</td>
</tr>
</tbody>
</table>

For the 32-bit variant: is an arrangement specifier, encoded in "Q":

<table>
<thead>
<tr>
<th>Q</th>
<th><code>&lt;T&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2S</td>
</tr>
<tr>
<td>1</td>
<td>4S</td>
</tr>
</tbody>
</table>

- `<imm8>` Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".
- `<amount>` For the 16-bit variant: is the shift amount encoded in "cmode<1>":

<table>
<thead>
<tr>
<th><code>cmode&lt;1&gt;</code></th>
<th><code>&lt;amount&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>8</td>
</tr>
</tbody>
</table>

defaulting to 0 if LSL is omitted.

For the 32-bit variant: is the shift amount encoded in "cmode<2:1>":
<table>
<thead>
<tr>
<th>cmode&lt;2:1&gt;</th>
<th>&lt;amount&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
</tr>
<tr>
<td>01</td>
<td>8</td>
</tr>
<tr>
<td>10</td>
<td>16</td>
</tr>
<tr>
<td>11</td>
<td>24</td>
</tr>
</tbody>
</table>

defaulting to 0 if LSL is omitted.

Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
  when ImmediateOp_MOVI
    result = imm;
  when ImmediateOp_MVNI
    result = NOT(imm);
  when ImmediateOp_ORR
    operand = V[rd];
    result = operand OR imm;
  when ImmediateOp_BIC
    operand = V[rd];
    result = operand AND NOT(imm);

V[rd] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
ORR (vector, register)

Bitwise inclusive OR (vector, register). This instruction performs a bitwise OR between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (vector).

</tr>
</tbody>
</table>

- **<Vn>** Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- **<Vm>** Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

### Operation

```assembly
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) product;
for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if poly then
        product = PolynomialMult(element1, element2)<esize-1:0>;
    else
        product = (UInt(element1)*UInt(element2))<esize-1:0>;
    Elem[result, e, esize] = product;
V[d] = result;
```

### Operational information

If PSTATE.DIT is 1:
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
**PMULL, PMULL2**

Polynomial Multiply Long. This instruction multiplies corresponding elements in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

For information about multiplying polynomials see *Polynomial arithmetic over \{0, 1\}*. 

The PMULL instruction extracts each source vector from the lower half of each source register, while the PMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the *CPACR_EL1, CPTR_EL2*, and *CPTR_EL3* registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

</tr>
</tbody>
</table>

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
  element1 = Elem[operand1, e, esize];
  element2 = Elem[operand2, e, esize];
  Elem[result, e, 2*esize] = PolynomialMult(element1, element2);
V[d] = result;

Operational information

If PSTATE.DIT is 1:
  • The execution time of this instruction is independent of:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
  • The response of this instruction to asynchronous exceptions does not vary based on:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
RADDHN, RADDHN2

Rounding Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see ADDHN.

The RADDHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

### Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in "Q":

<table>
<thead>
<tr>

    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
RAX1

Rotate and Exclusive OR rotates each 64-bit element of the 128-bit vector in a source SIMD&FP register left by 1, performs a bitwise exclusive OR of the resulting 128-bit vector and the vector in another source SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when FEAT_SHA3 is implemented.

Advanced SIMD
(Armv8.2)

• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
**REV32 (vector)**

Reverse elements in 32-bit words (vector). This instruction reverses the order of 8-bit or 16-bit elements in each word of the vector in the source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

Operational information

If PSTATE.DIT is 1:
  • The execution time of this instruction is independent of:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
  • The response of this instruction to asynchronous exceptions does not vary based on:
    ◦ The values of the data supplied in any of its registers.
    ◦ The values of the NZCV flags.
RSHRN, RSHRN2

Rounding Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the vector in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SHRN.

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<td>4S</td>
</tr>
<tr>
<td>01xx</td>
<td>2D</td>
</tr>
<tr>
<td>1xxx</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>
```

- <shift> Is the right shift amount, in the range 1 to the destination element width in bits, encoded in “immh:immb”: 0
### Operation

```c
CheckFPAdvSIMDEnabled64();

bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;

Vpart[d, part] = result;
```

### Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Rounding Subtract returning High Narrow. This instruction subtracts each vector element of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see SUBHN.

The RSUBHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSUBHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Example:

```
RSUBHN(2) <Vd>, <Tb>, <Ta>, <Vm>
```

```plaintext
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');
```

### Assembler Symbols

- **Q**
  - Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in "Q":
  ```plaintext
  \[
  \begin{array}{c|c}
  \text{Q} & 2 \\
  \hline
  0 & \text{[absent]} \\
  1 & \text{[present]} \\
  \end{array}
  \]
  
  - **<Vd>**
    - Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
  
  - **<Tb>**
    - Is an arrangement specifier, encoded in "size:Q":
      ```plaintext
      \[
      \begin{array}{c|c|c}
      \text{size} & \text{Q} & <Tb> \\
      \hline

**Operation**

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) absdiff;

result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<esize-1:0>;
    Elem[result, e, esize] = Elem[result, e, esize] + absdiff;
V[d] = result;
```
• The execution time of this instruction is independent of:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.

• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
SABAL, SABAL2

Signed Absolute difference and Accumulate Long. This instruction subtracts the vector elements in the lower or upper half of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, and accumulates the absolute values of the results into the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The SABAL instruction extracts each source vector from the lower half of each source register, while the SABAL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

  - The values of the NZCV flags.
Signed Absolute Difference. This instruction subtracts the elements of the vector of the second source SIMD&FP register from the corresponding elements of the first source SIMD&FP register, places the absolute values of the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Operational information

If PSTATE.DIT is 1:
The execution time of this instruction is independent of:
- The values of the data supplied in any of its registers.
- The values of the NZCV flags.

The response of this instruction to asynchronous exceptions does not vary based on:
- The values of the data supplied in any of its registers.
- The values of the NZCV flags.
SABDL, SABDL2

Signed Absolute Difference Long. This instruction subtracts the vector elements of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, places the absolute value of the results into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The SABDL instruction writes the vector to the lower half of the destination register and clears the upper half, while the SABDL2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SCVTF (vector, fixed-point)

Signed fixed-point Convert to Floating-point (vector). This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see Floating-point exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

```
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

V[d] = fltval;
SDOT (by element)

Dot Product signed arithmetic (vector, by element). This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an optional instruction. From Armv8.4 it is mandatory for all implementations to support it.

ID_AA64ISARO_EL1.DP indicates whether this instruction is supported.

Vector
(Armv8.2)

```

• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
SHA512H2

SHA512 Hash update part 2 takes the values from the three 128-bit source SIMD&FP registers and produces a 128-bit output value that combines the sigma0 and majority functions of two iterations of the SHA512 computation. It returns this value to the destination SIMD&FP register.

This instruction is implemented only when \textit{FEAT\_SHA512} is implemented.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Signed Halving Add. This instruction adds corresponding signed integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SRHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.
○ The values of the data supplied in any of its registers.
○ The values of the NZCV flags.
• The response of this instruction to asynchronous exceptions does not vary based on:
  ○ The values of the data supplied in any of its registers.
  ○ The values of the NZCV flags.
**SHL**

Shift Left (immediate). This instruction reads each value from a vector, left shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

### Scalar

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>1xxx</td>
<td>0</td>
<td>RESERVED</td>
</tr>
<tr>
<td>1xxx</td>
<td>1</td>
<td>2D</td>
</tr>
</tbody>
</table>

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in "immh:immb":

<table>
<thead>
<tr>
<th>immh</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xxx</td>
<td>RESERVED</td>
</tr>
<tr>
<td>1xxx</td>
<td>(UInt(immh:immb)-64)</td>
</tr>
</tbody>
</table>

For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in "immh:immb":

<table>
<thead>
<tr>
<th>immh</th>
<th>&lt;shift&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>SEE Advanced SIMD modified immediate</td>

<tr>
<td>01xx</td>
<td>(UInt(immh:immb)-32)</td>
</tr>
<tr>
<td>1xxx</td>
<td>(UInt(immh:immb)-64)</td>
</tr>
</tbody>
</table>

**Operation**

```cpp
CheckFPAdvSIMDEnabled64();

bits(datasize) operand = V[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = LSL(Elem[operand, e, esize], shift);

V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SHLL, SHLL2

Shift Left Long (by element size). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, left shifts each result by the element size, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. The SHLL instruction extracts vector elements from the lower half of the source register, while the SHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

SHLL, SHLL2

Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(2*datasize) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**SHRN, SHRN2**

Shift Right Narrow (immediate). This instruction reads each unsigned integer value from the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are truncated. For rounded results, see **RSHRN**.

The RSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the RSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the **CPACR_EL1, CPTR_EL2, and CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

</tr>
<tr>
<td>01xx</td>
<td>(64-UInt(immh:immb))</td>
</tr>
<tr>
<td>1xxx</td>
<td>RESERVED</td>
</tr>
</tbody>
</table>

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;
Vpart[d, part] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Signed Halving Subtract. This instruction subtracts the elements in the vector in the second source SIMD&FP register from the corresponding elements in the vector in the first source SIMD&FP register, shifts each result right one bit, places each result into elements of a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

</tbody>
</table>

- `<Vn>` Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- `<Vm>` Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer diff;
for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  diff = element1 - element2;
  Elem[result, e, esize] = diff<esize:1>;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
- The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Shift Left and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, left shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the left of each vector element in the source register are lost.

The following figure shows an example of the operation of shift left by 3 for an 8-bit vector element.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

```plaintext
SLI <V><d>, <V><n>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh<3> != '1' then UNDEFINED;
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;

integer shift = UInt(immh:immb) - esize;
```

Vector

```plaintext
SLI <Vd>.<T>, <Vn>.<T>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE(asimdimm);
if immh<3>:Q == '10' then UNDEFINED;
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
```
Assembler Symbols

<V> Is a width specifier, encoded in “immh”:

<table>
<thead>
<tr>
<th>immh</th>
<th>&lt;V&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xx</td>

<td>(UInt(immh:immb) - 32)</td>
</tr>
<tr>
<td>1xxx</td>
<td>(UInt(immh:immb) - 64)</td>
</tr>
</tbody>
</table>

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2 = V[d];
bits(datasize) result;
bits(esize) mask = LSL(Ones(esize), shift);
bits(esize) shifted;
for e = 0 to elements-1
    shifted = LSL(Elem[operand, e, esize], shift);
    Elem[result, e, esize] = (Elem[operand2, e, esize] AND NOT(mask)) OR shifted;
V[d] = result;

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SM3PARTW1

SM3PARTW1 takes three 128-bit vectors from the three source SIMD&FP registers and returns a 128-bit result in the destination SIMD&FP register. The result is obtained by a three-way exclusive OR of the elements within the input vectors with some fixed rotations, see the Operation pseudocode for more information.

This instruction is implemented only when FEAT_SM3 is implemented.

Operational information

If PSTATE.DIT is 1:
  • The execution time of this instruction is independent of:
    ○ The values of the data supplied in any of its registers.
    ○ The values of the NZCV flags.
  • The response of this instruction to asynchronous exceptions does not vary based on:
    ○ The values of the data supplied in any of its registers.
    ○ The values of the NZCV flags.
SM3TT1A

SM3TT1A takes three 128-bit vectors from three source SIMD&FP registers and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a three-way exclusive OR of the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the three-way exclusive OR.
- The result of the exclusive OR of the top 32-bit element of the second source vector, Vn, with a rotation left by 12 of the top 32-bit element of the first source vector.
- A 32-bit element indexed out of the third source vector, Vm.

The result of this addition is returned as the top element of the result. The other elements of the result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 9.

This instruction is implemented only when FEAT_SM3 is implemented.

V[d] = result;

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
• The response of this instruction to asynchronous exceptions does not vary based on:
  ◦ The values of the data supplied in any of its registers.
  ◦ The values of the NZCV flags.
SM3TT1B takes three 128-bit vectors from three source SIMD&FP registers and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a 32-bit majority function between the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the 32-bit majority function.
- The result of the exclusive OR of the top 32-bit element of the second source vector, Vn, with a rotation left by 12 of the top 32-bit element of the first source vector.
- A 32-bit element indexed out of the third source vector, Vm.

The result of this addition is returned as the top element of the result. The other elements of the result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 9.

This instruction is implemented only when \texttt{FEAT_SM3} is implemented.

### Operational Information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
• The values of the data supplied in any of its registers.
• The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  • The values of the data supplied in any of its registers.
  • The values of the NZCV flags.
SM3TT2A

SM3TT2A takes three 128-bit vectors from three source SIMD&FP register and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a three-way exclusive OR of the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the three-way exclusive OR.
- The 32-bit element held in the top 32 bits of the second source vector, Vn.
- A 32-bit element indexed out of the third source vector, Vm.

A three-way exclusive OR is performed of the result of this addition, the result of the addition rotated left by 9, and the result of the addition rotated left by 17. The result of this exclusive OR is returned as the top element of the returned result. The other elements of this result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 19.

This instruction is implemented only when FEAT_SM3 is implemented.

  ○ The values of the data supplied in any of its registers.
  ○ The values of the NZCV flags.
SM3TT2B

SM3TT2B takes three 128-bit vectors from three source SIMD&FP registers, and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a 32-bit majority function between the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the 32-bit majority function.
- The 32-bit element held in the top 32 bits of the second source vector, Vn.
- A 32-bit element indexed out of the third source vector, Vm.

A three-way exclusive OR is performed of the result of this addition, the result of the addition rotated left by 9, and the result of the addition rotated left by 17. The result of this exclusive OR is returned as the top element of the returned result. The other elements of this result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 19.

This instruction is implemented only when FEAT_SM3 is implemented.

Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

**<Vm>**

Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

**Operation**

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
integer element1;
integer element2;
integer maxmin;
for e = 0 to elements-1
  element1 = Int(Elem[concat, 2*e, esize], unsigned);
  element2 = Int(Elem[concat, (2*e)+1, esize], unsigned);
  maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
  Elem[result, e, esize] = maxmin<esize-1:0>;
V[d] = result;
```
Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
Signed Maximum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are signed integer values.

Depending on the settings in the \texttt{CPACR\_EL1}, \texttt{CPTR\_EL2}, and \texttt{CPTR\_EL3} registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

\begin{verbatim}
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then UNDEFINED;
if size == '11' then UNDEFINED;
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean min = (op == '1');
\end{verbatim}

SMINP

Signed Minimum Pairwise. This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of signed integer values into a vector, and writes the vector to the destination SIMD&FP register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Operational information

If PSTATE.DIT is 1:
   • The execution time of this instruction is independent of:
     ◦ The values of the data supplied in any of its registers.
     ◦ The values of the NZCV flags.
   • The response of this instruction to asynchronous exceptions does not vary based on:
     ◦ The values of the data supplied in any of its registers.
     ◦ The values of the NZCV flags.
SMLSL, SMLSL2 (by element)

Signed Multiply-Subtract Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLSL instruction extracts vector elements from the lower half of the first source register, while the SMLSL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

**Operation**

```c
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = Vpart[n, part];
bits(idxdsize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
   element1 = Int(Elem[operand1, e, esize], unsigned);
   product = (element1*element2)<2*esize-1:0>;
   if sub_op then
      Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
   else
      Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] + product;
V[d] = result;
```

**Operational information**

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SMLSL, SMLSL2 (vector)

Signed Multiply-Subtract Long (vector). This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMLSL instruction extracts each source vector from the lower half of each source register, while the SMLSL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

    if sub_op then
        accum = Elem[operand3, e, 2*esize] - product;
    else
        accum = Elem[operand3, e, 2*esize] + product;
    Elem[result, e, 2*esize] = accum;
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SMMLA (vector)

Signed 8-bit integer matrix multiply-accumulate. This instruction multiplies the 2x8 matrix of signed 8-bit integer values in the first source vector by the 8x2 matrix of signed 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2, this is an **OPTIONAL** instruction.  

ID_AA64ISAR0_EL1.I8MM indicates whether this instruction is supported.

Vector  
(Armv8.6)

### Operation

```c
CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n];
```

```c
X[d] = SignExtend(Elem[operand, index, esize], datasize);
```

### Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
**SMULL, SMULL2 (by element)**

Signed Multiply Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the result in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The SMULL instruction extracts vector elements from the lower half of the first source register, while the SMULL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the `CPACR_EL1`, `CPTR_EL2`, and `CPTR_EL3` registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<td>RESERVED</td>
</tr>
</tbody>
</table>
```

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
Operation

```c
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, 2*esize] = (element1*element2)<2*esize-1:0>;
V[d] = result;
```

Operational information

If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
SQABS

Signed saturating Absolute value. This instruction reads each vector element from the source SIMD&FP register, puts the absolute value of the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

**Scalar**

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Operation

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
boolean sat;
for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    (Elem[result, e, esize], sat) = SignedSatQ(element, esize);
    if sat then FPSR.QC = '1';
V[d] = result;
SQADD

Signed saturating Add. This instruction adds the values of corresponding elements of the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register. If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

**SQDMLAL, SQDMLAL2 (by element)**

Signed saturating Doubling Multiply-Add Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit $FPSR.QC$ is set.

The $SQDMLAL$ instruction extracts vector elements from the lower half of the first source register, while the $SQDMLAL2$ instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the $CPACR_EL1$, $CPTR_EL2$, and $CPTR_EL3$ registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

        accum = SInt(Elem[operand3, e, 2*esize]) + SInt(product);
    (Elem[result, e, 2*esize], sat2) = SignedSatQ(accum, 2 * esize);
    if sat1 || sat2 then FPSR.QC = '1';
V[d] = result;
```
SQDMLAL, SQDMLAL2 (vector)

Signed saturating Doubling Multiply-Add Long. This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQDMLAL instruction extracts each source vector from the lower half of each source register, while the SQDMLAL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

for e = 0 to elements-1
    element1 = SInt(Elem[operand1, e, esize]);
    element2 = SInt(Elem[operand2, e, esize]);
    (product, sat1) = SignedSatQ(2 * element1 * element2, 2 * esize);
    if sub_op then
        accum = SInt(Elem[operand3, e, 2*esize]) - SInt(product);
    else
        accum = SInt(Elem[operand3, e, 2*esize]) + SInt(product);
    (Elem[result, e, 2*esize], sat2) = SignedSatQ(accum, 2 * esize);
    if sat1 || sat2 then FPSR.QC = '1';
V[d] = result;
```
SQDMLSL, SQDMLSL2 (by element)

Signed saturating Doubling Multiply-Subtract Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and subtracts the final results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQDMLSL instruction extracts vector elements from the lower half of the first source register, while the SQDMLSL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

**SQDMLSL, SQDMLSL2 (vector)**

Signed saturating Doubling Multiply-Subtract Long. This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, doubles the results, and subtracts the final results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQDMLSL instruction extracts each source vector from the lower half of each source register, while the SQDMLSL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

### Scalar

SQDMULL, SQDMULL2 (by element)

Signed saturating Doubling Multiply Long (by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the final results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The SQDMULL instruction extracts the first source vector from the lower half of the first source register, while the SQDMULL2 instruction extracts the first source vector from the upper half of the first source register. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

    if sat then FPSR.QC = '1';

V[d] = result;
**SQDMULL, SQDMULL2 (vector)**

Signed saturating Doubling Multiply Long. This instruction multiplies corresponding vector elements in the lower or upper half of the two source SIMD&FP registers, doubles the results, places the final results in a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit $FPSR.QC$ is set.

The SQDMULL instruction extracts each source vector from the lower half of each source register, while the SQDMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the $CPACR_EL1$, $CPTR_EL2$, and $CPTR_EL3$ registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

SQRDMLAH (by element)

Signed Saturating Rounding Doubling Multiply Accumulate returning High Half (by element). This instruction multiplies the vector elements of the first source SIMD&FP register with the value of a vector element of the second source SIMD&FP register without saturating the multiply results, doubles the results, and accumulates the most significant half of the final results with the vector elements of the destination SIMD&FP register. The results are rounded.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSR.QC, is set if saturation occurs. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

SQRDMMLSH (vector)

Signed Saturating Rounding Doubling Multiply Subtract returning High Half (vector). This instruction multiplies the vector elements of the first source SIMD&FP register with the corresponding vector elements of the second source SIMD&FP register without saturating the multiply results, doubles the results, and subtracts the most significant half of the final results from the vector elements of the destination SIMD&FP register. The results are rounded. If any of the results overflow, they are saturated. The cumulative saturation bit, FPSR.QC, is set if saturation occurs. Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

SQRDMULH (by element)

Signed saturating Rounding Doubling Multiply returning High half (by element). This instruction multiplies each vector element in the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see SQDMULH. If any of the results overflows, they are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

SQRSHL

Signed saturating Rounding Shift Left (register). This instruction takes each vector element in the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see SQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

SQRSHRN, SQRSHRN2

Signed saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SQRSHRN.

The SQRSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

### Scalar

    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';
Vpart[d, part] = result;
```
SQRSHRUN, SQRSHRUN2

Signed saturating Rounded Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are rounded. For truncated results, see SQRSHRUN.

The SQRSHRUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQRSHRUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

**SQSHL (immediate)**

Signed saturating Shift Left (immediate). This instruction reads each vector element in the source SIMD&FP register, shifts each result by an immediate value, places the final result in a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see **UQRSHL**.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit **FPSR.QC** is set.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

**SQSHL (register)**

Signed saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see **SQRSHL**.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit **FPSR.QC** is set.

Depending on the settings in the **CPACR_EL1, CPACR_EL2**, and **CPACR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**

**SQSHRN, SQSHRN2**

Signed saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts and truncates each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. For rounded results, see **SQSHRN**.

The SQSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit **FPSR**.QC is set.

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: **Scalar** and **Vector**
